Re: DG 10-____ EnergyNorth Natural Gas, Inc d/b/a National Grid NH Integrated Resource Plan

Dear Ms. Howland:

In accordance with the Commission's Order No. 24, 941 dated February 13, 2009 in Docket No. DG 06-105, enclosed is an original and (9) copies of the EnergyNorth Natural Gas, Inc. d/b/a National Grid NH's Integrated Resource Plan, for review and approval by the Commission. An electronic copy will be sent under separate cover.

Also, please include Steven V. Camerino on the service list in this matter. Mr. Camerino's contact information is:

Steven V. Camerino, Esq. McLane, Graf, Raulerson, & Middleton 11 South Street Concord, NH 03301 (603) 230-4403 (direct) steven.camerino@mclane.com (e-mail)

If you should have any questions, please do not hesitate to contact me.

Yours traly Thomas P. O'Neill

EXECUTIVE SUMMARY

This Integrated Resource Plan ("IRP" or "Plan") for the period November 1, 2010 through October 31, 2015 is filed with the New Hampshire Public Utilities Commission ("Commission") by EnergyNorth Natural Gas, Inc. d/b/a National Grid NH ("National Grid NH" or the "Company") in compliance with the Commission's Order No. 24,941 dated February 13, 2009 in Docket DG 06-105.

This IRP demonstrates that the Company's planning process ensures that it maintains a reliable resource portfolio and energy supply to meet the forecasted needs of its customers at the lowest possible cost. The Plan includes: (i) a step-by-step description of the methodology the Company uses to forecast demand on its system, (ii) a detailed description of the analysis the Company employs to determine its normal and design planning standards, (iii) a detailed description of how the Company develops its resource portfolio to meet customer requirements under design conditions, (iv) a complete inventory of the expected available resources in the Company's portfolio, including savings associated with the implementation of energy efficiency programs and (v) a demonstration of the adequacy of the portfolio to meet customer demands under a range of weather and economic conditions.

The Company's planning process begins with its methodology for forecasting demand using an econometric demand model to determine annual incremental growth for the traditional residential, and commercial industrial markets, and specific market analysis for non-traditional markets, including natural gas vehicles and large scale cogeneration projects. The econometric

ES-1

model uses the SAS statistical software package to perform data analysis that relates sales by class to factors such as population, labor force, gross state product and economic forecasts to develop annual incremental sales projections. The results of the incremental demand forecasting methodology indicate that, over the five year forecast period, sales in the residential market are projected to grow by an average of 87,477 MMBtu per year and sales in the commercial/industrial market are projected to grow by an average of 268,907 MMBtu per year. The Company projects no incremental growth opportunities in non-traditional markets over the forecast period. These incremental growth projections are added to the base line, or "springboard," normalized sendout figures from the April 2008 to March 2009 split year to generate the forecasted total demand requirements. The normalized sendout springboard figures are the result of a detailed regression analysis of daily sendout versus heating degree days ("HDD") that establishes a strong statistical relationship between weather and load on the Company's system. The end result of the demand forecasting process projects sendout growth over the forecast period to average 356,384 MMBtu, or 2.6 percent, per year under normal weather conditions.

To ensure that the Company maintains adequate supplies in its portfolio to meet customer demand, the planning process continues with the development of design year and design day planning standards based on a Monte Carlo statistical analysis to establish a reasonable level of reliability for firm customers. As a result of this analysis the Company defined a design year at 6,963 HDD and a design day at 72 HDD. Combining the results of the design planning standards

ES-2

definition and the load forecasting process, the Company is projecting design year sendout to increase over the forecast period by an average of 368,871 MMBtu, or 2.5 percent, per year, and design day sendout to increase by an average of 2,206 MMBtu/day, or 1.5 percent, per year.

After the forecast of customer requirements are determined, the Company's planning process continues with the design of a resource portfolio to meet those requirements in the most reliable and least cost manner possible. To do this the Company uses the SENDOUT[®] Model (a proprietary linear programming model developed by New Energy Associates) to determine the adequacy of the existing portfolio in meeting the forecasted requirements and to SENDOUT[®] allows the identify any shortfalls during the forecast period. Company to determine the least-cost, economic dispatch of its existing resources subject to contractual and operating constraints, and identifies the need for, and type of additional resources during the forecast period, if any. The resources available to the Company include domestic long-haul and short-haul transportation contracts, underground storage contracts, Canadian and domestic gas supply contracts, and supplemental resources. The results of this step of the process show that the existing resource portfolio is adequate to meet base case customer requirements on a design day throughout the forecast period.

The next step in the planning process is to test the adequacy of the portfolio design by evaluating how it would perform under high and low alternative demand scenarios, and a cold snap weather scenario. Under the high and low demand scenarios, the Company adjusted the annual growth rate that

ES-3

resulted from its base case forecast upward and downward by one percentage point. The Company's resource plan shows that the portfolio is adequate under design conditions in all years of the forecast period in both cases. For the cold snap weather scenario, the Company assumes that the coldest seven-day period experienced in the last twenty-eight years will occur in early February during an otherwise normal winter. The Company's resource plan shows that it has adequate resources available to meet cold snap sendout requirements.

In conclusion, National Grid NH's Integrated Resource Plan demonstrates that the Company's planning process ensures that it maintains a reliable resource portfolio and energy supply to meet the forecasted needs of its customers at the lowest possible cost.

I. INTRODUCTION

This is the Integrated Resource Plan (the "IRP" or "Plan") for EnergyNorth Natural Gas, Inc. d/b/a National Grid NH ("National Grid NH"" or the "Company") for the five-year forecasting period 2010/11 through 2014/15¹. This filing is made in accordance with the requirement of New Hampshire Public Utilities Commission (the "Commission") Order No. 24,941, dated February 13, 2009 in Docket DG 06-105. The persons to whom communications should be addressed concerning this IRP are:

Thomas P. O'Neill Senior Counsel National Grid 40 Sylvan Road Waltham, Massachusetts 02451

and

Steven V. Camerino, Esq. McLane, Graf, Raulerson & Middleton 11 South Main Street Suite 500 Concord, New Hampshire 03301

A. <u>Company Background</u>

National Grid NH is a local distribution company that provides natural gas sales and transportation service to nearly 87,000 residential and commercial customers in thirty cities and towns in the state of New Hampshire. In August 2007, National Grid NH became an indirect wholly owned subsidiary of National

¹ The forecasting period is based on split years from November 1 through October 31.

Grid USA. The Company's core obligation is to provide safe, reliable and leastcost gas service to its customers.

B. <u>Summary of the IRP Process</u>

The purpose of this IRP is to document the process undertaken by the Company to forecast customer sendout requirements and to design and manage its gas resource portfolio to meet that obligation.

The IRP process begins with the development of a long-range forecast of customer demand. Next, the Company matches its available resources against expected demand to determine if incremental resources are required over the If so required, the Company would identify the resources forecast period. available to meet the incremental demand requirements and procure a least-cost asset or mix of assets available. In determining the least cost available assets, the Company analyzes both price and non-price factors. Examples of non-price factors include diversity of supply source, flexibility and reliability. Next, the Company looks at its currently available assets and determines if there are any "decision points" with respect to any of its contracts such as expiration dates or options to increase or decrease volumes. If so, the Company determines whether to renew those supplies or replace them with an available alternative. Finally, the Company analyzes its portfolio of expected resources against a range of weather scenarios to determine if those resources are sufficient to reliably meet sendout requirements.

I-2

C. Organization of the Filing

This document is organized into the following principal sections:

- Section II provides an overview of the National Grid process for identifying and meeting customer requirements;
- Section III reviews the Company's demand forecasting methodology and discusses the development of the forecast of customer sendout requirements;
- Section IV discusses the design of the resource portfolio, the expected available resources, and the adequacy of the portfolio in terms of meeting forecasted requirements; and,
- Section V summarizes the Company's compliance with the directives from Order No. 24,941.

II. OVERVIEW OF THE NATIONAL GRID PROCESS FOR IDENTIFYING AND MEETING CUSTOMER REQUIREMENTS

The principal objective of National Grid's gas management process is the creation and utilization of a portfolio of gas supply, interstate pipeline transportation, underground storage and supplemental resources to meet daily and seasonal firm demand requirements in the most cost-effective manner while maintaining reliability. National Grid's process of planning for and meeting customer load requirements involves the coordination of a number of activities including demand forecasting, long-term resource planning, gas supply management and gas distribution. The majority of these activities are centralized within the Energy Portfolio Management Group, which includes the Company's Gas Load Forecasting Department, Gas Supply Planning Department, and Energy Trading Organization. The Energy Portfolio Management Group coordinates closely with the Gas Control Department, which is responsible for gas deliveries across the National Grid distribution system in New England as well as the Customer Choice Group, which is responsible for management of the Supplier Service program and the Energy Efficiency Group which is responsible for the design, implementation, and management the Company-sponsored energy efficiency programs. Among the responsibilities of the Energy Portfolio Management Group are to project the resource requirements of the National Grid system and to assemble a least-cost portfolio of reliable resources to meet those requirements. The projection of resource requirements requires two steps: (1) the preparation of forecasts of long-term trends in customer requirements under

II-1

normal weather conditions; and, (2) the preparation of forecasts of customer requirements under defined (design day and design year) weather conditions. Assembling the least-cost portfolio is also a two-step process involving: (1) the procurement of a sufficient and appropriate portfolio of resources to meet the design sendout requirements resulting from the demand forecasting process; and, (2) the economic dispatch of those volumes given available resources. The Company's resource portfolio provides a range of flexibility in making these determinations in the course of the day-to-day management of the portfolio.

National Grid's forecasting and gas supply planning activities are complemented by a centralized dispatch and control center. The daily process of obtaining sufficient resources to meet predicted customer needs requires a high level of coordination between the Gas Supply Planning Department and Gas Control. Each day, Gas Control provides Gas Supply Planning with projected sendout requirements that are developed based on the results of the load forecasting process. Gas Supply Planning determines the availability, reliability and pricing information necessary to satisfy the predicted customer loads taking into account both currently available projections of weather and prices as well as the possibility of design-forward conditions for the remainder of the heating season (design-forward planning). Gas Supply Planning and Gas Control then establish a daily "Game Plan" that matches available resources with sendout requirements for the National Grid system. The Game Plan is designed to balance the demand requirements of the system for the current gas day with

II-2

scheduled supply volumes and also projects a three-day supply/demand balance.

National Grid NH customers receive significant benefits as a result of the coordinated and centralized gas management process because resource planning and purchasing decisions are made from an overall system perspective to meet customer requirements. Given the diversity and flexibility of the resource portfolio, this decision-making framework allows the Company to utilize its resources efficiently rather than on mere availability.

III. FORECAST METHODOLOGY

A. Introduction

National Grid NH developed its five-year forecast of customer requirements

under design weather planning conditions using the following process:

1. <u>Forecast Incremental Sendout</u>

Incremental sendout is the additional sendout that National Grid NH forecasts to occur over the five-year forecast period above the level established for an identified actual reference year, which was 2008/09 for purposes of this plan.¹ The Company used econometric models to develop a forecast of incremental sendout for traditional markets (i.e., residential, and commercial and industrial ("C&I") customers. Incremental sendout forecasts of non-traditional markets, such as natural-gas vehicles ("NGVs") and large-scale power generation were developed outside of the econometric models because the sendout associated with these markets is not included in the historical data used to develop the econometric equations. Forecasts of incremental sendout for traditional and nontraditional markets were summed to determine the total incremental sendout over the forecast period. One change reflected in this filing as compared to the Company's previous filing in Docket DG 06-105 is the treatment of volume reductions associated with demand side management In the past the Company treated the volume programs ("DSM"). reductions associated with its DSM programs as reductions to the demand forecast. In this filing, however, in accordance with the Commission's Order No. 24,941, DSM is treated as a supply option, and optimized with other supply options in the design of the supply portfolio and is therefore not reflected in the forecast of incremental sendout.

2. <u>Develop Reference Year Sendout Using Regression Equations</u>

Next, the Company developed the reference year sendout using regression equations. The level of the Company's sendout in the 2008/09 reference year served as the "springboard" to which incremental sendout was added. The actual sendout data used for the springboard are a function of the weather conditions experienced in the reference year. Therefore, the Company uses regression equations to normalize the sendout in the reference year based on normalized weather data.

¹

The reference year is the split year April 1, 2008 through March 31, 2009.

3. Normalize Forecast of Customer Requirements

The Company then summed the incremental sendout requirements with the weather-normalized springboard sendout requirements to determine National Grid NH's total normalized forecast of customer requirements over the five-year forecast period.

4. <u>Determine Design Weather Planning Standards</u>

Pursuant to Order No. 24,941, the Company based its planning standards on a Monte Carlo analysis of average daily temperature as the variable to be modeled and HDD, which is a linear transformation of average daily temperature.

5. <u>Determine Customer Requirements under Design Weather Conditions</u>

Using the applicable design day and design year weather planning standards, National Grid NH determined the design year sendout requirements and the design day (peak day) sendout requirements. These design sendout requirements established the Company's resource requirements over the forecast period.

Based on the foregoing process, the Company has projected incremental throughput of 1,425,535 MMBtu over the forecast period, or 356,384 MMBtu per year, assuming normal weather. (See, Chart III-A-1) Overall, this growth in firm sales represents a 10.5 percent total increase in sendout requirements over the forecast period, or 2.6 percent per year on average. The development of the Company's five-year forecast of customer sendout requirements, based on the steps set forth above is described in the following sections

B. Forecast of Incremental Sendout

1. Introduction

The first step in National Grid NH's forecast process is to prepare a five-year forecast of annual incremental sendout. Annual incremental sendout is the net increase in load that the Company expects to experience over the forecast period. This annual projection of incremental sendout is then added to the reference or "springboard" year

sendout, which is derived from the Company's regression analysis of the latest splityear daily sendout and weather data, as described in Section III.C. below, to determine total firm sendout requirements.

The process used to forecast incremental sendout over the forecast period consists of five components. First, National Grid NH develops a demand forecast of loads associated with traditional residential heating, residential non heating, C&I heating and C&I non heating markets. To accomplish this, the Company developed econometric models, which are discussed in Section III.B.2 (a). Throughput in the residential sector is discussed in Sections III.B.2 (b) (i-vi), below, and the C&I sector is discussed in Sections III.B.2 (b) (vii-xii), below.

Second, National Grid NH develops a forecast for non-traditional markets that includes NGVs and large-scale power generation. While non-traditional markets are part of National Grid NH's forecasting process, the Company is forecasting no demand in the NGV and large-scale cogeneration markets (Sections III.B.3. (a) and III.B.3. (b), respectively) based on the current and anticipated lack of activity in those markets. The Company's natural gas demand forecast for traditional customers, together with its forecasts of non-traditional market demands, results in a total forecast of incremental customer demand over the 2010/11 through 2014/15 forecast period.

Third, National Grid NH monitors migration of sales customers to transportation service to determine if adjustments to its forecast are warranted (discussed in Section III.B.5, below).

III-3

Fourth, National Grid NH reviews the Sales and Marketing Group's forecast to determine if any adjustments to the forecast are necessary, as discussed in Section III.B.6, below.

Finally, National Grid NH develops two alternatives to the base case demand forecast, that represent high and low sendout cases, as discussed in Section III.B.7, below. The development of these alternative forecasts enables the Company to evaluate its ability to meet customer requirements with portfolio resources under a range of weather and economic conditions.

2. Demand Forecast for Traditional Markets

As mentioned above, the first step of the forecasting process is to prepare a fiveyear forecast of annual incremental sendout. To prepare this forecast, the Company first develops a demand forecast of loads associated with traditional residential heating, residential non heating, C&I heating and C&I non heating markets using econometric models. The analysis is similar to the one presented in the most recent integrated resource plan the Company filed with the Commission, except for the disaggregation of the residential and C&I classes into heat and non heat categories, and the elimination of the autoregressive integrated moving average ("ARIMA") method. The Company began by reviewing the econometric models specified in its 2006 Integrated Resource Plan filed with the Commission on August 21, 2006 in Docket DG 06-105, and then updated those models by re-estimating the parameters of the models using updated historical data for the dependent and independent variables.

111-4

(a) The Econometric Models

The statistical models used by the Company relate sales by class to economic and demographic factors such as households, housing starts, personal income, gas price and gross state product, as well as time trends, degree days and lagged variables. Historical annual sales data cover the twenty year period of January 1990 through April 2009. This information was used in conjunction with forecasts of economic factors provided by IHS Global Insight, Inc. to develop the sales forecast. The Company has a contract with IHS Global Insight, Inc. to provide forecasts of economic and demographic variables for its service territory along with the historic values of those variables.

The Company used the SAS statistical software package, licensed from SAS Institute, Inc., to perform the statistical data analysis that determined the relationships between the dependent variables and the explanatory variables in each of the equations used in the econometric models.

(b) The Forecast

The Company segmented its sales forecast by sector producing forecasts for residential heating sales, residential non heating sales, C&I heating sales and C&I non heating sales.

For each of the sectors, the Company tested two modeling structures. The first structure begins with forecasts of both number of customers and the use per customer for each class and multiplies the results of each to calculate total sales volumes for that class. The second structure produces a forecast of total sales volumes directly, by relating total sales to independent variables. In the first structure, the number of customers is based on growth rates of generally available variables such as

III-5

households, gross state product and time trends, while use per customer captures price effects, as well as appliance saturation, and efficiency improvements through time trends. Multiplying the results of these two forecasts creates the forecast of total sales. The first structure assumes that it is easier to forecast each component separately. However, if one forecasts sales directly, it is possible that the effects of variables such as degree days, population and employment will overwhelm the effect of variables such as price. Because it is not clear which structure will produce the best forecast, the Company combined the results of the two models to minimize the errors that might be inherent in either one of them

For the modeling effort, the Company evaluated a broad range of explanatory variables from sources such as the US Bureau of the Census, the US Bureau of Labor Statistics, the US Bureau of Economic Analysis, the Energy Information Administration of the US Department of Energy and the Company's own database. In nearly all cases, the Company collected statewide New Hampshire data because data specific to National Grid NH's service territory were limited or non-existent. The variables evaluated for the residential models were:

- State population
- State personal income
- State per capita income
- State wage and salary disbursement
- Statewide employment
- Statewide housing units and statewide households
- Statewide residential fuel oil sales and unit cost
- Statewide residential natural gas sales and unit cost
- Manchester, NH normal and actual degree days
- National Grid NH therm sales and average rates to residential customers

• New Hampshire City Gate gas price

Table III-I provides additional details on these variables. Similar variables were identified for the C&I sector:

- All of the above variables except those relating specifically to the residential sector
- National Grid NH average rates for C&I customers
- National Grid NH therm sales and customer totals for C&I customers
- Other EIA energy consumption and unit cost data for the C&I sector

The Company developed models based on monthly data. This approach accounts for the seasonality of both customer and sales data. Although, SAS offers a variety of forecasting models including dynamic regression, Box-Jenkins, exponential smoothing, and moving averages, the Company focused on dynamic regression (i.e. econometrics) because it is the most commonly used method in the utility industry and allows the user to develop relationships between independent or explanatory variables and energy sales.

In addition to the explanatory variables, SAS allows the user to incorporate both lagged variables and autocorrelation functions ("AR") into the models to correct for serial correlation², and exponential autoregressive conditional heteroscedastic ("EARCH") variables to correct for heteroscedasticity.³ When developing a forecasting model, there will always be "error" when comparing the "fitted" data from the model to the actual data. One would expect, however, that these errors (or residuals) would be relatively small and random in nature. If the errors are not random (e.g., every fourth quarter the forecast is too high and every second quarter it is too low), then a pattern exists, and the error terms are not random. In these instances better models should be designed. Lagged variables, AR, and EARCH variables are estimated statistically to eliminate or reduce the significance the non-random components of the errors and provide a better fit of the models to the historical data.

Because SAS allows the user to develop a large number of models, it is important to develop criteria regarding what constitutes a "good" model. In general the Company applied the following criteria:

- The t-tests for all explanatory variables are significant (i.e. exceed 2.0)
- The relationship between the dependent and explanatory variable is logical and

² "Serial correlation occurs in time-series studies when the errors associated with observations in a given time period carry over into future time periods. ("*Econometric Models and Economic Forecasts*", Pindyck and Rubenfeld, at p. 159, (1998.)

³ In an ordinary least squares analysis, there is an assumption that the error terms of the estimated equation are random variables with a normal distribution and a constant variance. When the variance is not constant over the observations, heteroscedasticity is said to exist. (id. p. 146.). The EARCH variable is the result of the SAS program formula for correcting heteroscedasticity using the generalized autoregressive conditional heteroscedasticity (GARCH) procedure.

of the correct sign (e.g., higher gas prices should produce lower sales)

- The resulting forecast is reasonable (e.g., a forecast that shows sales decreasing to zero by year 2010 would be eliminated regardless of the power of the other statistics).
- That significant autocorrelation between the residuals (errors) has been eliminated (i.e. Durbin-Watson statistic is insignificant)
- That significant heteroscedasticity among the residuals has been eliminated
- The addition of new variables does not improve model performance
- Reliable forecasts of the independent variables are available.

i. Residential Heating Customer Forecast

The Company found that there is significant seasonality to the number of residential heating customers with a higher customer base in the winter than in the summer. Therefore, while the Company found that the household variable was the most significant economic/demographic variable, the model developed for residential heating customers also contains a term for residential customers lagged one period, five AR variables to correct for serial autocorrelation, and four EARCH variables to correct for heteroscedasticity. The model also includes several monthly dummy variables to further capture the seasonality of customer counts. The details of this model are contained in Appendix A RHC, and the form of the model is presented below:

Residential Heating Customers is a function of: Intercept Customers lagged one month (CUSH 1) Households (HH) Dummy Variable for January (d1) Dummy Variable for June (d6) Dummy Variable for July (d7) Dummy Variable for December (d12) AR term of period 2 (AR2) AR term of period 5 (AR5) AR term of period 6 (AR6) AR term of period 7 (AR7) AR term of period 10 (AR10) EARCH term 0 (EARCH0) EARCH term 9 (EARCH9) EARCH term 10 (EARCH10) EARCH term 12 (EARCH12)

After completing the estimation of the parameters for the equation in the above model, the Company then applied a forecast of the explanatory variables to produce the forecast of residential heating customers. The forecasts of the explanatory variables were provided by IHS Global Insight, Inc., along with the historic values of those variables.

Using the model specification described above, the residential heating customer forecast was produced and is presented in Table III-2 below.

ii. Residential Non-Heating Customer Forecast

The Company found that the most significant independent variable related to the number of residential non-heating customers is a simple time trend. The Company included that variable, along with five monthly dummy variables to capture the seasonality on residential non-heating customer counts, and an AR variable to correct for serial autocorrelation. The details of the residential non-heating customer model are presented in Appendix A RNHC, and the form of the model is presented below:

Residential Non-Heating Customers is a function of: Intercept Time Trend (Date) Dummy Variable for February (d2) Dummy Variable for March (d3) Dummy Variable for April (d4) Dummy Variable for September (d9) Dummy Variable for October (d10) AR term of period 1 (AR1)

Using the model specification described above, the residential non-heating customer forecast was produced and is presented in Table III-2 below.

Nov. 2014- Oct. 2015	2.45%	-7.23%	2.04%
Average	1.84%	-6.36%	1.44%

The result shown in Table III-2 is a forecasted average annual growth rate in residential customers from 2010/11 - 2014/15 of 1.4 percent, or 1,091 per year, with a total of 79,187 residential customers expected in 2014/15. The complete residential customer forecast results are presented in Appendix A.

iii. Residential Heating Use-Per-Customer Forecast

For the residential heating use-per-customer forecast, there was a strong relationship between normalized use-per-customer and actual billing heating degree days, the price of gas and real personal income. Therefore, the model developed for use-per-residential heating customer used these variables as independent variables, along with nine monthly dummy variables to account for the seasonality of the use per customer, three AR variables to correct for serial autocorrelation and eight EARCH variables to correct for heteroscedasticity. The details of the use-per-residential heating customer model are presented in Appendix A RHU, and the form of the model is presented below:

Residential Heating Use-Per-Customer is a function of:

Intercept Actual Billing Degree Days (BDDA) Price of Gas (prcG) Real Personal Income (PIR) Dummy Variable for January (d1) Dummy Variable for February (d2) Dummy Variable for March (d3) Dummy Variable for April (d4) Dummy Variable for May (d5) Dummy Variable for June (d6) Dummy Variable for October (d10) Dummy Variable for November (d11) Dummy Variable for December (d12) AR term of period 12 (AR12) AR term of period 14 (AR14) AR term of period 23 (AR23) EARCH term 0 (EARCH0) EARCH term 1 (EARCH1) EARCH term 2 (EARCH2) EARCH term 5 (EARCH5) EARCH term 8 (EARCH8) EARCH term 11 (EARCH11) EGARCH term 6 (EGARCH6) EGARCH term 12 (EGARCH12)

Using the model specification described above, the residential heating use-percustomer forecast was produced and is presented in Table III-3 below. The complete residential heating use-per-customer forecast results are in Appendix A RHU.

iv. Residential Non-Heating Use-Per-Customer Forecast

The Company found that the most significant independent variables related to the residential non-heating use-per-customer are actual billing degree days, and the price of gas lagged one period. The Company included these variables, along with five monthly dummy variables to capture the seasonality on residential non-heating use-per-customer, and two AR variables to correct for serial autocorrelation. There was no significant heteroscedasticity that required correction. The details of the residential non-heating use-per-customer model are presented in Appendix A RNHU, and the form of the model is presented below:

Residential Non-Heating Use-Per-Customers is a function of:

Intercept Actual Billing Degree Days (BDDA) Price of Gas (prcG_1) Dummy Variable for February (d2) Dummy Variable for August (d8) Dummy Variable for September (d9) Dummy Variable for October (d10) Dummy Variable for November (d11) AR term of period 11 (AR11) AR term of period 14 (AR14)

Using the model specification described above, the residential non-heating useper-customer forecast was produced and is presented in Table III-3 below.

Nov. 2013- Oct. 2014	-0.50%	0.12%
Nov. 2014- Oct. 2015	-0.65%	-0.01%
Average	-0.02%	-0.05%

As shown in Table III-3, the result is a forecasted average annual rate of change in use per residential heating customer of -0.02 percent for the residential heating class, and - 0.05 percent for the residential non-heating class. The complete residential use-per-customer forecast results are presented in Appendix A RHU and RNHU.

v. Residential Heating Sales Forecast

As mentioned previously, residential heating sales forecasts were developed by (1) combining the results of the residential heating customer model and use-per-customer model and (2) by independently forecasting residential heating sales volumes. All data on residential heating sales were normalized by the Company to account for deviations in weather.

The Company produced an initial forecast of residential heating sales using the results of the residential heating customer model multiplied by the results of the use per residential heating customer model. The product of these two forecasts yielded a calculated residential heating sales forecast reflecting an overall annual average growth rate of 1.78 percent and an increase in sales to 6.58 million MMBtu in the year 2014/15. The results of this initial volume forecast are presented in Table III-4 below.

The second approach developed a single econometric model for residential heating sales. The econometric model includes a term for billing degree days, NH gross state product and housing starts, along with nine monthly dummy variables to capture the seasonality of residential heating volumes, three AR variables to correct for serial autocorrelation and an EARCH variable to correct for heteroscedasticity. The details of the residential heating volume model are presented in Appendix A RHV, and the form of the model is presented below:

Residential Heating Volume is a function of:

Intercept

Actual Billing Degree Days (BDDA)

Gross State Product (GSP)

Housing Starts (HSTT)

Dummy Variable for January (d1)

Dummy Variable for February (d2)

Dummy Variable for March (d3)

Dummy Variable for April (d4)

Dummy Variable for May (d5)

Dummy Variable for June (d6)

Dummy Variable for October (d10)

Dummy Variable for November (d11)

Dummy Variable for December (d12)

AR term of period 1 (AR1)

AR term of period 12 (AR12)

AR term of period 23 (AR23)

EARCH term of period 0 (EARCH0)

Using the model specification described above, the residential heating volume forecast was produced and is presented in Table III-5 below.

The Company then combined the calculated residential heating sales forecast with the results of the sales volume forecast model using a weighting factor (α) derived from a variance/covariance analysis⁴ on the two forecasts. Calculating the weighting factor this way minimizes the errors associated with using the two models in combination. The details of the weighting factor calculation can be found in Appendix A RHalpha. The results of the

$$P_{c,T+j} = \alpha \cdot P_{1,T+j} + (1-\alpha) \cdot P_{2,T+j} \text{ where: } \alpha = \frac{VAR[e_{2,t}] - COV[e_{1,t}, e_{2,t}]}{VAR[e_{1,t}] + VAR[e_{2,t}] - 2COV[e_{1,t}, e_{2,t}]}$$

 $^{^4}$ The α weighting factor is used and derived in the following respective formulae:

combined models produced the final residential heating sales forecast of 6.30 million MMBtu in 2014/15 for an annualized growth rate of 1.46 percent from 2010/11-2014/15. The results of this combined volume forecast are presented in Table III-6 below.

The complete residential heating load forecast results are presented in Appendix A RH Combined.

vi. Residential Non-Heating Sales Forecast

Similarly, the residential non-heating sales forecasts were developed by (1) combining the residential non-heating customer and use per customer forecasts and (2) by independently forecasting residential non-heating sales volumes.

The Company produced an initial forecast of residential non-heating sales using the residential non-heating customer model multiplied by the results of the use per residential non-heating customer model. The product of these two forecasts yielded a calculated residential non-heating sales forecast reflecting an overall annual average growth rate of -6.38 percent and MMBtu sales forecast of 0.072 million in the year 2014/15. The results of this initial volume forecast are presented in Table III-4 below.

The econometric model developed for residential non-heating sales includes a term for billing degree days, price of gas, real gross state product, per capita personal income, along with a lagged volume variable, several monthly dummy variables to capture the seasonality on residential non-heating volumes, and an AR variable to correct for serial autocorrelation. There was no significant heteroscedasticity that required correction. The details of the residential non-heating sales volume model are presented in Appendix A RNHV, and the form of the model is presented below:

Residential Non-Heating Volume is a function of:

Intercept Lagged Volumes (VOLN_1) Actual Billing Degree Days (BDDA) Price of Gas (prcG) Real Gross State Product (GSPR) Per Capita Income (PIP) Dummy Variable for January (d1) Dummy Variable for March (d3) Dummy Variable for December (d12) AR term of period 11 (AR11)

Using the model specification described above, the residential non-heating volume forecast was produced and is presented in Table III-5 below.

The Company then combined the calculated residential non heating sales forecast with the results of the sales volume forecast model using a weighting factor (α) derived from a variance/covariance analysis on the two forecasts. Calculating the weighting factor this way minimizes the error associated with using the two models in combination. The details of the weighting factor calculation can be found in Appendix A RNHalpha. The results of the

combined models produced the final residential sales forecast of 0.082 million therms in

2014/15 for an annualized growth rate of -4.26 percent from 2010/11-2014/15. The results

of this combined volume forecast are presented in Table III-6 below.

See Figure III-1 below for the MMBtu load forecast summary and Appendix A for

complete details of the forecast.

Figure III-1 Residential Natural Gas Sales Forecast

vii. Commercial/Industrial Heating Customer Forecast

Similar to the residential customer model, the C&I heating customer model shows seasonality, as well as a strong relationship to real gross state product, six monthly dummy variables, and three AR variables to correct for serial autocorrelation. Statistical tests indicated that there was no significant heteroscedasticity that needed correction. The details of this model are contained in Appendix A CIHC, and the form of the model is presented below:

C&I Heating Customers is a function of: Real Gross State Product (GSPR) Dummy Variable for February (d2) Dummy Variable for March (d3) Dummy Variable for April (d4) Dummy Variable for October (d10) Dummy Variable for November (d11) Dummy Variable for December (d12) AR term of period 1 (AR1) AR term of period 4 (AR4) AR term of period 5 (AR5)

The annual forecast results for C&I customers can be seen in Table III-7. Complete details of the C&I customer forecast results can be found in Appendix A CIHC.

viii. Commercial/Industrial Non-Heating Customer Forecast

The Company found that the most significant independent variables related to the number of C&I non-heating customers are labor force and retail sales. The Company included those variables, along with seven monthly dummy variables to capture the seasonality on C&I non-heating customer counts, three AR variables to correct for serial autocorrelation, and eight EARCH variables to correct for heteroscedasticity. The details of the C&I non-heating customer model are presented in Appendix A CINHC, and the form of the model is presented below:

C&I Non-Heating Customers is a function of:

Labor Force (LBF)

Retail Sales (RSALE)

Dummy Variable for March (d3)

Dummy Variable for May (d5)

ix. C&I Heating Use-Per-Customer

For the C&I heating use-per-customer forecast, there was a strong relationship between normalized use-per-customer and labor force. Therefore, the model developed for use-per-C&I heating customer had this variable as an independent variable, along with nine monthly dummy variables, one AR variable to correct for serial autocorrelation and six EARCH variables to correct for heteroscedasticity. The details of the use-per-C&I heating customer model are presented in Appendix A CIHU, and the form of the model is presented below:

C&I Heating Use-Per-Customer is a function of:

Labor Force (LBF) Dummy Variable for January (d1) Dummy Variable for February (d2) Dummy Variable for March (d3) Dummy Variable for April (d4) Dummy Variable for May (d5) Dummy Variable for June (d6) Dummy Variable for October (d10) Dummy Variable for November (d11) Dummy Variable for December (d12) AR term of period 24 (AR24) EARCH term 0 (EARCH0) EARCH term 1 (EARCH1) EARCH term 2 (EARCH2) EARCH term 8 (EARCH8) EARCH term 12 (EARCH12) EGARCH term 9 (EGARCH9)

Using the model specification described above, the C&I heating use-per-customer forecast was produced and is presented in Table III-8 below. The complete C&I heating use-per-customer forecast results are in Appendix A CIHU.

x. Commercial/Industrial Non-Heating Use-Per-Customer

For the C&I non-heating use-per-customer forecast, there was a strong relationship between normalized use-per-customer and lagged heating degree days and employment. Therefore, the model developed for use-per-C&I non-heating customer had these variables as independent variables, along with three monthly dummy variables, one AR variable to correct for serial autocorrelation, and three EARCH variables to correct for heteroscedasticity. The details of the use-per-C&I non-heating use-per-customer model are presented in Appendix A CINHU, and the form of the model is presented below:

C&I Non-heating Use-Per-Customer is a function of:

Lagged Heating Degree Days (HDDA_1) Employment (EMP) Dummy Variable for February (d2) Dummy Variable for June (d6) Dummy Variable for September (d9) AR term of period 3 (AR3) EARCH term 0 (EARCH0) EARCH term 7 (EARCH7) EARCH term 12 (EARCH12)

Using the model specification described above, the C&I non-heating use-percustomer forecast was produced and is presented in Table III-8 below. The complete C&I non-heating use-per-customer forecast results are in Appendix A CINHU.

xi. Commercial/Industrial Heating Sales Forecast

As with the residential models, the Company forecast C&I heating sales in MMBtu normalized for weather. Models were developed by combining the results of the C&I customer and use-per-customer forecasts, as well as directly using econometric methods. The Company produced an initial forecast of C&I heating sales using the C&I heating customer model multiplied by the results of the use per C&I heating customer model. The product of these two forecasts yielded a calculated C&I heating sales forecast reflecting an overall annual average growth rate of 2.79 percent and a sales forecast of 5.908 million MMBtu in the year 2014/15. The results of this initial volume forecast are presented in Table III-9 below.

The second approach developed a single econometric model for C&I heating sales. The econometric model includes a term for billing degree days, and NH gross state product, along with six monthly dummy variables to capture the seasonality of C&I heating volumes, an AR variable to correct for serial autocorrelation and four EARCH variables to correct for heteroscedasticity. The details of the C&I heating volume model are presented in Appendix A CIHV, and the form of the model is presented below:

C&I Heating Volume is a function of:

Intercept Actual Billing Degree Days (BDDA) Gross State Product (GSP) Dummy Variable for February (d2) Dummy Variable for March (d3) Dummy Variable for May (d5) Dummy Variable for October (d10) Dummy Variable for November (d11) Dummy Variable for December (d12) AR term of period 11 (AR11) EARCH term of period 0 (EARCH0) EARCH term of period 2 (EARCH2) EARCH term of period 3 (EARCH3)

Using the model specification described above, the C&I heating volume forecast was produced and is presented in Table III-10 below.

See Figure III-2 for the C&I MMBtu load forecast summary and Appendix A CIHV for complete details of the forecast.

xii. Commercial/Industrial Non-Heating Sales Forecast

As with the earlier models, the Company forecast C&I non-heating sales in MMBtu normalized for weather. Models were developed by combining the results of the C&I non-customer and use-per-customer forecasts, as well as directly using econometric methods. The Company produced an initial forecast of C&I non-heating sales using the C&I non-heating customer model multiplied by the results of the use per C&I non-heating customer model. The product of these two forecasts yielded a calculated C&I non-heating sales forecast reflecting an overall annual average growth rate of 2.22 percent and a

sales forecast of 1.270 million MMBtu in the year 2014/15. The results of this initial volume

forecast are presented in Table III-9 below.

The Company then combined the calculated C&I non-heating sales forecast with the results of the sales volume forecast model using a weighting factor (α) derived from a

variance/covariance analysis on the two forecasts as described in above in residential heating volume forecast section. Calculating the weighting factor this way minimizes the errors associated with using the two models in combination. The calculation of the weighting factor for the C&I non heating volumes can be found in Appendix A CINHalpha. The results of the combined models produced the final C&I non-heating sales forecast of 1.377 million MMBtu in 2014/15 for an annualized growth rate of 3.45 percent from 2010/11-2014/15. The results of this combined volume forecast are presented in Table III-11 below.

Also shown in Table III-11, is the total C&I volume forecast, C&I heating plus non heating, of 7.67 million MMBtu in 2014/15, and an average annual growth rate of 3.43 percent.

Commercial & Industrial Firm Sales & Transportation Forecast

xiii. Summary of Final Forecast

For the final forecast, the Company adds the results of the combined sales volumes forecast for the residential heating, residential non-heating, C&I heating and C&I non-heating forecast to obtain the total Company forecast.

Table III-12 summarizes the National Grid NH forecast by residential and C&I sector. Because the analysis thus far has been on customer billed sales volumes, the figures presented in Table III-12 are billed sales before adjusting for unaccounted-for-gas.

(Billed Sales Before Adjusting for Unaccounted-for-Gas)

To align these figures with throughput figures needed for resource planning, the Company next applies an unaccounted-for-gas factor of 2.6 percent⁵ to them to derive the throughput figures presented in Table III-13 below.

Throughput = BilledSales *
$$\left[\frac{1}{(1-0.026)}\right]$$

⁵ The formula for adjusting billed sales volumes to throughput is:

Table III-13

(Throughput After Adjusting for Unaccounted-for-Gas)

(c) Forecast of Incremental Demand for Traditional Markets

National Grid NH's incremental demand forecasts (base case) for traditional markets are presented in Chart III-B-1. The incremental demand forecast is calculated as the year-to-year change in demand that results from the econometric forecast models. The Company adds the annual incremental demand determined in this way to the reference year sendout described in Section III C. As set forth in Chart III-B-1, the Company projects total net throughput additions over the forecast period (2010/11 through 2014/15) of 1,425,535 MMBtu for traditional core markets. Overall, this growth

in traditional-market firm sales represents a 10.5 percent increase in sendout requirements over the forecast period, or 2.6 percent per year on average (see Chart III-A-1).

The following sections describe the specific steps involved with the development of National Grid NH's incremental demand forecast for traditional market segments, including residential, and C&I customers.

(i) <u>Residential Market</u>

Chart III-B-1 presents the Company's demand forecast for residential customers. This forecast shows 351,867 MMBtu of net incremental load additions over the forecast period. Chart III-B-1 shows that National Grid NH is projected to add an average of 87,967 MMBtu net load annually, between 2010/11 and 2014/15. As shown on Chart III-A-1, this growth in residential sales represents an overall increase in residential sendout of 1.4 percent per year on average or 5.5 percent over the forecast period.

(ii) <u>Commercial and Industrial Market</u>

Chart III-B-1 presents National Grid NH's updated C&I demand forecast. This forecast shows 1,073,667 MMBtu of net incremental load over the forecast period. Chart III-B-1 shows that the Company is projected to add an average of 268,417 MMBtus net load annually between 2010/11 and 2014/15. As shown on Chart III-A-1, this increase in C&I sales represents an overall increase in C&I sendout of 3.7 percent per year on average, or 14.8 percent over the forecast period.

3. Demand Forecast for Non-Traditional Markets

(a) <u>Natural Gas Vehicles</u>

As shown on Chart III-B-1, the Company's forecast indicates no incremental demand in the natural gas vehicle market in the National Grid NH service territory. The Company's forecast of demand in the NGV market is driven by governmental regulations requiring or encouraging NGV use among certain commercial and governmental vehicle fleets, and the Company's marketing efforts with those vehicle fleet operators. At the time that this forecast was prepared, the Company's marketing representatives did not anticipate any significant demand in this market.

(b) Large-Scale Cogeneration Market

National Grid NH's assessment of the large-scale cogeneration market is that the natural gas required to meet the demands of the potential customers in this market during the forecast period will not have an impact on the Company's sendout requirements or resource plan. National Grid NH is not currently aware of any large-scale gas-fired cogeneration facilities planned for locations within the Company's service territory over the forecast period that do not yet have their natural gas requirements in place. However, consistent with National Grid NH's recent experience, if a new gas-fired cogeneration power plant were to be located in the Company's service territory, the Company believes that the gas requirements of such facilities would likely be served by third-party gas suppliers in conjunction with a transportation only service provided by National Grid NH from the city gate to the facility. Accordingly, National Grid NH's forecast shows no demand for the large-scale cogeneration market and no impact on the resource plan.

4. Demand-Side Management

National Grid NH is approximately half way through a twenty (20) month energy efficiency program approved by the Commission in Order No. 24,995 dated July 31, 2009 in Docket DG 09-049. A copy of the program description is attached in Appendix B. Subject to Commission review and approval, the Company expects to continue its efficiency program beyond the December 31, 2010 expiration of the current plan through to the end of the forecast period. In past filings the Company treated the impact of its energy efficiency programs as a reduction to its forecasted demand because they are driven by specific incentives that occur outside of the normal operation of the energy market in its territory. In this filing, in accordance with Commission Order No. 24,941, the Company is treating demand side management as a resource integrated with its available supply-slide resources. A more detailed description of this integration process to guantify demand side management savings volumes and the costs to acquire them.

- 5. <u>Transportation Migration</u>
 - (a) Introduction

Since the introduction of the National Grid NH's C&I transportation program in 2001, the Company has gained nearly eight years of experience with unbundled transportation service in New Hampshire. See Chart III-B-5 for the Company's transportation customer activity since 2001. National Grid NH currently has in place a comprehensive customer-choice program that provides C&I customers with an

opportunity to share in the benefits provided by increased competition in the retail market for natural gas.

(b) Impact of Transportation Migration on Sendout Requirements

The Company's resource portfolio is currently structured to have a high level of flexibility to adapt to changing market conditions and regulatory obligations. This is especially true with respect to the Company's domestic gas commodity commitments. Generally speaking, National Grid NH enters into agreements that allow it the flexibility to eliminate up to 100 percent of its existing domestic gas commodity purchases in less than a twelve-month period. With respect to capacity resources, the Company currently has an obligation to plan for the needs of firm customers whether they receive sales, or transportation-only services. Therefore, the Company plans for the needs of sales customers and assigns a pro-rata share of pipeline capacity, underground storage capacity and supplement resources to third-party suppliers on behalf of those sales customers who convert to Supplier Service.⁶ Under the Company's Delivery Terms and Conditions, capacity is assigned to third party suppliers, on behalf of migrating sales customers, in block increments based on the profile of the aggregated customer group served by the supplier (rather than on a customer-by-customer basis). The supplier is assigned an initial block of capacity that is subject to monthly changes consistent with increases or decreases (in increments of 200 MMBtu) in the customer load served by the supplier. National Grid NH retains recall rights on the capacity contracts that are released to suppliers on behalf of their customers to ensure that the capacity remains

⁶ In accordance with the Company's Delivery Terms and Conditions, new customers (as defined by a meter location) who have not previously been served by the Company as a sales customer, may opt directly to Supplier Service, and therefore, are not eligible for mandatory capacity assignment.

available to serve load within the Company's service territory. In addition, the Company monitors the addition of transportation customers who elect Supplier Service directly and are not eligible for mandatory capacity assignment, as well as any migration of grandfathered customers, who were exempted from the capacity assignment requirements established by the Commission in connection with the unbundling of capacity and supply services, to sales service. For National Grid NH, the customer load opting directly for Supplier Service (without first becoming a Sales Service customer) is relatively small in proportion to the Company's overall firm sendout. From 2001 through the end of 2009, the total annual volumes of such load, 223,000 MMBtu, represents 1.7 percent of total annual sendout forecast for the 2009/10 split year. For the calendar year 2009, there were no customers that opted to go directly to Supplier Service. Moreover, the Company has not noted any significant movement of grandfathered firm transportation customers back to sales service.

In Order No. 24,941 at page 19, the Commission noted that the Staff and the Company agreed that it is not appropriate to plan for a capacity reserve to meet the potential supply needs of grandfathered firm transportation customers. Further, the Commission ordered the Company in this filing to address whether circumstances have changed such that a capacity reserve is warranted. The Company has noted no change in circumstances that would warrant a establishing a capacity reserve.

The Company will continue to monitor growth in new transportation load opting directly for Supplier Service to determine whether, in the future, the Company's growth forecasts should be adjusted. To the extent that the Company projects a need for incremental capacity on the peak day, the Company will consider the trend in these

transportation loads as a factor in determining the best way to meet that need. In the interim, the Company will rely on the Commission approved penalties for underdeliveries by suppliers serving the Company's customers as an appropriate deterrent to prevent suppliers from failing to meet their supply obligation to customers.

6. <u>Advertising and Marketing Incentives</u>

National Grid plans on marketing gas conversions to low use customers and prospects in the Nashua, Concord and Manchester areas during fiscal year 2011. These marketing efforts will be primarily in the form of direct mail with several campaigns planned during the year. The estimated budget for these marketing initiatives is \$60,000 based upon the number of prospects and low use customers that the Company plans on mailing to (approximately 15,000), the number of campaigns during the year (approximately 4) and a cost per prospect per mailing (\$1.00). In addition, the fiscal year 2011 forecasted budget for National Grid NH for incentive rebates is \$125,000. Rebates are offered to prospective new conversion customers and/or low use upgrade prospects. Incentives are offered only where a four year payback on the conversion can be achieved after taking into account the incentive. The Company has not prepared forecasts of advertising and marketing incentives beyond fiscal year 2011. Because these amounts are relatively small and not likely to have a significant impact on the forecasted model results, which would include the impact of historic marketing activities, the Company did not make any adjustments to the forecast results to account for this activity.

7. <u>Sensitivity Analysis</u>

(a) <u>Overview</u>

National Grid NH's resource portfolio must be designed to have adequate and reliable resources available to meet forecasted demand at the lowest possible cost. Because the future cannot be predicted with precision, the Company evaluates whether the portfolio resources will be adequate and reliable when actual experience departs from the forecast. Specifically, the Company considered the levels of uncertainty in the demand and sendout forecasts and developed high- and low-demand scenarios relative to the base case forecast to determine the impact a range of alternatives would have on its resource portfolio. A comparison of the average annual load additions for the base case, high- and low-demand scenarios is presented in Chart III-B-2.

(b) <u>Development of Demand Scenarios</u>

National Grid NH used the results of the econometric models to develop the high and low demand scenarios. The growth rates of the combined results of econometric model for customers, use per customer and sales, for the residential heating and non heating and C&I heating and non heating classes were adjusted up and down by 1 percentage point. For the high case, the Company increased the growth rates on the resulting forecast by 1 percentage point to calculate the high demand values. Similarly, for the low case, the Company decreased the growth rates on the resulting forecast by 1 percentage point to calculate the low demand values.

(i) <u>High-Demand Scenario</u>

The high-demand scenario, shown in Chart III-B-3, results in total net additions of 2,417,629 MMBtu, or 513,523 MMBtu per year, compared to 1,425,534 MMBtu, or

356,384 MMBtu per year, in the base case (see Chart III-B-1). For the high-demand scenario, National Grid NH increased the annual growth rates that resulted from the base case forecast by 1 percentage point. For example, the average annual growth rate in the base case is 2.6 percent and in the high case it is 3.8 percent.

(ii) Low-Demand Scenario

The low-demand scenario, shown in Chart III-B-4, results in total net additions of 940,609 MMBtu, or 210,551 MMBtu per year, compared to 1,425,534 MMBtu, or 356,384 MMBtu per year, in the base case (see Chart III-B-1). For the low-demand scenario, National Grid NH decreased the annual growth rates that resulted from the base case forecast by 1 percentage point. For example, the average annual growth rate in the base case is 2.6 percent and in the low case it is 1.5 percent.

C. Regression Analysis

In the second step of National Grid NH's forecasting methodology set forth in Section III.A, above, the Company uses regression equations of daily sendout versus daily temperature for the most recent twelve months to calculate the reference-year "springboard." This serves as the most accurate starting point for National Grid NH to forecast its future customer requirements. Once this step is completed, the incremental sendout requirements developed in Section III.B can be added to the reference-year sendout requirements to determine National Grid NH's normal year forecast of customer requirements over the forecast period for gas cost recovery purposes and to determine National Grid NH's design year forecast of customer requirements over the forecast

period for resource planning purposes. To perform its regression analysis, the Company used version 2.10.1 of the R statistical software package.⁷

To establish normal-year springboard sendout requirements, the Company developed a linear-regression equation using data for the reference-year period April 1 2008 through March 31, 2009. Its regression equation uses sendout as its dependent variable and temperature as its independent variable.⁸

Through the use of the linear-regression equation, the Company is able to normalize daily sendout. Specifically, the actual daily firm sendout is regressed against heating degree day ('HDD") data as calculated from hourly temperature data from the National Weather Service, HDD data lagged by one day, and a weekend dummy variable. These data elements were selected for the regression analysis since these elements have been, and continue to be, the major explanatory variables underlying National Grid NH's daily sendout requirements.

National Grid NH selected the Manchester, New Hampshire weather station (KMHT) as the source of the weather data that is used as the principal explanatory variable in its regression equations. The Manchester weather station was selected because it is close to the center of the Company's service territory, on a load-weighted basis. Specifically, the Company used the HDD value calculated from the average of the hourly air temperature readings measured for each 24-hour period of 10 a.m. to 10 a.m., which constitutes the gas day and therefore corresponds to the same daily time

⁷ "R is a language and environment for statistical computing and graphics. It is a GNU project which is similar to the S language and environment which was developed at Bell Laboratories (formerly AT&T, now Lucent Technologies)... R can be considered as a different implementation of S. There are some important differences, but much code written for S runs unaltered under R. R is available as Free Software under the terms of the Free Software Foundation's GNU General Public License in source code form. It compiles and runs on a wide variety of UNIX platforms and similar systems (including FreeBSD and Linux), Windows and MacOS." (Source: The R Project for Statistical Computing)

period of observation of the sendout data. Throughout its regression analysis, the Company defined HDD as 65° F minus the daily average air temperature without setting values less than zero to zero (left-truncation) as is done in the standard definition of HDD.

Based on its observations of the relationship between sendout and HDD over the split years 2001/02 through 2008/09, the Company chose to develop its regression equation as a segmented model, a *"regression model where the relationships between the response and one or more explanatory variables are piecewise linear, namely represented by two or more straight lines connected at unknown values: these values are usually referred as breakpoints."* (Source: "segmented: an R package to fit regression models with broken-line relationships," R News, Volume 8/1, May 2008, page 20). Since a significant portion of the Company's sendout is due to space heating usage and space heating only occurs when average air temperatures fall below a certain level, the segmented model serves as an excellent starting point for modeling the relationship between sendout and HDD.

The results of regressing sendout vs. HDD alone over the split years 2001/02 through 2008/09 show how significant temperature is as an explanatory variable for Company sendout as R^2 values over the period range from 0.97 to 0.98 (Table III.C.1 below).

⁸ Sendout includes both sales and supplier service customer requirements

Table III.C.1: Segmented Regression Results for sendout vs. HDD								
Split Year	Intercept	Slope1	Slope2	Standard Error	Adjusted R ²	Breakpoint HDD		
2001/02	11,209.90	228.60	1,671.10	2,974	0.9767	9.25		
2002/03	10,725/33	189.11	1,832.30	3569	0.9841	8.78		
2003/04	11,982.32	334.44	1,874.30	3,623	0.9831	9.70		
2004/05	11,444.23	225.98	1,923.94	3,085	0.9868	9.33		
2005/06	11,801.62	191.28	1,803.81	3,116	0.9833	7.75		
2006/07	13,032.92	308.79	1,957.23	3,430	0.9829	10.31		
2007/08	11,292.85	166.81	1,874.25	3,347	0.9837	7.70		
2008/09	11,931.39	318.08	1,883.55	3,658	0.9825	9.17		

In Table III.C.1, *Intercept* is the MMBtu sendout predicted at HDD=0, *Slope1* is the MMBtu/HDD usage below the Breakpoint HDD level, *Slope2* is the MMBtu/HDD usage above the Breakpoint HDD level, the *Standard Error* is expressed in MMBtus, and the *Breakpoint HDD* is the HDD value at which space heating equipment is observed to turn on. The signs of the Slope1 and Slope2 coefficients (positive) imply that as temperatures get colder and HDD increases in value, then sendout will increase, which agrees with what the Company observes.

From the frequency plot (periodogram) of the residuals of the sendout vs. HDD regression, the Company observed a significant peak at frequency 0.14 (and its harmonic at 0.28), which indicates a correlation in the error term once in 1/0.14, or 7, days, confirming the Company's observations that weekday and weekend sendout requirements are different at similar HDD levels. Examining the average of the 2008/09 residuals by day of the week (Table III.C.2), the Company added a second independent

variable, a weekday/weekend dummy variable set to zero for Mondays through Thursdays, 1 on Fridays and Sundays, and 2 on Saturdays.

Table III.C.2: Average Residual By Day of the Week for 2008/09 (MMBtu/day)					
Monday 908					
Tuesday	1539				
Wednesday	1353				
Thursday	898				
Friday	-914				
Saturday	-2,658				
Sunday	-1,067				

The introduction of the second independent variable added an incremental improvement in the adjusted R^2 of the equations and, more importantly, eliminated the 7-day correlation of the residuals. Table III.C.3 lists the regression results after adding the weekend dummy variable. The sign of the coefficient (negative) implies that there is a reduction in sendout on weekend days versus weekday days at similar temperatures, as has been observed by the Company.

Table III.C.3: Segmented Regression Results for sendout vs. HDD and Weekend								
Split Year	Intercept	Slope1	Slope2	Weekend	Standard Error	Adjusted R ²	Breakpoint HDD	
2001/02	11,998.00	215.31	1,654.49	-1,643.69	2,726	0.9804	8.81	
2002/03	11,522,34	197.78	1,824.12	-1,358.36	3,434	0.9853	8.72	
2003/04	12,661.35	323.47	1,871.17	-1,367.45	3,484	0.9844	9.50	
2004/05	12,357.52	231.80	1,923.48	-1,559.93	2,869	0.9886	9.37	
2005/06	12,913.03	208.71	1,808.79	-1,727.54	2,853	0.9860	7.98	
2006/07	14,196,94	308.40	1,947.13	-2,254.98	3,011	0.9868	10.06	
2007/08	12,383.46	176.01	1,879.34	-1847.24	3,067	0.9863	7.82	
2008/09	12,935.28	286.60	1,878.51	-1,976.01	3,366	0.9852	8.82	

Lastly, the Company observed a correlation between lagged temperature and the residuals of the above equation and it investigated adding a third independent variable. Its three choices were: (1) the difference between HDD on day t and HDD on day t-1, (2) the difference between HDD on day t and mean of the HDD on day t-1 and day t-2, or (3) the difference between HDD on day t and the mean of the HDD on day t-1 and day t-2 and day t-3. The differences were used in lieu of the actual lagged values to avoid correlation among the independent variable. The Company chose option (2) as the optimal additional independent variable. The underlying theory of this analysis is that heating requirements increase as two consecutive days of cold weather occur, which cools down structures to a greater degree than would be experienced on a single day. Table III.C.4 lists the regression results after adding the lagged HDD-difference variable. The sign of the coefficient (negative) implies that, if a day is colder than the previous day, the increase in sendout will be somewhat lower than what would be forecast without the coefficient, and vice versa.

Table	Table III.C.4: Segmented Regression Results for sendout vs. HDD and Weekend and Lagged Delta HDD								
Split Year	Intercept	Slope1	Slope2	Weekend	Lagged Delta HDD	Standard Error	Adjusted R ²	Breakpoint HDD	
2001/02	11,785.17	280.88	1,712.17	-1,367.82	-231.45	2,226	0.9869	9.77	
2002/03	11,925.99	303.73	1,869.98	-1,565.62	-241.72	2,931	0.9893	10.09	
2003/04	12,622.81	397.73	1,922.02	-1,347.64	-290.60	2,811	0.9899	10.52	
2004/05	12,276.80	358.03	1,963.13	-1,424.72	-273.33	2,168	0.9935	10.49	
2005/06	12,783.89	243.75	1,840.82	-1,690.16	-225.37	2,397	0.9902	8.36	
2006/07	13,708.51	317.82	1,976.10	-1,991.89	-235.66	2,523	0.9908	10.05	
2007/08	12,687.66	324.71	1,918.56	-1697.29	-264.47	2,473	0.9912	9.21	
2008/09	12,859.90	363.70	1,948.81	-2,014.95	-312.03	2,466	0.9921	10.03	

The functional form of the equation is given in Chart III.C.4. Table III.C.4 sets forth the regression coefficients for the National Grid NH system. The adjusted R-square is 0.9921, and all of the t-statistics of the independent variables are greater than 2.0, indicating that these variables are significant to the explanatory power of the equation.

This regression equation captures the observed characteristics of the Company's sendout requirements. The observed characteristics include the following: (1) sendout requirements are directly related to HDD; (2) sendout requirements are affected by HDDs that occur over a multi-day period; and (3) sendout requirements differ by day of the week. Thus, National Grid NH has developed a reliable regression equation to establish the basis upon which future sendout requirements can be forecast. Using its forecast of load additions and an appropriate set of daily HDD values for a design year, the Company can successfully plan its operational requirements to provide a low-cost, adequate and reliable supply of natural gas to its customers.

D. Normalized Forecasts of Customer Requirements By Year

Pursuant to Order No. 24,941, the Company bases its planning standards on a Monte Carlo analysis, having selected average daily temperature as the variable to be modeled and HDD, which is a linear transformation of average daily temperature, as the independent variable for its regression analysis. The Company decided to perform its Monte Carlo analysis on average daily temperature in this filing based on the experience it gained in its 2006 Long-Range Plan filing (DG 06-105). In Docket DG 06-105, the Company performed its Monte Carlo analysis on Effective Degree Days ("EDD")⁹ and it learned that there a number of accommodations that have to be made when using data that is not continuous, i.e. EDD is a left-truncated data series in that it is the set of integer numbers greater than or equal to zero, whereas average daily temperature at Manchester, NH.

The Company has two sources of temperature data to use for its analysis. For data from 1977-2000, the Company used maximum and minimum temperatures (in °F) observed at the Manchester NH airport (KMHT). This data was available from the National Weather Service and Weather Underground, Inc. Average daily temperatures (from 12 midnight to 12 midnight) were calculated and rounded to one decimal place of precision. For data from 2001 to the present, the Company calculated average daily temperatures for the Gas Day (from 10am - 9am) from hourly national Weather Service METAR data from the Manchester NH airport (KMHT). These hourly observations are

⁹ EDD incorporates the effects of both temperature and wind speed.

expressed in °C. The Company calculated average daily temperature (in °F) as the mean of the 24 hourly temperature observations in °C taken through the Gas Day. The average daily temperatures were then converted from °C to °F and they are specified with three decimal places of precision. There are no gaps in the data from January 1, 1977 – July 31, 2009.

a. The Theory of the Company's Monte Carlo Methodology

For its 2010 filing, the Company has used a Monte Carlo simulation method to generate synthetic daily EDD values for Manchester, NH for purposes of establishing its normal and design planning standards. The application of this Monte Carlo method provides the Company with a much larger time series of daily temperature values on which to base its standards.

The Monte Carlo methodology generally implies the generation of a dataset of synthetic values, larger than a given dataset of actual observations, based on the observed statistical properties of the actual dataset. The larger size of the synthetic dataset (4,096 simulated years) can assist in the determination of a better approximation of average expected temperatures (normal) as well as the likelihood of extreme weather events, such as those the Company seeks to define in its design standards.

In developing a time series of daily temperature values much larger than the Company's existing actual historical observations from 1977-present, greater consideration had to be given than to generate 365 random values for each year of the synthetic dataset. First, consideration of the seasonality of temperature values had to be given. Second, consideration of the interdependence of one day's temperature

value with the prior day's value had to be given, as well. To generate its set of synthetic data values, the Company chose to model its temperature data using a first-order autoregressive process (denoted AR(1)). Such a model has been commonly assumed for meteorological time series.

Letting X_t denote the temperature value on the tth day, the AR(1) process requires that the conditional probability distribution of X, given the past record of observed temperatures, X_{t-1} , X_{t-2} , , depends only on X_{t-1} , the observed temperature value for the previous day. This property can be expressed as:

$$X_t - \mu = \Phi(X_{t-1} - \mu) + \varepsilon_t,$$
 (1)

where the daily temperature values are expressed in terms of deviations from their common mean μ , and Φ denotes the first-order autocorrelation coefficient. The error terms (ϵ_t) in equation (1) are assumed to constitute a "white-noise process"; that is, they are uncorrelated random variables with zero mean and constant variance σ_{ϵ}^2 . It is further assumed that the ϵ_t , are normally distributed [denoted N(0, σ_{ϵ}^2)].

The first-order autocorrelation coefficient Φ measures the degree of dependence between the temperature values on consecutive days, X_{t-1} and X_t. A value of $\Phi = 0$ implies that X_{t-1} and X_t are uncorrelated (i.e., X_t is completely unpredictable from the past record of daily temperatures), whereas a value of $\Phi = 1$ or -1 implies that the X_t are perfectly correlated (i.e., X_t is completely predictable). For daily temperature time series, typically 0 < Φ < 1, meaning that the X_t are positively, but not perfectly, correlated. An AR(1) process is stationary (i.e., all the joint probability distributions of the X, are time invariant) if $|\Phi| < 1$.

The requirement that the error term ε_t is normally distributed implies that the daily temperature X_t also is normally distributed. Letting σ^2 denote the variance of X_t, it is straightforward to show that σ^2 is related to σ_{ϵ}^2 , the variance of an error term, by

$$\sigma_{\epsilon}^{2} = (1 - \Phi^{2}) \sigma^{2}$$
⁽²⁾

We see by equation (2), that the stronger the dependence between X_{t-1} and X_t , the greater the reduction in the variance of an error term relative to the variance of daily temperature. More importantly, (2) implies that an AR(1) process can be completely characterized in terms of three parameters, μ , Φ and σ^2 .

b. The Application of the Company's Monte Carlo Methodology

The Company used the dataset of thirty-two calendar years of daily average air temperature (in ${}^{o}F$; 1977-2008) at Manchester NH airport as the source data for its Monte Carlo analysis. For the purposes of this analysis, the data for leap days were removed. To begin its analysis, the Company determined the annual (365-day) cycle in the dataset Fourier analysis and removed it from the input dataset (i.e. it "deseasonalized" the temperature pattern over the course of the year) to conduct its analysis on the variations in temperature about the long-term mean values. The Company then calculated Φ , the first-order autocorrelation coefficient, over the entire dataset of deseasonalized daily average temperatures. For each calendar day, the

Company then computed the mean and standard deviation values (32 observations per day) to establish the μ and σ^2 parameters required for its AR(1) process.

To create 4,096 years of synthetic daily temperature time series, the Company generated 365 random EDD deviation values (January 1st – December 31st) denoted by X'₁, X'₂,..., X'₃₆₅, from the AR(1) process. The initial daily temperature deviation value (for the day of January 1st), X'₁ was produced from the N(μ , σ^2) normal distribution by means of a random number generator. Each subsequent daily temperature deviation value, X'_n, was produced using Equations (1) and (2) from the N(μ , σ^2) normal distribution by means of a random number generator and the first-order autocorrelation coefficient Φ . Finally, the entire Monte Carlo data series was re-seasonalized by adding back in the 365-day seasonal component removed at the beginning of the analysis.

c. Definition of the Normal Year

Since it is important to model resource utilization using realistic weather scenarios, the Company could not directly take the mean of the 4,096 Monte Carlo values for each calendar day to define its normal year. National Grid NH needed to design a "Typical Meteorological Year" which would be actual observed weather patterns that would, on average, represent the normally-expected year.

From the Monte Carlo dataset, the Company calculated for each calendar month the mean monthly air temperature as well as the mean of the monthly standard deviations of the air temperature within each calendar month. It then referred back to the 32 years of actual data on record and, for each calendar month, it selected the month in the Manchester, NH weather database that most closely approximated the average temperature and standard deviation for each month. Since the actual values never exactly equaled the target monthly value, the Company then scaled the actual daily values by the ratio of the target mean temperature from its Monte Carlo analysis to the actual mean temperature for each month.

Lastly, the Company's Typical Meteorological Year was converted from temperature to HDD for modeling purposes (Table III.D.1). The normal year is defined as 6,409.8 HDD (rounded to 6,410 HDD) with a standard deviation of 276.88 HDD. Within the normal year, the coldest expected day is 61.51 HDD with a standard deviation of 5.40 HDD.

Table III.D.1: Normal Year HDD						
January	1,214					
February	1,040					
March	919					
April	550					
Мау	227					
June	45					
July	8					
August	17					
September	118					
October	423					
November	766					
December	<u>1,083</u>					
Total	6,410					

d. Normal Year Customer Requirements

In the third step of the Company's forecasting methodology set forth in Section III.A, above, the Company combines the April 2008 – March 2009 reference-year

sendout, which is derived from the regression analysis, with the annual incremental sendout forecast discussed in Section III.B, to yield the following forecast of customer requirements under normal weather conditions:

Base Case Demand Scenario Customer Requirements (MMBtu)

	<u>2010/11</u>	<u>2011/12</u>	<u>2012/13</u>	<u>2013/14</u>	<u>2014/15</u>
Heating Season	9,257,057	9,460,883	9,667,358	9,862,266	10,060,888
Non-Heating Season	<u>3,841,316</u>	<u>3,995,891</u>	<u>4,160,845</u>	<u>4,314,283</u>	<u>4,463,019</u>
Total	13,098372	13,456,774	13,828,203	14,176,549	14,523,907
Per-Annum Growth		2.7 %	2.8 %	2.5 %	2.5 %

The heating season is defined as the months of November through March; the nonheating season is defined as the months of April through October. The leap day in 2012 is not factored in these tables.

High Case Demand Scenario Customer Requirements (MMBtu)

	<u>2010/11</u>	<u>2011/12</u>	<u>2012/13</u>	<u>2013/14</u>	<u>2014/15</u>
Heating Season	9,430,576	9,730,752	10,038,810	10,339,946	10,650,091
Non-Heating Season	<u>3,917,886</u>	<u>4,120,179</u>	<u>4,336,812</u>	<u>4,545,257</u>	<u>4,752,464</u>
Total	13,348,462	13,850,931	14,375,621	14,885,203	15,402,555
Per-Annum Growth		3.8 %	3.8 %	3.5 %	3.5 %

Low Case Demand Scenario Customer Requirements (MMBtu)

	<u>2010/11</u>	<u>2011/12</u>	<u>2012/13</u>	<u>2013/14</u>	<u>2014/15</u>
Heating Season	9,086,718	9,198,596	9,309,939	9,407,214	9,505,192
Non-Heating Season	<u>3,766,145</u>	<u>3,875,063</u>	<u>3,991,458</u>	<u>4,094,139</u>	<u>4,189,877</u>
Total	12,852,863	13,073,659	13,301,397	13,501,353	13,695,069
Per-Annum Growth		1.7 %	1.7 %	1.5 %	1.4 %

E. Resource Planning Standards

In the fourth step of the Company's forecasting methodology, the Company determines the appropriate design-day and design-year planning standards to develop

a least-cost reliable supply portfolio over the forecast period. Design day and design year are two types of extreme weather events for which the Company must maintain adequate resources. These two types of standards are significant in that the design day standard determines the most cost-effective amount of daily transportation capacity (both interstate and supplemental) and the design year standard determines the most cost-effective amount of storage supply to maintain to ensure reliable seasonal service to the Company's customers.

The design day standard is based on the statistical distribution of the coldest day of each calendar year. The design year standard is based on the statistical distribution of the total HDDs in each calendar year.

Pursuant to Order No. 24,941, the Company bases its planning standards on its Monte Carlo analysis, using the method found to be acceptable by the Commission Staff in Docket DG 06-105. In Docket DG 06-105, Staff stated that a design day/year of mean plus two standard deviations "…establishes a reasonable level of reliability for firm customers."

Therefore, the Company's design day is defined as 61.51 + 2*5.40, or 72.3 HDD (rounded to 72 HDD) and its design year is defined as 6409.8 + 2*276.88 HDD, or 6963 HDD. To create its design year of daily HDD values, the Company scaled upward each of the daily HDD values in its normal year by the ratio of 6,963 / 6,410.

The Company's design year is summarized in Table III.E.1

III-62

Table III.E.1: Design Year HDD					
January	1,324				
February	1,129				
March	998				
April	597				
Мау	246				
June	49				
July	8

September	128				
October	459				
November	831				
December	<u>1,176</u>				
Total	6,963				

F. Forecasts of Design Year Customer Requirements By Year

In the fifth and final step of the Company's forecasting methodology set forth in Section III.A above, the Company uses the applicable design day and design year planning standards to determine the design day and design year sendout requirements. To accomplish this, the Company combines the 2008/09 reference-year sendout, which is derived from the regression analysis, with the annual incremental sendout forecast discussed in Section III.B, to yield the following forecast of customer requirements under design weather conditions:

Base Case Demand Scenario Customer Requirements (MMBtu)

	<u>2010/11</u>	<u>2011/12</u>	<u>2012/13</u>	<u>2013/14</u>	<u>2014/15</u>
Heating Season	10,116,909	10,330,955	10,547,145	10,751,397	10,960,122
Non-Heating Season	<u>4,032,928</u>	<u>4,190,246</u>	<u>4,357,806</u>	<u>4,513,752</u>	4,665,199
Total	14,149,837	14,521,200	14,904,952	15,265,149	15,625,321
Per-Annum Growth		2.6 %	2.6 %	2.4 %	2.4 %

The heating season is defined as the months of November through March; the nonheating season is defined as the months of April through October. The leap day in 2012 is not factored in within these tables.

High Case Demand Scenario Customer Requirements (MMBtu)

	<u>2010/11</u>	<u>2011/12</u>	<u>2012/13</u>	<u>2013/14</u>	<u>2014/15</u>
Heating Season	10,303,316	10,620,471	10,945,267	11,263,019	11,590,844
Non-Heating Season	4,112,956	<u>4,319,806</u>	<u>4,540,930</u>	<u>4,753,834</u>	<u>4,965,786</u>
Total	14,416,272	14,940,277	15,486,197	16,016,852	16,556,630

IV. DESIGN OF THE RESOURCE PORTFOLIO

A. Portfolio Design

To generate the long-term resource plan, the Company evaluates the current resource portfolio in relation to the firm sendout forecast developed in Section III above. Specifically, the Company evaluates the possible strategies for meeting demand with current resources and identifies the sensitivities and contingencies that need to be tested. Using the SENDOUT[®] model (described below), the Company is able to determine the least-cost portfolio that will meet the forecasted demand and test the sensitivity of the portfolio to key inputs and assumptions, as well as its ability to meet all of the Company's planning standards and contingencies. Based on the results of this analysis, the Company then makes preliminary decisions on the adequacy of the resource portfolio and its ability to meet system requirements in the longer term.

National Grid NH has been using the Ventyx SENDOUT[®] model as its primary analytical tool in the portfolio design process since 2000. The SENDOUT[®] model is a linear programming optimization software tool used to assist in evaluating and selecting long-term portfolio strategies.

The SENDOUT[®] model can be used in one of two ways: the optimization mode or the resource mix mode. In the optimization mode, the model can be used to determine the best use of a given portfolio of supply, capacity and storage contracts to meet a specified demand. That is, it can solve for the dispatch of resources that minimizes the cost of serving the specified demand given the existing resource and system-operating constraints. The model

dispatches resources based on the lowest variable cost to meet demand, assuming that demand charges are fixed. In the resource mix mode, the SENDOUT[®] model can be used to determine the optimal portfolio to meet a given demand. To do this, the model uses a linear programming algorithm to analyze the combination of contracts and the size of each contract (i.e., MDQ) to determine the combination that results in the lowest total cost, taking into account both variable and fixed costs.

In this IRP, when performing optimization mode simulations, the 2009/10 long-term, short-term and market-area portfolio was used as a proxy for the gas supply portfolio that will be used in all years of the forecast. Although the actual contracts and contract terms will differ in every year, the Company believes that the current resource mix is representative of the actual supplies that the Company will use over the forecast period. Therefore, gas commodity costs were estimated using NYMEX futures prices for natural gas. All other costs represent actual contract costs including transportation and storage, fixed charges, variable charges, and other related costs. Fixed costs were not escalated over the forecast period because escalating all fixed costs at the same rate would maintain the relative ranking of the resources and would not, therefore, alter the decisions that the Company would make with respect to resource dispatch. Also, there is no indication that annual pipeline and underground-storage rate increases are a reasonable assumption.

B. Analytical Process and Assumptions

In preparing this IRP, the Company analyzed three demand scenarios: a lowdemand case, a base case and a high-demand case, as described in Section III. Each of these three demand scenarios is based on the Company's 2008/09 springboard (as described in Section III.C) plus incremental demand, as forecast for the period of the filing (2010/11 through 2014/15). The Company's traditional resource portfolio (as described below in Section IV.C) was then tested for adequacy to address the customer requirements under design weather conditions. The Company has assumed that, throughout the forecast period, there is no change in its current service obligation and that, as a result, it is responsible for planning for the capacity requirements for all firm customers¹.

The Company then ran these different demand scenarios in combination with three levels of penetration of incremental demand-side management ("DSM") measures: low case, base case, and high case. All three DSM penetration scenarios were SENDOUT® model runs in optimization mode alone to test the reduction in utilization of the Company's traditional resource portfolio due to different levels of DSM. The Company then utilized the resource mix mode of the SENDOUT[®] model to optimize its resource portfolio with both supply-side and demand-side resources. In its resource mix run, the Company evaluated the conversion of a portion of its Tennessee long-haul transportation to short-haul from the Marcellus Basin, as well as the optimal mix of DSM expiring transportation The Company's and two of its contracts.

¹ As noted in section III B above, this obligation excludes those firm transportation customers that are exempt from the Commission's mandatory capacity assignment rule. i.e. customers who had migrated to transportation service prior to the implementation of the mandatory capacity assignment rule or new customers who go direct to delivery only service.

expiring Niagara and Dawn supply transportation contracts were optimized sideby-side with its demand side management resource options.

In its Order No. 24,941 in Docket DG 06-105 dated February 13, 2009, the Commission required the Company to use as the basis of its demand-side assessment in this IRP filing, the information on the technical and economic potential of demand side resources contained in the report "Additional Opportunities for Energy Efficiency in New Hampshire" by GDS Associates (January 2009). A copy of the report is provided as Appendix C. The Company reviewed the details of this report as it prepared this filing. The Company concluded that the most realistic scenario presented in this report was the "Potentially Available Scenario" and chose to evaluate it as the upper limit constraint on reasonably available demand side management savings. Under this scenario, the report concludes that the potentially obtainable demand side management savings is approximately 10.7 percent of the residential fossil fuel consumption (See, Appendix C at Table 43, Summary of Residential Non-Electric Energy Efficiency Savings Potential, p. 66), 7.0 percent of commercial fossil fuel consumption (See, Appendix C Table 47, Summary of Commercial Non-Electric Energy Efficiency Savings Potential, p. 88), and 4.4 percent of industrial consumption (See, Appendix C Table 57, Summary of Industrial Non-Electric Energy Efficiency Savings Potential, p. 108). Because the Company's records combine the C&I classes, the Company calculated a weighted average of the two

percentages for these classes and derived a combined potential of 6.5 percent² for the C&I class. Applying these percentages for the residential and C&I classes to the 2009/2010 sendout volumes presented in Table III-13 above, results in an over-all savings potential of 8.5 percent or 1,084,787 MMBtu. Given that this potential is more than 8.7 times the 2010 goal of 124,318 MMBtu in the Company's currently approved energy efficiency program, the Company determined that the savings potential estimated in this report does not represent a practical target or limit of demand side management savings for supply planning purposes. Therefore, it developed the assumptions described below to determine the demand side management volumes available to its supply portfolio.

The Company started with the costs and MMBtu savings goals presented and approved in its current energy efficiency program, from Order No. 24,995 dated July 31, 2009 in Docket DG 09-049. The annual savings goal under this program is 124,318 MMBtu at a total annual cost of \$9,527,217, including \$4,986,415 of Company cost, \$4,141,889 of participant cost and \$398,913 of Company incentive. These costs and savings provided the initial structure needed to enter demand side management into the SENDOUT[®] model as a supply resource.

As a base case, the Company assumed that these program savings and costs would be repeated for each year of the five-year forecast, and included

² (Commercial Savings + Industrial Savings) / (Commercial Consumption + Industrial Consumption) = (3,252,204 MMBtu + 683,836 MMBtu) / (45,329,915 MMBtu + 15,673,818 MMBtu) = 6.5 percent

them in the supply portfolio as such. The result is a total of 621,950 MMBtu of demand side management savings in the portfolio by year five of the forecast representing 4.3 percent of the customer requirements in 2014/15.

As a low case, the Company assumed that it would realize the average level of savings actually achieved over the past five years of program implementation resulting in 395,990 MMBtu of demand side management savings by year five of the forecast. This represents 2.7 percent of the customer requirements in 2014/15.

For the high case, the Company allowed the SENDOUT[®] model to determine the reasonably available demand side management savings to be included in the portfolio. To model demand side management in this way, the Company started with the program costs and MMBtu savings and made the following simplifying assumptions:

- o The average lives of the measures in the program are 15 years,
- Any increase in demand side management volumes, would result from increasing the number of installations of measures that rely strictly on rebates (Residential Weatherization and Commercial Energy Efficiency Program) and not from measures that require equipment replacement, demonstration projects or information dissemination,
- That the cost of these increased volumes would be at the variable costs associated with these program measures,
- As a constraint on the maximum demand side management volumes that could be obtained, the Company limited the number of installations of the Residential Weatherization and Commercial Energy Efficiency Programs to two times the goal by the third year of the forecast and four times the goal by the fifth year of the forecast. This assumption is based on experience the Company has implementing the programs over the past six years.

The result of the high case is an additional 23,007 MMBtu of demand side management annually with a per-annum cost of \$1,574,436. The results of this analysis are presented in Chart IV-D-1.

In its Order No. 24,941, the Commission further states that the Company should include in this filing a description of the methodology for calculating the avoided costs (i.e. cost savings) associated with not having to purchase additional gas supplies or constructing new peaking capacity. Because the SENDOUT[®] model's resource mix mode performs a least-cost selection of the available supplies including demand side management savings, there is no

explicit avoided cost calculation involved. The model selects the optimum level of demand side management savings in the portfolio based on their costs relative to the costs of the other supplies in portfolio and subject to the constraints identified above for demand side management and the constraints for the other supplies.

However, as described in the attached *Energy Efficiency Plan, May 2009 through December 2010* (Appendix B) submitted by the Company on May 8 2009 and approved by the Commission in DG 09-049, Order No. 24,995, the Company used the avoided energy costs from the regional "Avoided Energy Supply Costs in New England: 2007 Final Report," in performing the benefit/cost analysis. The avoided costs are presented as the benefits in benefit/cost analyses for each measure of each program in Exhibit B of the Plan. Hence, the Company's analysis includes the evaluation of the combinations of scenarios listed in the four tables below:

No demand side management Scenarios				
	Low Case Base Case High Case Demand Demand

High Case demand side management Scenarios				
	Low Case Base Case High Cas Demand Demand Demand			
Design Year		~		
Normal Year		~		

In addition, the Company analyzed two final scenarios: first, a cold-snap scenario using the Company's current supply and capacity portfolio with no demand side management resources to test portfolio adequacy for its seven-day storage requirement; and, second, a scenario that tested the benefit of optimizing the balance between the Company's traditional Gulf Coast long-haul transportation contract with the potential to convert a portion of it to short-haul transportation of supply from the Marcellus Shale supply basin in the Northeast.

The detailed tables of results from all of these scenarios can be found in Appendix D: Resource and Requirements Tables.

C. Expected Available Resources

This section describes National Grid NH's current resource portfolio and discusses the modifications that the Company anticipates making to the portfolio during the forecast period to meet sendout requirements. As discussed below, to meet design day and design year sendout requirements, the Company's resource portfolio is composed of the following categories of available resources: (1) long-haul and short-haul transportation; (2) underground storage services; (3) gas supply contracts; (4) supplemental resources; (5) market area supply purchases and (6) Demand Side Management ("DSM") resources.³ Chart IV-C-1 is a schematic of the Company's transportation and underground storage contracts effective November 1, 2009. Chart IV-C-2 is a table listing and description of the Company's resource portfolio. Appendix B is a description of the Company's most recently approved DSM program.

1. Long-haul and Short-haul Transportation

National Grid NH has capacity entitlements on multiple upstream pipelines that provide access to various production areas that afford the Company a level

³ In the past the Company treated the volume reductions associated with DSM programs as reductions to demand forecast. In this filing DSM is treated as a supply option, and optimized with other supply options in the design of the supply portfolio.

of operational flexibility to ensure the least-cost and reliable delivery of gas supplies.

The Company's pipeline capacity contracts fall into four primary categories. First, the Company has contract entitlements to long-haul capacity from the lower 48 states that are used to transport gas from production areas located in the Gulf of Mexico to the Company's New Hampshire citygates. The long-haul transportation capacity from the Gulf of Mexico is also used to transport gas from the production areas to the Company's underground storage facilities in Pennsylvania and New York. By using long-haul capacity to fill storage, the Company is able to use these resources at a higher load factor. Second, the Company has contract entitlements to short-haul capacity that is used to transport gas from the underground storage fields in Pennsylvania and New York to the Company's citygates. These short-haul capacity entitlements are also used to transport non-storage supplies from the storage market area to the Company's citygates when the capacity is not being used to transport underground storage supplies. Third, the Company has a short-haul contract with entitlements to transport gas from the Dracut, Massachusetts interconnect on Tennessee Gas Pipeline ("Tennessee") to the Company's citygates. Lastly, the Company holds capacity on Union Gas Limited ("Union") and TransCanada Pipelines Limited ("TransCanada"). This capacity path consists of entitlements from Dawn, Ontario to Kirkland/Parkway on Union and from Parkway to Waddington on TransCanada. The gas is then transported to National Grid NH's citygates using transportation capacity on Tennessee and the Iroquois Gas

Transmission System ("Iroquois"). The Company's long-haul and short-haul transportation contracts are described in more detail below:

Iroquois Gas Transmission System

National Grid NH has contract entitlements to 4,047 MMBtus/day of firm transportation service on Iroquois on a 365-day basis. Firm Canadian supplies are transported from the Canadian/New York border from Waddington, New York via the Iroquois system to the Tennessee interconnect at Wright, New York. Effective May 1, 2009, National Grid NH entered into an amendment extending the term from December 1, 2011 to November 1, 2017. This amendment aligns the Iroquois contract with the upstream contracts on Union and TransCanada.

Portland Natural Gas Transmission System

National Grid NH has contract entitlements to 1,000 MMBtus/day of firm transportation service on the Portland Natural Gas Transmission System ("PNGTS") on a 365-day basis. PNGTS transports gas from Pittsburg, New Hampshire to the Company's city gate in Berlin, New Hampshire.

• Tennessee Gas Pipeline

In the production area, Tennessee splits into three legs: the 100 leg, the 800 leg, and the 500 leg. In addition, the Tennessee system is divided into six market Zones, from Zone 0 and Zone 1 in Texas and Louisiana to Zone 6 in New England. See Chart IV-C-3 for a map showing the Tennessee Zone locations. National Grid NH has capacity

entitlements of 107,833 MMBtus/day on Tennessee to its New Hampshire The Company's contract entitlements consist of transport citygates. volumes from Zone 0 and Zone 1 of up to 21,596 MMBtus/day to the Company's citygates in New Hampshire located in Zone 6 and to the Company's storage fields located in Zone 4 and Zone 5; from the Zone 4 and Zone 5 storage market area the Company's contract entitlement consists of transport volumes of up to 28,115 MMBtus/day to the Company's citygates; from the interconnect at Niagara in Zone 5 the Company's contract entitlements transport volumes of up to 3,122 MMBtus/day to the Company's citygates; from the interconnect at Wright, New York with Iroquois in Zone 5 the Company's contract entitlements transport volumes of up to 4,000 MMBtus/day to the Company's citygates; and finally, the Company has contract entitlements of up to 50,000 MMBtus/day from Dracut, Massachusetts located in Zone 6 to the Company's citygates.

TransCanada Pipelines Limited

National Grid NH has contract entitlements to 4,047 MMBtu/day of firm transportation service on TransCanada on a 365-day basis. Firm Canadian supplies are transported from the receipt point on Union at Dawn, Ontario, to the interconnection with Iroquois at Waddington.

Union Gas Limited

Effective November 1, 2007 TransCanada and National Grid NH entered into a permanent assignment, whereby the Company permanently assigned to TransCanada 4,092 MMBtu/day of capacity on Union with an expiration date of October 31, 2017. This assignment provides for a contiguous nomination path. Firm Canadian supplies are still transported from the receipt point at Dawn, Ontario to the interconnection with Iroquois at Waddington, New York.

2. <u>Underground Storage Services</u>

National Grid NH's underground storage contracts provide the Company with the ability to meet winter-season loads, while avoiding the expense of adding 365-day long-haul transportation capacity. These contracts enable National Grid NH to store approximately 2.5 million MMBtus of gas. These underground storage supplies allow National Grid NH to serve a percentage of the winter period requirements with gas injected during the off-peak period and to manage short-term fluctuations in demand during the winter period. It is the Company's practice to have storage inventories approximately 95% full as of November 1st of each year, thus leaving approximately 5% of the storage capacity available for balancing purposes.

The Company contracts with the following storage providers:

• Dominion Transmission, Incorporated

Under rate schedule GSS which provides 102,700 MMBtus of storage capacity with a withdrawal rate of 934 MMBtus/day and an injection rate of 934 MMBtus/day.

Honeoye Storage Corporation

Under rate schedule SS-NY that provides 245,280 MMBtus of storage capacity with a withdrawal rate of 1,957 MMBtus/day and an injection rate of 1,362 MMBtus/day.

National Fuel Supply Corporation

Under rate schedule FSS that provides 670,800 MMBtus of storage capacity with a withdrawal rate of 6,098 MMBtus/day and an injection rate of 4,472 MMBtus/day. Along with this storage service, the Company also contracts for 365-day firm transportation under rate schedule FST in order to transport the storage gas into and out of the storage field.

• Tennessee Gas Pipeline

Under rate schedule FS-MA that provides 1,560,391 MMBtus of Storage capacity with a withdrawal rate of 21,844 MMBtus/day and an injection rate of 10,404 MMBtus/day.

3. Gas Commodity

The Company is responsible for contracting for the necessary gas supply to meet firm sendout requirements. In order to meet customer requirements the Company will contract for a mix of seasonal, monthly and daily supplies from a diverse group of suppliers that are designed to take advantage of the interstate pipeline capacity paths held by the Company.

(a) Domestic Gas Supply

As described above, the Company's resource portfolio is currently structured to have a high level of flexibility to adapt to changing market conditions

and regulatory obligations as they relate to Supplier Service. This is especially true with respect to the Company's domestic gas commodity commitments. Generally speaking, National Grid NH enters into agreements that allow it the flexibility to eliminate up to 100 percent of its existing domestic gas commodity purchases in less than a twelve-month period. As of the date of this filing, the Company has supply agreements in place for seasonal supplies sourced from domestic gas supply markets to meet customer requirements for the both 2009/10 peak season and the 2010 off peak season. These volumes are priced as index-based first of the month and/or daily market purchases. Chart IV-C-2 (Page 3 of 4) is a table listing and description of the Company's supply portfolio. These seasonal volumes will later be supplemented, as necessary, with additional index-based first of the month and/or daily market purchases.

(b) Market Area Supply

Market area purchases are short-term arrangements that the Company makes in order to achieve a higher utilization of existing portfolio resources and to prolong the effective utilization of the Company's short-haul capacity. On a daily basis during the peak period, the Company has the opportunity to take advantage of market-area resource opportunities to bring gas supplies to the Company's citygates or to inject them into the Company's underground storage fields. In the past, gas injected into storage during the off-peak season was generally lower priced than gas purchased in the peak season. However, experience indicates that market prices during the winter period can drop below storage inventory costs. Furthermore, prices in the later part of the winter

season can be higher or lower than prices in the early part of the winter season, depending on market conditions. Market-area purchases generally refer to purchase in either Tennessee Zone 4 at or near the storage region or Zone 6 at Dracut, MA, or at the Company's citygates. These purchases minimize the cost of the resource portfolio because: (1) the Company is avoiding demand charges for capacity that is not needed on a design-day or design-season basis; and (2) the Company is able to better utilize existing transportation capacity that is available when underground storage supplies are not being transported to the Company's citygates.

(c) Canadian Gas Supply

In addition to domestic gas supplies, the Company currently holds several long-term supply contracts with Canadian suppliers. Effective November 1, 2006, National Grid NH entered into transportation agreements on TransCanada for transportation from Dawn, Ontario to the interconnect with Iroquois at Waddington, New York. The Canadian transportation and gas supply contracts consists of a gas commodity from Dawn, Ontario Canada pursuant a contract with Alberta Northeast, Ltd. ("ANE-II"), which commenced on November 1, 2006. Supply contracts have been executed with BP Canada Energy Company ("BP Canada") for up to 4,047 MMBtu/day plus applicable fuel commencing on November 1, 2009 through March 31, 2010. The supply will be transported on TransCanada from Dawn, Ontario to the interconnect with Iroquois at Waddington, New York. In addition, the Company entered into a Capacity Assignment and Gas Delivery Agreement with BP Canada for a term of

November 1, 2009 through October 31, 2010. BP Canada provides a fixed fee to the Company for the rights to optimize the assets along the TransCanada path to the interconnect with Iroquois at Waddington, NY.

The Company also holds a contract with BP Canada Energy Company for 3,199 MMBtu/day. This contract delivers into Tennessee at Niagara, NY.

Lastly, as a result of the completion of the Concord Lateral, for additional supply at Dracut, Massachusetts a Request for Proposal ("RFP") was issued on September 29, 2009 for an Asset Management and Gas Supply Agreement effective November 1, 2009 for a term of one year. With the utilization of the SENDOUT® Model the appropriate resource mix was determined to set both the baseload and swing volume requirements by month. As a result of the output of the SENDOUT® Model, it was determined that it would be best to present the need as two packages in the RFP for a term of November 1, 2009 to October 31, 2010.

Package 1 was presented as an Asset Management Arrangement and Gas Supply requirement. In order to match the two (2) Tennessee FT-A Agreements; Package 1 was further subdivided into Agreement #1 and Agreement #2. Agreement #1 has an MDQ of 25,500 MMBtu/day with both a baseload and swing component. Agreement #2 has an MDQ of 17,000 MMBtu/day with a daily swing component for the months of November 2009 through April 2010. The delivery points for both agreements are the National Grid NH citygates. Please see Tables IV-C-1 and IV-C-2 below for a description of the monthly baseload and swing quantities for each agreement. Once, the

delivery obligations are met the successful bidder retains the rights to optimize the released assets, while providing a fixed fee to the Company.

Package 2 was presented as a Gas Supply Package with an MDQ of up to 7,500 MMBtu/day. Package 2 was designed to be used by the Company to meet the full sendout requirements as well as meet the obligations of the Customer Choice Program with regards to migration. The combination of Packages 1 and 2 provides the Company with an MDQ of up to 50,000 MMBtus.

As a result of the RFP for Package 1, the Company entered into an Asset Management and Gas Supply Agreement with Repsol Energy North America Corporation ("Repsol") for supply at the National Grid NH citygates. Provided in the tables below is a breakdown of Gas Supply agreements with Repsol.

Period	Base-Load Quantity (dt/day)	Maximum Daily Call (dt/day)	Maximum Monthly Quantity (dt)
Nov-09	0	25 <i>,</i> 500	765,000
Dec-09	25,500	0	790,500
Jan-10	25,500	0	790,500

Jul-10	0	0	0
Aug-10	0	0	0
Sep-10	0	0	0
Oct-10	0	0	0

Table IV-C-2: Asset Management and Gas Supply Agreement #2

As a result of the RFP for Package 2, the Company entered into a supply arrangement with Sempra Energy Trading for the months of December 2009 to March 2010 to provide for a daily swing quantity of up to 7,500 MMBtu/day.

These Canadian gas supplies represent an important component in maintaining the diversity, flexibility and reliability of the resource portfolio.

4. <u>Supplemental Resources</u>

In addition to interstate pipeline and storage resources, National Grid NH utilizes supplemental peaking supplies to meet its design day and design season requirements in excess of pipeline resources. Peaking supplies are an important component of the resource mix because these supplies provide the Company with the ability to respond to fluctuations in weather, economics and other factors driving the Company's sendout requirements. The Company utilizes both offsystem and on-system supplemental resources.

Off system supplemental resources include the Company's contract with Granite Ridge, L.L.C. ("Granite Ridge," formerly "AES Londonderry") as well as the Company's firm liquid service ("FLS") contract with Distrigas of Massachusetts ("DOMAC").

On-system supplemental resources are the local production plants that store LNG and liquid propane until vaporized. It is the Company's practice to have its supplemental storage facilities full as of November 1st of each year.⁴ National Grid NH's on-system supplemental facilities are distributed strategically across the service territory, which enhances service reliability and provides a source of supply for the entire distribution system. Chart IV-C-4 shows the locations of these facilities. Because these resources can be brought on line quickly, these plants can be used to meet hourly fluctuations in demand, maintain deliveries to customers and balance pressures across portions of the distribution system during periods of high demand. Most importantly, these resources are vital in preserving delivery pressures in the event that an off-system resource becomes unavailable. These supplemental volumes are the supplies that must be available to the Company's distribution system to ensure service to customers when the Company has exhausted its available pipeline supplies. Thus, the availability of liquid natural gas and propane gas to refill the Company's local

storage tanks throughout the winter season is a reoccurring necessity. The Company's DOMAC contract (FLS-160) is currently the primary sources of LNG refill throughout the winter season. The Company will enter into negotiations during the 2010 off peak season for its DOMAC FLS-160 contract that expires on October 31, 2010. In addition, as it has for the last several years, the Company has contracted for a dedicated trucking arrangement in order to guarantee the availability of both trailers and drivers to truck the LNG from the source point to the Company's facilities during the upcoming winter season. Lastly, the Company has a contract for seasonal transportation for propane amongst the National Grid facilities with Eastern Propane Company. The transportation agreement provides for up to 3 loads per day with a maximum of 10 days per month for a term of December 1, 2009 to March 31, 2010. The Company expects to enter into a similar arrangement in subsequent years throughout the forecast period.

5. <u>Replacement and Incremental Resources</u>

Changes in National Grid NH's resource needs are caused by changes in its firm demand, (i.e., load growth, load loss and changes in load shape). The Company differentiates incremental and replacement resource needs primarily in terms of how a need arises. The need to increase (or decrease) resources arises when the capacity of the Company's resource portfolio is not substantially equivalent to its firm demand requirements. A replacement resource need occurs when the term of an existing resource comes up for expiration and the

⁴ The on-system LNG storage capacity is not sufficient to meet the full seasonal requirements

Company's firm demand requirements are substantially the same (i.e., the resource is not avoidable). The Company applies the same decision-making process to meet replacement needs as it applies to incremental needs.

A critical component of identifying a resource need is defining the load shape of the demand that needs to be met. "Shape" refers to the degree of uniformity that a resource need exhibits throughout the course of a year. In characterizing the shape of resource needs, three general terms are applied herein: "baseload," "seasonal," and "peaking". A need that is substantially uniform throughout the year is described as a "baseload" need; a need that is driven by temperature fluctuations, and is therefore concentrated in a finite portion of the year (i.e. 60-180 days), is described as a "seasonal" need; a need that is observed at the very upper limits of the demand profile (i.e., the coldest days of the year) is described as a "peaking" need. The Company notes specific resource needs do not necessarily fall discretely into one of these categories, but rather can exhibit characteristics of any or all of these classifications.

Determining the shape of a need is also important in terms of narrowing the range of possible resource options that may be able to satisfy the need. Baseload needs for example, tend to be best met through pipeline supply options. On the other hand, 365-day pipeline resources tend to be less efficient in meeting seasonal needs because the fixed capacity charges become concentrated across a relatively short demand period, which drives the unit cost up. Conversely, resources that can be inventoried and dispatched in response to

without refill throughout the winter season.

temperature variations (such as underground storage and LNG) tend be costeffective in meeting seasonal demands. Finally, peaking demands are likely to be best met by on-system LNG or propane facilities because of the flexibility with which these resources can be dispatched.

When a resource need arises, the Company attempts to identify all of the possible resource options that may be able to meet that need. The Company regularly requests, receives and reviews promotional material regarding new or revised services from various supply-related entities. In addition, the Company endeavors to maintain continuous contact with suppliers, pipelines operators and other service providers. Thus, the Company is able to develop a list of potential, creditworthy service providers to whom Requests for Proposals ("RFPs") will be The RFP process effectively generates tailored service bids at market sent. prices from potential service providers. The responses to an RFP establish the set or "universe," of potential resource options available to meet a particular need at a given point in time. The Company then performs a preliminary review to narrow the set down to an appropriate range for further analysis. This preliminary screening is dictated in part by the nature of the demand (i.e., the size and shape of the need) and by the planning time horizon. The time horizon is also an important element because the availability of specific resource alternatives may not perfectly coincide with the initial timing of an identified need. For example, an incremental seasonal need arising four years into the future may be met best by a storage option that will become available in three years if no other storage alternatives are available until the fifth year.

During the forecast period, National Grid NH is faced with key decisions regarding the expiration and renewal of a number of contracts in its resource portfolio. Existing resources from the Company's 2009/10 portfolio that are set to expire during the five-year forecast period are listed in Table IV-C-3.

Contract	MDCQ	Annual Quantity (MMBtu)	Date of Expiration
Granite Ridge Energy, LLC	15,000	450,000	9/30/10
BP Canada Energy Company		1,167,635	3/31/12
BP Canada Energy Company	4,047	1,477,155	03/31/2010
Chevron Natural Gas	21,596	3,908,876	04/30/2010
Repsol Energy North America Corporation	42,500	7,607,500	10/31/2010
Distrigas of Massachusetts Corporation FLS160		100,000	10/31/10
Sempra Energy Trading	7,500	907,500	03/31/2010
Honeoye Storage Corporation	1,957	245,280	04/01/11Evergreen
National Fuel Company N02358	6,098	2,225,770	3/31/11 Evergreen
National Fuel Company O02357	6,098	670,800	3/31/11 Evergreen
Tennessee Gas 523	21,844	1,560,391	10/31/2015
Tennessee Gas 632	15,265	5,571,725	10/31/2015
Tennessee Gas 2302	3,122	1,139,530	10/31/2015
Tennessee Gas 8587	25,407	9,273,555	10/31/2015
Tennessee Gas 11234	9,039	3,299,235	10/31/2015
Tennessee Gas 33371	4,000	1,460,000	10/31/2011
Tennessee Gas 42076	20,000	7,300,000	10/31/2015

 Table IV-C-3: National Grid NH Contract Expiration Dates

Following the Company's planning process described above, during the forecast period; the Company will employ a three-step analysis to reach its conclusions on contract renewals. First, the Company will evaluate the need to maintain the contracts as part of the resource portfolio. As part of this need analysis, the Company will consider the trends in transportation migration and the growth in transportation relating to new customers that have not previously been served by the Company, and therefore, are not subject to the assignment of capacity. If the Company determines that the resource is needed to meet firm sendout requirements, the Company will consult with competitive suppliers serving customers on National Grid NH's system to solicit their input on the Company's contract renewals. Second, depending on the type of need, the Company will canvas the marketplace to determine the availability of a replacement resource with consideration being given to demand-side resource options as discussed above. Where appropriate, the Company will solicit competitive bids to determine the lowest-cost available resource. Finally, the Company will evaluate non-price factors associated with the available replacement options such as flexibility, diversity, reliability and contract term to determine the least-cost, most reliable option to meet the Company's resource need. This same approach will be implemented when the need arises for a new resource to be added to the portfolio.

6. Northeast Gas Supply and Infrastructure

There have been a number of major supply and infrastructure additions that have gone into service in the Northeast since the Company's last filing in 2006. This trend is expected to continue and possibly accelerate over the forecast period.

The following projects providing additional gas and/or infrastructure to the Northeast have commenced service since 2006:

Union/TransCanada Expansions from Dawn to Waddington (ANE II):

This project provided for gas supplies to be purchased at Dawn, Ontario and be transported on Union from Dawn to an interconnection with TransCanada at Parkway and then transported by TransCanada from Parkway to Waddington, New York. The capacity path originating at Dawn provided customers in the Northeast access to a liquid trading hub as well as access to underground storage fields and diverse supply sources including Western Canada, Rockies, Mid-Continent, Gulf Coast, and the Chicago hub. This project went into service in November 2006 with an initial volume of 181,000/dth per day. Similar expansion projects in 2007 and 2008, have increased the total volumes sourced Dawn up to almost 312,000 MMBtu/day.

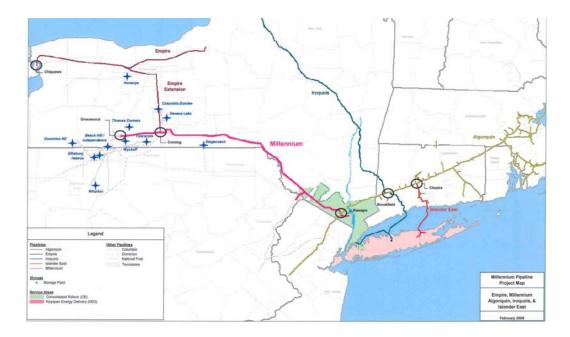

Tennessee ConneXion Project:

This project provided an incremental 136,300/dth per day transported on Tennessee Gas Pipeline from the points in the Gulf of Mexico to various delivery points throughout New England, located in Zone six. This project went into service in November 2007. • Northeast Gateway:

This off-shore LNG facility operated by Excelerate Energy, and located offshore Cape Ann, MA, became fully operational in early 2008, receiving its first shipment of LNG in May. The facility is capable of delivering approximately 400,000 MMBtu/day into Algonquin's offshore HubLine system. Since 2008, this facility has received at least six cargoes of LNG.

• Millennium Pipeline Company LLC:

This new pipeline commenced service in December 2008. The pipeline originates at the Independence interconnect with National Fuel and terminates at Ramapo, New Jersey at the interconnect with Algonquin and can move approximately 500,000 MMBtu/day. The original supply source is predominantly Canada; however Millennium also interconnects with Tennessee, Columbia Gas Transmission, Empire State Pipeline and Stagecoach Storage. In addition, this pipeline well is positioned to access other supply basins in the future.

Maritimes and Northeast Pipeline Phase IV Project:

This project commenced service in January 2009. The project included five new compressor stations, two compressor station upgrades and two miles of 30-inch looping of pipe. The project provided an incremental 833,000 MMBtu/day of capacity delivered to the Dracut interconnect with Tennessee or the Beverly interconnect with Algonquin. Under a twenty-five year deal, Repsol contracted for 735,000 MMBtu/day of this capacity.

• Canaport LNG:

Owned and operated by Repsol and Irving Oil, this new LNG facility became operational in mid-2009. It is located roughly sixty miles from the Maine border in New Brunswick, Canada. The facility includes 6.6 Bcf of storage (two tanks), with another third tank expected to be in service in Q2 2010 for a total of 9.9 BCF of on-site storage. The facility is capable of delivering up to 1 BCF/day of gas into the Brunswick Pipeline (owned by Emera), which connects with the Maritimes & Northeast Pipeline. Gas is sourced principally from Trinidad, however Repsol has plans to diversify supply sources in the future (a cargo from Qatar arrived in late 2009).

• Tennessee Concord Lateral Project:

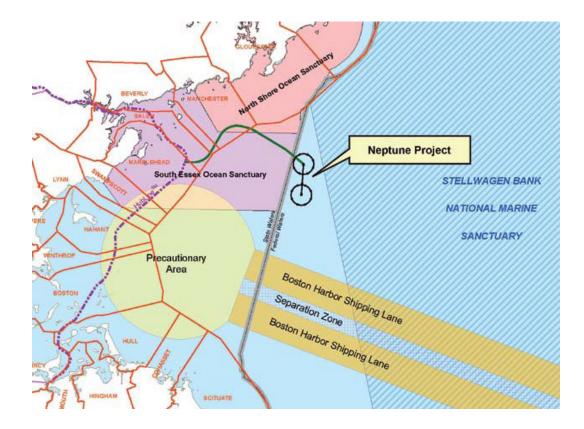

This project commenced service in November 2009. The project involved 6,130 hp of mid-point compression expansion on Tennessee's existing Concord Lateral. It is the first pipeline compressor station on Tennessee's system in New Hampshire, located in Pelham. The project provides an incremental 30,000 MMBtu/day of capacity from Dracut, MA to the Company's Laconia, NH citygate.

During the forecast period, the following projects providing additional gas and/or infrastructure to the Northeast are expected to commence service:

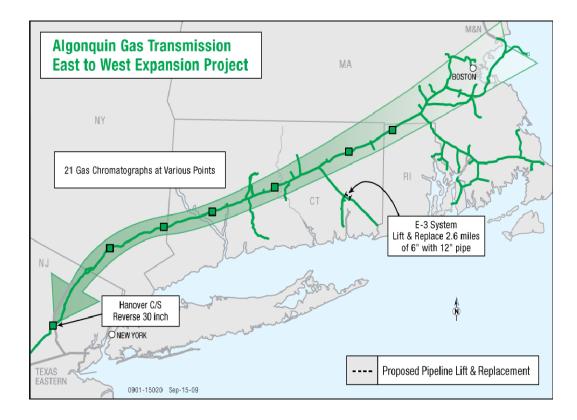

• Neptune LNG:

Owned by GDF Suez Gas NA LLD, this off-shore LNG facility located off Cape Ann, MA is expected to become operational in Q2 2010. The project consists of a thirteen mile lateral which will tie into Algonquin's HubLine. There will be two unloading buoys which will be connected to specially designed LNG vessels called Shuttle and Regasification Vessels or SRVs. These vessels are equipped with onboard vaporization and turn LNG into vapor and pump the vapor into the pipeline lateral. Each SRV will have an average sendout of 400,000 MMBtu/day.

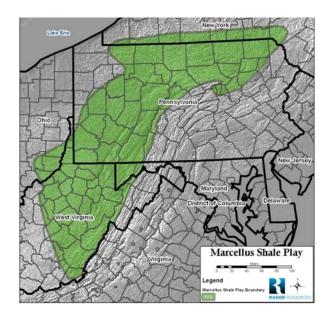

• Algonquin's East-to-West Project:

This project is expected to commence service in November 2010. This project will allow the Algonquin system to move supplies "east to west" rather than traditional "west to east". In particular, the project is designed to move new LNG supplies into the market. The project participant volumes total over 280,000 MMBtu/day.

Perhaps the biggest regional gas development for the next decade and beyond - is the emerging news on the potential of expanded gas production in the Marcellus Shale.

Referred to as a "game changer", this shale gas formation extends from West Virginia into Ohio, Pennsylvania and New York. Estimates are that this area may hold from 50 to 250 trillion cubic feet ("Tcf") of natural gas. A June 2009 study from Penn State put the potential at 500 Tcf. Although the amount that is economically recoverable had yet to be determined, Marcellus clearly is a major resource basin with the distinct advantage of market-area location. Gas from Marcellus is already flowing into the region, and the next few years promise further, greater volumes. The potential impact of this shale gas on the supply/demand dynamics in the Northeast is truly significant. If even the most conservative estimates of this supply basin come to fruition, the current landscape will be altered dramatically. As a large player in the Northeast, the Company will be closely monitoring this development in the coming years.

D. Adequacy of the Resource Portfolio

Although the base case scenario is intended to represent the most probable demand case, customer demand could vary within the range of the lowdemand and high-demand case. Accordingly, the resource plan must possess a level of flexibility to adjust to changing economic conditions, while ensuring that adequate resources are available to meet customer requirements on the peak day. As described below, the Company's resource portfolio currently possesses the flexibility to meet design-year and cold snap requirements in the high, base and low case demand scenarios on a reliable basis. This is true under the condition of no incremental penetration of demand side management measures into the marketplace, as well as under the condition of penetration of the low, base or high case demand side management scenarios.

1. <u>Resources and Requirements Tables</u>

In Appendix D: Resource and Requirements Tables, the Company has provided the detailed results of all of its simulation runs. There is one table per split year (Nov – Oct) with two sections: requirements and resources. The monthly resource requirement (net of reduction due to demand side management) includes customer requirements plus storage refill requirements. The monthly resources include all pipeline and supplemental resources used to satisfy the requirements.

In the methodology of the Company's modeling, the 'Other Purchased Resource' option is the default option used by the model when the Company's portfolio is unable to meet customer requirements. In all years and all scenarios, the 'Other Purchased Resource' option is zero. Hence, the Company's resource portfolio is adequate in serving its customers' requirements.

2. <u>Demand Side Management As a Resource Option</u>

In Charts IV-D-1 through IV-D-11, the Company has included summary tables for its high, base, and low demand case simulation runs with the three demand side management scenarios to summarize the differences in the demand scenarios and summarize the reductions in the supplies required with the penetration of the demand side management measures. The summary groups are:

- Summary of demand side management Measures
- Summary of Base Case Design Year Customer Requirements (No, Low Case, Base Case, and High Case demand side management)
- Summary of Design Year Customer Requirements (Base Case demand side management; Low Case, Base Case, and High Case Incremental Growth)
- Summary of Base Case Normal Year Customer Requirements (No, Low Case, Base Case, and High Case demand side management)
- Summary of Normal Year Customer Requirements (Base Case demand side management; Low Case, Base Case, and High Case Incremental Growth)
- Summary of Base Case Design Year (Resource Use With No demand side management, and Reductions In Load and Resourceby-Type with demand side management)

Chart IV-D-1 summarizes the demand side management programs modeled by the Company. As discussed in Section IV.B above, over 2004-2009, the Company has averaged 79,198 MMBtu of demand reduction using a variety of demand side management programs at an annual average total (Company plus participant) cost of \$3,258,139 (Program 1). The programs were divided into baseload and heat sensitive components for the residential and C&I customer groups, and the costs were entered in as one-time utility fixed charges with an assumed lifetime of 15 years for levelized costing purposes. For its Low Case demand side management scenarios, the Company assumed that it would continue with that annual level of expenditure and demand reduction.

For 2010, the Company has targeted 124,318 MMBtu of reduction at a total cost of \$9,527,217 (Program 2). The programs were divided into baseload and heat sensitive components for the residential and C&I customer groups, and the costs were entered in as one-time utility fixed charges with an assumed lifetime of 15 years for levelized costing purposes. For its Base Case demand side management scenarios, the Company assumed that beginning in the 2009/10 split year it would continue with that higher annual level of expenditure and demand reduction.

For its High Case demand side management scenarios, beginning in the split year 2010/11, the Company developed six demand side management resource options, three for the residential group and three for the C&I group. Each group has available as Tier 1 the level of cost and demand reduction from the Company's 2004-2009 average. As Tier 2, each group had available the incremental costs and demand reductions based on the difference between the 2004-2009 program averages and the 2010 program averages. Lastly, as Tier 3, the Company developed incremental programs for each group based on the programs it can readily increase in scale over the forecast period, with annual costs and demand reductions based on the rate of growth it expects to be plausible.

3. <u>Descriptive Results of Scenarios</u>

Chart IV-D-5 indicates that, relative to the 2008/09 springboard year, annual implementation of the Low Case demand side management programs can result in a reduction in customer requirements of 553,629 MMBtu/year by 2014/15. Relative to the 2008/09 springboard year, annual implementation of the Base Case demand side management programs can result in a reduction in customer requirements of 824,425 MMBtu/year by 2014/15. Under the resource mix simulation of the High Case demand side management programs, the model is allowed to choose the optimum mix and timing of the six programs available under Tiers 1, 2, and 3. Simulation results indicate that the Tier 1 C&I programs are favorable beginning in 2010/11. The Tier 1 Residential programs are favorable beginning in 2011/12. And, then, the Tier 2 Residential, Tier 3 Residential and Tier 3 C&I programs all become favorable in 2012/13. In isolation, the Tier 2 C&I programs are not favorable. Relative to the 2008/09 springboard year, annual implementation of the High Case demand side management programs can result in a reduction in customer requirements of 812,319 MMBtu/year by 2014/15.

4. <u>Cold Snap Analysis</u>

In addition to the design day, design year and normal year planning standards, the Company also evaluates the capability of the resource portfolio to meet sendout requirements during a protracted period of very cold weather, which is referred to as a "cold snap."

To generate its cold-snap scenario, the Company selected the actual seven-day period of coldest weather experienced by the Company leading to the highest supplementals requirement. This seven-day period for Manchester, NH, was January 9, 2004 through January 15, 2004.

The Company then substituted the coldest seven-day period in its normal weather scenario with the cold-snap scenario by creating an HDD pattern of (a) normal HDD through February 2nd; (b) the cold-snap HDD on February 3rd through February 9th, followed by; (c) normal HDD. Using base case demand, the Company analyzed the effectiveness of the portfolio in meeting the requirements of the cold-snap scenario. The results of the simulation using the SENDOUT[®] model (Appendix D-66 through Appendix D-70) show that the Company's portfolio can meet the cold-snap requirement adequately.

5. Evaluation of Alternative Resources

In addition to testing the Company's resource portfolio under varying weather conditions, growth assumptions, and demand side management penetration levels, the Company evaluated the potential to reduce the overall portfolio cost when a number of its resource contracts reach expiration as discussed in Section IV.C – Expected Available Resources. In its High Case demand side management scenario, the three demand side management tiers were evaluated in a resource mix along with the Company's:

- Tennessee short-haul capacity from Niagara to the citygate;
- Iroquois/Tennessee capacity from Waddington to the citygate; and the,
- Tennessee long-haul capacity from the Gulf Coast to the citygate.

All three traditional resources were selected at their existing levels with no evidence to indicate any could be reduced in size. Results of this scenario can be found in Appendix D-61 through Appendix D-65.

The Company then ran one additional scenario to evaluate the potential to convert a portion of its Tennessee long-haul capacity (specifically, 10,000 MMBtu/day) with supply located in the Gulf Coast to Tennessee short-haul capacity with supply located at the Marcellus Shale formation in the Northeast. The remainder of the Tennessee long-haul capacity would then be retained for supply diversity and storage refill reasons. At current Tennessee tariff rates and without additional costs to attach to the Marcellus supply basin, the conversion of the capacity would result in approximately \$1,000,000/year reduction in pipeline demand charges. Under current basis differentials, the higher cost of supply located at Marcellus would reduce this to a net savings of approximately \$500,000 to \$700,000 per year.

Before committing to such a change in its resource portfolio, however, the Company will have to further consider a number of factors including, but not limited to whether or not development of the Marcellus Shale supply will alter the currently-existing basis differentials, which could further reduce the advantage of converting its pipeline contract. Additionally, the Company will have to consider the implication from the model that the Marcellus shale supply is currently attractive only as a peak period supply and that, with the reduced access to offpeak supply from the Gulf Coast, the Company will have to depend on additional, off-peak period purchases of supply at its Dracut MA receipt point to achieve this potential cost savings.

E. <u>Contingency Planning</u>

As a final complement to the overall planning process, the Company must consider the possibility of supply/capacity interruptions and the contingency plan to implement in such an event. In the Company's last IRP, the Company included a contingency plan that would address the following supply/capacity interruptions:

Disruption at DOMAC

- Supply Disruption at Dracut, MA
- Supply and Capacity Disruptions in the Gulf of Mexico

The Company would implement the same contingency plans as provided in its last IRP in the event any one of these interruptions occurred.

• Disruption at DOMAC:

Throughout the forecast period, National Grid NH relies on liquid peaking supplies from DOMAC, now known as GDF Suez Gas North America LLC, to meet both the design year and design day needs of customers. Therefore, the loss of these resources would cause a supply deficit during the forecast period. National Grid has had experience in dealing with the disruption of its DOMAC supplies. In light of a ban imposed by the U.S. Coast Guard on LNG vessels in entering Boston Harbor following the events of September 11, 2001, National Grid was forced to implement a contingency plan to address this supply disruption.

Similar to its last IRP filing, National Grid NH is including a contingency plan in this filing to meet a supply deficit similar to that created by the loss of DOMAC LNG supplies in 2001. For this analysis, National Grid NH considers three scenarios: (1) no LNG shipments for the month of October, (2) no LNG shipments or sporadic shipments for the winter period; and (3) no shipments for the long term. For the first scenario the Company determined that there would not be a material effect on National Grid NH, since the Company's tanks are full in early fall. In addressing the other scenarios, the Company would consider its short-term, minimum liquid needs for a design winter.

With respect to the immediate and short-term liquid needs, the Company would immediately implement its contingency plan. This plan would call for liquid deliveries from various LNG facilities including, but not limited to; the NSTAR Gas facility in Hopkinton, Massachusetts, the Philadelphia Gas Works facility in Philadelphia, Pennsylvania, the Transco facility in Carlstadt, New Jersey, and/or the Gaz Metropolitain facility in Montreal, Canada. In addition to LNG deliveries, the Company would also call for incremental propane deliveries from its regional propane supplier as well as other suppliers in the northeast corridor. In the event of a long-term supply disruption, the Company would need to replace its existing DOMAC LNG contracts with another source of supply and related transportation. Should this become a reality, the Company would act immediately and initiate discussions with suppliers and Tennessee Gas Pipeline.

• Supply Disruption at Dracut:

Throughout the forecast period, National Grid NH relies on gas supplies sourced from the Dracut, MA interconnect on Tennessee Gas Pipeline to the Company's citygates to meet both the design-year and design-day needs of customers. Therefore, the loss of these resources would cause a supply deficit during the forecast period. The timing of the disruption as well as the extent of the disruption would determine the actions taken by the Company to fill the void.

A disruption to this pipeline delivered supply could be replaced with a mix of various gas supplies available to the Company. These supplies include but are not limited to:

- Citygate delivered spot-market purchases;
- Incremental long-haul supplies delivered from the Gulf using the Company's long-haul capacity;
- Underground storage volumes delivered from the storage fields using the Company's short-haul storage capacity;
- TGP Zone 4 market area supplies transported on the Company's short-haul capacity from zone 4 to zone 6;
- TGP Zone 6 market area supplies from off-shore LNG facilities;
- On-system propane resources
- Supply and Capacity Disruptions in the Gulf of Mexico:

Throughout the forecast period, National Grid NH relies on gas supplies being sourced from the Gulf of Mexico on Tennessee Gas Pipeline to the Company's citygates to meet both the design-year and design-day needs of customers. Therefore, the loss of these resources would cause a supply deficit during the forecast period. In the aftermath of Hurricanes Katrina and Rita in 2005, the Company took several steps in order to ensure supply reliability for its New Hampshire customers. Should a similar event again occur the Company would follow the same process it implemented following Hurricanes Katrina and Rita ("2005 Hurricanes"). First, the Company would determined its overall supply capabilities on a peak day and peak season basis, from "at risk" locations, *i.e.,* Tennessee's 500-leg and Texas Eastern's ELA and WLA regions during the 2005 Hurricanes. Next, the Company would fill both its underground and LNG storage facilities going into the winter and implement a conservative storage withdrawal strategy in order to guarantee maximum storage withdrawals as far into the winter as possible. Finally, the Company would firm-up winter supplies traditionally sourced in the Gulf Coast at points upstream of the constrained points.

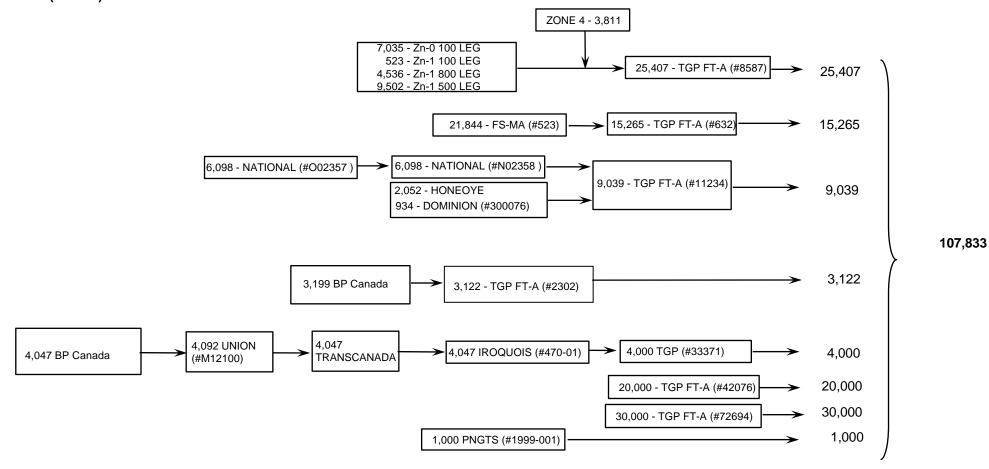

Lastly, albeit it not an event of force majeure, the Company must begin to plan for the likelihood that the Haverhill propane facility located in Haverhill, MA will no longer be available for use by New Hampshire customer to store propane inventories. If needed to meet customer requirements or to maintain compliance with the seven-day storage inventory rule, the Company would need to procure replacement supplies to replace these volumes.

It is also important to note that the Company is an active member of the Northeast Gas Association's ("NGA") Gas Supply Task Force. The Task Force meets periodically throughout the winter season, and more often if the situation warrants. As a member of this Task Force, the Company can request to convene a meeting in order address either a regional or a Company-specific issue and seek the assistance of fellow members if needed.

Emergency Curtailment Plan:

In the event that despite all reasonable efforts, a force majeure event prevents the Company from securing adequate supply to maintain deliverability to customers, the Company would implement its emergency curtailment plan. A copy of that plan was filed with the Commission in July 2008.

ENERGYNORTH NATURAL GAS INCORPORATED DESIGN DAY PIPELINE AND STORAGE TRANSPORTATION (MMBtu)

Long-haul and Short-haul Transportation Contracts

Shipper	Pipeline Company	Contract No.	Rate Schedule	City Gate MDQ	Annual Quantity	Expiration Date	Notes
EnergyNorth Natural Gas Incorporated	Iroquois	47001	RTS-1	4,047	1,477,155	11/01/2017	Part-284 transportation service (365-day). This contract is used to transport volumes from Waddington, NY to the Iroquois interconnect with TGP at Wright, NY. April 15, 2009, the Company amended this agreement to extend the term to November 1, 2017. The extension of the term aligns the agreement with its upstream contracts.
EnergyNorth Natural Gas Incorporated	National Fuel	N02358	FST	6,098	2,225,770	03/31/2011	Part-284 transportation service (365-day) associated with the FSS service O02357, used for storage injection and or withdrawal across National Fuel pipeline system and into and out of the FSS storage. The Company is currently exercising it right to the Evergreen provision. Therefore the contract is extended year to year, unless one-year written notice is provided by either party. Amendment dated March 21, 2002 gave National Fuel the option of notifying the Company by February 28, 2002 to discontinue the discounted rate. The Company was notified by National Fuel effective April 1, 2007 the discounted rate would no longer apply. Current tariff rates now apply.
EnergyNorth Natural Gas Incorporated	Portland Natural Gas	1999-001	FT	1,000	365,000	10/31/2019	Part-284 transportation service (365-day). This contract is used to transport volumes from Pittsburg, New Hampshire to EnergyNorth citygate located in Berlin, New Hampshire.
EnergyNorth Natural Gas Incorporated	Tennessee	632	FT-A	15,265	5,571,725	10/31/2015	Part-284 transportation service (365-day). This contract is used to transport volumes from FS-MA storage (zone 4) to EnergyNorth city gates. Effective November 1, 2010, The Company has extended the term for 5 years, pursuant to Article III, Section 10.4 of Tennessee Gas Pipelines General Terms and Conditions.
EnergyNorth Natural Gas Incorporated	Tennessee	2302	FT-A	3,122	1,139,530	10/31/2015	Part-284 transportation service (365-day). This contract is used to transport Canadian supply (BP Canada) from Niagara, New York (zone 5) to EnergyNorth city gates. Effective November 1, 2010, The Company has extended the term for 5 years, pursuant to Article III, Section 10.4 of Tennessee Gas Pipelines General Terms and Conditions.
EnergyNorth Natural Gas Incorporated	Tennessee	8587	FT-A	25,407	9,273,555	10/31/2015	Part 284 transportation service (365-day). This contract is used to transport volumes from the access area (zones 0 and 1) and storage (zone 4) to EnergyNorth city gates (zone 6) with primary receipt points of 21,596 MMBtu/day from zones 0 and 1 and 3,811 MMBtu from zone 4. Effective November 1, 2010, The Company has extended the term for 5 years, pursuant to Article III, Section 10.4 of Tennessee Gas Pipelines General Terms and Conditions.
EnergyNorth Natural Gas Incorporated	Tennessee	11234	FT-A	9,039	3,299,235	10/31/2015	Part 284 transportation service (365-day). This contract is used to transport volumes from three storage fields (Honeoye, National Fuel and Dominion) to EnergyNorth's city gates (zone 6). Effective November 1, 2010, The Company has extended the term for 5 years, pursuant to Article III, Section 10.4 of Tennessee Gas Pipelines General Terms and Conditions.
EnergyNorth Natural Gas Incorporated	Tennessee	33371	NET-NE	4,000	1,460,000	11/30/2011	Part 284 transportation service (365-day) used to transport gas from Iroquois at Wright, NY to EnergyNorth city gates.
EnergyNorth Natural Gas Incorporated	Tennessee	42076	FT-A	20,000	7,300,000	10/31/2015	Part 284 transportation service (365-day). This contract is used to transport volumes from Dracut, MA (zone 6) to the EnergyNorth city gates (zone 6). Effective November 1, 2010, The Company has extended the term for 5 years, pursuant to Article III, Section 10.4 of Tennessee Gas Pipelines General Terms and Conditions.
EnergyNorth Natural Gas Incorporated	Tennessee	72694	FT-A	30,000	10,950,000	10/31/2029	Part 284 transportation service (365-day). This contract is used to transport volumes from Dracut, MA (zone 6) to the EnergyNorth city gates (zone 6).
EnergyNorth Natural Gas Incorporated	TransCanada		FT	4,047	1,477,155	10/31/2017	Canadian Transportation service (365-day). This contract is used to transport volumes from Parkway-Union to TransCanada interconnect with Iroquois. Effective November 1, 2006, the Company assigned Union contract to TransCanada. The receipt point has been amended to Union Dawn from Parkway-Union.
EnergyNorth Natural Gas Incorporated	Union Gas	M12100	M12	4,092	1,493,580	10/31/2017	Canadian transportation service (365-day). This contract is used to transport volumes from Dawn to Union interconnect with TransCanada. See TransCanada contract above. The Company assigned this contract to TransCanada effective November 1, 2006.

Underground Storage Services

Shipper	Pipeline Company	Contract No.	Rate Schedule	City Gate MDWQ	Annual Quantity MSQ	Expiration Date	Notes
EnergyNorth Natural Gas Incorporated	Dominion	300076	GSS Storage	934	102,700	03/31/2016	Part-284 storage service that provides 102,700 MMBtu of storage capacity at a withdrawal rate of 934 MMBtu/day and an injection rate of 934 MMBtu/day. Injection ratchets if inventory is under 50% the calculation is 1/180 x 102,700 for injection rights. If the inventory is above 50% the calculation is 1/214 x 102,700. April to July Dominion allows for 115% of the daily injection rights The contract term has been extended from March 31, 2011 to March 31, 2016.
EnergyNorth Natural Gas Incorporated	Honeoye		SS-NY Storage	1,957	245,280	04/01/2011	Part-157 (7C) storage service that provides 145,280 MMBtu of storage capacity at a withdrawal rate of 1,957 MMBtu/day and an injection rate of 1,957 MMBtu/day. The Company is currently exercising the evergreen provision provided in the contract and extending the contract on a year to year basis. If operational integrity should be in jeopardy, Honeoye reserves the right to institute a storage ratchet calculation as follows MSQ/210 days.
EnergyNorth Natural Gas Incorporated	National Fuel	O02357	FSS Storage	6,098	670,800	03/31/2011	Part-284 storage service (150-day) that provides 670,800 MMBtu of storage capacity, with a withdrawal rate of 6,098 MMBtu/day and an injection rate of 4,472 MMBtu/day. The 110-day service has injection ratchets 0 to 70% the calculation is 1/170 x MSQ and 70% to 100% the calculation is 1/200 x MSQ. The contract is associated with National Fuel transportation contract (No. N02358). The Company is currently exercising the evergreen provision provided in the contract and is extending the contract on a year to year basis.
EnergyNorth Natural Gas Incorporated	Tennessee	523	FS-MA Storage	21,844	1,560,391	10/31/2015	Part-284 storage service that provides 1,560,391 MMBtu of storage capacity with a withdrawal rate of 21,844 MMBtu/day and an injection rate of 10,404 MMBtu/day or 1/150 of Shipper's MSQ. The contract term has been extended from October 31, 2003 to October 31, 2010. Effective October 31, 2009, the Company extended the term for 5 years, pursuant to Article III, Section 10.4 of Tennessee Gas Pipelines General Terms and Conditions.

Chart IV-D-11 (Revised)

V. SUMMARY OF COMPLIANCE Order No. 24,941

On February 13, 2009, the Commission issued Order No. 424, 941 accepting the Company's IRP filed in Docket DG-06-105. The order identified certain items to be included in the Company's next IRP. This section documents the Company's compliance with the order.

1. The Planning Period should be five years. The length of the planning horizon should not limit the time period over which long-lived resource options are evaluated. (<u>Order, at 18</u>);

The planning period for this filing is the five year period November 1, 2010 through October 31, 2015. The Company did not use this planning horizon to limit the evaluation of the expected available resources or future resource options presented in Section IV-C.

2. The demand forecast should continue to be based on the econometric forecasting model developed by the Company pursuant to the settlement agreement approved in Order No. 24, 531 (<u>Order, at 18</u>);

The Econometric forecasting model used in this IRP is consistent with the model developed as a result of the settlement and is documented in Section III-B of this IRP.

3. For purposes of establishing design planning standards, the Company should continue to utilize a Monte Carlo weather forecasting analysis (<u>Order</u>, at 18);

VI-1

The Monte Carlo weather forecasting analysis used by the Company to develop its design planning standards is described in detail in Section III-E.

4. The Company should assess the capability of its resource portfolio to satisfy its design day, design year and cold snap standards and evaluate how its portfolio would perform under alternative high and low demand scenarios. (<u>Order, at 19</u>)

The adequacy of the portfolio under various scenarios is documented at Section IV-D.

5. The Company should address whether circumstances have changed since its last IRP such that a capacity reserve to plan for the potential needs of grandfathered firm transportation customers is warranted. (Order, at 19);

The Company has evaluated the impact of transportation migration on the forecast, as documented in Section III-B-5, and concluded that circumstances have not changed. Therefore, a capacity reserve is not warranted.

6. The Company's IRP should include a systematic evaluation of reasonably available demand-side management programs on an equivalent basis with its evaluation of supply side resources. The

VI-2

evaluation will include a description of the methodology for calculating avoided costs associated with not having to purchase additional gas supplies or constructing new peaking capacity, reflect any differences in the reliability of demand –side measures compared to supply-side resources and discuss the process for integrating demand–side and supply-side resources so that customer needs will be met at the lowest reasonable cost while maintaining reliability and taking into account other non-cost planning criteria. Cost-effectiveness shall be determined using the total resource cost test. The Company is required to use to use the information contained in the report titled "Additional Opportunities for Energy Efficiency in New Hampshire" that was prepared by GDS Associates for the Commission as the basis for its demand-side assessment. (<u>Order</u>, at 20-23);

The Company's evaluation of reasonably available demand-side management resources is discussed in detail in Sections IV-B and IV-D.

VI-3

LIST OF APPENDICIES AND EXHIBITS

Appendix A: Explanation of Budget Categories

Exhibit A: Projected Program Expenses: presents detailed budgets by program and year.

Exhibit B: Benefit Cost Analysis: summarizes the two-year benefit cost (BC) ratios for the programs as well as each year's BC ratio by sector with and without shareholder incentive.

Exhibit C: Program Input Assumptions: shows the per participant savings, costs, and rebates for each program measure.

Exhibit D: Shareholder Incentive Calculation: estimates the Company's projected shareholder incentive for successful implementation of its energy efficiency programs.

I. FORWARD

This document presents to the New Hampshire Public Utilities Commission (NHPUC or the Commission) EnergyNorth Natural Gas, Inc.¹ d/b/a National Grid NH's (the Company) proposed Energy Efficiency (EE) plan for the twenty-month period May 1. 2009² through December 31, 2010. The Company's current programs, which were approved by Commission Order 24,636, were set to expire on April 30, 2009. By Secretarial Letter dated April 21, 2009, the Commission authorized the continuation of those programs until a new energy efficiency plan is approved. This proposed EE Plan provides updated program descriptions, benefit/cost analyses, program budgets and program goals for this twenty-month time period and is premised on the existing program structure. The Company is proposing a few additions to its current program offerings. On the residential side, the Company is including rebates for residential energy efficient storage water heaters and adding a program element to address individually metered gas multifamily facilities (five or more units) in both the Residential Weatherization program and Energy Audit and Home Performance program. The Residential Weatherization program provides insulation to customers in conjunction with air sealing. Energy Audit and Home Performance provides education to participants either through phone support or an in-home audit. The Low Income Program will also be expanded and will serve individually metered gas multifamily facilities within the Low Income Program. Low Income program budgets have been increased to account for these individually metered low income multifamily facilities and to accommodate the expiration of other funding sources. The increased budget will allow the Company to serve a similar volume of participants as in the past two years. New commercial and industrial initiatives include the steam savings initiative and enhanced commercial kitchens.

National Grid's Energy Efficiency Plan covers a twenty-month period rather than the traditional three-year plan in anticipation of a joint electric and gas Energy Efficiency multi-year plan beginning on January 1, 2011. The proposed budget for the Company's

¹ EnergyNorth Natural Gas, Inc. is one of four local distribution companies that do business as National Grid Energy Delivery New England. The other companies provide service in Massachusetts as Boston Gas Company, Colonial Gas Company and Essex Gas Company.

² The Company initially proposed that the Plan take effect on May 1, 2009. The Company will implement the proposed Plan upon approval by the Commission.

EE efforts for the eight months in 2009 is \$2,815,786 and is \$4,986,415 in calendar year 2010. Detailed budgets are set forth in Table I.

This energy efficiency plan incorporates several changes and enhancements compared to prior plans submitted by the Company. One change to this plan, as compared to previous gas energy efficiency filings, is the adoption of the cost categories currently in use in the electric energy efficiency plan filings when presenting the energy efficiency budget (Exhibit A). In addition, the current Plan covers a shorter time period than the three-year plans that have been submitted by the Company in prior years. After a CORE Electric meeting on February 9, 2009, National Grid discussed with PUC staff and OCA the potential of moving toward common planning elements between the gas and electric utilities. The discussion concluded with an agreement that the gas energy efficiency plan would consist of the twenty-month period May 2009 through December 2010 in anticipation of a joint electric and gas EE plan beginning January 1, 2011. At that meeting, National Grid also noted its intent to transition the previously used traditional gas cost categories to the electric cost categories so that efforts to better coordinate gas and electric energy efficiency efforts will be simplified. Appendix A defines the traditional gas and electric cost categories. The 2008 energy efficiency plan costs are mapped to both the prior gas cost categories and the electric costs categories that the Company proposes to adopt moving forward. In Exhibit A: Projected Program Expenses, costs are also presented in gas cost categories as well as electric cost categories for 2009 and 2010.

Exhibit B, the Benefit Cost Analysis, uses the same benefit cost model as the CORE electric utilities. Avoided energy costs are from the regional "Avoided Energy Supply Costs in New England: 2007 Final Report." Both the costs and benefits are presented in 2009 dollars for the twenty-month period. Information for a specific program year is presented in that year's dollars. Finally, Exhibit D, the Shareholder Incentive Calculation is presented in a similar manner as the electric Shareholder Incentive calculations. The target Benefit/Cost ratio is net of shareholder incentive. Target Incentive levels are 8% of utility costs or total resource costs minus participant costs and shareholder incentives.

Table-I: May 1, 2009 - December 31, 2010 Budget					
Electric Cost Categories	2009 Budget	2010 Budget	Gas Cost Categories		
Internal Administration	\$272,602	\$437,475	Company Administration		
External Administration	\$225,702	\$381,323	Vendor Admin/Support		
Rebates/Services	\$1,862,548	\$3,483,770	Services		
Internal Implementation	\$0	\$0	Other		
Marketing (sum of communication and trade	\$363,486	\$519,636			
ally)	\$272,388	\$382,575	Communication		
	\$91,098	\$137,061	Trade Ally		
Evaluation	\$91,448	\$164,211	Evaluation and Reporting		
Total	\$2,815,786	\$4,986,415			

In an effort to begin to achieve some consistency between the gas and electric energy efficiency programs, the Company is presenting some aspects of this filing in a different format than its prior filings:

- The electric utilities provide program budgets in different cost categories than have been used by the Company in its gas energy efficiency filings. In this filing, the Company is providing its proposed EE budgets using the budget categories in the electric energy efficiency filings.
- 2. The presentation of the performance-based shareholder incentive mechanism has been different in the gas and electric EE plans. The Company is adopting the presentation that can be found in the electric EE plans here (see Exhibit D) but maintaining the current methodology for calculation of the incentive.

The remainder of this EE Plan provides an overview of proposed programs, a more detailed discussion of EE efforts for residential customers, a more detailed discussion of EE efforts for commercial and industrial customers, proposed outreach and communication efforts, evaluation and reporting, and a discussion about proposed performance-based shareholder incentives.

Four exhibits are provided in support of this EE Plan:

- 1. Exhibit A: Projected Program Expenses presents detailed budgets by program and year.
- 2. Exhibit B: Benefit Cost Analysis summarize the two-year benefit cost (BC) ratios for the programs as well as each year's BC ratio by sector with and without shareholder incentive.
- 3. Exhibit C: Program Input Assumptions shows the per participant savings, costs, and rebates for each program measure.
- 4. Exhibit D: Shareholder Incentive Calculation estimates the Company's projected shareholder incentive for successful implementation of its energy efficiency programs.

II. OVERVIEW OF ENERGY EFFICIENCY PROGRAMS

This document presents the Company's twenty-month (May 1, 2009 through December 31, 2010) EE plan (the Plan). Regional initiatives and collaborative groups also have influenced the Plan. Many of the programs described are a continuation of programs currently offered and approved by the Commission. Overall, the Company has developed programs that address a wide variety of energy efficiency opportunities for natural gas customers. These programs are summarized in Table II. The Company has included recent rebate changes and program updates agreed to by the regional GasNetworks[™] collaborative to ensure the same rebate levels are offered by Northern Utilities and gas companies throughout the region and to support coordinated program delivery with NH Saves (Core electric programs).

Table-II: Proposed Energ	y Efficiency Plan Off	erings (Programs) of the	e Company
--------------------------	-----------------------	--------------------------	-----------

Table-II: Energy Efficienc	y Programs
Residential Market	
High-Efficiency Heating, Water Heating, and Controls Program	 \$500 incentive for boilers (85% AFUE), \$1000 incentive (90% AFUE) \$200 incentive for steam boilers (with electronic ignition, 82% AFUE), \$400 incentive for high-efficiency furnaces (92% AFUE) with ECM Motor and \$100 incentive on furnaces (92% AFUE). \$300 incentive for indirect water heating system connected to an ENERGY STAR® rated natural gas forced hot water boiler and \$300 for on demand water heaters (EF .82 with an electronic ignition). \$50 for ENERGY STAR® .62 EF storage water heaters. \$25 incentive each for up to two ENERGY STAR® labeled programmable thermostats. \$100 for boiler reset controls.
New Home Construction with ENERGY STAR®	Free building plans review and certification for new ENERGY STAR® residential construction.
Residential Weatherization Program: Residential Weatherization, ENERGY STAR® Replacement Windows, and <u>Energy Analysis: Internet Audit</u>	 \$10.00 each for qualifying ENERGY STAR® labeled windows (U-factor of .35 or less). \$500 maximum. Incentive available in 2009 and no longer available in 2010. Incentive of 75% of installed cost of qualifying insulation and weatherization measures installed by participating contractors up to \$4,000 for 1-4 unit homes, up to \$750 for 5+ unit dwellings where each dwelling is individually metered. Air sealing on average up to \$650. Free online energy analysis service that makes customized energy efficiency recommendations based on a customer's energy consumption profile.
Energy Audit and Home Performance	Tier One – Educational, technical, and audit assistance by phone. Tier Two – Home Energy Assessment and low-cost energy saving measures.
Residential Building Practices and Demonstration Program	Participate in funding for demonstration projects that apply to new or underutilized technologies.
Residential Low Income Program	Energy audit conducted and measures installed (up to \$4,500 per residence) at no cost to income eligible customers (up to 200% of Federal Poverty Level Guidelines).
Commercial & Industrial Marke	
Commercial Energy Efficiency Program Commercial and Industrial	 Co-funding for Energy Auditing or Engineering Services; Prescriptive and custom incentives for more sophisticated systems and controls up to \$100,000. New construction projects eligible for up to \$250,000. Incentive of up to 50% of projects installed costs for eligible measures, cap of \$100,000 per project. Multifamily projects include redesign of space heating or water heating systems, steam system upgrades, building insulation, high-efficiency windows, and related measures. Matching grants up to \$100,000 for energy saving measures in commercial properties in designated Economic Redevelopment areas. Incentives up to \$6,000 for high-efficiency furnaces (90% AFUE), boilers (85% thermal
High-Efficiency Heating Equipment Program	efficiency) or steam boilers (82% thermal efficiency).
Building Practices & Demonstration Program	Participate in funding for demonstration projects that apply to new or underutilized technologies.
Business Energy Analyzer	Free online energy analysis service that makes customized energy efficiency recommendations based on a commercial customer's energy consumption profile.
Codes Training Outreach etc.	
Building Operator Certification	Energy management training sessions targeted to individuals responsible for the maintenance and operation of equipment and systems in commercial buildings, industrial plants, and public facilities. Provide information and training on energy efficiency issues to plumbing & heating contractors, builders, architects, engineers, realtors, appraisers and others.

During the 2009 – 2010 program years, the Company will build upon the existing portfolio of programs by:

- Continuing to manage existing programs cost-effectively;
- Coordinating closely with the NH Saves Core Electric Energy Efficiency programs and Northern Utilities;
- Identifying and developing new, cost-effective programs; and,
- Integrating discrete initiatives to more comprehensively address all energy uses and markets and barriers to energy efficiency.

The energy efficiency programs provide incentives to customers to choose energy efficient products. These products may be purchased from and installed by any qualified contractor selected by the customer. The Company's programs are designed to encourage contractor participation. The Company generally does not perform direct product installations. Customers are afforded the opportunity to use the contractor of their choice for some programs. All contractors are permitted to compete for the customer's business on an equal basis, though weatherization contractors will need to be trained in proper air sealing techniques to participate in program rebates.. Through its trade ally program, the Company provides training and encourages contractors to recommend and provide bids for qualifying energy efficient products.

In designing the proposed energy efficiency programs, wherever practical, the Company has established efficiency standards consistent with the ENERGY STAR® labeling program standards of the U.S. Environmental Protection Agency (EPA) and the U.S. Department of Energy (DOE). ENERGY STAR® is a collaborative effort of the DOE and EPA to prevent pollution and encourage conservation by helping consumers buy products that use less energy. The ENERGY STAR® label and promotional activities raise awareness of the environmental and economic benefits of energy efficient products and help consumers easily identify them.

In other instances the Company has established program criteria consistent with the specifications adopted by Consortium for Energy Efficiency (CEE) on products including furnaces, boilers and windows.

III. RESIDENTIAL PROGRAMS

A. Residential High-Efficiency Heating, Water Heating and Controls Program

The foundation for this program is incentives for customers to purchase high-efficiency gas heating equipment and controls. The program goals include:

- Making customers aware of high-efficiency gas heating equipment, controls, and the energy savings achievable;
- Increasing market sector awareness and demand for high-efficiency gas heating equipment and controls;
- Facilitating the purchase of high efficiency gas heating equipment and controls;
- Providing training to Trade Allies such as plumbing and heating contractors and increasing trade ally awareness of the benefits of high-efficiency gas heating equipment and controls.

The program is jointly operated with GasNetworksTM and will be promoted through a variety of marketing and educational awareness campaigns including, but not limited to: direct mail campaigns, bill inserts, trade ally events, sponsorships, and program brochures. The program will also be promoted via the Company's website, <u>www.nationalgrid.com</u> and the GasNetworksTM website, <u>www.gasnetworks.com</u>, where consumers and contractors will have the opportunity to download program incentive applications, as well as learn about program announcements and updates. The Company's products website, <u>www.thinksmartthinkgreen.com</u>, will also be used to promote this program.

In addition, the Company will continue its retailer outreach program with national home improvement chains, local hardware stores, suppliers, and distributors. This outreach effort provides training for sales personnel regarding the rebate programs and coordinates the ongoing distribution of program brochures and rebate applications.

A strong emphasis will be placed on working with builders and contractors who install gas heating equipment and controls. Target markets for the program include both new construction and existing residences. Incentives are available to residential customers (builders and/or homeowners). The Company encourages customers to choose high-efficiency by offsetting a portion of the high efficiency price premium. Information collected from the Company's field services contractors suggests that installation contractors have a large impact on the choice of heating equipment to be installed. The Company will also offer an incentive to installation contractors to further stimulate the installation of high-efficiency heating equipment. The Company may make changes to incentive levels for eligible heating, water heating, and control equipment during the program year. Additional cost effective measures may also be added if there is reliable evidence of cost effectiveness. See Table II for a list of eligible measures and the associated incentive level.

The Advanced Residential Controls category includes programmable thermostats and boiler reset controls. The ENERGY STAR® Programmable Thermostat initiative has been a mainstay of National Grid's residential energy efficiency offerings. National Grid plans to continue to offer its customers incentives for high performance programmable thermostats, which the Company views as an excellent means of controlling and reducing energy use. The following describes National Grid's ongoing commitment to the highlysuccessful thermostat program and incentives for boiler reset controls.

National Grid's residential heating customers are eligible for a \$25 mail-in incentive for the installation of up to two ENERGY STAR® qualified programmable thermostats, for a maximum of \$50 per household. When applying for a thermostat incentive, customers are required to submit proof-of-purchase for the unit. Eligible thermostats may be installed by homeowners and HVAC contractors.

Earning the ENERGY STAR® label means products meet strict energy efficiency guidelines. ENERGY STAR® thermostats are more accurate than manual models and contain no mercury. When used properly, they can save a notable amount of energy, and are better for the environment. Because older model thermostats are a common source of mercury, these thermostats should be properly recycled. On the Company's website and incentive forms, National Grid directs its customers to recycle mercury thermostats through municipal hazardous waste collection programs.

The U.S. Environmental Protection Agency (EPA) modified its thermostat program from a performance specification to consumer education on May 1, 2007. The EPA's action is based partly on studies weighted toward regions of the country where central cooling is the major energy load and, as a result, use of programmable thermostats result in minimal savings. However, in New England, where a major energy load is heating, there is ample evidence that ENERGY STAR® thermostats can significantly reduce energy consumption. A 2007 RLW Analytics study, commissioned by GasNetworksTM, estimated an average savings of 75 ccf of natural gas per heating season per thermostat installed. While there will be changes to this EPA designation, National Grid continues to see merit in promoting programmable thermostats and thus intends to continue offering incentives to customers.

National Grid is offering incentives for the installation of boiler reset controls. This technology works by monitoring the outdoor temperature and adjusting the frequency that the boiler responds to heat demand. For example, on a relatively mild winter day, a thermostat won't call for heat as often, so the boiler will not need to work as hard. The reset control adjusts the water supply temperature allowing it to drop to lower temperatures before firing.

Boiler reset controls have been available for residential heating systems for more than 30 years. However, due to relatively high installation costs, lack of promotion by manufacturers, and the lack of incentives in energy efficiency programs, there has been little market penetration. The Company offers an incentive of \$100 per reset control installed. This incentive is only available for newer boilers without built-in controls.

Table-III: Residential High-Efficiency Heating, Water Heating and Controls Program

B. New Home Construction with ENERGY STAR®

National Grid will continue its support of energy efficient new home construction through the New Hampshire New Home Construction with ENERGY STAR® Program. This Program is designed to encourage builders to construct their homes to a higher level of energy efficiency beyond standard code requirements. The New Home Construction With ENERGY STAR® Program offers a combination of utility incentives geared specifically to home buyers and builders, incentives which promote the construction of homes that meet national ENERGY STAR® Home efficiency standards. The program's objective is to transform the residential new construction market to build homes that are designed beyond code expectations and meet stricter guidelines for energy efficiency.

ENERGY STAR® Homes are recognized nationally for lower operating costs and energy consumption, increased durability, comfort, safety and greater resale value. ENERGY STAR® Homes feature the best in efficient building practices and technologies, including: increased insulation levels, high-efficiency heating and air conditioning equipment, superior duct systems, and high performance windows. Most segments of the housing market are eligible to participate in the New Homes with ENERGY STAR® Program, including new and existing residential single family and low-rise multifamily dwellings, townhouses and condominium developments.

All participants in the program receive design and technical support services, testing and inspection of energy efficiency measures, and an ENERGY STAR® certification following the passing of the ENERGY STAR® Homes rating test by qualified home raters. Each participating home receives a complete plan evaluation, computer energy model, and inspections during construction, and ongoing builder consultation, and on-site training as the home is being built. In order to earn an ENERGY STAR® Homes certificate, each house, or sampling of model units within a larger development, is performance tested to verify the quality of installed energy features. This involves conducting a blower-door test once the home is completed to measure the building's overall air leakage, and a ventilation test to verify airflow rates.

This program is jointly sponsored through a consortium of participating New Hampshire utilities that meet on a regular basis to plan and implement the program. The natural gas and electric utility provider in the specific territory of an ENERGY STAR® Home being developed will share the costs of providing technical support and certification testing services, from "sign-up" through certification testing for each qualifying home. This sharing of administrative and implementation fees between gas and electric sponsors are replicated with other gas utility sponsors of the New Hampshire ENERGY STAR® Homes program. In certain cases, the Company may pay the entire cost of an ENERGY STAR® Home's participation fee if the home is constructed in a community served by a municipal electric utility that does not participate in the Program.

Since the Company began its support of the New Hampshire ENERGY STAR® Homes program, Conservation Services Group, Inc. (CSG) has been the Company's sole rater for the ENERGY STAR® Homes program in New Hampshire. CSG is a third-party energy conservation consulting group responsible for the review and certification of each participating house in the Company's territory to ensure it meets strict ENERGY STAR® criteria. In the coming year, the Company may explore the opportunity to further align both gas and electric ENERGY STAR® Homes programs.

Marketing activities for the ENERGY STAR® Homes program consist primarily of direct outreach to builders by qualified home raters and home inspectors throughout the state's most active building regions. The ENERGY STAR® Homes toll-free phone number and website are essential resources for prospective builders that link home construction projects to participating home raters in the region. In addition to outreach, participating utilities may sponsor ENERGY STAR® training sessions specifically for builders and homebuyers throughout the year.

During the coming year, National Grid anticipates that participation in this program could be impacted by certain barriers, including the downturn in the New Hampshire new construction market. In an effort to combat this, National Grid will look to increase builder trainings as well as program marketing.

Table-IV: New Home Construction with ENERGY STAR®			
Electric Cost Categories	2009 Budget	2010 Budget	Gas Cost Categories

C. Energy Audit and Home Performance

The Energy Audit and Home Performance program, formerly known as Residential Conservation Services, is designed to help customers who either live in 1 to 4 unit homes or in individually metered multifamily dwellings with 5 or more units to optimize their home's energy use. The program provides a free assessment of a customer's energy usage and recommends various ways customers can improve their home's energy efficiency. Customers are provided with a detailed report containing recommendations for action and how to utilize the Company's other energy efficiency programs.

National Grid has become an active participant in the New Hampshire Residential Energy Performance Association (REPA), a New Hampshire organization whose goals are to provide training and promote consistency in the delivery of energy efficiency services. The auditor who performs the majority of the Company's audits in New Hampshire, as well as the vendor's supervisory staff, participates in REPA. The Company has also established www.energyfederation.org/nationalgrid. This website assists customers in purchasing materials to make their homes more energy efficient. Selections include all non-major measures that are recommended during the audit. The Company plans to promote the Energy Audit and Home Performance program through advertising, including bill inserts, direct mail, the National Grid website www.thinksmartthinkgreen.com, its website and product www.energyfederation.org/nationalgrid, online Home Energy Analyzer and *e-fficiency* news electronic newsletters. Customers can also call the toll-free number to learn more about the Energy Audit and Home Performance program and all of the Company's residential energy efficiency programs.

1. One to Four Unit Homes

For customers living in 1 to 4 unit homes, there are two levels of service provided by the program. Tier One screening offers referrals to educational web sites and information about energy efficiency programs, and captures requests for literature such as the DOE "Energy Savers" booklet. Technical assistance regarding installation of energy savings measures is also available by phone. The Company has adopted a customized version of the online audit tool to guide the customer through Tier One. The tool provides the customer service representatives with discussion points that allow a dialogue to better understand the customer's needs. Ultimately, the information collected by Tier One staff may result in a referral to Tier Two services.

Tier Two services consist of two audits. The first, the walk through audit, provides a home energy assessment and includes the installation of low-cost energy efficiency Instant Savings Measures (ISMs) that have an average total value of \$30. These measures are installed by the energy auditors at no charge to the customer as a way of educating the customer to the value of do-it-yourself measures. The customer is also provided a computer generated report describing the results of the home energy assessment which includes recommendations for energy saving measures. If the customer is willing to implement additional energy efficient measures, a combustion safety test will be performed at the walk through. The primary goal of the home energy assessment is to give customers an opportunity to understand the impact of energy efficiency measures and to motivate them to implement the recommendations.

The second audit National Grid is proposing is a two person energy audit team for customers who will proceed with energy efficiency upgrades. The two person team would provide a comprehensive home assessment in conjunction with whole house air sealing. This added value service averages \$650 and would be provided at no cost to the customer. To address health and safety concerns, pre-and post-blower door and CO testing is required. The procedures described in Tier 1 and Tier 2 above will be performed through a single implementation coordinator (IC) Selected by the Company. The cost, participation and benefits of customers who continue to this second audit will be accounted for in the Residential Weatherization program.

2. Five or More Unit Homes - Individually Metered Units

For customers living in individually metered units in a facility with five or more dwelling units, this program provides a free, comprehensive assessment of energy use in the individual unit. Customers will be given a detailed report containing the recommendations of the audit including information about improving the efficiency of their home which may lead to participation in other energy efficiency programs. Incentives will be provided to encourage participation and overcome the split incentive that often exists between landlords owning buildings but not paying utility bills and tenants paying utility bills but not owning the properties and therefore not having an incentive to invest in energy efficiency.

Tenants and landlords will benefit from improvements made by their utility in their facilities. Insulation, air sealing, and domestic hot water measures will improve tenant health and comfort and reduce tenant heating bills.

National Grid will administer the Energy Audit and Home Performance Program through a single implementation coordinator (IC). This IC will be responsible for the day to day administration of the Program. This IC will perform all site visits to determine which measures can be installed. Eligible building owners, and/or facility managers or associations will receive a comprehensive energy audit, energy education, and the installation of no-cost efficiency measures. The implementation coordinator will be responsible for all air sealing and DHW measures. All insulation measures for properties with greater than 20 units will be put out to competitive bid. Insulation contractors that have been previously approved by the Company will be eligible to bid on these jobs.

The Company plans to promote the Energy Audit and Home Performance Program through advertising, including bill inserts, direct mail, and the National Grid website. Customers interested in learning more about the program will be able to call a toll-free number where they will also be able to learn about all of the Company's residential energy efficiency programs. The program will be coordinated with the New Hampshire electric utilities' multifamily building programs.

Major measures will include attic insulation, wall insulation, basement/crawl space insulation, rim joist insulation, duct insulation, heating system pipe insulation, attic ventilation (in conjunction with attic insulation), ductwork leakage testing, ductwork leakage sealing, air infiltration testing, and air infiltration sealing. In addition, this Program will be coordinated with the New Hampshire electric utilities. Other measures may be added to the program menu, upon demonstration of cost-effectiveness and subject to available funding.

The Company will pay 50% of the cost of installed insulation measures, duct insulation and duct sealing up to a maximum of \$750 per dwelling unit. The Company

will pay 100% of the cost of air sealing and installed domestic hot water measures such as showerheads, aerators, pipe wrap and tank wraps installed by the IC. The customer will be responsible for paying 100% of the cost of installing attic ventilation.

Customers will apply for incentives for residential-sized heating and hot water heating equipment, thermostats and window rebates through the Residential High Efficiency Heating, Water Heating and Controls Program, and the ENERGY STAR® Replacement Windows Program. Facilities with central heating plants and domestic hot water systems that are interested in natural gas savings measures will be served through the Commercial High-Efficiency Heating and Commercial Energy Efficiency Programs

Table-V: Energy Audit and Home Performance

D. Residential Weatherization Program³

1. Residential Weatherization

The Residential Weatherization program currently provides an incentive covering 75% of the cost of installing weatherization measures in residential heating customers' homes. The maximum incentive offered through this program currently is \$4,000 in homes with 1-4 units and \$750 per dwelling unit in homes with five or more units where each unit is individually metered. In order to be eligible for the weatherization incentive, the residential customer must first have a site visit performed by the Energy Audit and Home Performance program as a pre-requisite to the following measures: attic insulation, attic stairs insulators, wall insulation, basement/crawl space insulation, rim joist insulation, duct insulation, heating system pipe insulation, attic ventilation (only in conjunction with attic insulation), ductwork leakage testing, ductwork leakage sealing, and air infiltration testing. Air sealing is required to be performed prior to installing any insulation measures. Other measures may be added to the program menu upon demonstration of cost effectiveness.

To be eligible for an incentive, a National Grid pre-qualified contractor must install program measures. Do-it-yourself work is not permitted. Contractors wishing to become a pre-qualified contractor eligible to offer this program to the Company's heating customers must meet Company contractor requirements. This includes providing evidence of Building Performance Institute (BPI) certification and carrying insurance in amounts and coverage at the Company's contractor partner specified levels.

The Company will continue to reach out to the contractor community in order to increase the number of pre-qualified contractors participating in the program. For quality control purposes, at least twenty percent (20%) of completed jobs will be inspected. The inspection process will consist of a visual review of all work reported to be performed at the job site. Infrared scanning may be selectively employed to inspect wall insulation and air sealing work that cannot be observed with the naked eye. Infrared scanning not only provides a quality control tool, but also serves to raise insulation installation standards.

³ This program is available to residential customers living in homes with 1-4 units and to residential customers with individually metered dwelling units where the facility has 5 or more units.

Ongoing annual training will be conducted to familiarize contractors with industry building science best practices.

It is the responsibility of the installation contractor to complete and submit incentive applications with proper supporting documentation to verify that the work was performed. Work completed through the program must meet all applicable state and local code requirements. It is anticipated that all measures installed will meet ENERGY STAR® OR Building Performance Institute (BPI) guidelines, where applicable.

The program is promoted to residential heating customers through National Grid's contractor allies, home shows, direct mail promotions, and bill inserts. The program is also marketed through the Company's *e-fficiency news* electronic newsletter, the Home Energy Analyzer on-line audit, and the corporate website.

Potential participants are also made aware of the Residential Weatherization program through their participation in the Residential Energy Audit and Home Performance program. Energy Audit and Home Performance program energy auditors receive supplemental training for the purpose of seamlessly integrating the Weatherization program and the Energy Audit and Home Performance program.

Utilizing a Building Performance Institute (BPI) certified installation contractor is required to be eligible for the maximum incentive. To address health and safety concerns, pre- and post-blower door and CO testing is required.

In conjunction with the enhanced incentive, National Grid will require BPI certification of installers. BPI is a recognized global leader in setting building science based standards. BPI certification ensures that knowledge and competency are demonstrated by means of written and field testing.

National Grid will require BPI certification and will provide contractors with a percentage of reimbursement incentives for training and the purchase of required diagnostic tools. In this manner, National Grid will assist in building an infrastructure of trained and certified contractors to deliver the highest quality workmanship to customers, and the public at large.

The Company will continue to seek out opportunities to better serve National Grid customers by integrating the offerings of all of its energy efficiency programs, and by utilizing programs administered by other utilities.

Table–VI: Residential Weatherization

Goal	550 participants	1,100 participants	
2.	· - •	· - •	•

ENERGY STAR® Replacement Windows

The Company will continue to promote the installation of ENERGY STAR® Replacement Windows in the Residential Weatherization program, and will provide a \$10 mail-in incentive for each high-efficiency window installed in existing residential customers' homes. Eligible participants must be residential heating customers who have installed ENERGY STAR® labeled replacement windows with a U-factor of .35 or less^{*4} during the program year as specified on the incentive form. Windows installed in new construction or home additions will not qualify for the per window incentive. Each customer will be subject to a \$500 maximum incentive per account. National Grid will continue working with contractors for multi-family or other large residential renovation projects on a case- by-case basis.

When applying for this incentive, residential customers are required to submit proof-of-purchase, as well as proof of the windows' U-factor. Efficiency ratings can be confirmed by the customer using either a copy of the National Fenestration Rating Council (NFRC) label from the window, or by providing detailed specifications from the window manufacturer confirming the window's U-Factor. The Company recommends inspections of the first two installations per new participating installation contractor. In addition, random inspections of self-installations may be administered to verify that the windows noted on the incentive forms were, in fact, installed.

The Company will promote ENERGY STAR® Replacement Windows through The Residential GasNetworksTM program using various methods, including the Company website: <u>www.thinksmartthinkgreen.com</u> and its product website: www.efi.org/nationalgrid/, the *e-fficiency news* electronic newsletter, as well as through bill inserts. In addition, the Company has established an outreach program with retailers Home Depot[®] and Lowe's[®], and regional hardware stores. This outreach includes training of the retailer's sales personnel regarding the Company's replacement window incentive, and supplying those stores within the Company's territory with incentive applications.

⁴ The U-Factor is a measurement of thermal conductivity. A lower U-factor indicates a higher level of window insulation.

National Grid recognizes that an efficient window is only as good as its installation. As such, the Company will expand its contractor training and outreach efforts, and promote best practices guidelines among "do-it-yourselfers" as well as professional window installers.

The Company and GasNetworks[™] plan to discontinue this incentive in 2010.

Table-VII: ENERGY STAR® Replacement Windows

Goal	300 participants	0 participants	

3. Energy Analysis: Internet Audit

This self-service audit tool allows customers to complete an electronic survey about their home, including age, size, appliances and average use patterns. The process starts with twelve basic questions to produce a report that compares the participant's home with similar homes and generates their "Top Ways to Save," including estimated annual cost savings if recommended measures are taken.

Subsequent steps require more detailed information from the customer, resulting in more personalized tips to improve the home's efficiency. The analyzer is fuel blind and lists opportunities to save in heating/cooling, lighting, water use, etc. The customer

٦

also receives information about any relevant energy efficiency opportunities such as incentive programs.

There are several levels of service the customer can receive through the analyzer, all of which can be accessed through the Company's website. A continued analysis consists of more in-depth questions about the numbers and types of appliances, the current state of the home's weatherization and mechanical equipment, and offers additional advice on how to improve the energy efficiency and comfort of the home. Users are invited to sign up to receive the Company's seasonal electronic newsletter, which includes seasonal tips to save energy, information about new energy saving technologies and the Company's other energy efficiency programs, and a link to continue the analysis of their homes.

E. Residential Building Practices and Demonstration Program

The purpose of the Residential Building Practices and Demonstration Program is to explore and demonstrate new and/or underutilized energy efficiency practices and equipment that can enhance a home's overall energy saving potential. This unique program allows the Company to support new and/or advanced energy saving technologies installed by residential customers.

The Company plans to explore renewable energy for water heating, advanced home heating systems, insulation and building envelope techniques, and new home construction practices. Ideas will be drawn from experience in the Company's Commercial & Industrial Building Practices and Demonstration Program, as well as from other utilities, program vendors, and interested business partners. Eligible participants in this program will include home owners, landlords, and new home builders. Each participant may be asked to allow monitoring of the installation and publication of the results in case study format.

Marketing of the program will rely on networking with industry, developing or offering new or underutilized natural gas energy efficiency technologies, as well as other interested organizations, such as the Office of Energy and Planning Renewable Energy Program, Massachusetts Technology Collaborative (MTC), the Northeast Sustainable Energy Association (NESEA), and the U.S. Green Building Council's Leadership in Energy and Environmental Design (LEED).

Table-IX: Building Practices and Demonstration Program

Goal	15 participants	20 participants			

F. Residential Low Income Program

The Residential Low Income Program offers weatherization services to income eligible customers at up to 200% of the Federal Poverty Level Guidelines. The Residential Low-Income program currently allows eligible customers to receive up to \$4,500 in qualifying measures at no cost to the customer. Whenever possible, program funds are leveraged with Department of Energy (DOE) weatherization and participating electric utility funding. The Company continues to seek out opportunities to strengthen its relationships with the State administered weatherization program, and other utility administered programs, in order to leverage funds and better serve National Grid customers.

Eligible measures provided through the program include an energy audit, attic insulation, wall insulation, air sealing, heating system repair/replacement (on a qualifying basis) and safety inspections. Small energy-related repairs for eligible heating units can also be performed. The Company will continue to install water saving measures (low-flow showerheads and aerators) and to fund the installation of carbon monoxide detectors when DOE is unable to fund this measure.

New Hampshire Community Action Program (CAP) agencies are responsible for ensuring that customers meet the eligibility requirements for program participation, and for providing weatherization services to customers. CAP agencies work with installation contractors to ensure that program requirements are met.

The CAP agencies provide Action Energy, Inc. (Action), the Company's administrative vendor for the program, detailed documentation demonstrating the work that was performed. Action also conducts quality control oversight of the work performed through the program.

The Company holds quarterly meetings with Action, the CAP agencies, and the Office of Energy and Planning to improve program implementation, address questions or emerging concerns, and to ensure that program goals are being met.

The Low Income Weatherization internet website, <u>www.weatherize.net</u>, continues to be a valuable tool. This website serves as a central information source for all of the CAP agencies and for Company personnel associated with the program. Weatherize.net has the capability to search data and determine whether a particular applicant is eligible for assistance. The site can also be used to communicate with the CAP agencies and provide timely information and updates.

The Company solicits direct feedback from program participants through its postinstallation comment cards. The card, mailed directly to those customers where weatherization work was performed, allows customers to share their input and impressions of the program directly with the Company. The Company then shares the customers' responses with the corresponding CAP agency. This direct link from customer to CAP allows the Company to monitor program performance and customer perception of the program. The Company markets the program via Company brochures, bill inserts, and the National Grid website.

The Company continues to work with the CAP agencies to identify and enlist additional contractors to participate in the program. The Company is committed to train its existing contractors and market to new, eligible contractors in order to expand the contractor base. Efforts may also include outreach to technical/trade schools, and providing assistance to potential contractors for technical training.

The primary focus of the program will continue to be servicing income eligible customers in the 1-4 unit housing stock, as well as income eligible customers living in individually metered multifamily dwellings with five or more units. The Company will continue to explore energy saving opportunities, on a case-by-case basis, to provide weatherization services to organizations that provide critical services to the program's target audience, e.g. housing authorities, food banks, homeless shelters, and organizations whose mission is to work with low income citizens.

IV. COMMERCIAL AND INDUSTRIAL PROGRAMS

A. The Commercial Energy Efficiency Program

1. Commercial Energy Efficiency

The Commercial Energy Efficiency Program "CEEP" is designed to provide support services and financial incentives that encourage the Company's Commercial, Industrial and Multifamily customers to install energy efficient natural gas related equipment. Energy efficient technologies or system designs that exceed the minimum requirements of the local energy code and are not covered by another utility company program offering may be eligible for an incentive under this program. This program is open to all firm gas rate customers on any of the Company's commercial tariffs. Incentives provided through this program must be pre-approved by the Company and/or the administrative vendor prior to delivery and installation of product(s) and/or service(s).

Customers may apply for program services or incentives via a variety of channels including contacting Company representatives, plumbing and heating contractors, engineering firms, energy service companies, or equipment vendors. Customers will be able to take advantage of audit services that range in scope from a prescriptive level to custom review to technical assistance and new construction design assistance. After reviewing the customer's energy efficiency needs, the customer will be offered the appropriate program services. Customers will then be able to take advantage of either prescriptive or custom incentives. Services and incentives structures are described in the following sections.

Audit services

Energy Assessment

Regardless of market segment, all qualifying customers contacting the Company will be provided with an opportunity for an energy efficiency assessment. This assessment will educate small to medium sized customers on basic gas energy efficiency measures and practices. This assessment will determine which prescriptive incentives a customer may be eligible to receive. Where applicable, the assessment will provide industry-specific recommendations. As part of the assessment process, customers will receive a report that includes all of the information associated with service delivery, including costs and estimated savings and identifies next steps for implementing energy efficiency measures and information and instruction for receiving energy efficiency incentives. This energy efficiency assessment is currently delivered to the customer as a walk through audit. The Company works with the vendors to determine the most cost-effective way to deliver this assessment, which may include remote delivery mechanisms.

Custom Assessment

National Grid recognizes the diverse needs of its customers when identifying energy efficiency opportunities. In that regard, the custom assessment will be made available to customers who require more energy analysis than is provided through the energy efficiency assessment. The custom assessment will also be made available for specific applications such as combustion controls, solar DHW, and heat recovery from combined heat and power (CHP). As part of a custom assessment, a site visit will be conducted at multifamily, commercial and industrial facilities in the Company's service area to identify gas energy efficiency opportunities for National Grid customers.

The assessment may also take place as a review of energy efficiency proposals presented by customers or third party vendors for inclusion in the program. Based on the assessment, a customer will receive recommendations on energy efficiency measures eligible for custom gas energy efficiency incentives. Customers will receive a report that includes all of the information associated with service delivery, identifies next steps for implementing energy efficiency measures, and information and instruction on next steps for receiving energy efficiency incentives.

Technical assistance

Customers requiring energy efficiency assistance beyond the scope of a custom audit will be provided with technical assistance. This may include, but is not limited to, thermal oxidizers in manufacturing, infrared process heat applications, central plant system redesigns, and other complex energy efficiency technologies. Technical assistance studies must be completed by either a Professional Engineer or Certified Energy Manager. Customers who receive this service will receive a detailed report, including recommended measures, estimated costs, energy saving potential, custom incentives and simple paybacks. Technical assistance will be provided at the discretion of National Grid program management staff. The Company may provide these services at no cost to the customer up to an amount equal to the cost of a custom audit. If the project exceeds the cost of a custom audit, the Company will provide up to 50 percent of the cost of assessment but not more than \$10,000. The Company has under retainer engineering firms that have been selected through a competitive solicitation and qualified to offer customers technical services. Additionally, when appropriate, these firms will identify electric savings as well as gas savings opportunities particularly when working in conjunction with electric energy efficiency programs.

New Construction Services

National Grid proposes to provide New Construction Services, a service in which customers will be guided through a review of the design or design process to increase the energy efficiency of a new building by identifying appropriate energy saving measures for new construction. The intent of these services is to better address the special considerations needed to address energy efficiency at the time of new construction. This process will involve working on the project design with the customer and members of their construction team including, but not limited to, building committees, architects, engineers, and contractors. This service goes beyond engaging customers at the front end of the new construction process. It continues through project completion. New construction resources will be provided through a variety of means including, but not limited to, design team assistance, matched funds for study costs and potential assistance for system commissioning at project completion. Customers will be eligible for up to \$25,000 in total design assistance funding. Customers taking advantage of design assistance must be willing to move forward with the installation of energy efficiency measures with acceptable payback periods. Customers will receive a report about energy efficiency recommendations that include recommended measures, estimated costs, energy savings potential, custom incentives and simple paybacks.

Incentives

Energy efficiency incentives will be made available to customers through the individual programs. Currently both prescriptive and custom incentives are available to National Grid customers. Prescriptive measures include but are not limited to high efficiency heating and water heating, windows, insulation, thermostats, boiler reset control and steam traps. Custom incentives will be developed through the analysis conducted in the Custom Assessment, Technical Assistance and New Construction services. Information regarding incentive structure by program service follows.

Prescriptive Incentives

Prescriptive incentives will be available for common energy efficiency measures including programmable thermostats, boiler reset controls, steam trap replacements, pipe and duct insulation, building shell (wall, roof, floor, and crawlspace) insulation, and highefficiency windows. Other prescriptive measures include high efficiency commercial kitchen equipment, such as high efficiency fryers, steamers, and combination ovens. The company proposes to incorporate high efficiency dishwashers, broilers, woks, combination ovens, and griddles into the commercial kitchen equipment program after evaluation. Prescriptive incentives will be targeted primarily toward the small and medium sized Commercial & Industrial customers. The Company will rely primarily upon contractors and engineers to locate qualified facilities and to install the eligible prescriptive measures. This effort will be supported by the extensive outreach and education effort to contractors and engineers, as well as promotions directed to customers themselves. Energy audits will not be required for participation and no pre-approval will be required for applications at a single customer site. As outlined in the program terms and conditions, the Company reserves the right to negotiate incentives for multiple installations at a single site and/or multiple installations within a portfolio of properties. The Company also reserves the right to inspect the property for the installation of the measures prior to issuing the rebate. The Company plans to evaluate the prescriptive rebate incentives during the 2009 program year. Results of the evaluation will be used in the next available planning cycle.

Table-XI. Trescriptive incentives for instance weasures				
Measure	Available Incentive			
Programmable Thermostat	\$25.00 each, up to 5 units			
Digital Boiler Reset Control	\$150.00 single stage; \$250.00 multi-stage			
Steam Trap Replacements	\$25.00/replaced trap			
Pipe or Duct Insulation; duct sealing	\$1.50/lf up to 500lf			
Building shell insulation (roof, wall, or	Up to 20% of project cost with a maximum			
floor)	of \$10,000.00			
Premium efficiency windows	$1.00/\text{ft}^2$ of rough window opening with a			
	maximum of \$2,500.00			
High Efficiency Gas Fryers	\$1,000.00/each			
ENERGY STAR® Gas Steamers	\$1,000.00/each			
ENERGY STAR® Gas Convection Oven	\$1,000.00/each			

Table-XI: Prescriptive Incentives for Installed Measures

Custom Incentives

Custom incentives will be available for projects that demonstrate the use of natural gas more efficiently than typical industry practices, or more efficiently than the minimum building code requirements. Incentives will be limited to no more than 50 percent of the eligible installed project costs, and the Company's contribution will be capped at \$100,000 per site and/or project for existing buildings and \$250,000 for buildings under the new construction program.

Custom incentives will be based upon \$2.25 per first year of estimated therm savings for cost-effective projects. Examples of custom projects are redesigned HVAC systems, energy recovery applications, combustion controls, building automation/energy management systems, and advanced technology burners and/or burner controls. Incentives may not be applied toward normal maintenance costs, or for disabling or abandoning equipment without an energy efficiency replacement.

Steam Savings Initiative

The Company plans to implement a new initiative designed to help customers with steam systems to save natural gas. The Steam Savings Initiative includes steam trap surveys, steam system surveys, and focuses on identifying gas savings measures which qualify for prescriptive and custom incentives. Examples of such measures are steam traps, economizers, combustion controls, blow down recovery, water treatment, and condensate control. New construction projects are not eligible.

The Company will pay 25 percent of a steam trap survey, up to \$2,500. Once the survey is completed, and at least 50 percent of the recommended repairs have been installed and paid for, the Company will pay an additional 25 percent of the survey cost, up to \$2,500. In return for funding from the Company, the customer agrees to start a comprehensive steam trap management plan, following the Department of Energy's recommended steam trap management procedures. The customer pays for the other 50 percent of the survey.

Solar Incentives

The Company will continue to offer solar thermal incentives to encourage the installation of highly efficient solar thermal technologies by customers. Examples of these technologies include solar domestic hot water (DHW) heating, solar pool heating, and solar space heating. Solar thermal incentives will be provided at a special incentive of \$5.00 per therm.

Table-XII: Commercial Energy Efficiency Program				
Electric Cost Categories	2009 Budget	2010 Budget	Gas Cost Categories	
Internal Administration	\$45,000	\$98,000	Company Administration	
External Administration	\$28,095	\$71,415	Vendor Admin/Support	
Rebates/Services	\$481,640	\$930,061	Services

Marketing (sum of communication and trade	\$35,000	\$60,000		
ally)	\$25,000	\$35,000	Communication	
	\$10,000	\$25,000	Trade Ally	
Evaluation	\$28,549	\$46,169	Evaluation and Reporting	
Total	\$618,284	\$1,205,645		
Goal	109 participants	227 participants		

2. <u>Multifamily Housing</u>

The Multifamily Housing offering provides energy audits and financial incentives for energy saving measures to multifamily facilities that receive gas service on a qualifying commercial rate. The program includes existing retrofit situations as well as new construction. Examples of measures that qualify for funding through this program include the redesign of space heating or water heating systems, steam system upgrades, building insulation and premium efficiency windows and doors. Programmable thermostats, heat recovery ventilation systems, digital energy management systems, and sophisticated burners and/or controls for boilers are also energy saving measures the Company may recommend or support through this program. The program serves both privately owned properties as well as public housing authorities.

Through the new service delivery model being developed collaboratively with other gas and electric providers, customers can participate in the multifamily program by accessing incentives, Energy Efficiency Assessment, a custom audit, New Construction Assistance, or Technical Assistance. An increased need for affordable housing in the Company's service territory has brought several new construction projects through the program. The enhanced level of support for new construction ensures that energy efficiency becomes a focus of the project during the design phase, to avoid lost opportunities or the burden of incorporating them later in costly redesigns. Through a customer intake process, the Company will determine the level of energy efficiency advice and oversight needed by the customer. Gas consumption history, building type and size, plans for renovation or expansion and known energy efficiency measures already in place should determine the level of audit necessary for the site. Delivery of energy efficiency services and incentives will also be coordinated with electric services and programs.

Multifamily customers will be eligible for prescriptive and custom incentives. Prescriptive incentives will include high efficiency heating and water equipment, controls, envelope, and restaurant equipment. In addition, custom incentives will be made available to customers who enter the program through the custom audit, new construction assistance or technical assistance services. Savings for this program have been low in recent years so the Company plans to focus on custom projects with controls and steam system enhancements to support higher energy savings for the multifamily segment. The Company also plans to work with customers on benchmarking properties to determine the buildings with the greatest need for energy efficiency upgrades. Custom audits will identify measures for energy efficient installations. These installed measures are eligible to receive an incentive of \$2.25 per first year estimated therm savings for cost-effective energy efficiency installations. Customers will be eligible for up to 50 percent of the eligible installed project costs with a cap of \$100,000 for existing buildings.

The program is promoted through the Company's internal departments such as Sales and Marketing, as well as Customer Service. The Company also promotes the program through industry partners such as the National Association of Housing and Redevelopment Officials, local housing authorities, local chambers of commerce events and through conference attendance and contractor outreach. The Company will seek out partnerships to leverage the use of energy efficiency funding.

National Grid is beginning coordination efforts between its electric and gas multifamily programs. Gas incentives and services may be adjusted if it is determined that a specific customer may receive a more comprehensive service through coordinated delivery of the two programs.

Table-XIII: Multifamily Housing					
Electric Cost Categories	2009 Budget	2010 Budget	Gas Cost Categories		
Internal Administration	\$17,000	\$30,000	Company Administration		
External Administration	\$14,960	\$23,895	Vendor Admin/Support

ally)	\$8,000	\$15,000	Communication		
	\$5,000	\$10,000	Trade Ally		
Evaluation	\$2,210	\$5,018	Evaluation and Reporting		
Total	\$73,660	\$167,255			
Goal	10 participants	20 participants			

3. <u>Economic Redevelopment</u>

The Economic Redevelopment Program leverages energy efficiency funds to revitalize buildings in our service territory with the aim of rejuvenating the local area. The Company has found that energy saving measures can be the first project design features cut due to the higher incremental costs of installation, and lack of education and technical expertise. This can be particularly true in blighted communities where money is tight and community development corporations (CDC's) and other non-profits are responsible for much of the development.

Funding through the Economic Redevelopment Program ensures energy efficiency measures become part of a viable project. Beyond additional incentive dollars, National Grid works to partner, whenever possible, with other government entities and other energy efficiency programs, serving as a link between various funding sources and providing technical expertise. National Grid's long term commitment to its Economic Redevelopment Program creates opportunities for energy efficient technologies, increases the standard for efficiency in economically-disadvantaged communities, and works to revitalize neighborhoods.

The Economic Redevelopment Program is available to all multifamily, commercial and industrial customers. Maximum funding per project is 50 percent of the project cost up to \$100,000 with a minimum of 50 percent matching funds required from the customer. Qualifying customers entering the program through new construction assistance will be eligible for up to \$250,000 in incentives with a minimum of 50 percent of matching funds required from the customer. Applications for funding must include a description of the redevelopment project, information on the sponsoring organization, identification of additional funding sources, types of energy conserving measures to be installed, project schedule and the community and local economic impacts. Each application for funding is evaluated on these criteria.

An analysis is performed to identify cost-effective opportunities for reducing a customer's energy usage. The analysis performed leads to a report that summarizes recommendations and provides a detailed description of the alternatives evaluated, including: total installation costs, annual energy costs, annual savings and simple payback periods. The analysis establishes projected first year therm savings and the associated incentives available to the customer through the standard Multi-family, Commercial and Industrial Programs based on the therm savings.

The total award amount through the Economic Redevelopment Program uses the standard incentive amount as a baseline, but takes into consideration community and economic impacts in determining a total award amount. All award amounts are paid out as an incentive after the project is completed and all recommended gas saving measures that formed the basis for the award have must be installed in order to receive total funding. Community impacts include, but are not limited to, the overall environmental

impact of a development beyond the gas savings, the creation of low income or affordable housing, aesthetic impact of the development on the surrounding community, recreational and educational services and job creation.

With the new program delivery model for Commercial & Industrial and Multifamily customers, the Company can identify potential participants as candidates for the Economic Redevelopment program through their involvement in custom assessment, technical assistance or new construction assistance. The Company will simultaneously work to increase program awareness and identify candidates through partnerships with other development organizations, business organizations, government agencies, and other energy efficiency groups. This year the Company plans to work with cities and towns to identify projects, which include schools, low-income housing, and public libraries, that are good candidates for this program.

Table-XIV: Economic Redevelopment

39

B. Commercial High-Efficiency Heating Program

The Commercial High-Efficiency Heating Program is designed to overcome supply side and demand side market barriers to the purchase and installation of highefficiency heating equipment and water heating equipment. The program is available to National Grid's commercial, industrial, governmental, institutional, non-profit and multifamily facilities. The equipment under the high-efficiency heating program includes a range of innovative technologies in heating systems that are applicable across National Grid's diverse commercial customer base. The incentive schedule is set to reduce the incremental cost between the standard options and high-efficiency Heating program will continue to be promoted primarily to engineers, equipment vendors, contractors and other trade allies.

In the small commercial business segment and the smaller multifamily segment, the application of heating and water heating technology is analogous, as is the size range of equipment. Efficiency ratings for smaller furnace and boiler equipment (up to 300,000 Bbtu input) are measured using AFUE ratings. Efficiency ratings for larger boiler equipment, which exceeds the size ranges for AFUE, are measured using thermal efficiency which has been confirmed by a third party.

Since many of the trade allies serving the residential market also serve the smaller multifamily and commercial markets, the program will often be promoted together with the Residential High-Efficiency Heating, Water Heating and Controls Program and the GasNetworksTM program activities. Trade ally training activities will also be leveraged with the residential activities and GasNetworksTM trade ally programs. Trade ally training in the larger equipment markets will continue through product training workshops, participation in industry working groups and trade associations, outreach to engineering firms, advertisements in trade publications, trade shows/seminars, and field calls and site visits.

The program's incentive schedule applies to a variety of product types and a broad range of equipment sizes that are appropriate for the commercial market segments. This range provides equal opportunity for participation among National Grid's small and large commercial customers. There are also incentives for natural gas fired, low intensity infrared heaters, high-efficiency condensing unit heaters and direct fired make-up air systems that are appropriate for the larger commercial and industrial segments. Boiler incentives are available in a two-tiered matrix: Tier One for high-efficiency non-condensing boilers and Tier Two for high-efficiency fully condensing boilers.

As outlined in the program's terms and conditions, National Grid reserves the right to negotiate a lower incentive amount per-unit for multiple installations at a single site. In large multifamily complexes and facilities, customers and/or contractors making bulk equipment purchases have a lower incremental cost per unit. Negotiating incentives helps to keep the program within budget and maintains the cost effectiveness of installed measures. The incentives are also set to help participants reduce the true incremental costs, considering the bulk purchase cost of installing multiple pieces of high-efficiency heating equipment.

Table-XV: Commercial High-Efficiency Heating Program					
Electric Cost Categories	2009 Budget	2010 Budget	Gas Cost Categories		
Internal Administration	\$20,000	\$30,000	Company Administration		
External Administration	\$15,620	\$20,000	Vendor Admin/Support

	Efficiency	
Condensing Boilers (1701 Mbtuh and larger)>	90% Thermal	\$6,000
	Efficiency	
Indirect fired water heaters (up to 50 gallon storage)		\$100
Indirect fired water heaters (over 50 gallon storage)		\$300
On-Demand Tankless Water Heaters with and Energy		\$300
Factor of 0.82 or higher and electronic ignition		

Table-XVI: Commercial High-Efficiency Heating Program Incentive Qualifications

C. Building Practices and Demonstration Program

The purpose of the Building Practices and Technology Demonstration Program is to establish successful applications of new or underutilized energy efficient procedures, processes, or technologies. Participants in the program may be identified through the Company's other program offerings. Customers interested in presenting a project for consideration may request financial and technical assistance from the Company. Applicants must include a description of the scope of work and an estimate of the savings and benefits to be realized. Participants are required to allow monitoring of the installation and/or results, tours on the installation by potential users or other interested stakeholders, and publication of the results in case study form. To market the program, the Company will rely on the industry vendors and industry organizations such as Gas Technology Institute, Energy Solutions Center, and Consortium for Energy Efficiency developing and/or offering new or underutilized natural gas energy efficiency technologies. The program will also be promoted through the Company's sales force.

Throughout the program's history, National Grid has encountered resistance from customers to install new technologies that often require significant investment on their behalf. In order to overcome market barriers associated with the installation new technologies, National Grid is proposing to develop technologies in two program phases. The first phase would be a direct install by National Grid at one or two customer sites. These initial test sites would allow for increased monitoring and evaluation. The second program phase would be for multiple installations at National Grid customer facilities. This second phase would provide installations with cost-sharing between National Grid and the customer at fifty percent each and again allow for significant monitoring. The increased focus on monitoring and evaluation will require additional resources and funding. As a result, the Company is proposing to limit participation in the Building Practices and Demonstration Program to no more than three participants each year.

National Grid is currently working to identify a superboiler project, commercial kitchen equipment, and a high efficiency HVAC rooftop unit that the Company could include in the Building Practices and Demonstration Program.

Table-XVII: Building Practices and Technology Demonstration				
Electric Cost Categories	2009 Budget	2010 Budget	Gas Cost Categories	
Internal Administration	\$31,656	\$40,000	Company Administration

D. Business Energy Analyzer Program

The Business Energy Analyzer is a convenient online self-directed audit tool that provides customers with customized and practical recommendations for saving energy. This user-friendly tool, developed by Aclara Software, provides business customers: (1) an opportunity to learn about energy savings as it relates both to their facility and their industry; (2) the flexibility of addressing energy concerns at their leisure; and (3) the ability to return to the site and review the recommendations. The tool also allows customers to identify the energy-saving incentives for which they may be eligible.

Customers complete a Level I profile that includes their location, business type, size of facility and hours of operation. Based on this information, the system generates energy saving recommendations or "Ways to Save". At this point, the customer can opt to move on to Level II and enter in more specific information about their facility. This information includes actual energy use from utility bills or they can choose to have the

system estimate usage. Based on the additional information, the system generates an analysis of the business's energy usage that provides more accurate energy saving suggestions and targeted "Ways to Save". The customer can view these tips either showing those with the greatest savings or the shortest payback. The recommended measures have been customized to reflect information on incentives for which the customer may be eligible. Customers can also create a plan for energy efficiency from these measures that can be retrieved any time they log on. Additionally, the tool offers the customer the ability to compare their energy usage to similar businesses and view industry-specific case studies.

In the past program year, the Company had great success marketing the tool through direct calling campaigns. The Company found that using direct calling to contact customers and then assisting each customer in using the energy analyzer was the best way to increase awareness and utilization of this online program. Once a customer completes the online audit with the help of a call center representative, a comprehensive report is e-mailed to the customer highlighting the results and the best ways to save. A profile is set up so that the customer can return to the site at any time to review their results, work on an energy plan, and learn more about the Company's other energy efficiency offerings. The Company will continue to market the energy analyzer in this way. Additionally, the energy analyzer is being marketed through the Company's sales force, energy efficiency staff, trade organizations and outreach events.

The Company will continue to provide energy efficiency information to businesses though the business version of the *e-fficiency news*. *E-fficiency news* is an e-mail based, quarterly newsletter that customers can opt to receive while at the Business Energy Analyzer website. The first issue of the *e-fficiency news* was e-mailed to customers in September of 2005 and continues to be sent on a quarterly basis.

With the goal of continuing to improve the products and services provided to our customers, the Company may evaluate other online energy analyzers. Evaluation of other online energy analyzer will include, but not be limited to, quality of energy efficiency information, ease of use and cost. If it is determined that another energy analyzer provides more value for our customers, appropriate changes will be made.

Table-XVIII: Business Energy Analyzer Program					
Electric Cost Categories	2009 Budget	2010 Budget	Gas Cost Categories		
Internal Administration	\$10,000	\$12,500	Company Administration		
External Administration	\$5,000	\$7,500	Vendor Admin/Support

Internal Implementation	\$0	\$0	Other		
Marketing (sum of communication and trade	\$5,000	\$5,000			
ally)	\$5,000	\$5,000	Communication		
	\$0	\$0	Trade Ally		
Evaluation	\$0	\$0	Evaluation and Reporting		
Total	\$20,000	\$25,000			
Goal	40 level 1 users	60 level 1 users			

v. OUTREACH AND COMMUNICATION

A. Energy Efficiency Communication and Education

Communication to and education of customers and trade allies is critical to the success of the Company's energy efficiency efforts. One of the most common barriers to the increased use of energy efficient equipment or practices is a lack of awareness by customers of the potential energy and financial savings. Another common barrier is the lack of customer awareness as to how their utility can help reduce their energy costs. To overcome these barriers and help customers make informed energy decisions, the Company plans to maintain a consistent and high level of program outreach to its customers and trade allies.

One component of program outreach will be the ongoing development and refinement of brochures, direct mail pieces, bill inserts, and educational literature for the Company's initiatives.

The Energy Efficiency staff will continue to take advantage of every opportunity to disseminate energy efficiency information through personal contact at home shows, trade shows, community events, landlord events, new homeowner workshops, energy information fairs, and energy awareness events at major employers. The Company also will continue to use its website as a tool to promote energy efficiency. National Grid also offers regular training to its call center representatives about the Company's energy efficiency programs and how to direct customers to participate in energy efficiency programs.

In addition, the Company plans to partner with technical schools, community colleges, contractors, and trade organizations to promote energy efficiency and opportunities in the energy efficiency industry.

B. Trade Ally Training and Codes & Standards Program

Energy efficiency awareness by the Company's trade allies and customers is crucial to reducing market barriers to energy efficiency and increasing acceptance of new technologies. Educational activities will be a critical piece of the Company's promotion efforts.

The Company will support and undertake a wide range of training events in collaboration with GasNetworksTM and the manufacturing representatives and other trade allies. GasNetworksTM was recently authorized to award continuing education credits for the Plumbing, Heating and Cooling Contractors (PHCC) of New Hampshire. The PHCC requires training and education credits as a part of membership.

Additional outreach will extend to engineers, architects, builders, landlords, facility managers, housing authorities and other customers. The objective of all training activities will be to increase trade ally awareness of the benefits of energy efficiency and the technology options in high-efficiency equipment. Trade ally training also works to provide trade allies with the technical tools to properly size, install and maintain energy efficient products and provide customers with the knowledge to select energy efficient products. Training activities will be promoted via site visits, direct mail and newsletters. The Company works with the PHCC local chapters and attends the regional shows.

The GasNetworks[™] website (<u>www.gasnetworks.com</u>) will also be used as a vehicle for promotion, offering trade allies a central source of information on special event training efforts, in addition to joint energy efficiency programs.

The budget for the Trade ally training program is included within each program's budget.

C. Building Operators Certification Program

The Company plans to offer the Building Operator Certification (BOC) program. The BOC program provides curriculum selection, instructors, testing, certifications, as well as administrative functions. The target audience for the BOC program is individuals responsible for the maintenance and operation of equipment and systems in commercial buildings, industrial plants and public facilities. A BOC certificate is awarded to students who complete eight full days of classroom instruction, homework projects and testing.

In 2009, the BOC program will offer two to four sessions throughout the New England region. Each session will enroll approximately 40 students. The gas program will coordinate with the electric programs to reach out to a greater number of building

operator population. Each student is scheduled for two days of classroom instruction per month over a four month training cycle.

Table-XIX: Building Operator Certification				
Electric Cost Categories	2009 Budget	2010 Budget	Gas Cost Categories

Goal	20 participants	60 participants		

VI. EVALUATION AND REPORTING

1. Evaluation

National Grid anticipates expanding its focus on evaluation during 2009. The Company is conducting a review of how initial savings are calculated in support of the development of a new program tracking system.

Planned evaluation studies include the following:

• Completing an impact evaluation of the Low Income Program.

- With GasNetworks[™], completing an impact evaluation of advanced heating and water heating equipment promoted through the Residential High-Efficiency Heating and Water Heating Program⁵.
- Process evaluations to determine customer satisfaction with program services and to identify potential program implementation improvements.
- Ongoing review of measure and program cost-effectiveness, informed by evaluation findings.

National Grid and Northern Utilities plan to go out to bid for a qualified contractor to conduct an impact evaluation of their 2007-2008 Low Income Weatherization Programs. The impact evaluation's primary objective is to re-examine and update impacts across the range of measures offered through the programs. The methodology for the evaluation will most likely be an econometric/statistical billing analysis that will result in savings estimates by measure category and/or a realization rate.

In January of 2009 the Company sent out a Request for Qualifications (RFQ) to 40 consultants to determine what methodologies are currently used in the evaluation of Residential High-Efficiency Heating and Water Heating Programs. The Company is using the responses to that RFQ to develop an RFP for a process and impact evaluation of the program and hopes to work jointly on the study with members of GasNetworks[™] including Northern Utilities. The methodology will likely focus on billing analysis, either to determine hours of use which will be used in conjunction with equipment capacity and the difference in rated efficiencies to calculate savings or to do a direct comparison of the usage of customers with standard efficiency units versus high efficiency units. Other methodologies suggested included using various time of use meters to determine equipment runtimes.

⁵ The Company recently conducted an assessment of the gas savings associated with the equipment promoted through the Commercial High-Efficiency Heating program. This assessment suggests that savings for eligible equipment will be lower than previously assumed. In spite of reduced savings per installed piece of equipment, the Company projects that this program will continue to be cost-effective. The per unit decrease in energy savings affects the overall Commercial & Industrial portfolio savings. As noted above, the Company plans to initiate an advanced heating and water heating equipment impact evaluation this next year in collaboration with GasNetworksTM.

As part of that RFP, the Company also plans to conduct a process evaluation to evaluate overall program performance and suggest areas for improvement. Key components of that evaluation include an assessment of:

- Level of customer satisfaction
- Trade ally satisfaction
- Company staff and trade ally training
- Effectiveness of the program delivery mechanism
- Effectiveness of program promotion
- Remaining barriers to program participation including an assessment of why some customers choose to not participate in the program
- Review of measures offered through the program, i.e., are they acceptable, appealing, and valued by the customers
- Identification of lessons learned and specific actionable recommendations for program improvement
- A review of program tracking databases to ensure that data that will likely be required to support future program evaluation efforts, including impact evaluations, are being collected

As with the impact evaluation, the Company anticipates conducting this evaluation with members of GasNetworks[™] including Northern Utilities.

The Company continually updates its estimates of measure and program savings in its analysis of program cost effectiveness. Results of these evaluations will be used to screen programs for future filings.

Additional impact evaluations may be conducted during this 20-month period.

The budget for evaluation is included within each program's budget. Wherever possible, the Company will explore opportunities to decrease the cost of planned evaluation efforts by performing research in collaboration with industry partners GasNetworksTM, GTI, NEEP, AESP, JMC, CEE and other utilities.

2. Reporting

National Grid NH proposes to provide the Commission with the following reports:

Quarterly Reports:

The Company, consistent with the practice adopted by the electric utilities in the state, will provide the Commission with quarterly reports about ongoing program efforts. These reports will provide information about program costs and savings compared to annual budgets and savings goals by month. These reports will be filed with the Commission no later than 45 days following the end of each quarter in the year.

Updated Program Plans for 2010:

By August 31, 2009, the Company will file an update to its calendar year 2010 energy efficiency plans. The update will include updated program descriptions, benefit/cost analyses, program budgets, and program goals.

Shareholder Incentive Report:

By April 15, 2010, the Company will file a report with the Commission to document its performance for the May 1, 2009 – December 31, 2009 time period under the proposed shareholder incentive mechanism. The Company will also file a report with the Commission to document its performance for 2010 by April 15, 2011.

Next Multi-Year Energy Efficiency Plan:

National Grid anticipates filing its next multi-year gas energy efficiency plan by October 15, 2010. The Plan will likely be filed jointly with the other gas and electric utilities in the state.

VII. SHAREHOLDER INCENTIVE

For the current EE Plan, the Company's Shareholder Incentive has been designed in accordance with Commission Orders 24,109, 24,636 and the guidelines set forth for electric utilities in NH PUC 23,850. In Order 23,850, the Commission approved a Utility Performance Incentive designed to encourage utilities to achieve superior program costeffectiveness while maximizing program savings. It is a sliding scale incentive with a design level equal to 8% of the Company's program budgets (before incentives) and a maximum of 12% of the budgets. There are also threshold performance criteria, explained below, which the Company must achieve before any incentive is earned.

The Company's proposed Performance Incentive has two components. The costeffectiveness component is based on the relationship between the projected TRC Test and the actual program-year-end TRC Test, and the energy savings component is based on the relationship between the projected lifetime installed MMBTU savings and actual lifetime installed MMBTU savings. Each of these ratios are calculated at the sector level, one for the combined residential programs and one for the combined C&I programs, and then applied to each sector's program budgets.

The Company must achieve minimum "threshold" performance before being eligible to earn an incentive. For the cost-effectiveness component, the Company must achieve sector level actual year-end TRC of 1.0 before any incentive can be earned on this component. Likewise, for the energy savings component, the Company must achieve a minimum of 65% of projected lifetime MMBTU savings before being eligible to earn an incentive on this component. Once the threshold is achieved, the earned incentive will be on a sliding scale from 0% to 12%, with a design target incentive of 8%.

Appendix A

Explanation of Budget Categories – Traditional Gas Cost Categories

Services

Costs associated with rebates paid to customers for implementing energy efficiency. Additionally, this includes services provided to customers such as energy audits, technical assessments, engineering studies, plans reviews, blower door tests and infrared scans.

Vendor Administration and Support

Costs associated with vendors and contractors administering programs on the Company's behalf. Tasks associated with this budget category include but are not limited to; lead intake, customer service, rebate application processing, rebate application problem resolution, equipment installation inspections, rebate processing and individual program reporting.

Company Administration

Costs to administer energy efficiency programs that include but are not limited to; staff salaries (management personnel, program managers, accounting personnel, evaluation staff, regulatory staff, and administrative support staff), and company overhead (i.e., office space, supplies, computer and communication equipment, staff training, industry related sponsorships and memberships).

Communication

Promotion of energy efficiency programs which includes but is not limited to; production of all energy efficiency program literature, advertising, promotion, displays, events, promotional items, bill inserts, internal and external communications. Advertising encompasses all forms of media such as direct mail, print, radio, television, and internet.

Trade Ally Training

Trade Ally Training includes all activity associated with energy efficiency training/education of the trade ally community which includes but is not limited to; heating contractors, weatherization contractors, efficiency equipment/products installers, residential and C&I auditors, residential and C&I builders and developers.

Evaluation and Reporting

All activities associated with the evaluation of current and potential energy efficiency programs. These activities include but are not be limited to; benefit cost ratio analysis, program logic models, cost per therm analysis, efficiency product saturation analysis, customer research and all ad hoc analyses that are necessary for program evaluation. In addition any activities that pertain to regulatory compliance or reporting conducted by energy efficiency group personnel or contractors would fall under this category. Expenses associated with evaluation include all internal and external costs (i.e., consultant contracts including legal services).

Other

Database administration costs associated with the Low Income program. When mapped to the Electric Cost Categories, this expense is divided 50% between internal administration and 50% between external administration.

Explanation of Budget Categories – Traditional Electric Cost Categories

Internal Administration = Company Administration from gas categories

Internal utility costs associated with program design, development, regulatory support, and quality assurance of energy efficiency programs. Costs include but are not limited to; staff salaries (management personnel, program managers, accounting personnel, evaluation staff, regulatory staff, and administrative support staff), and company overhead (i.e., office space, supplies, computer and communication equipment, staff training, industry related sponsorships and memberships).

External Administration = Vendor Administration from gas categories

Costs associated with vendors and contractors administering programs on the Company's behalf. Tasks associated with this budget category include but are not limited to; lead intake, customer service, rebate application processing, rebate application problem resolution, equipment installation inspections, rebate processing and individual program reporting.

Rebates/Services = Services from above

Costs associated with rebates paid to customers for implementing energy efficiency. Additionally, this includes services provided to customers such as energy audits, technical assessments, engineering studies, plans reviews, blower door tests and infrared scans.

Internal Implementation = Gas accounting does not differentiate this from internal administration

Internal utility costs associated with delivering program services to customers. Costs to implement energy efficiency programs include but are not limited to; staff salaries (management personnel, program managers, accounting personnel, evaluation staff, regulatory staff, and administrative support staff), and company overhead (i.e., office space, supplies, computer and communication equipment, staff training, industry related sponsorships and memberships). There are no gas internal implementation expenses tracked by the Company's accounting system.

Marketing - Combines Communication and Trade Ally gas categories

Promotion of energy efficiency programs which includes but is not limited to; production of all energy efficiency program literature, advertising, promotion, displays, events, promotional items, bill inserts, internal and external communications. Advertising encompasses all forms of media such as direct mail, print, radio, television, and internet. The marketing category also includes trade ally training associated with energy efficiency training/education of the trade ally community which includes but is not limited to; heating contractors, weatherization contractors, efficiency equipment/products installers, residential and C&I auditors, residential and C&I builders and developers.

Evaluation = Evaluation and Reporting from gas categories

All activities associated with the evaluation of current and potential energy efficiency programs. These activities include but are not be limited to; benefit cost ratio analysis, program logic models, cost per therm analysis, efficiency product saturation analysis, customer research and all ad hoc analyses that are necessary for program evaluation. In addition any activities that pertain to regulatory compliance or reporting conducted by energy efficiency group personnel or contractors would fall under this category. Expenses associated with evaluation include all internal and external costs (i.e., consultant contracts including legal services).

EXECUTIVE DIRECTOR AND SECRETARY Debra A. Howland

THE STATE OF NEW HAMPSHIRE

PUBLIC UTILITIES COMMISSION 21 S. Fruit Street, Suite 10 Concord, N.H. 03301-2429

October 13, 2009

Debra A. Howland, Executive Director N.H. Public Utilities Commission 21 S. Fruit Street, Suite 10 Concord, N.H. 03301-2429

> Re: DG 09-049 - EnergyNorth Natural Gas, Inc. d/b/a National Grid NH Energy Efficiency Plan for January 1, 2010 to December 31, 2010

Dear Ms. Howland:

On September 30, 2009, in accordance with Order No. 24,995 dated July 31, 2009, and Section II(I)(3) of the settlement agreement adopted and approved by that order, EnergyNorth Natural Gas, Inc. d/b/a National Grid NH filed updated program descriptions, cost benefit analyses, program budgets and program goals for Program Year Two.¹ Program Year Two covers the period January 1, 2010 to December 31, 2010. National Grid states that it has no changes to make to the programs it expects to provide between January 1, 2010 and December 31, 2010, which is Program Year Two. National Grid did, however, update the avoided cost data associated with these programs and provided that information as Exhibits B and D in its September 30, 2009 filing.

Staff has reviewed National Grid's filing and is of the opinion that the filing and the proposed updates of the avoided cost data associated with the programs falls within the guidelines of the settlement agreement approved by Order No. 24,995. Staff believes that no action on the proposed change is required by the Commission and submits this recommendation accordingly.

Sincerely. James J. Cunningham, Jr.

Utility Analyst IV

cc: Service List

¹ On August 27, 2009, the Executive Director granted the Company an extension from August 31, 2009 to September 30, 2009.

Additional Opportunities for Energy Efficiency in New Hampshire

Final Report – January 2009

Prepared for the

New Hampshire Public Utilities Commission

Prepared and Submitted by:

GDS Associates, Inc.

Engineers and Consultants

In partnership with RLW Analytics and Research Into Action With Telephone Survey Support Provided by RKM Research and Communication

GDS Associates, Inc. • 1181 Elm Street • Suite 205 • Manchester, NH 03101 • www.gdsassociates.com Marietta, GA • Austin, TX • Auburn, AL • Manchester, NH • Madison, WI • Indianapolis, IN • Augusta, ME

ACKNOWLEDGEMENTS

This report was prepared for the New Hampshire Public Utilities Commission (NHPUC) by GDS Associates, Inc. with substantial data collection and analysis assistance provided by RLW Analytics, Research Into Action, and RKM Research and Communications (collectively, the GDS Team). The GDS Team would like to acknowledge the many helpful data sources and the technical input provided by the NHPUC, the New Hampshire electric and gas utility sponsors and the Office of the Consumer Advocate. GDS would like to give special recognition to Tom Frantz, Anne Ross and Commissioner Clifton Below all of the NHPUC, and Gil Gelineau and Tom Belair (PSNH), Derek Buchler (Northern Utilities), Lisa Glover (Unitil), David Jacobson (National Grid), Carol Woods (NHEC), Stephen Eckberg (NH OCA), and Tom Rooney and Eric Readdy of TRC Companies, Inc., all of whom were instrumental in providing insights and information and reviewing detailed plans, data collection instruments and inputs and results from analyses developed by the GDS Team including electric and gas load forecasts, energy efficiency measures, costs, energy savings, useful lives, saturation levels and remaining potential estimates.

This report provides valuable and up-to-date electric and natural gas (and associated propane and oil) energy efficiency potential savings information for New Hampshire's regulators and utility decision-makers. It will also be useful to electric and gas energy efficiency program designers and implementers and for others who may need a template for their own energy efficiency potential studies. This report includes a thorough and up-to-date assessment of the impacts that energy efficiency measures and programs can have on electricity and gas, propane and oil use in New Hampshire. Clearly there remains a significant amount of cost effective energy savings potential to be tapped within the state.

NOTICE

This report was prepared by GDS Associates, Inc., in the course of performing work contracted for and sponsored by the New Hampshire Public Utilities Commission, with review participation by National Grid (electric and gas), the New Hampshire Electric Cooperative, Northern Utilities, Public Service Company of New Hampshire, and Unitil Energy Services (hereinafter the "Sponsors"). The opinions expressed in this report do not necessarily reflect those of the Sponsors or the State of New Hampshire, and reference to any specific product, service, process, or method does not constitute an implied or expressed recommendation or endorsement of it. Further, the Sponsors, the State of New Hampshire, and the contractor make no warranties or representations, expressed or implied, as to the fitness for particular purpose or merchantability of any product, apparatus, or service, or the usefulness, completeness, or accuracy of any processes, methods, or other information contained, described, disclosed, or referred to in this report. The Sponsors, the State of New Hampshire, and the contractor make no representation that the use of any product, apparatus, process, method, or other information will not infringe privately owned rights and will assume no liability for any loss, injury, or damage resulting from, or occurring in connection with, the use of information contained, described, disclosed, or referred to in this report.

Scott M. Albert, Principal & Northeast Region Manager GDS Associates, Inc., January 2009

Section 1: Executive Summary

This study presents results from an evaluation of additional opportunities for energy efficiency in New Hampshire. Estimates of technical potential, maximum achievable potential, and maximum achievable cost effective potential by the year 2018 (a 10-year period) are provided for electricity, natural gas and related propane and fuel oil savings at the state level and for each of the four New Hampshire retail electricity providers and two natural gas distribution companies. Results from a potentially obtainable savings scenario are also presented to estimate that portion of the cost effective potential that might be achievable after consideration of customer behavior. Finally, estimates are presented of the installed costs required to achieve resulting savings for each scenario (excluding costs for marketing, program design and administration)

All results were developed using customized residential, commercial and industrial sector-level energy efficiency potential assessment models and New Hampshire Public Utilities Commission (NHPUC)-specified cost-effectiveness criteria¹ including the region's most recent avoided energy cost projections.² To help inform these models, actual electric and gas utility customer information was collected through a combination of telephone surveys with residential and small commercial/industrial customers and site visits at larger commercial and industrial facilities. Work was conducted by GDS Associates, Inc. with important input and assistance provided by RLW Analytics, Research Into Action and RKM Research and Communications (the GDS Team).

Technical potential studies need to be understood and viewed as a highly theoretical construct/tool – therefore, the data used for this report was based on the best data available at the time the models were run – when better data was identified, it was used where possible, but given the demands and limits of time for this project, it is possible that some sources were overlooked.

1.1 Study Scope

The objective of this study was to evaluate additional opportunities for energy efficiency in New Hampshire to provide insights for continued electric and gas utility program filings and implementation plans and to inform expanded planning for energy efficiency programs that may rise from New Hampshire's participation in the Regional Greenhouse Gas Initiative and the recommendations of the NH Climate Change Policy Task Force. Following is a listing and a brief overview of the approach undertaken to complete each of the major tasks required for this study effort:

¹ The NHPUC's total resource cost effectiveness test (TRC) derives from the 7/6/99 report from the NH Energy Efficiency Working Group (pp. 14-18) in DR 96-150, available at: <u>www.puc.nh.gov/Electric/96-150%20%20NH %20Energy%20Efficiency%20Working%20Group%20Final%20Report%20(1999).pdf</u>, and was modified by

Attachment C of the 2008 Core Energy Efficiency filing approved by Order No. 24,815 in DE 07-106 that provided that "[t]he use of the 15% adder to represent environmental and other benefits as recommended by the [NHEEWG] ...was discontinued because the 2007 AESC avoided costs include market-based price proxies for power plant emission of NOx, SO2, Mercury and CO2."

² Avoided Energy Supply Costs in New England: 2007 Final Report, August 10, 2007, prepared by Synapse Energy Economics, Inc., available at: <u>www.synapse-energy.com/Downloads/SynapseReport.2007-08.AESC.Avoided-Energy-Supply-Costs-2007.07-019.pdf</u>.

Analyze current saturations of energy using equipment and penetrations of energy efficiency equipment and practices in each end-use category. This task was completed through analysis of a combination of primary and secondary data sources including carefully designed questions and a statistically valid sample of telephone surveys and site visits.

Produce an up-to-date list of currently available and soon to be commercially available technologies which may play a part in future efficiency programs – This task was based initially on existing GDS databases of sector-specific electricity and natural gas end-use technologies and efficiency measures. It was extensively supplemented to include other technology areas of interest to the New Hampshire Public Utilities Commission, the New Hampshire Office of the Consumer Advocate, and the four electric and two natural gas utilities supporting this project.

Estimate customer participation rates/levels by program, based on different payback/incentive levels and define/analyze significant barriers that customers face when investing in additional energy efficiency – This task was based on results from the GDS Team's phone surveys and site visits. Where insufficient customer-specific data was available, these estimates were informed through the project sponsors' and Team's combined existing and extensive knowledge of not only NH's current electric/gas utility programs, but also best practices and barriers associated with programs being implemented elsewhere in the region and throughout the country.

Develop, by sector, a simplified end-use model of state electricity and natural gas consumption and peak demand – This task was completed using data provided directly by each participating New Hampshire electric and gas utility. Results were assessed against forecasts published through the New England Power Pool (NEPOOL) and ISO-New England, Inc. to ensure reasonableness.

Estimate, state-wide and for each of the four New Hampshire retail electricity providers and two natural gas distribution companies, the technical, maximum achievable, maximum achievable cost effective potential, and a potentially obtainable scenario, for electricity, natural gas and related propane and fuel oil savings over the next 10-year period, and the budgets (where appropriate) required to achieve that potential – These activities were based on the GDS Team's existing sector-level supply curve and potential analysis models, NHPUC cost-effectiveness criteria/methodologies and associated up-to-date assumptions³ including the region's current avoided energy cost projections, elements of which were already in hand. Wherever possible, these models were customized based on state utilityspecific data and the saturation and penetration survey results obtained through this project's primary data collection (telephone survey and site visit) activities. All results were analyzed and compared for reasonableness against overall state consumption and consideration of past New Hampshire utility energy efficiency program participation.

³ The measure specific savings values used to develop the following estimates of technical potential vary considerably in the level of certainty. Some measures, such as commercial lighting, have a long history of implementation and have fairly well documented costs and savings while some measures which also show large potential, such as retro-commissioning, have had little large scale implementation to date and estimates of their savings and cost effectiveness are based on a limited number of real world installations. Other high potential measures, such as floating head pressure controls have tended to work well in the short term but are often overridden by on-site maintenance personnel who are not comfortable with running their systems at lower pressures. It is important for anyone using this study to set actual program budget and savings targets to further refine the less certain estimates before starting large scale implementation of such measures.

Evaluate extent to which past and current energy efficiency programs have achieved energy savings to date, provide sensitivity analysis of realized energy savings based on different resource levels (including absence of current SBC-funded model), and recommend modifications to program and measure offerings that would increase the likelihood of achieving identified potential – These activities were based on a combination of factual data comparisons, analysis of survey results associated with end-use customer sector barriers identification, the collective GDS Team's experience with looking at programs from a logic-modeling perspective, and the GDS Team's extensive knowledge of other local, regional and national programs and best practices.⁴ Focus of these evaluations and sensitivities were at the statewide level (vs. utility-specific).

More information on each of these items is presented in the methodologies and subsequent sections of this report.

The definitions used in this study for energy efficiency potential estimates are as follows:

- **Technical potential** is defined in this study as the complete and immediate penetration of all measures analyzed in applications where they were deemed technically feasible from an engineering perspective. For the residential sector, two technical potential scenarios were developed: a technical potential (best) scenario, where "best" options are assumed to be installed in situations where "good/better/best" options exist; and a technical potential (traditional) scenario, where "good/better/best" options are allocated for model installation across applicable populations.
- Maximum Achievable potential is defined as the maximum penetration of an efficient measure that would be adopted absent consideration of cost or customer behavior. The term "achievable" refers to efficiency measure penetration, based on estimates of New Hampshire-specific building stock, energy using equipment saturations and realistic efficiency penetration levels that can be achieved by 2018 if all remaining standard efficiency equipment were to be replaced on burnout (at the end of its useful measure life) and where all new construction and major renovation activities in the state were done using energy efficient equipment and construction/installation practices. In certain circumstances, where early replacement of specific measures is becoming standard practice, maximum achievable potential includes the retrofit of measures before the end of their useful measure life (i.e., T8 lighting, thermostats, insulation and weatherization of existing homes).
- Maximum Achievable Cost Effective (M.A.C.E.) potential is defined as the portion of the maximum achievable potential that is cost effective according to the economic criteria currently used to determine energy efficiency program cost-effectiveness (New Hampshire Public Utility Commission's approved Total Resource Cost Test – NH TRC), before consideration of customer behavior. Application of the TRC test is based on the

⁴ Assessments based on a logic-modeling perspective recognize current program resources (dollars, staffing, etc.) and activities (measure installations, promotional rebates/incentives, marketing/outreach, education/training, etc.) and seek to identify their causal links to anticipated outputs (measures installed, in-program energy and capacity savings, # of customers served, market actors trained, etc.), short-, intermediate- and long-term outcomes (changes in awareness and behavior, market-wide/sustainable energy, economic and environmental benefits, etc.). In addition, logic models recognize the existence and potential impacts of external influences (price of energy, state of the local and regional economy, federal tax incentives, other non-program sponsored activities, etc.).

latest values for avoided cost (electric, natural gas and other fuels) and excludes environmental externalities not already captured with avoided cost values, consistent with current utility and PUC procedures.

• **Potentially Obtainable scenario** is a new output developed for this study⁵ and can be defined as an estimate of the potential for the realistic penetration over time of energy efficient measures that are cost effective according to the NH TRC, taking customer behavior into consideration (including consideration of priorities and price). To achieve this potential, a concerted, sustained campaign involving aggressive programs and market interventions would be required. As demonstrated later in this report, the State of New Hampshire and its electric and gas utilities would need to continue to undertake, and perhaps aggressively expand its efforts to achieve these levels of savings.

LIMITATIONS TO THE SCOPE OF STUDY As with any assessment of energy efficiency potential, this study necessarily builds on a large number of assumptions, from average measure lives, savings and costs, to the discount rate for determining the net present value of future savings. The RFP for this study also called for a simplifying assumption that new buildings are constructed to meet minimum energy codes, even though that may not actually be the case. While, as noted above, the authors have sought to use the best available data, there are many assumptions where there may be reasonable alternative assumptions that would yield somewhat different results. For example, the "good, better and best" scenarios for housing weatherization and retrofit, while constructed to be reasonable illustrations, are not necessarily typical of many homes because of the wide diversity in size, age, type, and quality of construction, renovation and maintenance of existing homes. Furthermore, while the measures lists are extensive and represent most, if not all, commercially available, and some emerging, energy efficient measures, they are not exhaustive, particularly for peak electric demand reduction measures and potential fuel oil and propane savings, as further noted in footnote 30 of this report. Also, there was no attempt to place a dollar value on some difficult to quantify benefits that may result from some measures, such as increased comfort or reduced maintenance, which may in turn support some personal choices to implement particular measures that may otherwise not be cost-effective or only marginally so.

Thus, the various potential estimates are specific to and limited by the detailed measures lists and assumptions described in this study. As new and improved energy efficiency products and strategies emerge and as regulatory, market, and behavioral barriers are reduced, the potentially obtainable estimate of energy efficiency might reasonably be expected to increase. In any case, we have provided here one well informed reasonable scenario of potentially obtainable increases in cost-effective energy efficiency for New Hampshire. Others are plausible. With this report we are providing the PUC with a complete copy of the spreadsheet model with all the measures and assumptions to facilitate further analysis by them, including revisions and updates to the assumptions and measures list.

The main outputs of this study are summary data tables and figures identifying the potential for additional energy efficiency opportunities in New Hampshire over the ten-year period, 2009 through 2018. Wherever possible, this study makes use of actual New Hampshire residential,

⁵ There has been a recent trend to temper estimates of cost-effective potential by taking into consideration behavioral, market, regulatory, financing and/or political barriers. A just released study by the Electric Power Research Institute used a similar concept that they called the "Realistically Achievable Potential (RAP)." See: *Assessment of Achievable Potential from Energy Efficiency and Demand Response Programs in the U.S.:* (2010– 2030), EPRI, Palo Alto, CA: 2009. 1016987, p. xiv. See also National Action Plan for Energy Efficiency (2007), *Guide for Conducting Energy Efficiency Potential Studies*, prepared by Philip Mosenthal and Jeffrey Loiter, Optimal Energy, Inc., www.epa.gov/eeactionplan, p. 2-4.

commercial and industrial customer data collected through phone surveys and site visits. Given the magnitude of efficiency measures included for consideration in this study, in cases where New Hampshire customer-specific information was not available, data on measure savings, costs and penetration rates were compiled through a combination of secondary research (including reviews of other previous relevant studies), utility-provided data, manufacturer specifications, and direct calculation through energy calculators and building simulation modeling. Collectively, these data sources provided an important and extensive foundation for estimates of electric energy, natural gas and related oil and propane savings potential by measure type, end-use and customer sector.

1.2 Results Overview

Energy-efficiency opportunities typically are physical, long-lasting changes to buildings and equipment that result in decreased energy use while maintaining the same or improved levels of energy service. This study shows that there is still significant savings potential in New Hampshire for cost effective electric and natural gas energy-efficiency measures and practices (and associated oil and propane savings).

As shown in Table 1, the Technical potential savings (all sectors combined) for electric energy efficiency measures in New Hampshire is over 27 percent of projected 2018 kWh sales in the State, and similarly over 27 percent for non-electric (natural gas, oil and propane) efficiency measures. The Maximum Achievable Cost Effective potential (before consideration of customer behavior) is over 20 percent (nearly 2,700 gWh annually) of projected 2018 kWh sales (over 15 percent summer peak demand reduction), and over 16 percent of projected 2018 non-electric sales (more than 15,440,000 MMBTu).⁶ It is important to note, in the industrial sector, that the Maximum Achievable and Maximum Achievable Cost Effective potentials are the same. As explained in more detail in Section 6 of this report, this is because all end uses assessed in the industrial sector were screened as cost effective during the modeling process. The Potentially Obtainable scenario (including consideration of customer behavior) shows savings from electric and non-electric efficiency measures of approximately nearly 11 percent of 2018 kWh sales and approximately eight percent of projected 2018 non-electric (natural gas, oil and propane) sales. The Potentially Obtainable electric savings is equal to approximately 78 percent of the projected growth in electricity consumption over the next decade.

Estimates of the associated potential reductions in CO_2 emissions are also shown in Table 1, along with estimated costs that would be required to achieve these potentials. Depending on the scenario considered, these emission reductions and costs to achieve can be quite substantial (i.e., over three million tons at nearly seven billion dollars, based on the combined electric and non-electric Technical potential scenarios; or more than one million tons and nearly nine hundred million dollars based on the Potentially Obtainable scenarios).⁷ In developing these estimates, savings opportunities from market driven (replace on burnout and new construction) and retrofit (early retirement) energy efficiency program strategies were considered, where applicable.

The potential savings estimates, and costs to achieve those savings, are shown separately for electric, non-electric, and natural gas (a subset of non-electric) efficiency measures in Table 2,

⁶ Based on cost-effectiveness screening using the NH PUC- approved Total Resource Cost Test methodology as specified and described in Footnote 1, excluding environmental externalities not already captured within avoided cost values, consistent with current utility and NHPUC procedures.

⁷ This is equivalent to removing over 509,000 cars from New Hampshire's highways under the Technical Potential scenarios, or 178,000 cars under the Potentially Obtainable scenario.

Table 3, and Table 4 respectively. As shown in these tables, more electric savings can be obtained within the residential sector than in the commercial or industrial sectors. However, the cost to achieve that savings is substantially lower in the commercial and industrial sectors and highest in the residential sector. This implies that programs targeting the commercial and industrial sectors will yield the greatest electric energy savings per dollar spent, while substantial savings can also be obtained within the residential sector, but at nearly twice the cost per kWh saved. For instance, as shown in Table 2 under the commercial sector potentially obtainable scenario, 492 million kWh of annual savings is estimated by the year 2018 at an installed cost of just under \$125 million (approximately 26 cents per kWh saved). In comparison, the residential sector yields approximately 698 million kWh of annual savings of estimated potential by the year 2018 at an installed cost of \$383 million (55 cents/kWh saved). Similarly in the non-electric sectors, although there is more savings potential within the residential sector, the cost to achieve that savings is substantially greater than that required to save energy in the non-electric commercial and industrial sectors. For instance, per Table 3 under the commercial sector potentially obtainable scenario, nearly 3.3 million MMBTu of annual non-electric energy savings is estimated by the year 2018 at an installed cost of just over \$102 million (\$31/MMBTu). In comparison, approximately 3.6 million MMBTu of annual savings potential is estimated in the residential sector by the year 2018 at an installed cost of over \$200 million. (\$56/MMBTu).

Table 1. Summary of Energy Savings Potentials by 2018 – Combined Electric and Non-Electric Measures

*The average vehicle in the United States produces around 12,100 lbs of carbon dioxide per year. This means that realizing the full Technical Potential calculated here would be the carbon equivalent of taking over 509,000 cars off the road. Realizing the Potentially Obtainable figure would be the equivalent of removing 178,000 cars.

Potentially Obtainable	133,064					

As shown in Figure 1, in the residential sector, New Hampshire's greatest areas for electric energy savings from the installation of cost-effective energy efficiency measures come from combined single family (SF) and multifamily lighting⁹ (MF) (52% of the annual savings by the year 2018), electric appliances (16% by 2018, combined SF and MF), and space heating and cooling combined SF and MF (10% by 2018) followed by standby (phantom) power (9%) and water heating (9% – 5% SF and 4% MF) and new construction activities (4%). Figure 2 shows the greatest areas for non-electric savings come from space heating (oil-fueled) and water heating (all fuels), nearly 30% each when SF and MF potentials are combined, and weatherization packages (all fuels) in single family homes (16% SF and MF combined). The large potential for savings from oil-fueled space heating measures is not surprising since nearly 60 percent of all homes in New Hampshire heat with oil. The greatest potential for natural gas savings in the residential sector comes from replacement of inefficient gas furnaces and boilers in multifamily and single family homes (nearly 9% and 6% respectively).

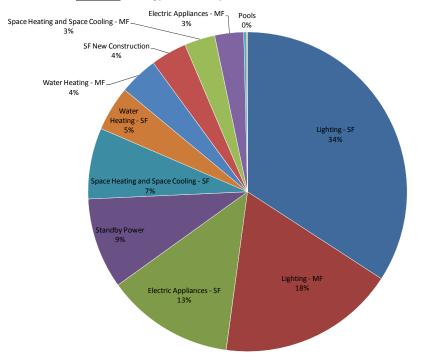

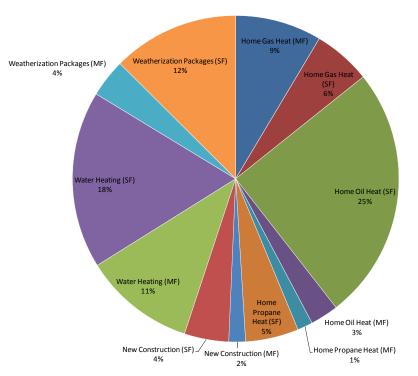

Figure 1. Residential <u>Electric</u> Energy Efficiency Maximum Achievable Cost Effective – by End Use

⁹ Lighting savings in the residential sector are largely being driven by savings from CFL bulbs and or CFL fixtures in single family and multi-family homes. It is very important to note, that these savings might be overstated for the post-2012 period for two main reasons. First, this study does not take into direct consideration future changes to energy codes as they relate to residential lighting applications, including improved federal efficiency standards for incandescent bulbs (the base technology from which current lighting savings are calculated) that are designated to become effective in 2012. This study was conducted based on the standards and energy savings differentials (e.g., between CFLs and incandescent bulbs) in existence as of 2009. Secondly, although this study includes emerging lighting technologies (i.e., LEDs), there is a high likelihood that as these new and emerging lighting technologies enter the market, the penetration of CFLs will be significant and new improved efficiency incandescent light bulbs will also be entering the market. Thus, the incremental savings going from a CFL to a new technology (such as LED or super high efficiency incandescent) will be dramatically lower than the current incremental savings going from standard incandescent to compact florescent (CFL). This consideration was addressed partially by the assumption that new technologies will always emerge, and savings will always be present as a result – however, it is true, that those savings, as stated previously, will be lower, and as a result, may be somewhat overstated during the second half of the study's 2009 through 2012 forecast horizon.

Savings within the commercial sector were assessed separately for existing buildings and for potential new construction. As shown in Figure 3 (existing buildings) and Figure 4 (new construction), New Hampshire's greatest areas for electric savings from the installation of cost-effective energy efficiency measures come from lighting and/or lighting controls – i.e., 39% by 2018 from existing buildings, including retrofit of existing lighting systems; and 42% from new construction activities, mainly from lighting design. The next significant area for electric savings is from refrigeration – i.e., 19% by 2018 from existing buildings and 18% from new construction activities. HVAC systems and controls (in existing buildings) and building envelope improvement packages (in new construction) also provide substantial savings.

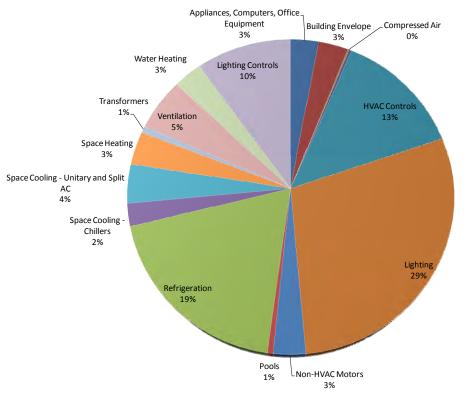

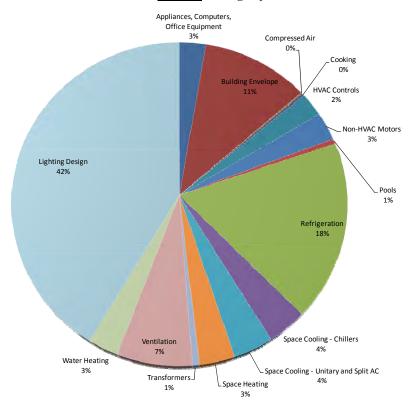

Figure 4. Max Achievable Cost Effective Electric Savings by End Use for Commercial New Construction

New Hampshire's greatest areas for non-electric energy savings in the commercial sector come from the installation of cost-effective space heating (44%), water heating and HVAC controls (17% each) and building envelope (13%) in existing buildings, as shown in Figure 5. Space heating measures also provide the greatest potential for non-electric savings in the commercial new construction area (44%) as shown in Figure 6, followed by building envelope and water heating (16%), and HVAC controls (15%).

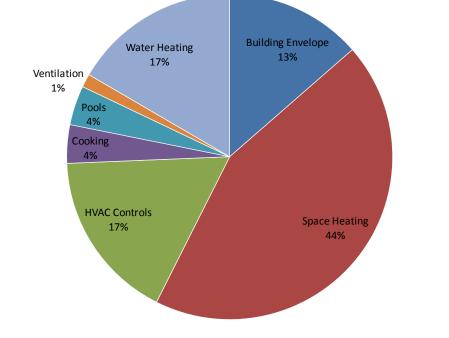

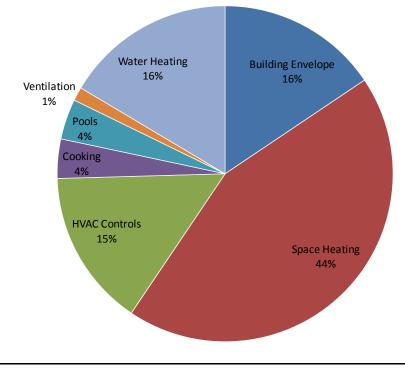

Figure 5. Max Achievable Cost Effective <u>Non-Electric</u> Savings by End Use - Commercial <u>Existing Buildings</u>

Figure 6. Max Achievable Cost Effective Non-Electric Savings by End Use - Commercial New Construction

Within the Industrial sector, Figure 7 shows that the greatest areas for electric energy savings come from machine drives (40%), sensors and controls (16%), lighting (15%), process heating measures (13%), and facility HVAC (11%). As shown in Figure 8, the greatest areas for non-electric savings in the industrial sector come from process heating, conventional boiler use and facility HVAC measures (52%, 33% and 13% respectively).

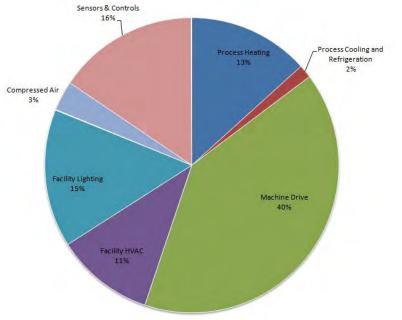

Figure 7. Max Achievable Cost Effective <u>Electric Savings</u> by End Use for NH Industrial Sector

Figure 8. Max Achievable Cost Effective Non-Electric Savings by End Use for NH Industrial Sector

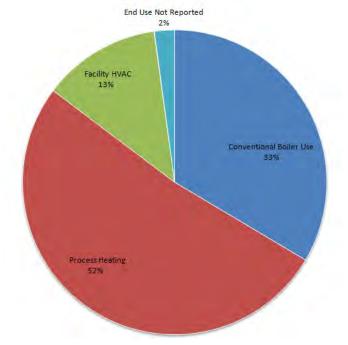

Table 5 and Table 6 present the estimated 2018 Technical, Maximum Achievable, Maximum Achievable Cost Effective potentials and results from the Potentially Obtainable scenario for each of the four New Hampshire retail electricity providers and two natural gas distribution companies. As can be seen from these tables, the greatest potential for electric savings exists within PSNH's service territory (approximately 73% of the state's projected kWh and MW savings), followed by Unitil (nearly 12%), National Grid (over 8%) and the NH Electric Cooperative (just under 7%). Seventy-seven percent of the natural gas savings potential exists within National Grid's service territory, with the remaining 23% coming from Northern Utilities territory. It is important to note that a majority of the non-electric savings potential comes from measures installed in oil and propane-fueled homes and businesses.

1.3 Potentially Obtainable Scenario

In the Potentially Obtainable scenario developed for this report, all cost-effective energy efficiency measures were assessed in light of customer priorities and estimated pricing behaviors (i.e. sensitivity to payback). Concerning priorities, customers' responses to questions included in this projects' sector-specific telephone surveys and site visits were used to determine the percentage of customers that stated they were "extremely likely" to purchase energy efficient equipment (73% of residential customers, and 48% of commercial and industrial customers). Customer behaviors regarding pricing were estimated based on some simplifying assumptions that all "extremely likely to purchase" customers would potentially install energy efficient measures if the price were below a certain level (i.e., 7 cents levelized cost per /kWh saved) and half of those same customers would likely install cost-effective measures in cases where the costs were more than 7 cents/kWh saved (the model also built in functionality to eliminate those measures with extremely high levelized costs in order to avoid outliers from being considered in the Potentially Obtainable scenario). Embedded within this approach was the assumption that fifty percent of the associated energy efficiency measure cost would be provided to these customers through a measure rebate to achieve the desired customer purchase action (essentially reducing the customer's out-of-pocket cost to 3.5 c/kWh in this example, or equivalent to approximately a 1 to 2 year payback on the customers' portion of the energy efficiency measure investment). This rebate level assumption is based upon a previous review conducted by GDS of numerous energy efficiency studies, including a National Energy

Efficiency Best Practices Study and was supplemented with data collected through the phone surveys and site visits conducted as part of this current project.^{10,11}

1.4 Implementation Costs

To achieve the Potentially Obtainable amount of energy efficiency savings by 2018, substantial efforts, including continued and expanded utility programmatic support will be required. Such programmatic support would include rebates to customers (including potential targeted midstream and upstream market actors), program marketing and outreach, administration, planning, and program evaluation activities. Although not included in this report's "cost to achieve estimates," all such costs would be required to ensure the delivery of quality and reliable energy efficiency products and services to New Hampshire's consumers. As noted above, the projection for Potentially Obtainable electricity and non-electric energy savings assumes that customers receive rebates equivalent to fifty percent of measure incremental (or full) costs. This incentive level assumption will help to reduce customer out-of-pocket costs and will quicken the paybacks on measures installed to more actionable levels. The fifty percent incentive is based both upon customer provided input (via this project's phone surveys and site visits data collection efforts), and from review of numerous energy efficiency studies including the National Energy Efficiency Best Practices Study. If customers had to receive 100% of measure incremental or full costs to achieve the Potentially Obtainable scenario's savings levels, then program budgets would double.

1.5 Market-Driven vs. Retrofit

Energy efficiency potential in the existing stock of buildings can be captured over time through two principal processes:

- 1. as equipment replacements are made normally in the market when a piece of equipment is at the end of its useful life (often referred to as "market-driven" or "replace-on-burnout"); and,
- 2. at any time in the life of the equipment or building (referred to as "retrofit").

Market-driven measures are generally characterized by incremental measure costs and savings (e.g., the incremental costs and savings of a high-efficiency versus a standard efficiency air conditioner); whereas retrofit measures are generally characterized by full costs and savings (e.g., the full costs and savings associated with retrofitting ceiling insulation into an existing attic). A specialized retrofit case is often referred to as "early replacement" or "early retirement". This refers to a piece of equipment whose replacement is accelerated by several years, as compared to the market-driven assumption, for the purpose of capturing energy savings earlier than they would otherwise occur.

¹⁰ See "National Energy Efficiency Best Practices Study, Volume NR5, Non-Residential Large Comprehensive Incentive Programs Best Practices Report", prepared by Quantum Consulting for Pacific Gas and Electric Company, December 2004, page NR5-51.

¹¹ As part of this project, telephone surveys were conducted with 400 residential customers and 200 small commercial customers, and site visits were conducted with 100 larger commercial customers and 100 industrial customers. Questions were included in these surveys and site visits to assess customer interest in energy efficiency and the value of incentives to the customer decision-making process.

For this study, the GDS Team has examined the impacts of "early replacement" for a select group of measures (i.e., T-8 lighting, insulation and weatherization measures in existing buildings). For these measures, GDS assumed that customers would receive an incentive equivalent to 50% of the <u>full cost</u> of the energy efficiency measures at the time of retrofit.¹²

1.6 Customer Participation and Barriers

Based on results from the customer telephone surveys and on-site interviews, a number of insights regarding customer participation, preferences and barriers have been identified. Highlights are presented below. Please refer to Section 7 of this report for more detailed information.

1.6.1 Residential Customer Program Participation and Barriers Summary

- Over 90% of the residential customers surveyed said they pay "some" or "substantial" attention to controlling energy costs
- After being read a definition of energy efficiency and the fact that such measures typically cost more than less efficient models (often 20 to 30% more), 73% stated that they were "extremely likely" to purchase energy efficient equipment if it lowered their energy bill, increased comfort, or helped the environment.
- Installation of energy efficiency features are commonly considered as part of remodeling projects (64% among recently remodeled homes, and 90% among homes with a future remodeling plan).
- About half of the households surveyed are aware of their utility offering energy efficiency programs, and 30% have participated in them in some way.
- Low income households were found to have a significantly higher participation rate (they are twice as likely to report participating in such programs).
- Among participants, satisfaction with their utilities' programs seems extremely high.
- The two most frequently cited reasons for nonparticipation were: (1) there was no recent purchase of energy-using household items, and (2) unawareness of program resources.

1.6.2 Commercial and Industrial Customer Program Participation and Barriers

<u>Summary</u>

- Of the small and large commercial and industrial customers surveyed, 86% of respondents reported some or high level of attention to controlling energy costs.
- 48% stated that they were "extremely likely" to purchase energy efficient equipment if it lowered their energy bill, increased comfort, or helped the environment.
- Overall awareness of energy efficiency programs and incentives offered by utility providers was significantly higher in the large commercial/industrial respondents (86%) compared to the small commercial/industrial respondents (60%).
- Past participation in utility provider offered programs was similarly higher in the large customer group who was aware of the programs offered (86%) compared to the small customer group aware of the programs offered (30%).
- Of respondents who have participated in their utility's energy efficiency programs, a significant majority of both small customers (94%) and large customers (98%) reported that they would participate in the programs again if given the opportunity.

¹² Tying incentives to the full installed cost of targeted measures in the case of early replacement (retrofits) is typical of the way that retrofit programs are currently being implemented here in New Hampshire and throughout the country.

- The single largest barrier to respondents investing in energy efficiency measures was concern about initial premium costs of equipment and insufficient payback (69%).
- Respondents indicated that the two most important factors influencing decisions to invest in energy efficient equipment are: (1) expectations of lower monthly energy bills and (2) rebates or incentives for purchasing energy efficient equipment that would help offset some of the initial costs.
- Other factors such as business image, environmental impact, occupant comfort, and sales person recommendation were less likely to influence decisions to invest in energy efficient equipment.

1.7. Past/Current Program Capture and Recommendations

To date, New Hampshire's electric and gas utilities have been quite effective in achieving energy and capacity savings and energy efficiency measure penetration across the state. But, as shown in Table 7 and Table 8 below, there is much room for additional penetration. In total, from 2002 through 2008, the electric energy efficiency programs are saving an estimated cumulative total of nearly 560 million kWh per year of energy¹³. This represents a savings of five percent of the total forecast energy usage for New Hampshire in 2008. Similarly from 2003 through 2008, the natural gas efficiency programs saved an estimated total of over 2.4 million therms per year¹⁴. This represents a savings of 1.1 percent of the total forecasted natural gas usage for New Hampshire in 2008.

Sector	Total Annual Savings Since 2002 (MWh)	Forecasted Sales 2008 (MWh)	Cummulative Annual Savings as a Percent of 2008 Sector Sales	Cummulative Annual Savings as a Percent of 2008 Total Sales
Residential	120,064	4,537,480	2.6%	1.1%
Commercial/Industrial	437,210	6,650,732	6.6%	3.9%
Total	557,274	11,188,212		5.0%

Table 7	Cumulative Annual Progra	m Savings as Percen	t of 2008 Sales: 2002_2	008 _ Flectric
Table 7.	Cumulauve Annual I Togra	in Savings as I citen	t 01 2000 Sales. 2002-2	000 - Electric

Table 8. Cumulative Annual Program Savings as Percent of 2008 Sales: 2003-2008 – Natural Ga

Sector	Total Annual Savings Since 2003 (decatherms)		Cummulative Annual Savings as a Percent of 2008 Sector Sales	Cummulative Annual Savings as a Percent of 2008 Total Sales
Residential	95,387	8,435,900	1.1%	0.4%
Commercial/Industrial	150,248	14,267,000	1.1%	0.7%
Total	245,635	22,702,900		1.1%

It is important to note that the figures in the above two tables are conservative in several ways. First, the utility providers have been actively offering efficiency programs since well before 2002 so the total amount of energy saved since the inception of efficiency programs is much higher.

¹³ Estimate is based on reported lifetime savings from 2005-2008 available on NHPUC website, GDS estimates for program measure lives used to calculate annual savings, and extrapolated kWh savings estimates for 2002-2004.

¹⁴ Estimate based on reported savings from 2003-2007 and GDS estimates for program measure lives

Second, these figures consider only cumulative annual savings, not lifetime savings¹⁵. In reality, annual savings are realized every year over the assumed measure life of the programs. The data was reported in the above manner to provide an appropriate comparison to the forecast 2008 usage. More details regarding this analysis are presented in Section 8 of this report.

To increase the likelihood of achieving the additional energy efficiency savings potential highlighted in this study, the following findings/recommendations are suggested (see Section 8 for more details):

To date, the efficiency programs offered in New Hampshire by the state's four largest electric utilities and two natural gas distribution companies have been successful and have saved a substantial amount of energy. Many of the programs have and are continuing to perform quite well in terms of cost per unit of energy saved and customer participation. Several other programs have shown positive trends becoming more cost effective on a yearly basis.

For all programs, but most notably in the electric market, the cost per kWh saved in the commercial and industrial sectors has been better than in the residential market. This might explain why in general, commercial and industrial customers have indicated a higher awareness of the utilities' efficiency programs available to them as well as an increased likelihood of program participation compared to residential customers. Given the scale of energy consumption in the commercial and industrial sectors, these customers continue to represent a substantial area for potential energy savings in the upcoming years.

 Recommendation: Additional penetration can be achieved through increased outreach to small commercial/industrial customers and by expanding current program offerings to include other cost effective measures not currently included in the companies' CORE and utility-specific programs.

Residential customer participation in the state's electric and natural gas energy efficiency programs has met or exceeded program expectations on a yearly basis. However, in the phone surveys more than half of respondents indicated that they were not aware of the programs offered by their utilities, or that they were even eligible. Of the customers who were aware of the programs, a high percentage participated and indicated they would participate in the future.

• Recommendation: This data underscores the importance of increasing consumer education on the programs available to residential customers and of the associated benefits.

One final finding from the study is that nearly all of the most cost effective energy efficiency measures are included in current programs in some manner. In several programs, however, the cost effective measures are targeted to a small percentage of consumers. The best example of this is the *Home Energy Solutions* program which targets consumers with 65% or greater electric heating. Customers with electric heat as their primary heating source represent approximately 4% of the total population based on the phone surveys.¹⁶

¹⁵ Cumulative annual savings were calculated by determining the annualized savings in a given year and summing those annual savings for each of the program years reviewed.

¹⁶ The 4% represents total number of customers with electric heat as their <u>primary</u> source for heating. A smaller percentage than 4% would qualify for participation in the Home Energy Solutions program, since 65% or more of their space heating needs to be met with electric heat.

 Recommendation: Expanding the number and types of products and services available through the existing residential energy efficiency programs, and promotion of those programs to include a larger number of potential participants may lead to increased overall energy savings. It is important to recognize that such expansion would require providing services to customers that heat with fuels other than electric or natural gas. Issues regarding who would pay for the provision of services to such customers would need to be addressed.

1.8 Structure of this Report

Section 2 of this report provides an overview of current and forecasted electric and natural gas energy usage in New Hampshire. Information on geographic, economic, demographic and energy usage characteristics of the State is also presented in Section 2. Section 3 of this report provides a detailed discussion of the research plan and methodologies used for the collection and analysis of all data in this report. Results from the participation, preferences and barriers questions asked as part of this project's phone surveys and site visit interviews are also presented in Section 3. Sections 4, 5 and 6 provide detailed results from the electric and nonelectric energy efficiency potential analysis conducted for the residential, commercial and industrial sectors, respectively. Detailed results are presented in these sections regarding technical potential, maximum achievable potential, maximum achievable cost effective potential and the potentially obtainable scenario. Energy (kWh), capacity (kW), and associated therm (MMBTu) and environmental (tons of CO_2) savings are presented along with additional description of the methodologies used, where applicable.

This project included a major enhancement to a majority of the technical potential studies that have been conducted across the country in the past. Rather than relying on best available information from existing secondary sources to estimate current levels of energy using equipment saturations and penetration of energy efficiency measures, significant primary data collection efforts were undertaken to help inform and derive New Hampshire-specific values where possible within the time requirements and work scope specified for this project. As such, this effort was completed through a combination of primary and secondary data collection and analysis activities. Detailed findings and an assessment of the value resulting from this enhanced, New Hampshire-specific data collection effort is presented in Section 7 of this report.

Section 8 assesses the amount of energy savings that past and current energy efficiency programs in the state have already captured. Recommendations for potential program modifications and measure offerings are also included in this section.

Section 2: Characterization of Customer Base, Electric and Natural Gas Usage, and Load Forecasts for the State of New Hampshire

This section of the report provides electric and natural gas utility forecasts for energy usage in the State of New Hampshire based on data provided by the four electric and two natural gas utilities supporting this project. The utility-provided forecast information has been compared against the latest available ISO-NE forecasted data, where appropriate, to ensure reasonableness. In order to develop estimates of energy savings potential, it is important to understand how energy is used by households and businesses in New Hampshire. Therefore, this section also provides information on geographic, economic, demographic and energy usage characteristics of the State.

2.1 New Hampshire Geographic and Demographic Characteristics

New Hampshire is the third largest state in New England after Maine and Vermont by total land area (fourth largest by population after Massachusetts, Connecticut and Maine).¹⁷ The State is bordered by Canada, Vermont, Massachusetts, and Maine. The Connecticut River forms the western boundary with Vermont, while Maine forms a boundary for nearly its entire eastern border, until meeting the Atlantic Ocean near its southeastern border with Massachusetts. Manchester is the largest of New Hampshire's 221 towns with an estimated population of 109,497 in 2006 according the US Census data.¹⁸

New Hampshire ranks 41st in the country (by population), and at approximately 9,000 square miles, is the fourth smallest state by total area (68 miles at its widest point, and 190 miles long). New Hampshire is the second most forested state in the country, after Maine, in percentage of land covered by woods. Major regions of the state include the Great North Woods, the White Mountains, the Lakes Region, the Merrimack Valley, the Monadnock Region, the Dartmouth-Lake Sunapee Region, and the Seacoast.

The White Mountain National Forest covers approximately 1,171 square miles in the northcentral portion of the state (including 5.6% of which is in the neighboring state of Maine). Lake Winnipesaukee is the largest lake in New Hampshire, covering approximately 72 square miles in the east-central part of the state.¹⁹ The Seacoast area of New Hampshire has the smallest shoreline of any coastal state (just 18 miles long). Figure 9 provides a map of the state.

¹⁷ <u>http://quickfacts.census.gov/qfd/states/44000.html</u>. New Hampshire's population density of 137.8 persons per square mile is higher than the population density in Vermont (65.8) and Maine (41.3), but it is much lower than the other three New England states. For more detailed information, see http://www.answers.com/topic/list-of-u-s-states-by-population-density.

Figure 9. New Hampshire Map²⁰

²⁰ http://www.infoplease.com/atlas/state/newhampshire.html

2.2 New Hampshire Economic and Demographic Characteristics

New Hampshire is a rural state with a population of approximately 1,350,000 persons in 2008 and 604,000 housing units.²¹ According to the Energy Information Administration, the state's energy consumption per capita is among the lowest in the country. This is due, in part to the low demand for air conditioning and the fact that relatively few households use electricity as their primary energy source for home heating. Over half of the households in New Hampshire heat their homes with fuel oil in the winter.²²

The New Hampshire Employment Security Economic and Labor Market Information Bureau prepares an annual Economic Analysis Report for the state.²³ The Bureau's 2008 Report noted that New Hampshire has been growing faster than any of the other New England states, although this growth is occurring as a decreasing rate. Gross Domestic Product was \$57.3 billion at the end of 2007, a 2.3% increase from 2006, but well below the 4.9% and 4.0% growth in 2005 and 2004 respectively. The seasonally adjusted unemployment rate for New Hampshire was 3.8% at the end of the first quarter 2008, and has been consistently below the country's average rate over the past fifteen years. Total employment is projected to grow in the state by 13.9% from 2006 to 2016. Although real estate activity has declined 5.6% from April 2007 to April 2008, this decline has been one of the smallest compared to the other New England states. Major areas for job growth are expected to include: healthcare, social services, computers and mathematics, and personal services.

To get a sense of the population mix in the state, electric and natural gas utility customer information was provided and is summarized below. This information was used in sample plan development for telephone surveys and site visits that were conducted as part of this project. As shown in Table 9, the four investor-owned electric utilities analyzed for this report have a collective total of 612,636 residential and low income customers, with PSNH serving a majority of these customers (67% and 83% respectively). A majority of natural gas customers are served by National Grid (61%).

Utility Residential		Low Income		Total		
PSNH	392,202	67%	22,118	83%	414,320	68%
NH Electric Coop	64,164	11%	2,423	9%	66,587	11%
Unitil	58,550	10%	2,083	8%	60,633	10%
National Grid-Electric	70,986	12%	110	< 0.5%	71,096	11%
Subtotal Electric*	585,902	100%	26,624	100%	612,636	100%
National Grid-Gas	33,882	61%	1,117	100%	34,999	61%
Northern Utilities	21,988	39%	0	0%	21,988	39%
Subtotal Natural Gas+	58,870	100.0%	1,117	100.0%	56,987	100.0%

Table 9. Total Customer Counts – Residential, Low Income NH Electric and Natural Gas Utilities	4

²¹ Data obtained by GDS from "On-demand reports and maps from Business Analyst Online", based on U.S Bureau of the Census, 2000 Census of Population and Housing, ESRI forecasts for 2008 and 2013.

²² Primary data collection – results from this project's residential telephone surveys

²³ New Hampshire Economic Analysis Report 2008, New Hampshire Employment Security Economic and Labor Market Information Bureau

²⁴ Likely underestimates the number of low-income customers for each utility. As shown in this table, the estimated percentage of New Hampshire's population within these combined utility service territories is 4.3%

^{(26,624/612,636),} excluding double counting from natural gas utility customers that are also electric utility customers. In comparison, according to the 2007 American Community Survey of the U.S. Census Bureau, the percentage of the state's population at or below the poverty level is 7.1%.

- * Excludes municipal electric utility customers
- + Represents subset of electric customers

The State's commercial and industrial customer base, to accommodate data collection efforts required for this report, were separated into small (<100 kW peak demand or 300,000 kWh/year) and larger customer groupings. As shown in Table 10, the majority of small non-residential electric customers are located in PSNH's service territory (74%). The number of small commercial/industrial natural gas customers are split fairly evenly at 53% Northern Utilities and 47% National Grid. Based on review of Standard Industrial Classification (SIC) Code data included in some of the utility-provided customer data files, it appears that approximately 40% of New Hampshire's small non-residential electric and natural gas customers are in the Services sector (SIC codes 70-89). Between 11% and 12% of the state's small commercial/industrial customer sappear to be in the Retail Trades sector (SIC Codes 52-59). The Finance, Insurance and Real Estate sector (SIC Codes 60-67) make up the next largest small C/I customer focus at approximately 4%. Followed by Manufacturing and Transportation/Public Utilities (SIC Codes 20-39 and 40-49 respectively).

Utility	Count	% Total
PSNH	72,031	74%
NH Electric Coop	9,845	10%
Unitil	9,092	9%
National Grid-Electric	6,627	7%
Subtotal Electric*	97.595	100%
National Grid-Gas	5,708	47%
Northern Utilities	6,470	53%
Subtotal Natural Gas+	12,178	100.0%

* Excludes municipal electric utility customers

+ Represents subset of electric customers

The overall number of estimated large commercial and industrial accounts, as shown in Table 11 is 2,369. In summarizing data by SIC code in the top portion of the table, information provided by the utilities during the data acquisition/submission process was used. Not all utilities had complete customer SIC code information available for use, but based upon the SIC information received, manufacturing, services and retail trade were the three largest sectors observed. The bottom portion of the table allocates those SIC codes associated with Manufacturing as Industrial and the remainder as Commercial. As can be seen, just over 31% of those accounts classified in the data are industrial accounts.

The information presented in Table 11, shows an estimate of New Hampshire's large commercial and industrial (C&I) customer population based on a count of the number of utility-provided customer accounts. For these larger accounts, it is helpful to view the customers based on their energy usage. As shown below in Table 12, the overall amount of electric consumption among the utilities' larger commercial and industrial customers is estimated to be over 3,700 GWh. Although the industrial sector customers represent less than one third of all accounts classified in the utility data, these industrial sector customers represent nearly 43% of the consumption of all classified accounts.

2.2.1 Survey Respondent Characteristics

The primary data collection efforts for this project included a combination of phone and site surveys of residential, commercial and industrial New Hampshire customers. The surveys were used to obtain a great deal of customer demographic information. The most relevant customer demographic information is summarized below; additional information obtained from the surveys is presented in Appendix J to this report.

Of residential survey respondents, 94% were permanent as opposed to seasonal residents, and nearly 80% of respondents owned the property they were living in. Over 53% of homes were more than 28 years old. Over 72% of respondents had completed at least some college and nearly 18% have completed postgraduate studies.

Among the small commercial and industrial respondents, 62% owned the property and 38% leased the space. 98.5% of respondents pay for electricity in the space. The mean square footage of the small commercial and industrial facilities surveyed was 11,747 square feet.

Among the large commercial and industrial respondents, 73% owned the property and 27% leased the space. The mean square footage of the large commercial and industrial facilities surveyed was nearly 90,000 square feet.

2.3 Forecasted Electricity and Natural Gas Sales in New Hampshire

Based on sales information provided directly by this project's four participating electric utilities and two participating natural gas distribution companies, total and customer sector-specific energy (GWH), demand (MW) and fuel (MMBTu) forecasts were compiled. Where applicable, these forecasts were compared against relevant ISO-NE and EIA data to assess reasonableness. As shown in Figure 10, electric energy sales projected by the four participating electric utilities in New Hampshire is projected to grow from approximately 11,200 GWH in 2008 to over 13,000 GWH by the year 2018. This represents an annual rate of 1.3 percent. This represents nearly 93 percent of the total electric energy sales in the state, when compared with ISO-NE's latest forecast and appears reasonable given that the utility forecasts do not include sales from a number of smaller municipal electric utilities that also serve customers in the state. Figure 11 shows how the utilities' electric energy sales projections are broken down between residential, commercial and industrial customer sectors. The residential sector has the greatest sales, approximately 40 percent of total sales (4,537 GWH) in 2008, and is projected to grow slightly to 5,590 GWH by 2018 (representing a 1.7 percent annual growth rate). Commercial sector sales also currently make up approximately 40 percent (4,525 GWH) of the combined utilities' total 2008 electric energy sales, and are projected to grow just slightly to 5,354 GWH by 2018 (a 1.4 percent projected annual growth rate). The industrial sector currently represents 19 percent of total 2008 sales (2,126 GWH) and is expected to stay fairly constant, dropping slightly to 2,103 GWH by the year 2018 (a 0.1 percent annual decline). This figure also shows approximately 42 GWH/year in projected street lighting sales (representing 0.3 percent of total projected sales in 2018).

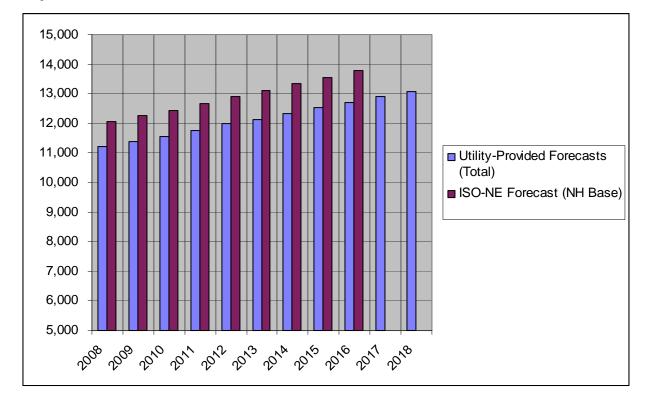

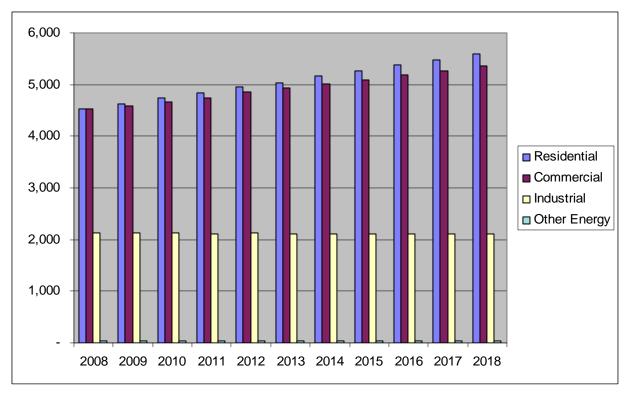

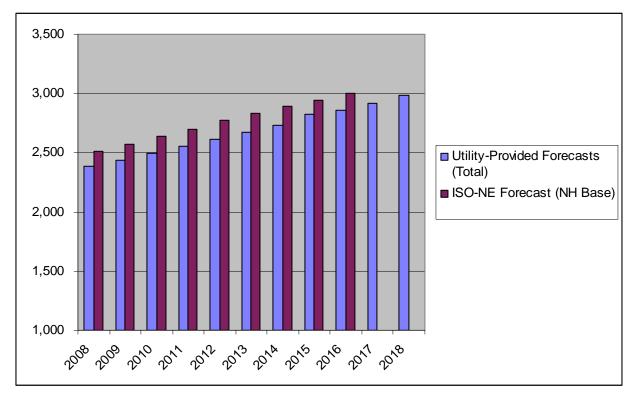

Figure 10. Forecasted Electric GWH Sales Total (2008 – 2018) - from Utility Data vs. ISO-NE Projections

Figure 11. Forecasted Electric GWH Sales By Sector (2008 – 2018)

Electric system peak load for the combined four participating electric utilities in New Hampshire, as shown in Figure 12, is projected to grow from approximately 2,400 MW in 2008 to nearly 3,000 MW by the year 2018 (an annual rate of 1.8 percent). This represents nearly 95% of the state's total forecasted electric demand, when compared with ISO-NE's latest forecast, and appears reasonable given that the utility forecasts do not include peak load projections from a number of smaller municipal electric utilities that also serve customers in the state. Figure 13 shows how the utilities' electric peak load projections are broken down between residential, commercial and industrial customer sectors. The commercial sector has the greatest peak demand, approximately 43 percent (1,023 MW) in 2008, and is projected to grow slightly to 1,279 MW by 2018 (representing a 1.8 percent annual growth rate). Residential sector demand currently makes up approximately 40 percent (962 MW) of the combined utilities' total 2008 peak, and is projected to grow to 1,206 MW by 2018 (also a 1.8 percent projected annual growth rate). The industrial sector currently represents just under 17 percent of total 2008 peak load (962 MW) and is expected to grow to 498 MW by the year 2018 (a 1.9 percent annual increase). This figure also shows approximately 3 MW per year in projected street lighting demand (constant for the period 2008 through 2018).

Figure 12. Forecasted Electric Demand (MW) Total 2008 – 2018 - Utility Data vs. ISO-NE Projections

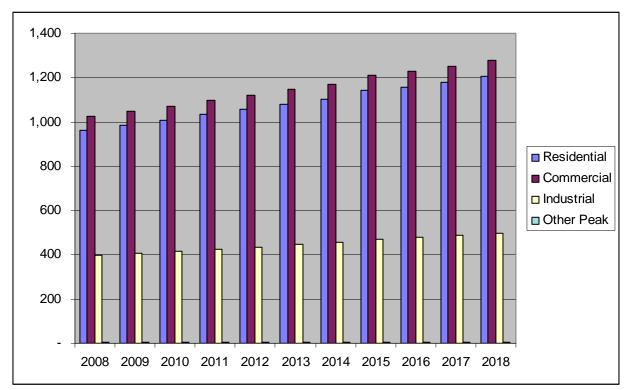

Figure 13. Forecasted Electric Demand (MW) By Sector 2008 – 2018

In addition to electric energy and peak demand, this study estimates the potential for additional natural gas energy efficiency and related propane and fuel oil savings opportunities. As such, Figure 14, shows that natural gas sales is projected to grow from 20,640 MMBTu in period 2008 to 26,283 MMBTus by 2018 (an annual growth rate of 2 percent).²⁵ This compares reasonably to the most recent data available from the US Department of Energy's Energy Information Administration (EIA), where New Hampshire's natural gas sales for 2007 was estimated to be 21,722 MMBTu. Figure 15 shows how New Hampshire's the natural gas utilities' MMBTu sales projections are broken down between residential, commercial and industrial customer sectors. The commercial sector has the greatest sales approximately 44 percent (9,428 MMBTu) in 2008, and is projected to grow to 12,666 MMBTu by 2018 (representing a 2.6 percent annual growth rate). Residential sector sales currently makes up approximately 36 percent (7,698 MMBTu) of the combined utilities' total 2008 natural gas sales, and is projected to grow to 8,189 MMBTu by 2018 (a 0.6 percent projected annual growth rate). The industrial sector currently represents just over 19 percent of total 2008 sales (4,041 MMBTu) and is expected to grow to 5,428 MMBTu by the year 2018 (a 2.6 percent annual increase).

²⁵ Based on participating New Hampshire Natural Gas distribution company-provided projections.

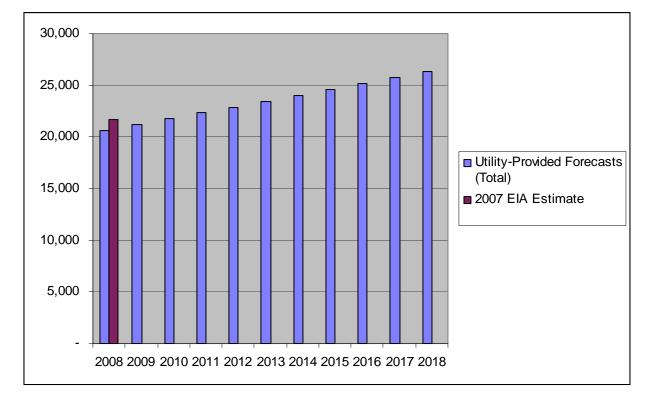

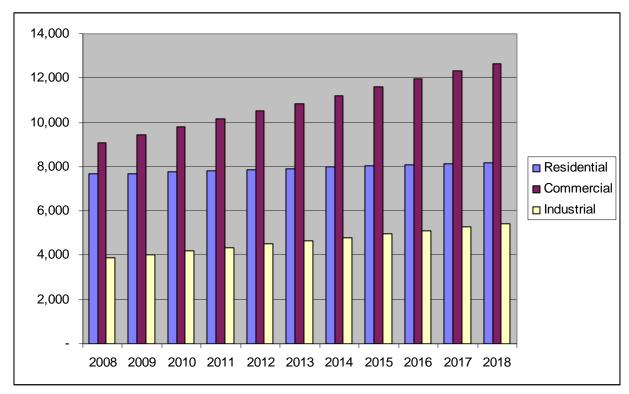

Figure 14. Forecasted Natural Gas MMBTu Sales Total (2008 – 2018) - Utility Projections vs. EIA Data

Figure 15. Forecasted Natural Gas MMBTu Sales By Sector (2008 – 2018)

GDS Associates, Inc.

New Hampshire's electric and natural gas utilities have been operating energy efficiency programs for a number of years. The above forecasts reflect the energy savings that have already resulted from these utilities' previous efficiency program efforts.

In New Hampshire, as with all states, the growth in the demand for electricity and natural gas will vary by region where some regions may see much higher growth rates. On a statewide basis, however, areas showing faster growth are offset by slower growth areas of the state to produce an overall projected growth rate of approximately only 1.3, 1.8 and 2.0 percent for electric energy, demand and natural gas sales respectively.

Section 3: Overall Project Implementation Approach

This section of the report presents an overview of the approach and methodologies used by the GDS Team for completion of each of the following tasks:

- Analyzing current saturations of energy using equipment and penetrations of energy efficiency equipment and practices in each end-use sector
- Producing an up-to-date list of currently available and soon to be commercially available technologies which may play a part in future efficiency programs
- Estimating customer participation rates/levels by program, based on different payback/incentive levels and define/analyze significant barriers that customers face when investing in additional energy efficiency
- Developing, by sector, a simplified end-use model of state electricity and natural gas consumption and peak demand
- Estimating, state-wide and for each of the four New Hampshire retail electricity providers and two natural gas distribution companies, the technical, maximum achievable, maximum achievable cost effective, and potentially obtainable scenario for electricity, natural gas, and related propane and fuel oil savings over the next 10 year period, and the budgets (where appropriate) required to achieve that potential
- Evaluating extent to which past and current energy efficiency programs have achieved energy savings to date, provide sensitivity analysis of realized energy savings based on different resource levels (including absence of current SBC-funded model), and recommend modifications to program and measure offerings that would increase the likelihood of achieving identified potential

3.1 Energy Using Equipment Saturations and Efficiency Penetrations Analysis

This task represents a major enhancement to technical potential studies that have been conducted across the country in the past. Rather than relying on best available information from existing secondary sources to estimate current levels of energy using equipment saturations and penetration of energy efficiency measures, significant primary data collection efforts were undertaken to help inform and derive New Hampshire-specific values where possible within the time requirements and work scope specified for this project. As such, this effort was completed through a combination of primary and secondary data collection and analysis activities. Detailed results and an assessment of the value resulting from this enhanced, New Hampshire-specific data collection effort is presented in Section 7 of this report. Following is a discussion of the methodologies utilized to complete this task.

First, a measure list was compiled, the approach for which is described in Section 3.2 below. The current saturation of each relevant type of energy using equipment and the penetration of associated energy efficiency equipment and practices was then determined. In this effort, it was important to recognize and quantify differences in end-use saturations and penetrations between the residential, commercial and industrial sectors, and building types within in each sector (see Table 13, Table 14 and Table 15).

Table 15. Industrial Sector Business Types and Energy Using Equipment

As noted above, a combination of primary and secondary data collection and analysis activities were conducted by the GDS Team to develop the New Hampshire sector and building-specific saturation and penetration rates used for this report. Primary data collection consisted of telephone surveys of a statistically valid sample of residential and small commercial/industrial customers (400 residential customers and 200 small commercial customers) and site visits for a sample of 100 larger commercial and 100 industrial customers.

3.1.1 Survey Instruments and Site Visit Data Collection Forms

The process of developing survey questions and site visit data collection forms was mostly dictated by the types of data required by the computer models being used by the GDS Team to estimate energy saving potential. For the questions that examined current saturations and penetrations of energy efficient equipment and practices, GDS first identified a list of currently and soon-to-be commercially available technologies that may play a part in future efficiency programs; then specific questions that address these technologies were developed.

For the phone surveys, survey instruments from two existing studies served as references: the 2004 California Statewide Residential Appliance Saturation Study (for the residential questionnaire), and the U.S. Department of Energy's 2003 Commercial Buildings Energy Consumption Survey (for the small commercial/industrial questionnaires). For the site visit data collection forms, instruments based on somewhat relevant previous projects were used as a starting point. In addition, the survey instruments included questions to explore customers' attitudes toward and perceptions of energy efficiency. These questions addressed factors that affect the adoption of energy efficiency measures, significant barriers customers may face when investing in energy efficiency measures, awareness of energy efficiency, program participation and satisfaction, and past purchase practices. A major challenge in this effort was to develop instruments that would provide useful information on a number of important energy end-use measures, without requiring respondents to spend too much time on the phone, or on site. Targeted durations of 15 minutes per phone survey and 2.5 hours per site visit were set.

New Hampshire Public Utility Commission reviewed preliminary research instruments, both for the phone surveys and site visits, in several phone conferences, and discussed their priorities with the GDS Team. Based on these discussions, RIA finalized the phone survey instruments for the residential and the small commercial/industrial surveys which primarily asked questions in a closed-ended format, with a few opportunities for verbatim responses. GDS and RLW finalized the site visit data collection forms using identical questions from the phone surveys wherever practical and a tabular format for collection of end-use area and measure specific saturation and penetration data. Appendix A presents the Team's Residential Sector Telephone Survey. Appendix B is the Small Commercial/Industrial Sector Telephone Survey. Appendix C provides a copy of the On-Site Data Collection Instrument for the Larger Commercial and Industrial Sector.

3.1.2 Sampling

The sampling plans for residential and small commercial/industrial telephone surveys were developed based on records received from each of the electric and gas utilities. Records that represented duplicates due to multiple program participation were combined and participation codes were retained for programs. In residential accounts, all low-income customers were identified based on their rate code or income flag. Identified low-income customers represented 5% of the customer accounts received. A similar approach was taken with the small commercial/industrial accounts, which were also screened to ensure that all electric accounts had less than 100kW demand or 300,000 kWh annual consumption.

By definition, all records for gas utility customers are duplicates since all gas customers also are customers of one of the electric utilities and would be included in those records. Therefore, as an initial step, each gas customer record was matched by telephone number to one of the electric utilities. The next step was to remove records with no phone number. Table 16 and Table 17 display the final sample quotas for the residential and small commercial/industrial phone surveys. As shown in Table 16, quotas were included in the residential sample to ensure representation from both the non-low-income and low-income populations, and for electric and gas customers associated with each of the four major electric and two major natural gas utilities

in the state. The residential sample is designed to achieve 5 percent precision at a 95 percent confidence level, with 10 percent precision and 90 percent confidence level for each of the utilities.²⁶

Table 16. Sample Quotas - Residential NH Electric and G	Gas Utilities
---	---------------

As shown in Table 17, specific quotas were also included with the small commercial/industrial sector to ensure representation from both electric and gas customers. This small commercial/industrial sample is designed to achieve 5 percent precision at the 85 percent confidence level, with 12 percent precision at the 85 percent confidence level for each of the utilities.

Totals	7,000	183	17	200

In the end, 411 interviews with residential customers and 200 interviews with small commercial/industrial customers were completed. As shown in Table 18 and Table 19, over 6,100 and 4,000 calls to residential and small commercial customers respectively had to be made to fill the 400/200 quotas targeted. More information and summary results from the phone survey efforts are presented later in this report.

A key element of the larger commercial and industrial on-site surveys was the systematic selection of sample points to visit. As originally proposed, 200 site visits were targeted for performance overall. A sample size of 68 provides an expected absolute precision of 10% for proportional results. This suggests that a sample size of 200 can be considered adequate for the consideration of targeting sub-groups of the sample such as commercial versus industrial or fuel types (gas).

Table 20 below presents the number of accounts determined to be Large C&I after identifying²⁷ them from the sponsor provided electric customer data. The overall number of estimated large commercial and industrial accounts is 2,369. In summarizing data by SIC code in the top portion of the table, information provided by the sponsors during the data acquisition/submission process was used. Not all sponsors had SIC code information available for use, but based upon the SIC information received, manufacturing, services and retail trade were the three largest sectors observed. The bottom portion of the table allocates those SIC codes associated with Manufacturing as Industrial and the remainder as Commercial. Just over 31 percent of those accounts classified in the data are industrial accounts.

²⁷ For PSNH, Large C&I were defined as their rate code GV or LV. For Unitil, they were defined as having a demand greater than 100 kW based upon a provided Total Demand field or as having more than 300,000 kWh of annual consumption if demand was not available. Similarly for National Grid they were defined as customers having a demand greater than 100 kW based upon a provided Average Bill Demand kW field or as having more than 300,000 kWh/year if demand was not available. NHEC provided a list of Small C&I customers as queried to meet the study designated Small C&I definition of accounts with less than 100 kW of demand when available, otherwise less than 300,000 kWh/year.

To identify gas customers, the GDS Team gathered gas customer data from the sponsors. Using the address, company name, and phone numbers within the gas customer data, a total of 645 customers within the large C&I electric customer dataset were identified as having gas service. There are sure to be more gas customers in the sample frame beyond those identified. In fact we received a total of 12,178 total (small and large) gas commercial or industrial customer records from National Grid and Northern Utilities from which the 645 Large Commercial and Industrial accounts were successfully mapped in to the dataset of identified large electric Commercial and Industrial customers. This identified group represents just over 31 percent of the Large C&I population gathered from the electric sponsors.

Table 20. Large C&I Population Summary (Accounts)

Table 21 below presents the electrical consumption (kWh) of the Large C&I customers, also by SIC Code and Commercial versus Industrial. The overall amount of electric consumption among the large Commercial and Industrial sample frame is estimated to be 3,725 GWh. Although the industrial accounts represent a third of the accounts classified in the sponsor data, they represent nearly 43 percent of the consumption of all classified accounts.

Total	1,081,111,126	2,643,763,935	3,724,875,061			

Based upon the exploration of the Large C&I data gathered, a sample approach that targeted large industrial and large commercial equally seemed reasonable – particularly given that the modeling and analysis of additional energy efficiency potential will be done discretely for each and that the consumption of industrial versus commercial accounts is moderately close to 50/50.

The sample design requested in the RFP asked for adequate representation of each sponsor (i.e., the four electric utilities and the two natural gas distribution companies) in the final sample. Table 22 presents the number of accounts by utility for electric and gas as determined from aggregating the entire large commercial and industrial electric customer information and an effort to map in information from the gas utilities based upon information in common fields.

	Comm	nercial	Industrial		Unclassified		Total

 Table 22. Large C&I Accounts by Sponsor and by Commercial versus Industrial

Due to an inability to fully categorize all of the sponsor information by the various sectors among electric customers, the GDS Team felt that the best approach to sampling for the large C&I site visits would be to target 100 commercial facilities and 100 industrial facilities with minimum sample quotas for each electric utility with an overall quota for gas customers. Such a sample would further seek to balance the need for targeting the number of large C&I customers from each sponsor to their approximate portion of the total (with a minimum quota size of 7) with the need to visit customers with gas use. This would be done iteratively as the recruitment process proceeds depending upon the actual incidence of gas customers among the recruited Large C&I sample frame (discussed later).

Table 23 below provides the GDS Team's proposed sample design in which we have allocated the targeted visits within the commercial and industrial categories similarly as the proportion of accounts by utility in each category are very similar (Table 22). The predicted gas column in

Table 23 provides an estimate of the number of gas customers that would naturally fall into the sample for each sponsor given the identified gas customers in each sector – along with the gas utility they are likely to represent. An estimated 64 gas customers were anticipated to be recruited naturally in this regard, comprised of 30 in the large commercial sector and 34 in the industrial. Given the interest in gas measures as part of this study, the GDS Team believed that additional targeting of this group of customers was needed. Therefore, visiting 68 gas customers overall was suggested, which targets a 90 percent confidence with +/-10 percent relative precision for proportional results. Therefore, depending on the incidence of gas customers experienced in the recruitment process, an additional 4 gas sites may need to be explicitly targeted to achieve a total of 68.

	Large Commercial		Large Industrial		
Utility	N	Predicted Gas Subset	N	Predicted Gas Subset	
NHEC	7	0	7	0	
PSNH	76	16 NGRID and 9 Northern	75	21 NGRID and 7 Northern	
Unitil	8	2 NGRID and 1 Northern	7	5 NGRID	
GSE	9	2 (Northern)	11	2 (Northern)	
Total	100	30	100	34	

 Table 23.
 Large C&I Sample Design

In the end, all the electric utility-specific quotas were met for both the commercial and industrial sectors. The predicted gas utility subsets were exceeded (23 Northern Utility completes vs. predicted 21, and 59 National Grid completes vs. predicted 44).

Scheduling and fielding began on June 9th and all site visits were completed before August 9th, 2008. Advance letters were sent by the PUC to 500 randomly selected customers within the quota areas targeted and a drawing for a \$500 gift card was offered to increase likelihood of participation.²⁸ Appendix D provides a copy of the PUC advance letter and the GDS Team's recruiting script. Although the GDS Team was able to achieve a 40% response rate (200 completes, out of a 500 customer sample frame), as discussed in more detail in the section below, the time required to recruit, schedule and conduct the site visits, and hard enter and analyze all resulting data greatly exceeded original estimates.

3.1.3 Data Collection and Analysis

The telephone interviews were conducted from RKM Research and Communication's call center using trained, professional survey managers and interviewers who utilized a computer assisted telephone interviewing (CATI) system. All staff were thoroughly trained as to the nature of the study, the importance of the information being collected, and management of the sample. Before the final data collection phase, RKM conducted a pretest with 20 residential and 22 commercial/industrial completes to identify any problems the respondents or interviewers might have understanding questions, or with the survey length. Some modifications were made to questions based on the results of the pretest, but these were insignificant and the total number of pretests was included in the final dataset.

Fielding of the phone surveys was conducted from June 17th through 26th, 2008, during the day, evening, and weekend hours to reach as many targets as possible. The average length of the

²⁸ NH Industries, Lebanon, NH was the winner of the drawing held on September 5th at the PUC offices. Instead of a \$500 gift card, per their request, a charitable donation was made on their behalf to the United Way of the Upper Valley.

survey was 16 minutes for the residential survey and 17 minutes for the small commercial/industrial survey. To counteract non-response bias, up to six attempts per telephone number were made to complete the surveys. All soft refusals were put into a separate sample file and were assigned to different interviewers to call back. All were called back except those refusals received in the very last days of the study, as a result of the waiting period between when the initial refusal was received and when the callback was attempted. Detailed call disposition information was presented earlier in Table 18 and Table 19. The completed survey data was analyzed using SPSS statistical software and appropriate data entry accuracy verification and data cleaning procedures.

The site visits were conducted by experienced RLW and GDS engineers and trained staff. Starting with development of the site visit data collection form, key staff from both RLW and GDS (including a number of those that would be conducting the actual site visits) were actively involved in the development of the form and the planning/scheduling approach for the site visits. All dedicated site visit staff (totaling more than 8 individuals) were thoroughly trained as to the nature of the study, the importance of the information being collected, and management of the sample.

As part of the initial data collection phase, RLW and GDS staff pretested the site visit data collection form by jointly conducting visits during the first two weeks in the field to identify any problems the auditors might have understanding questions or with the visit length, collecting the required measure data, and ensuring consistency of interpretation and treatment of equipment and situations encountered in the field by multiple auditors. Some modifications were made to implementation approaches based on the results of the pretest, but these were insignificant and the total number of pretests was included in the final dataset. Open and regular communication between the multiple auditors was encouraged and conducted throughout the site visit fielding period to maximize consistency.

Fielding of the site visits was conducted from June 9th through August 9th, 2008, during the workday hours to reach as many targets as possible. The average length per site visit was 3.25 hours. Project sponsors were kept aware of weekly schedules and attended as observers on a number of the site visits. To counteract non-response bias, up to six attempts per potential respondent were made to recruit facilities for the site visits. After identifying the correct person or persons to speak with at the targeted facility, all soft refusals or referrals to other personnel within the office or corporate headquarters location, were noted in the sample file and called back. All were called back except those refusals received in the very last days of the study, as a result of the waiting period between when the initial refusal was received and when the callback was attempted. After preparing the random sample required to fill specified quotas, additional facility names were not added until a direct refusal was received or six attempts were made to recruit each facility on the quota list.

The completed survey data for each site was recorded in paper files (22 pages per completed site visit) and was entered manually into an analyzable Excel spreadsheet file. Direct conversations between data entry personnel and field data collection staff were held when necessary to ensure proper interpretation of field notes. Data entry accuracy verification and data cleaning procedures were employed and analyses were conducted using pivot tables and targeted data mining where appropriate.

3.1.4 Derivation of Saturation and Penetration Values and Weighting of Results

Results from the phone surveys and site visits were analyzed to derive values for saturation of energy using equipment and penetration of energy efficiency equipment and practices, where applicable, in each end-use sector. Results from these analyses are discussed in more detail in

Section 7 of this report. For the residential sector and small commercial/industrial sector phone surveys, multiple cross tabulations were run to identify appropriate measure-specific responses based on heating source, single and multifamily housing types, building type and numerous other relevant variables.

For the larger commercial and industrial facility results, values were derived using multiple pivot tables. In all cases where sufficient responses existed (N>30, or lower if deemed to be reasonably representative of the building type of interest), values from the site surveys were reported for the specific building type. Otherwise, values were averaged across and applied to all building types for a specific measure. This was done to ensure that statistical validity was maintained in the model and that results were not skewed by a small number of responses.

Results from the small commercial and industrial phone surveys and large commercial and industrial site visits were combined using a weighted average. The weighting factors were developed using customer-specific energy sales information provided by the electric and gas utilities for their small (less than 100kW demand) and large customers. The weighting factors were based on the ratio of total electrical consumption in the small commercial and industrial sector. This ratio was applied to the results for the small and large customers to determine a weighted average for both the electric and non-electric models.

Excellent New Hampshire-specific information was collected on saturations and penetrations (referred to in our models as base and remaining factors) for a number of residential, commercial and industrial energy using equipment through the phone surveys and site visits conducted as part of this project. Such real customer-specific values have typically not been collected as part of the numerous technical potential studies that have been completed to-date for others across the country. Given the extensive list of measures identified for assessment in this study (as discussed in more detail in the section below), it was not possible to develop survey and site visit instruments of sufficient depth and breadth to collect information from which to derive values for all measures of interest to the Commission, OCA and the project's participating utilities. As such, in numerous cases, secondary sources for penetration and saturation data were identified, used and documented. Wherever possible, these secondary sources were verified for reasonableness, or modified based on results obtained through this project's primary data collection activities.

3.2 Measures List Development

This task was initially proposed to be based mainly on the GDS Team's existing information and databases of sector-specific electricity, gas and other fossil fuel end-use technologies and efficiency measures, and was to be supplemented as necessary to ensure inclusion of other technology areas of interest to the Commission, the OCA, and the four electric and two gas utilities supporting this project. Initial lists of electric and natural gas measures were compiled by GDS for the state's residential, commercial and industrial customer sectors, and were shared with the project sponsors on April 3rd for review and comment. As shown in Table 24, Table 25, and Table 26, these initial sector-specific lists contained a total of 252 unique measures (79 residential, 130 commercial, and 43 industrial).

Total Measures in Sector	9	34	43 (total)			

Following multiple meetings and discussions over the subsequent 5 month period, ending September 26th, 2008, these lists grew by nearly a factor of two to 471 individual measures as shown in Table 27, Table 28 and Table 29. A significant amount of time was also expended during this period identifying, reviewing and documenting secondary and other available data sources to develop reasonable assumptions regarding measure lives, installed incremental and full costs (where appropriate), and electric energy, demand, and MMBTu savings associated with each of the measures included on the final lists.²⁹ Please refer to Appendix E for a comprehensive listing of all residential electric and non-electric measures and associated

²⁹ The GDS Team's existing sector-specific technical potential calculation models were also modified substantially during this period to accommodate the large increase in the number of measures and expanded measure categories to be assessed.

assumptions and sources assessed in this report. Appendix F and Appendix G provide similar detailed information for the commercial and industrial sectors respectively.³⁰

³⁰ Although the measures lists are extensive, they are not exhaustive, particularly for potential fuel oil and propane savings. Some potential measures were identified that were not modeled due to data or other limitations. These include, but are not limited to air conditioning peak demand savings from off peak cooling with energy storage, more advanced windows than double pane with low-E, super high efficiency gas condensing hot water heaters used particularly in combo systems that provide both space and hot water heating, data center and certain information technology potential energy saving measures, and some emerging but not yet commercialized technologies.

3.3 Customer Program Participation Rates and Barriers

Estimates of customer participation rates/levels by program and identification of barriers that customers face when investing in additional energy efficiency were developed based mainly on direct results from the GDS Team's phone surveys and site visits. Specifically, for each customer sector, questions were asked to assess customers' attitudes towards energy efficiency, past program participation and satisfaction, and barriers that might be preventing them from making future investments in energy efficiency.

3.3.1 Residential Customer Attitudes

The residential survey included questions about respondents' attitudes toward energy efficiency. More specifically, these questions attempted to explore respondents' level of consideration of energy saving and to assess factors that affect the adoption of energy efficiency measures. First, the respondents were asked to rate the level of attention their household pays to controlling energy costs through general energy efficiency operational practices such as adjusting room temperatures, shutting computers and lights off, etc. Table 30 provides the result. In general, the level of attention paid to controlling energy cost seems high. About two thirds (63 percent) said they pay "substantial attention," and 30 percent said they pay "some attention." Only a small percentage of the respondents said they pay "very little" or "no attention" to these matters (6 percent).

	Frequency	Valid Percent
Substantial attention to these matters	256	63.4%
Some attention	121	30.0%
Very little attention	20	5.0%
No attention	5	1.2%
Don't know	2	0.5%
Total	404	100%

Respondents rated their likelihood of purchasing energy efficient equipment instead of standard equipment given several conditions generally assumed to increase the attractiveness of adopting energy efficient equipment. Just before introducing this question, the term "energy efficient equipment" was defined by stating "I am referring to new equipment specifically designed to be more energy efficient than other new models. Energy efficient models typically cost more than other models, perhaps 20-30 percent more." The order of these factors was randomized to avoid any response biases. The result is shown in Table 31. Overall, it seems the respondents found these factors appealing. In particular, a high percent of respondents (78 percent) said they would be "extremely likely" to purchase energy efficient equipment if their monthly energy bill would be less. This was rated significantly higher than any other factor (p<.05). The next highest rated factors were increased comfort, increased home value, feeling pro-environment, and receiving a rebate (more than 70 percent of the respondents said they are "extremely likely" to choose energy efficiency equipment as a result of these factors).³ In contrast, "sales persons' recommendation" was rated significantly lower than any other factors (p<.05). Twenty-four percent reported they were "not at all likely" and 35 percent said they were "extremely likely" to purchase energy efficient equipment over standard items given this (sales person recommendation) condition.

³¹ Respondents with lower educational achievement rated this factor significantly lower (p<.05).

Note: "Don't know" responses were treated as missing data. Frequency of "it increased the home value" (d) is shown only if the respondents were home owners.

Table 32 shows factors respondents identified as barriers to investing in energy efficiency measures. The table provides a coded summary of the open-ended responses. Nearly three quarters of the responses dealt with uncertainty of payback and initial higher upfront costs (71 percent). In a distant second place, 10 percent of respondents said that current equipment is meeting their needs; 5 percent said they are renters and not able to do home improvements. Six percent of the respondents were concerned about various aspects of energy efficient equipments such as quality, design, features, and safety.

Note: "Don't know," "refusal," and "no reason" responses were treated as missing data.

3.3.2 Residential Customer Program Awareness and Participation

Finally, the surveyed households were asked about their awareness of and participation in their utilities' energy efficiency programs. Table 33 shows the respondents' awareness of their

utilities' energy efficiency programs. Overall, approximately 50 percent of the households know their utility offers energy efficiency programs. NH Electric Coop's customers have the highest awareness level (61 percent) and Granite State Electric's customers have the lowest awareness (42 percent) of their utilities' efficiency programs.³² However, the differences in customers' awareness among the four utilities were not statistically significant.

	Column %	100%	100%	100%	100%	100%

 Table 33. Awareness of Utility's Energy Efficiency Programs

Note: "Don't know" responses were treated as missing data.

Table 34 shows the respondents' participation in their utilities' energy efficiency programs, including participation by purchasing products promoted through these programs. Of the respondents who are aware of their utilities' program, the overall participation rate was 31 percent (15 percent of the sample population). There was no difference in the participation rates among the four utilities. One interesting finding was that the low income households reported significantly higher participated in such programs (58 percent) as the non-low income group was about twice as likely to have participated in such programs (58 percent) as the non-low income group (29 percent). Though not shown in the table, the data indicate an extremely high rate of satisfaction among participants. Almost all participating respondents reported they would participate again in their utilities' efficiency program if they have a future opportunity. Satisfaction and interest in repeat participation was equally high among both low and non-low income groups.

Table 34.	Participation in	Utility's Energy	Efficiency Programs
-----------	------------------	------------------	---------------------

Note: This question was asked only if the previous question (PS1) is "yes". "Don't know" responses were treated as missing.

 ³² It is important to note that Granite State Electric customers differed significantly from those of the other utilities, having a larger proportion of lower income families and the demographic characteristics associated with that.
 ³³ Low income was defined as 183% of Federal Poverty line (per utility low income program eligibility criteria).

For those who reported not participating in their utilities' energy efficiency program, an additional question was asked about the reasons why they have not participated. Each possible reason was read by interviewers and the respondents were allowed to provide multiple reasons. If a respondent agreed that a certain reason contributed to their non participation, they were considered to have "endorsed" that particular reason.

Table 35 summarizes the responses. The most frequently mentioned reason was they have not recently purchased items that use energy (44 percent). The next most frequent reasons for nonparticipation seem to relate to their lack of awareness of or knowledge about utility efficiency programs. Twenty-eight percent reported they "did not know they are eligible," followed by "did not know how to find out about the program" (18 percent). It is possible that some respondents have not made recent purchases because they are unaware of programs that may alleviate their financial concerns about investing in energy efficient products. Several other reasons were mentioned with notably high frequencies. Those are: the sales person did not mention the program (13 percent), insufficient incentive (12 percent), bought unqualified equipment (11 percent), and "was not worth the hassle" to participate in programs (10 percent).

Note: Respondents were allowed to provide multiple answers to this question, and later all responses were coded. Thus, the N=134 represents the total number of valid responses.

3.3.3 Residential Customer Program Participation and Barriers Summary

Installation of energy efficiency features are commonly considered as part of remodeling projects (64 percent among recently remodeled homes, and 90 percent among homes with a future remodeling plan). About half of the households surveyed are aware of their utility offering energy efficiency programs, and 30 percent have participated in them in some way. Low income households were found to have a significantly higher participation rate—they are twice as likely to report participating in such programs (one likely reason for this higher participation could be the fact that these households qualify to receive rebates of 100%). Among participants, satisfaction with their utilities' programs seems extremely high. The most frequently cited reasons for nonparticipation were there were no recent purchase of energy-using household items, and unawareness of program resources. It is possible the former reason may be triggered by the latter reason—that is, they have not made a recent purchase of efficient products because they are not informed of available programs.

Awareness of the ENERGY STAR® logo also seems fairly high (82 percent), especially among non-low income households. Reducing the monthly energy bill, in particular, appears to be an important driving factor when making decisions of energy efficient product purchases. Other factors such as increased comfort, protection of the environment, increased home value, and receiving rebates are also highly appealing in making decisions on such purchases. The single biggest barrier for households in investing in energy efficient measures is their concern and uncertainty of payback and initial higher costs.

3.3.4 Commercial and Industrial Customer Attitudes

This section summarizes commercial and industrial customer attitudes on energy efficiency practices and programs. The results are based upon phone surveys of small commercial and industrial customers in addition to site surveys and discussions with larger commercial and industrial customers. Large customers are defined as properties using over 300,000 kWh's of energy per year. The surveys were utilized to obtain information on past purchases and practices, awareness of efficiency programs and equipment, and overall attitudes toward energy efficiency.

3.3.5 Commercial and Industrial Customer Respondent Characteristics

The analyses began with an examination of characteristics of commercial and industrial respondents, followed by question-by-question analysis. Ownership characteristics of respondents and the primary business activities were recorded to determine the distribution of respondents among the four electric utility providers. A summary for both small commercial and industrial customers and large commercial and industrial customers is provided in Table 36 below.

3.3.6 Commercial and Industrial Customer Program Awareness and Participation

Respondents were polled to determine customer awareness and participation in the existing energy efficiency and incentive programs offered by the utility providers. Program awareness was significantly higher among the large commercial and industrial customers (86 percent) compared to small commercial and industrial customers (60 percent). Past participation in efficiency and incentive programs was also notably higher among large customers (85 percent) compared to small customers (30 percent). Differences in awareness and participation levels among utility providers were not statistically significant. Results of small and large customer surveys are summarized below in Table 37.

Table 38. Participation in Utility's Energy Efficiency Programs

Note: This question was only asked of respondents who were aware of their utilities' energy efficiency programs

Small commercial and industrial respondents who indicated that they had not participated in the energy efficiency programs were asked additional questions regarding their nonparticipation. The most frequently given response for nonparticipation among small customers was they "have not purchased energy-using equipment" (49 percent). The next three most frequently cited reasons seem to relate to their lack of awareness of the programs. Of respondents who have participated in their utility's energy efficiency programs, a significant majority of both small customers (94 percent) and large customers (98 percent) reported that they would participate in the programs again if given the opportunity.

3.3.7 Commercial and Industrial Customer Motivations and Barriers

To first assess customer attitudes towards energy efficiency, respondents were asked to qualify the amount of attention they spend on controlling energy costs through general efficiency practices such as adjusting room temperatures when not occupied and shutting off computers and lights at night. As shown in Table 39, 86 percent of respondents indicated that they pay at least "some attention" to controlling energy costs. No significant differences were observed among any groups or between small and large customers.

	Frequency	Valid Percent
Substantial attention to these matters	165	43%
Some attention	163	43%
Very little attention	37	10%
No attention	13	3%
Don't know	4	1%
Total	382	100%

Table 39.	Attention Paid to	Controlling Company	y Energy Costs -	– Small/Large Resp	ondents Combined
-----------	--------------------------	----------------------------	------------------	--------------------	------------------

Respondents were then asked to rate the likelihood of purchasing energy efficient equipment instead of standard equipment given several conditions generally assumed to increase the attractiveness of adopting energy efficient equipment. Respondents were told to assume that the energy efficient cost between 20 and 30 percent more than standard models. Among all respondents, reduction of monthly energy bills and receiving a rebate were the reasons most likely to encourage the purchase of energy efficient equipment. Increasing occupant comfort, environmental protection and improving business image were less likely to motivate respondents to specify energy efficient equipment in both small and large customers. A complete summary of results across all building types is provided in Table 40 below.

Table 40. Likelihood of Purchasing Energy Efficient Equipment

Respondents were asked to identify the primary reasons why they would not purchase energy efficient equipment or make energy efficient improvements to the space. Table 41 provides a coded summary of the open-ended responses. By far the most frequent response was concerns over the cost of the equipment and the payback (69 percent). Other responses included satisfaction with current equipment (6 percent), purchasing decisions made at corporate level (5 percent), tenants unwilling to invest in capital improvements for spaces they do not own (4 percent), and no need to replace equipment that is currently in working order (3 percent). Other reasons cited included the use of specialized equipment and the belief that

energy efficient equipment would be not available for the specialized process (3 percent), and the quality and reliability of energy efficient equipment (3 percent).

	Frequency	Valid Percent
Cost / benefit, payback	225	69%
Current equipment is satisfactory/no need	20	6%
Corporate decision	16	5%
Renting, not owner of property	13	4%
Replacing as needed	8	3%

Quality	9	3%
Not well informed	4	1%
Other	21	6%
Total	326	100%

3.3.8 Commercial and Industrial Customer Program Participation and Barriers Summary

Of the small and large commercial and industrial customers surveyed, 86 percent of respondents reported some or high level of attention to controlling energy costs. Overall awareness of energy efficiency programs and incentives offered by utility providers was significantly higher in the large commercial/industrial respondents (86 percent) compared to the small commercial/industrial respondents (60 percent). Past participation in utility provider offered programs was similarly higher in the large customer group who was aware of the programs offered (86 percent) compared to the small customer group aware of the programs offered (30 percent). Of respondents who have participated in their utility's energy efficiency programs, a significant majority of both small customers (94 percent) and large customers (98 percent) reported that they would participate in the programs again if given the opportunity.

The single largest barrier to respondents investing in energy efficiency measures was concern about initial premium costs of equipment and insufficient payback (69 percent). Respondents indicated that the two most important factors influencing decisions to invest in energy efficient equipment are expectations of lower monthly energy bills and rebates or incentives for purchasing energy efficient equipment that would help offset some of the initial costs. Other factors such as business image, environmental impact, occupant comfort, and sales person recommendation were less likely to influence decisions to invest in energy efficient equipment.

3.4 Forecast Model of State Electricity and Natural Gas Consumption and Peak Demand

Results from this task were presented in Section 2.3 above. As noted previously these forecast models were compiled by RLW for this project based on sales information provided to the GDS Team directly by the project's four participating electric utilities and two participating natural gas distribution companies. Separate total and customer sector-specific energy (MWH), demand (MW) and fuel (MMBTu) forecasts were developed for the state as a whole and by utility service territory. Where applicable, these forecasts were compared against relevant ISO-NE and EIA data to assess reasonableness. Please refer to Figure 10, Figure 11, Figure 12, Figure 13, Figure 14, and Figure 15, presented in Section 2.3 of this report for a summary of these model forecast results.

As will be discussed in more detail in the additional energy efficiency potential modeling methodology section below, these customer-sector electric and gas forecast models served as critical inputs used to estimate the percent potential values for additional energy efficiency opportunities statewide. They were also used to develop energy efficiency potential percentages at the utility-specific territory level.

3.5 Estimates of 10-Year Technical, Maximum Achievable, Maximum Achievable Cost Effective Potentials and Potentially Obtainable Scenario

A main objective of this study was to estimate, state-wide and for each of the four New Hampshire retail electricity providers and two natural gas distribution companies, the technical, maximum achievable, maximum achievable cost effective potentials, and savings from a potentially obtainable scenario for electricity, natural gas, and related propane and fuel oil savings over the next 10 year period, and the budgets (where appropriate) required to achieve that potential. As described in more detail below, the activities undertaken to develop these estimates were based on the GDS Team's existing sector-level models, DR 96-150 cost-effectiveness criteria, and the region's current avoided energy cost projections, as expanded to reflect the increased list of measures to be assessed and customized based on state utility-specific data and the saturation and penetration survey results obtained through this project's survey and site visit activities. All results have been analyzed and compared for reasonableness against overall state consumption and consideration of past participation.

This section of the report presents an overview of the approach and methodology that was used to ultimately determine the various savings potentials additional energy efficiency opportunities in New Hampshire.

3.5.1 Energy Efficiency Potential – Key Data Sources

Data required for performing the energy efficiency potential analysis elements of this study can be grouped into three major categories:

- Measure-specific data including: energy savings (kWh, kW, MMBTu), measure costs (full/incremental), measure lives (full/effective and persistence), etc.
- New Hampshire customer-specific historical, current and forecasted data including: number and types of customers (residential, low income, single/multi-family, commercial, industrial), customer sales by customer class and end use (space heating, space cooling, water heating, lighting, etc.), customer types (SIC/NAICS), average size (square footage of typical single, multi-family homes and commercial/industrial buildings), typical energy use intensity broken down by end use (lighting, cooling, water heating, process), saturation of electric water heating, central cooling, other energy efficiency measures and appliances (and associated appliance saturation trends), and peak load coincidence factors for major electric end-uses by sector.
- New Hampshire statewide and utility-specific and other system-related data including: forecast of electric and natural gas avoided costs (generation, transmission, distribution), electric line losses, reserve margin planning assumption, general rate of inflation and appropriate discount rate, and information on environmental benefits that may occur per kWh or MMBTu saved from energy efficiency programs. Values and sources for these data are provided in Appendix H.

3.5.2 Energy Efficiency Potential Calculation Stages

Three key calculations that have been undertaken to complete this assessment are described below. Following the descriptions, these three stages of potential energy savings calculation are shown graphically in a Venn diagram in Figure 16.³⁴ A fourth stage, developed for this project, relates to calculation of the likely obtainable potential (a subset of the maximum achievable cost effective potential), and is described separately at the end of this section. Savings interactions for measures like lighting and lighting controls are taken into account at every potential stage listed below.

The first stage in determining energy efficiency potential requires estimation of the technical potential for energy savings in New Hampshire. **Technical potential** is defined as the complete penetration of all measures analyzed in applications where they are deemed to be technically feasible from an engineering perspective. The technical potential for electric energy efficiency for this study was developed from estimates of the technical potential of individual energy efficiency measures applicable to each sector and for relevant end-uses within each sector (residential, commercial, industrial, energy efficient space heating, energy efficient water heating, etc.). For each energy efficiency measure, GDS calculated the electricity savings that could be captured if 100 percent of inefficient electric appliances and equipment were replaced instantaneously (where they are deemed to be technically feasible). Separate technical potentials were calculated for natural gas and related propane and oil saving measures, also by sector and end-use.

The second stage relates to calculation of the maximum achievable energy efficiency potential. **Maximum Achievable potential** is defined as the maximum penetration of an efficient measure that would be adopted absent consideration of cost or customer behavior. The term "achievable" refers to efficiency measure penetration, based on estimates of New Hampshire-specific building stock, energy efficient equipment saturations and realistic penetration levels that can be achieved by 2018 if all remaining standard efficiency equipment were to be replaced on burnout (at the end of its useful measure life) and where all new construction and major renovation activities in the state were done using energy efficient equipment and construction/installation practices. Under this scenario, energy efficient measures with measure lives over ten (10) years would have their potential savings calculated based on the study life divided by measure life ((Study Life = 10) / Measure Life).

In certain circumstances, where early replacement of specific measures is becoming standard practice, maximum achievable potential includes the retrofit of measures before the end of their useful measure life (i.e., T8 lighting, insulation and weatherization of existing homes). In such cases, the entire stock of measures to be retrofitted were modeled so that all were replaced over the ten year study period.

Calculation of the Maximum Achievable Cost Effective (M.A.C.E) potential is the third stage. **Maximum Achievable Cost Effective potential** is defined as the potential for the realistic penetration of energy efficient measures that are cost effective according to the Total Resource Cost (TRC) Test, and would be adopted given aggressive funding levels, and was determined absent consideration of customer behavior. A concerted, sustained campaign involving highly aggressive programs and market interventions would be required to achieve this level of savings.

To develop the maximum achievable cost effective potential, GDS retains only those electric and non-electric energy efficiency measures in the analysis that were found to be cost effective (according to the TRC) based on individual measure cost effective analyses conducted in this study. Energy efficiency measures that are not cost effective were excluded from the estimate of maximum achievable cost effective energy efficiency potential.

Potentially Obtainable scenario is a new output developed for this study and can be defined as an estimate of the potential for the *realistic penetration over time* of energy efficient measures that are cost effective according to the NH TRC, and would be adopted after consideration of customer behavior and given aggressive funding levels, and by determining the level of market penetration that can be achieved with a concerted, sustained campaign involving highly aggressive programs and market interventions. As demonstrated later in this report, the State of New Hampshire and its electric and natural gas utilities would need to continue to undertake, and perhaps aggressively expand its efforts to achieve these levels of savings.

Based on information collected through this project's telephone surveys and site visits, a Potentially Obtainable scenario was developed for each customer sector by electric and non-electric fuel types.

Figure 16 below shows the four stages of electric energy savings potential (this Venn diagram figure is for illustrative purposes only and does not reflect actual data for New Hampshire).

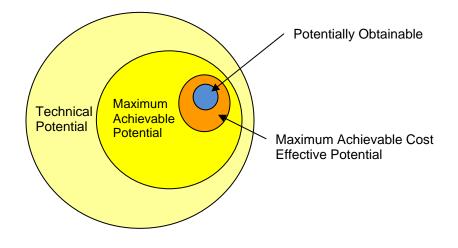

Figure 16. Venn Diagram of the Stages of Energy Savings Potential

3.5.3 General Methodological Approach

The GDS Team's analytical approach began with a careful assessment of the existing saturation of energy using equipment and penetration of energy efficiency measures that has already been achieved in New Hampshire. As discussed earlier in this section, this was accomplished through a combination of primary data collection and identification, review and documentation of secondary data sources. For each energy efficiency measure, this analysis assessed how much energy efficiency has already been accomplished as well as the remaining potential for energy efficiency savings. For example, if 100 percent of the homes in New Hampshire had electric lighting, and 30 percent of light sockets were already using high efficiency compact fluorescent bulbs (CFLs), then the remaining potential for energy efficiency savings is the 70 percent of light sockets in the residential sector that are not already using high efficiency fluorescent bulbs.

The general methodology used for estimating the potential for energy efficiency in the residential, commercial and industrial sectors in New Hampshire included the following steps:

- 1. Identification of energy efficiency measures to be included in the assessment.
- 2. Identification of data sources for determining costs and savings for all electric and nonelectric energy efficiency measures.
- 3. Determination of the characteristics of each energy efficiency measure including its incremental or total cost, electric energy consumption and savings, demand and MMBTu savings, current saturation, the percent of installations that are already energy efficient, and the useful life of the measure (with care taken to document the sources for each characteristic and to recognize potential difference in values by sector, building type and/or time of installation i.e., new construction, existing buildings, replace on burnout, retrofit). In addition, the determination of any technical limitations or barriers that may be present when attempting to install an energy efficient measure is also considered.
- 4. Calculation of cost-effectiveness screening metrics (e.g., the Total Resource Cost Test benefit cost ratio) and sorting of measures from least-cost to highest cost per kWh (or MMBTu) saved. Interactions between measures were not considered for determining measure specific benefit cost ratios.
- Collection and analysis (where data was available) of the baseline and forecasted characteristics of the electric and non-electric end use markets, including equipment saturation levels and consumption, by market segment and end use over the forecast period.
- 6. Integration of measure characteristics and baseline data to produce estimates of cumulative costs and savings across all measures.
- 7. Determination of the cumulative technical and maximum achievable potentials using supply curves, by sector (separately for electric and non-electric measures).
- 8. Determination of the achievable cost effective potential for electric and non-electric energy savings over the forecast period.
- 9. Estimation of the likely obtainable potential for electric and non-electric energy savings over the forecast period.

A key element in this approach is the use of energy efficiency supply curves. The advantage of using an energy efficiency supply curve is that it provides a clear, easy-to-understand framework for summarizing a variety of complex information about energy efficiency technologies, their costs, and the potential for energy savings. Properly constructed, an energy-efficiency supply curve avoids the double counting of energy savings across measures by accounting for interactions between measures. The supply curve also provides a simplified framework to compare the costs of energy efficiency measures with the costs of energy supply resources.

The supply curve is typically built up across individual measures that are applied to specific base-case practices or technologies by market segment. Measures are sorted on a least-cost basis and total savings are calculated incrementally with respect to measures that precede them. Supply curves typically, but not always, end up reflecting diminishing returns, i.e., costs increase rapidly and savings decrease significantly at the end of the curve. There are a number of other advantages and limitations of energy-efficiency supply curves (see, for example, Rufo 2003).³⁵

³⁵ Rufo, Michael, 2003. Attachment V – Developing Greenhouse Mitigation Supply Curves for In-State Sources, *Climate Change Research Development and Demonstration Plan*, prepared for the California Energy Commission, Public Interest Energy Research Program, P500-03-025FAV, April. <u>http://www.energy.ca.gov/pier/reports/500-03-025fs.html</u>

3.5.4 Energy Efficiency Potential Calculations - Core Equations

This section describes the calculations used to estimate the energy efficiency potential in the residential, commercial, and industrial sectors. There is a core equation, shown below, used to estimate the technical potential for each individual efficiency measure and it is essentially the same for each sector. However, for the residential sector, the equation is applied using a "bottom-up" approach where the equation inputs are displayed in terms of the number of homes or the number of high efficiency units (e.g., compact fluorescent light bulbs, high efficiency air conditioning systems, programmable thermostats, etc.). For the commercial and industrial (C&I) sectors, a "top-down" approach was used for developing the technical potential estimates. In this case, the data is displayed in terms of energy rather than number of units or square feet of floor area.³⁶ For the commercial and industrial sectors, GDS used New Hampshire-specific equipment saturation and end use data wherever such data was available. The core equations used by GDS are very similar to the equations used in prior energy efficiency potential studies.

3.5.4.1 Core Equations for Estimating Technical Potential

The core equation used to calculate the energy efficiency technical potential for each individual efficiency measure for the residential sector is shown below. Section 4 provides more details on how this core equation was applied within the residential sector's bottom-up modeling approach.

Technical Potential of Efficient Measure		Total Number of Residential Households	х	Base Case Equipment End Use Intensity (annual kWh use per home)	Х	Base Case Factor	Х	Remaining Factor	х	Convertible Factor	х	Savings Factor	
---	--	---	---	---	---	---------------------	---	---------------------	---	-----------------------	---	-------------------	--

where:

- Number of Households is the number of residential customers in the market segment.
- **Base-case equipment end use intensity** is the energy used per customer per year by each base-case technology in each market segment. This is the consumption of the energy using equipment that the efficient technology replaces or affects. For example purposes only, if the efficient measure were a high efficiency light bulb (CFL), the base end use intensity would be the annual kWh use per bulb per socket associated with an incandescent light bulb that provides equivalent lumens to the CFL.
- **Base Case factor** is the fraction of the end use energy that is applicable for the efficient technology in a given market segment. For example, for residential lighting, this would be the fraction of all residential electric customers that have electric lighting in their household.
- **Remaining factor** is the fraction of applicable dwelling units or lighting sockets that have not yet been converted to the energy efficiency measure; that is, one minus the fraction of households that already have the energy-efficiency measure installed.

³⁶ It is important to note that square-foot based saturation assumptions cannot be applied to energy use values without taking into account differences in energy intensity (e.g., an area covered by a unit heater may represent two percent of floor space but a larger percent of space heating energy in the building because it is likely to be less efficient than the main heating plant).

- **Convertible factor** is the fraction of the applicable dwelling units that is technically feasible for conversion to the efficient technology from an *engineering* perspective (e.g., it may not be possible to install CFLs in all light sockets in a home because the CFLs may not fit in every socket in a home).
- **Savings factor** is the percentage reduction in energy consumption resulting from application of the efficient technology.

The core equation used to calculate the electric energy efficiency technical potential for each individual efficiency measure for the commercial and industrial sectors is shown below. More information is presented in Sections 5 and 6 regarding how this core equation was applied within the commercial and industrial sectors using the top-down modeling approach.

where:

- Total end use kWh or MMBTu sales (by segment) is the forecasted level of electric or natural gas sales for a given end-use (e.g., space heating) in a commercial or industrial market segment (e.g., office buildings).
- **Base Case factor** is the fraction of the end use energy that is applicable for the efficient technology in a given market segment. For example, for fluorescent lighting, this would be the fraction of all lighting kWh in a given market segment that is associated with fluorescent fixtures.
- **Remaining factor** is the fraction of applicable kWh sales that are associated with equipment that has not yet been converted to the energy efficiency measure; that is, one minus the fraction of the market segment that already have the energy-efficiency measure installed.
- **Convertible factor** is the fraction of the equipment or practice that is technically feasible for conversion to the efficient technology from an *engineering* perspective (e.g., it may not be possible to install VFDs on all motors in a given market segment).
- **Savings factor** is the percentage reduction in energy consumption resulting from application of the efficient technology over the base technology.

Technical electric and non-electric energy efficiency savings potential was calculated in two steps. In the first step, all measures are treated *independently*; that is, the savings of each measure are not reduced or otherwise adjusted for overlap between competing or synergistic measures. By treating measures independently, their relative economics are analyzed without making assumptions about the order or combinations in which they might be implemented in customer buildings. However, the total technical potential across measures cannot be estimated by summing the individual measure potentials directly because some savings would be double-counted. For example, the savings from a weatherization measure, such as low-e ENERGY STAR[®] windows, are partially dependent on other measures that affect the efficiency of the system being used to cool or heat the building, such as high-efficiency space heating

equipment or high efficiency air conditioning systems; the more efficient the space heating equipment or electric air conditioner, the less energy can be saved from the installation of low-e ENERGY STAR windows.

For the residential and commercial sectors, GDS addressed the new construction market as a separate market segment, with measures targeted specifically at the new construction market. In the residential new construction market segment, for example, detailed energy savings estimates for the ENERGY STAR Homes program were used as a basis for determining energy savings for this market segment in New Hampshire. For the commercial sector, in addition to end-use specific measures applicable to new construction projects, integrated design measures (e.g., for building shell, lighting design, etc.) were assessed. Within the new construction market segment for the commercial sector, an assumption was built into the model that ½ the commercial new construction sales were attributed to new construction projects, while the other half was directly attributable to growth of the existing commercial market segment. In the case of the industrial sector, the model functions very similarly but uses an all-inclusive factor which incorporates the four (4) factors discussed above into one multiplier to achieve the same approximate end result as the individual factor approach.

3.5.5 Rates of Implementation for Energy Efficiency Measures

For new construction, energy efficiency measures can be implemented when each new home or building is constructed, thus the rate of availability is a direct function of the rate of new construction. For existing buildings, determining the annual rate of availability of savings is more complex. Energy efficiency potential in the existing stock of buildings can be captured over time through two principal processes:

- 1. as equipment replacements are made normally in the market when a piece of equipment is at the end of its useful life (we refer to this as the "market-driven" or "replace-on-burnout" case); and,
- 2. at any time in the life of the equipment or building (which we refer to as the "retrofit" case).

Market-driven measures are generally characterized by incremental measure costs and savings (e.g., the incremental costs and savings of a high-efficiency versus a standard efficiency air conditioner); whereas retrofit measures are generally characterized by full costs and savings (e.g., the full costs and savings associated with retrofitting ceiling insulation into an existing attic). A specialized retrofit case is often referred to as "early replacement" or "early retirement". This refers to a piece of equipment whose replacement is accelerated by several years, as compared to the market-driven assumption, for the purpose of capturing energy savings earlier than they would otherwise occur.

For the market driven measures, existing equipment is assumed to be replaced with high efficiency equipment at the time a consumer is shopping for a new appliance or other energy using equipment, or if the consumer is in the process of building or remodeling. Using this assumption, equipment that needs to be replaced (replaced on burnout) in a given year is eligible to be upgraded to high efficiency equipment. For the retrofit measures, savings can theoretically be captured at any time; however, in practice it takes many years to retrofit an entire stock of buildings, even with the most aggressive of efficiency programs.

As noted above, a special retrofit case is "early retirement" of energy equipment that is still functioning well, and replacing such equipment with high efficiency equipment. For this project, early retirements were considered only for a small number of measures (e.g.,

insulation/weatherization). For these early retirement energy efficiency measures, GDS assumed the same measure life for the measure that was replaced early as a time of replacement measure. In addition, savings were based on the whole measure life for retrofit / early replacement type measures.

3.5.6 Benefit/Cost (Cost-Effectiveness) Modeling

To determine maximum achievable cost effective potential GDS has used its existing energy efficiency measure and program screening tool. The GDS screening tool is user friendly, well documented, and provides the following benefit/cost ratio calculations: Total Resource Cost Test, Utility Cost Test, Participant Test, Rate Impact Measure Test, and Societal Test. For this Report, only the Total Resource Cost Test was used for screening purposes (consistent with New Hampshire utility and Commission procedures). The annual discount rate assumed for this test to determine net present values (NPV) is 5.0%.

The model is comprehensive and uses the following types of data as input: costs, useful lives and energy savings of energy efficiency, load management or demand response measures, load shape impacts of electric or natural gas energy efficiency measures, avoided costs of electricity for generation, transmission and distribution, avoided costs of natural gas and other fuels (propane, fuel oil, etc.), avoided water costs, projected or actual measure or program penetration assuming no program, projected or actual measure or program penetration with a program, participant costs, energy efficiency organization or utility costs (including rebates or financial incentives), non-energy benefits of measures or programs, electric line losses, discount rate, and inflation rate.

As noted above, the model provides calculations of five benefit/cost ratios as well as year-byyear and cumulative energy savings, dollar costs and dollar benefits. The GDS screening tool provides the flexibility to vary assumptions in the analysis to reflect uncertainty, changing market circumstance, statutory change or other factors that influence assessment of reasonably available potential through the efficiency utility. The GDS measure and program screening tool allows for the incorporation of changes to reflect real world circumstances and a dynamic environment. The GDS tool exists in a single Microsoft Excel file, and includes several linked worksheets that present clearly documented inputs and outputs. More information on the model and key input assumptions being used for this report is included in Appendix H.

3.6 Assessment of Past and Current Program Capture and Recommendations

For this task, the GDS Team evaluated the penetration of energy efficiency savings (electric and natural gas) resulting from past and current utility-sponsored program activities. A review of the utilities' annual Core New Hampshire Program Highlights reports formed the basis for this evaluation and results are presented from both a cumulative savings as a percent of sales and number of customers served as a percent of population basis. Recommendations for potential modifications to program and measure offerings that could increase the likelihood of achieving identified potentials are made and have been developed mainly through information on barriers collected directly from New Hampshire utility customers (through this project's telephone surveys and site visits) and supplemented by the GDS Team's experience with looking at programs from a logic-modeling perspective, and extensive knowledge of other local, regional and national programs and best practices.³⁷ Results from these analysis and assessments are presented in Section 8 of this report.

³⁷ Assessments based on a logic-modeling perspective recognize current program resources (dollars, staffing, etc.) and activities (measure installations, promotional rebates/incentives, marketing/outreach, education/training, etc.)

Section 4: Residential Sector Energy Efficiency Potential

This section of the report presents the estimates of electric and non-electric technical (best), technical (traditional), maximum achievable, maximum achievable cost effective, and potentially obtainable energy efficiency potential for the existing and new construction market segments of the residential sector in New Hampshire. More information regarding how these potentials were derived is also presented.

According to this analysis, there is still a large remaining potential for electric and non-electric energy efficiency savings in the residential sector. Table 42 and Table 43 below summarize the savings by potential type by the year 2018 for residential electric and non-electric measures respectively. The estimated total costs to achieve each level of savings by 2018 are also presented in these tables. In addition, Table 42 presents peak demand savings for each potential level of savings associated with the electric energy efficiency measures.

Table 42. Summary of Residential <u>Electric</u> Energy Efficiency Savings Potential

	Estimated Cumulative	Savings in 2018 as a Percent of		Estimated Total Cost	Estimated Total Cost to
	Annual Savings by 2018	Total 2018 Residential Sector	Estimated	to Achieve	Achieve
	(MWh)	Electric Energy Consumption	Summer MW*	(Cummulative)	(Annual)
Technical Potential (Best Only)	1,770,861	31.7%	66.7	\$ 2,554,517,348	\$ 255,451,735
Technical Potential (Good, Better, Best)	1,489,861	26.7%	56.1	\$ 2,149,167,880	\$ 214,916,788
Max Achievable Potential	1,217,145	21.8%	45.9	\$ 1,214,926,125	\$ 121,492,613
Max Achievable Cost Effective Potential	1,170,398	20.9%	44.1	\$ 632,287,942	\$ 63,228,794
Potentially Obtainable	698,069	12.5%	26.3	\$ 383,050,068	\$ 38,305,007

33% * Estimated Summer Load Factor

Table 43. Summary of Residential Non-Electric Energy Efficiency Savings Potential

	Estimated Cumulative Annual Savings by 2018 (MMBTU)	Savings in 2018 as a Percent of Total 2018 Residential Sector Other Fuels Energy Consumption	timated Total Cost to Achieve (Cummulative)	Est	timated Total Cost to Achieve (Annual)
Technical Potential (Best Only)	16,918,392	50.4%	\$ 3,220,297,934	\$	322,029,793
Technical Potential (Good/Better/Best)	12,099,639	35.7%	\$ 2,277,404,262	\$	227,740,426
Max Achievable Potential	7,463,743	22.0%	\$ 1,206,916,417	\$	120,691,642
Max Achievable Cost Effective Potential	6,313,954	18.6%	\$ 456,169,489	\$	45,616,949
Potentially Obtainable	3,633,554	10.7%	\$ 200,483,725	\$	20,048,372

On the electric side, the maximum achievable cost effective potential in the residential sector is over 1.1 million MWh, approximately 21 percent of the New Hampshire residential sector sales forecast in 2018. With regard to non-electric end uses, the maximum achievable cost effective potential in the residential sector is more than 6.3 million MMBTu, just under 19 percent of New Hampshire's residential sector fossil fuel (natural gas, oil and propane) sales forecast in 2018. The lists of measures that make up the savings for each of these levels are shown in Table 44 and Table 45 in Section 4.2.1 below.

and seek to identify their causal links to anticipated outputs (measures installed, in-program energy and capacity savings, # of customers served, market actors trained, etc.), short-, intermediate- and long-term outcomes (changes in awareness and behavior, market-wide/sustainable energy, economic and environmental benefits, etc.). In addition, logic models recognize the existence and potential impacts of external influences (price of energy, state of the local and regional economy, federal tax incentives, other non-program sponsored activities, etc.).

4.1 Residential Sector Savings Methodology Overview

The residential sector analysis was modeled using what is considered a "bottom-up approach". This methodology, shown visually in Figure 17 below:

Figure 17. Residential Sector Savings Methodology – Bottom Up Approach

of Residential Homes

As shown in this figure, the methodology started at the bottom based on the number of residential customers (splitting them into single-family and multi-family customers as well as existing vs. new construction). From that point, each home was then broken into a series of end-uses depending on whether the home fits the single-family or multi-family profile. An example of an end-use might be "Single-Family Water Heating". From that point, a series of measures are identified that belong to that end-use. To keep with our example, we would then create a series of measures such as "Energy Star Clothes Washer", "Energy Star Dishwasher", "Pipe-Wrap", etc – all these measures fit into that end use category of Single-Family Water Heating.

The next step in our bottom up approach was to determine how many of the homes in the profile we are looking at (single-family or multi-family) have each of those measures within each of those end uses. This is one of the multiple applicability factors that were used to screen each measure to determine savings. The applicability factors include the base case factor, the remaining factor, the convertible factor, and the savings factor. The full formula to determine savings at the measure level is shown below.

Technical Potential of Efficient Measure	Total Number of Residential Households	Base Case Equipment End Use X Intensity (annual kWh use per home)	x	Base Case Factor	x	Remaining Factor	x	Convertible Factor	x	Savings Factor	
---	---	---	---	---------------------	---	---------------------	---	-----------------------	---	-------------------	--

The goal of the formula is to determine how many households this measure applies to (base case factor), then of that group, how many already have the efficient version of the measure we are installing (remaining factor). From there, we looked to make sure there were not any technical reasons why the measure cannot be installed, and if so, made a correction (convertible factor) for that reason. The last factor which needed to be applied was the savings factor, which is the percentage savings achieved from installing the efficient measure over a

standard measure. In cases where multiple measures could interact within the same end use, a "more than one choice" factor was also included in the model to avoid double counting of potential savings. In addition, the model ranks measures by levelized cost in order to make assumptions about which measures will be installed in what order. This ranking also takes into account measure interactions where applicable so that savings are not over-stated due to double-counting. For example, if you install insulation and air seal, and then install a programmable thermostat, the savings potential for the thermostat is reduced to account for the reality that insulation has already been improved thus reducing the potential for higher levels of savings. This type of scenario is done throughout the residential model among a variety of scenarios within the models.

Another example to help illustrate the functionality of the model is single family homes with gas fired boilers. This measure would have space heating and space cooling measures installed in the following levelized cost order: programmable thermostats, energy efficient windows, and high efficiency boiler. The base use for space heating and space cooling would be adjusted based on savings from each measure. The full base use would have programmable thermostat savings applied. This new adjusted base use would then be used for the energy efficient window savings and finally the further adjusted base use would then be used for the high efficiency boiler savings.

One other example is single family homes with electric water heaters. In this case, the measure includes more than one choice for dishwasher upgrades and efficient electric water heaters upgrades. The electric water heating measures are in the following levelized cost order: low flow shower showerhead/faucets, Energy Star Dishwasher, efficient water heater, beyond Energy Star dishwasher, pipe wrap, high efficiency water heater, water heater blanket, Energy Star clothes washer, heat pump water heater, whole-house tankless water heater, and solar water heating. In this case the adjusted domestic hot water base use for calculated savings is more complicated. Where a second measure for the same use would be installed the base usage would not be reduced by the earlier measure. The most direct path for base usage reduction is the following: initial base usage is used for the low flow showerhead/faucets; then the Energy Star dishwasher reduces the domestic hot water base use by the percentage of this measure's electric savings that is associated with water heating; then the low flow and dishwasher reductions are used for the base usage for efficient water heater savings, then pipe wrap, then water heater blanket, then Energy Star Clothes Washer and finally solar water heating. In the case of high efficiency water heater- the base usage is decreased by low flow showerhead/faucets, Energy Star dishwasher water heating savings and pipe wrap before the high efficiency water heater savings are applied.

This type of process was run on every measure within all measure end-use categories and for all customer groups (single-family, multi-family, new construction, existing-construction – and blends thereof). This process, while described here at a very high level, was run within the confines of a complicated model under various scenarios to determine the varying savings potential levels.

In addition to the modeling technique described above, custom measures were included for the residential sector to achieve "Good, Better, Best" scenarios for weatherization (split further by each fuel type) and integrated building design (for each fuel type as well). All of these scenarios were reality-based through use of building simulation software to achieve targeted savings and cost levels for each distinct scenario level. This process required a mix of measures from lower cost and complexity to higher cost and complexity. The weatherization packages were designed to allow a degree of residential customers to follow a "good, better, or best" approach for insulating their existing home. For each of the weatherization approaches, a set of costs and

savings assumptions were developed, as well as assumptions regarding current market penetration.

For the new home stock, a good, better, best approach was also created along with assumptions regarding the percentage of new home customers who would be likely to follow each approach. The assumption made was that 80% of new homes would do one of the three (3) packages, while the remaining 20% would not participate in efficiency programs or install efficiency measures. More information regarding the specific measures and associated costs included within each good, better, best scenario is presented in Appendix I.

The costs to achieve savings potential estimates within the residential sector are calculated on a measure by measure basis using the levelized cost (\$/kWh in the electric model and \$/MMBTu within the non-electric model) for each measure. These figures (levelized costs) represent the cost to save a unit of energy. These levelized costs are then taken and multiplied (again at the measure level) by the 2018 annual savings associated with the potential level being addressed (technical potential, maximum achievable, etc.). A net present value (NPV) formula is then used in conjunction with each measure's measure life along with an overall discount rate to determine the \$ cost per /first year kWh (or MMBTu) saved for each measure. The cost per first year savings figure is then multiplied by the savings potential estimate being evaluated in order to yield the cost to achieve the savings potential level to yield the total cost to achieve savings in the residential sector (within the potential level being analyzed) to represent the cost to achieve the study length (10 years) in order to yield an estimate of annual spending needed to reach the potential level target in question.

4.2 Residential Sector – Energy Efficiency Potential Results

Eighty-seven (87) residential electric, and one-hundred-ten (110) residential non-electric energy efficiency measures or programs were included in the analysis for the residential sector. In order to develop the list of energy efficiency measures to be examined, GDS worked closely with project sponsors and reviewed recent measure life, savings and cost assumptions studies including a Measure Life Report prepared by GDS for the New England State Program Working Group in June 2007 and a GasNetworks measures assumptions update project completed by GDS during the summer 2008. In addition, GDS reviewed other related electric and non-electric residential energy efficiency measure-specific data sources and technical potential studies that have been conducted recently in the US. Focus was for comprehensiveness on the electric and natural gas measures, less so for fuel oil and propane. Even within electric and natural gas some measures were not analyzed due to a combination of measure-specific-limitations, and unavailability of reliable data (e.g., A/C peak demand savings from off peak cooling with thermal energy storage, more advanced windows than double pane with low-E, super high efficient gas hot water heaters/boilers and combo systems, air drying of laundry, etc.).

The set of energy efficiency measures considered was pre-screened to include mainly those measures that are currently commercially available and cost effective (i.e., achieving a TRC benefit/cost ratios equal to or greater than 1.0 – although measures with TRC ratios between 0.9 and 1.0 were also included). Thus, emerging technologies not currently in the marketplace that had benefit cost ratios below 0.9 were not included in the analysis. The portfolio of measures includes retrofit and replace on burnout programmatic approaches to achieve energy efficiency savings.

4.2.1 Characteristics of Energy Efficiency Measures

GDS collected data on the energy savings, incremental costs, useful lives and other key "per unit" characteristics of each of the residential electric and non-electric energy efficiency measures. Estimates of the size of the eligible market were also developed for each efficiency measure. For example, electric water heater efficiency measures are only applicable to those homes in New Hampshire that have electric water heaters. More information regarding measure-specific savings, cost and measure life assumptions can be found in Appendix E.

For the residential new construction market segment, GDS calculated a forecast of the number of new homes estimated to be built each year based on NH new housing permits as reported by the US census bureau³⁸ The sizes of various end-use market segments were informed based on project primary data collection efforts. This analysis is based on the most recent residential electric sales forecast for New Hampshire for the years 2009 to 2018.³⁹ Energy-efficiency measures were analyzed for the most important electric and non-electric consuming end uses in the residential sector.

Tables⁴⁰ 44 and 45 below list the residential sector electric and non-electric energy efficiency measures included in the technical (best), technical (traditional), maximum achievable, maximum achievable cost effective, and potentially obtainable potential analyses.

³⁸ The source of this economic/demographic forecast for NH is the US Census Bureau's reporting of new building permits. http://www.census.gov/const/www/permitsindex.html

³⁹ This residential sector load forecast was provided to GDS by project sponsors.

Table 44. Residential <u>Electric</u> Energy Efficiency Savings Potential by Measure

Measure Name	 Tech. Potential 	Max. Achievable	Max. Achievable C.E.	% of MACE	Pot. Obtainable
CFL Bulbs (Homes w/ partial CFL installation)-High Use	205,995,520	205,995,520	205,995,520	17.6%	150,376,729
Timers/Motion/Photocell controlled outdoor lighting	165,140,752	165,140,752	165,140,752	14.1%	60,276,374
CFL Bulbs (Homes w/ no CFL bulbs installed)-High Use	127,335,921	127,335,921	127,335,921	10.9%	92,955,222
Phantom Power	107,603,656	107,603,656	107,603,656	9.2%	39,275,334
Second Refrigerator Turn In	91,805,345	91,805,345	91,805,345	7.8%	67,017,902
CFL Bulbs (Homes w/ partial CFL installation)-Low Use	74,907,462	62,422,885	62,422,885	5.3%	45,568,706
Energy Star Clothes Washer (w/ Electric DWH)	44,725,994	40,659,995	40,659,995	3.5%	29,681,796
Energy Star office equipment including monitors, copiers, multi-function machines.	39,473,144	39,473,144	39,473,144	3.4%	28,815,395
CFL Bulbs (Homes w/ no CFL bulbs installed)-Low Use	46,303,971	38,586,643	38,586,643	3.3%	28,168,249
Efficient Furnace Fan (Non-Electric Furnace)	58,906,077	32,725,599	32,725,599	2.8%	11,944,843

4.2.2 Residential Energy Efficiency Potential Comparisons and Savings By Measure Type

Figure 18 and Figure 19 display a graphical comparison of the varying degrees of potential results for both the electric and non-electric sector.

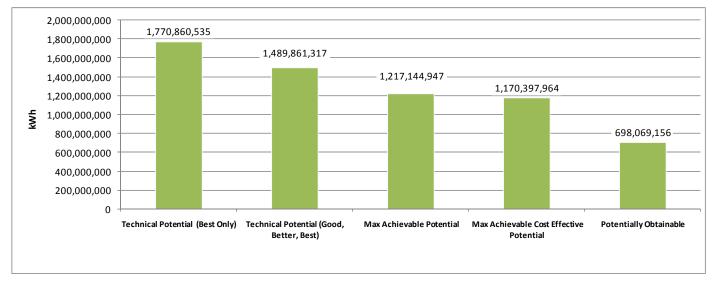

Figure 18. Residential Electric Savings Potential Results Comparison

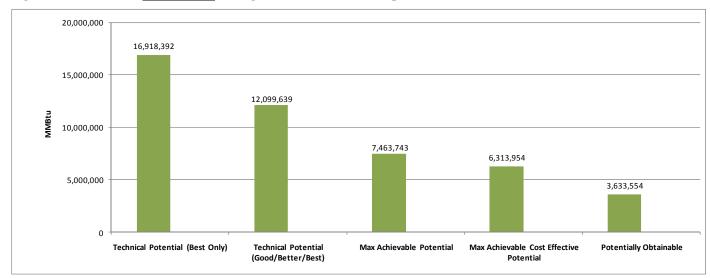

Figure 19. Residential Non-Electric Savings Potential Results Comparison

Figure 20 displays a graphical comparison of the varying electrical end-uses within the residential sector. As shown, lighting single-family and lighting multi-family make up the greatest savings potential focus areas (52% combined), followed by electric appliances at 16 percent (SF and MF combined), space heating and cooling (10% combined SF and MF), standby (phantom-load) power and water heating at nine percent each (SM/MF combined).

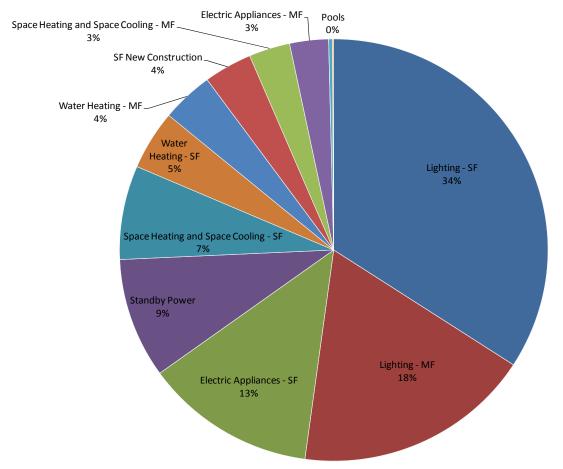

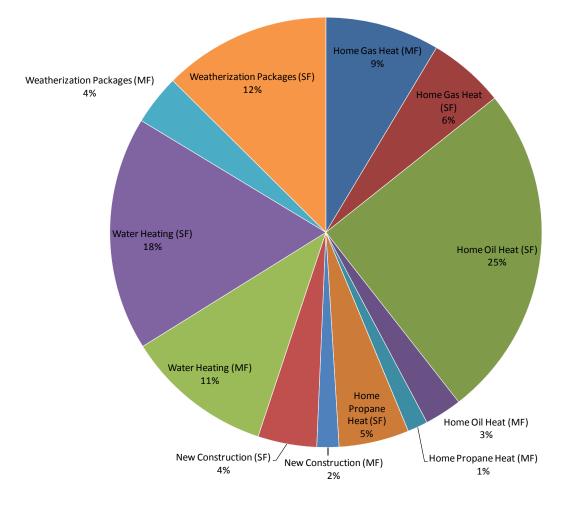

Figure 21 displays a graphical comparison of the varying non-electric end-uses within the residential sector. As shown, single-family home oil heating measures represent the largest area of savings potential at 25%, followed by single-family water heating at 18%, and then single-family weatherization packages at 12%. The remainder is comprised mostly of multi-family water heating, gas-heating measures for single and multi-family, and home propane heating measures.

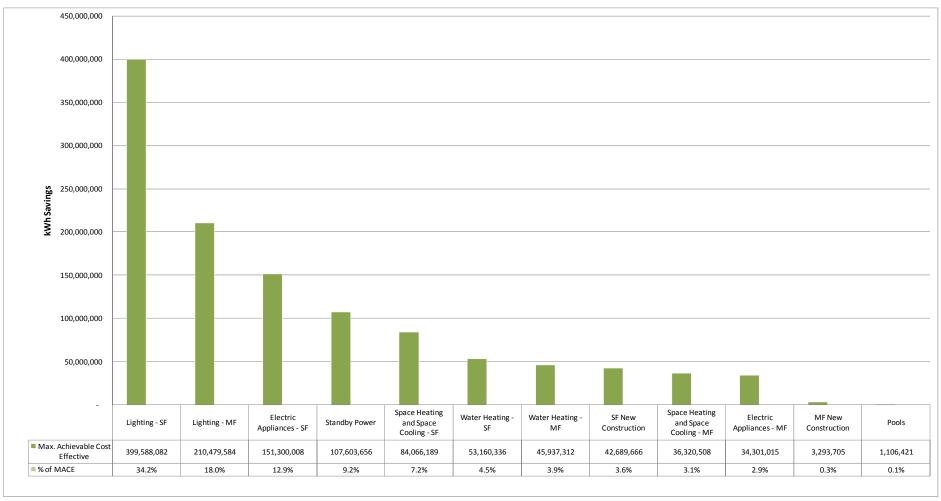

Figure 22 and Figure 23, displayed below, show a graphical comparison of the varying maximum achievable cost effective electric and non-electric savings by end use within the residential sector. While Figure 20 and Figure 21 show relative percent comparisons only, Figure 22 and Figure 23 show both relative and absolute (kWh and MMBTu) comparisons of the savings coming from each end use.

4.2.3 Residential Energy Efficiency Measure Supply Curves

This report also presents results in the form of electric and non-electric energy efficiency supply curves. As noted previously, the advantage of using an energy efficiency supply curve is that it provides a clear, easy-to-understand framework for summarizing a variety of complex information about energy efficiency technologies, their costs, and the potential for energy savings. Properly constructed, an energy-efficiency supply curve avoids the double counting of energy savings across measures by accounting for interactions between measures. The supply curve also provides a simplified framework to compare the costs of energy efficiency measures with the costs of energy supply resources.

The supply curves for residential electric energy efficiency savings are shown in Figure 24 through Figure 29. Supply curves for residential non-electric energy efficiency savings are shown in Figure 30 through Figure 35. These supply curves were built up across individual measures and were sorted on a lowest to highest cost basis per unit of energy saved. As shown in these figures, nearly 12 percent of the projected 2018 residential sector kWh sales could be offset by installing electric efficiency measures at a levelized cost of less than two cents per/kWh (see Figure 29). Nearly eight percent of the projected maximum achievable cost effective savings potential from non-electric efficiency measures could be obtained at a levelized cost of less than three dollars per/MMBTu (see Figure 35).

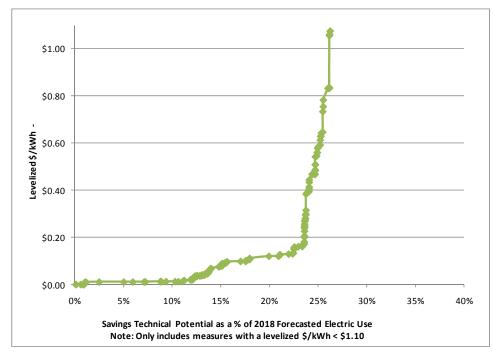

Figure 24. Residential <u>Electric</u> Energy Efficiency Supply (< \$1.10/kWh) Curve for NH – Technical Potential

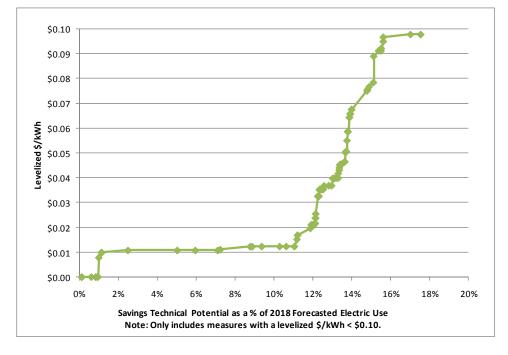

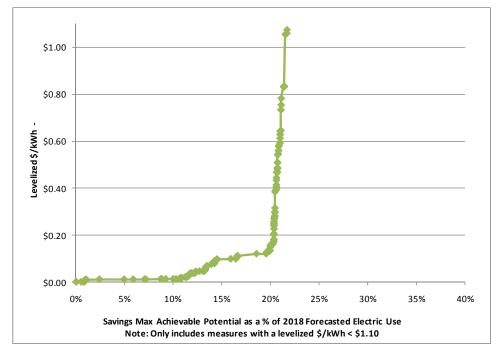

Figure 25. Residential <u>Electric</u> Energy Efficiency Supply (< \$0.10/kWh) Curve for NH – Technical Potential

Figure 26. Residential <u>Electric</u> Energy Efficiency Supply (< \$1.10/kWh) Curve for NH – Max Achievable

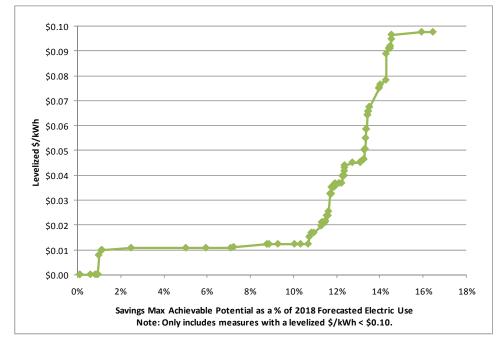

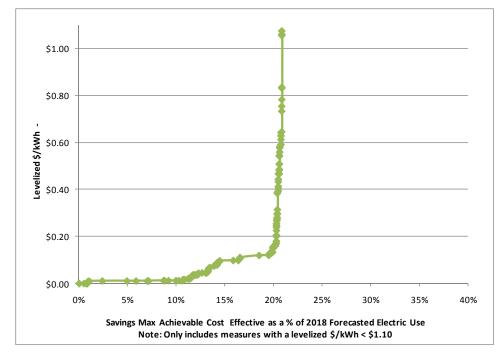

Figure 27. Residential <u>Electric</u> Energy Efficiency Supply (< \$0.10/kWh) Curve for NH – Max Achievable

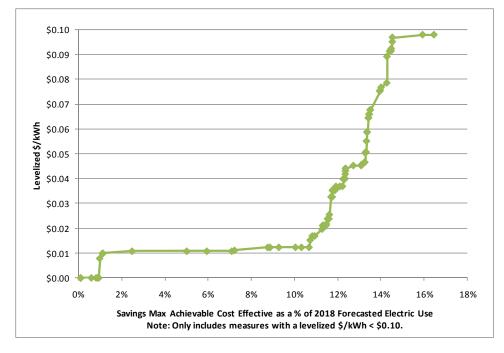

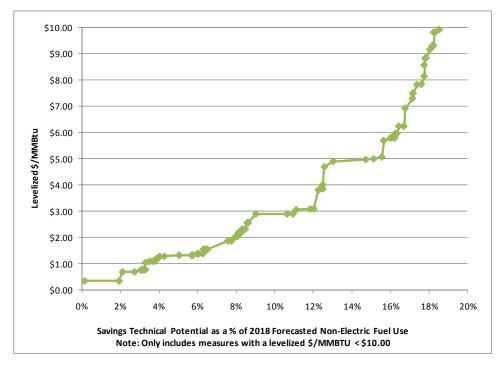

Figure 29. Residential <u>Electric</u> Energy Efficiency Supply (< \$0.10/kWh) Curve for NH – M.A.C.E.

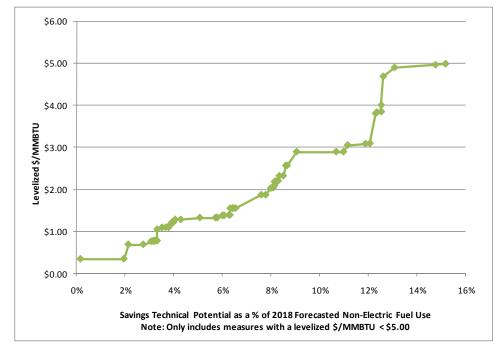

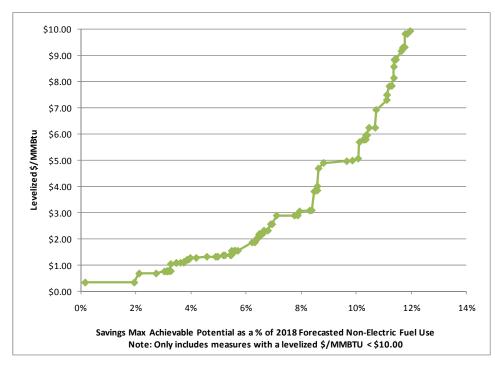

Figure 31. Residential <u>Non-Electric</u> Energy Efficiency Supply (< \$5/MMBTu) Curve for NH – Technical

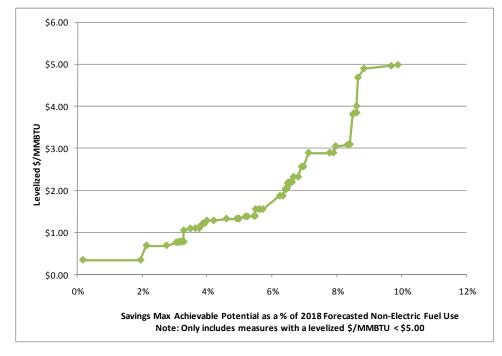

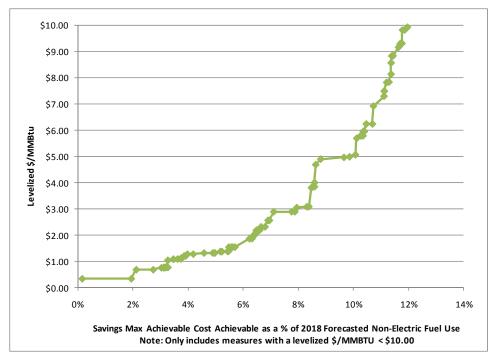

Figure 33. Residential <u>Non-Electric</u> Efficiency Supply (< \$5/MMBTu) Curve for NH – Max Achievable

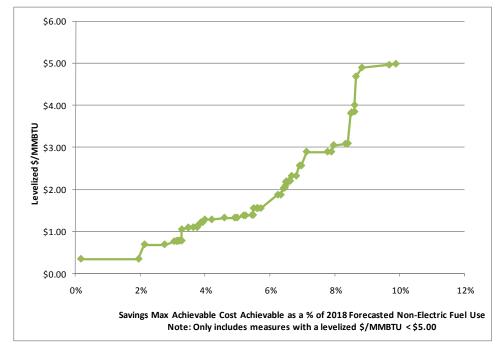

Figure 35. Residential <u>Non-Electric</u> Energy Efficiency Supply (< \$5/MMBTu) Curve for NH – M.A.C.E.

It is important to note that these levelized costs per unit of energy saved values exclude the costs for potential marketing, program design, administration and evaluation that would be required to encourage customer participation and to ultimately achieve any portion of this sectors savings potential.

Section 5: Commercial Sector Energy Efficiency Potential

This section of the report presents the estimates of electric and non-electric technical (traditional), maximum achievable, maximum achievable cost effective, and potentially obtainable energy efficiency potential for the existing and new construction market segments of the commercial sector in New Hampshire. More information regarding how these potentials were derived is also presented.

According to this analysis, there is still a large remaining potential for electric and non-electric energy efficiency savings in the commercial sector. Table 46 and Table 47 below summarize the savings by potential type by the year 2018 for commercial electric and non-electric measures respectively (separate potentials are shown for new construction, existing buildings and combined within each table).⁴⁰ The estimated total costs to achieve each level of savings by 2018 are also presented in these tables. In addition, Table 46 presents peak demand savings for each potential level of savings associated with the electric energy efficiency measures.⁴¹

Table 46.	Summary of	of Commercial	l Sector Electr	ic Energy Eff	ficiency Savings	s Potential

⁴⁰ The commercial sector sales forecast for the year 2018 was not available in terms of new and existing construction. As a result, in order to derive the split between new and existing construction, the growth of the sector over the ten (10) year study period was divided in half, and half was attributed to new construction sales, and the remaining half was attributed to growth in the existing sector.

⁴¹ For purposes of this study, a simplifying assumption was used to estimate peak demand savings. Percentage sector peak demand savings are calculated to show savings over the summer coincident peak demand period only and are not broken out separately for summer and winter peak periods.

Table 47. Summary of Commercial Non-Electric Energy E	Efficiency Savings Potential
---	-------------------------------------

On the electric side, the combined existing and new buildings maximum achievable cost effective potential in the commercial sector in 2018 is nearly 1 million kWh, just under 20 percent of the New Hampshire commercial sector sales forecast in 2018. With regard to non-electric potential for new and existing buildings combined, the maximum achievable cost effective potential in the commercial sector is over 7.7 million MMBTu, or 17% of the New Hampshire commercial sector fossil fuel (natural gas, oil and propane) sales forecast in 2018. The lists of measures that make up the savings for each of these levels are shown in Table 52 through Table 55 in Section 5.2.1 below.

5.1 Commercial Sector Savings Methodology Overview

The commercial sector analysis was modeled using what is considered a "top-down approach". This methodology, shown visually in Figure 36 below:

Figure 36. Commercial Sector Savings Methodology – Top Down Approach

As shown in this figure, the methodology is started at the top with the total projected 2018 kWh sales for the commercial sector. Those sales are then split up by building type using SIC codes of actual customer data (provided to us by project sponsors). After the sales are distributed across the building types, they are broken down further to end-uses (e.g. lighting, space heating, appliances) within each of the building types. From the end-use level, the energy is then applied to each of the measures using applicability factors. The base case factor is applied first, to inform the model regarding how much of the sales in a particular end use was applicable to the specific measure in question. After identifying how much energy each measure uses within that end use (i.e., what degree of the end use sales is going to each measure), then models then look at the remaining factor. As discussed in Section 3, the remaining factor identifies what percentage of the building type in question already has the efficient measure. The remaining factor is then one minus that penetration – resulting in the percentage, by building type, of each measure that can still be installed in within the commercial sector. The model then considers the savings factor, which is defined is the percentage savings achievable from moving from a standard efficiency measure to a high efficiency measure. Finally, adjustments are made for any technical limitations that would prevent the measure from being installed in certain applications via the convertible factor (engineering adjustment). This scenario is repeated for every measure within every building type, for new and existing construction, and for electric measures, and non-electric measures. The formula that has just been explained to calculate savings at the measure level is displayed below graphically.

Technical Potential of Efficient Measure	=	Total End Use kWh Sales by Building Type	x	Base Case Factor	x	Remaining Factor	x	Convertible Factor	x	Savings Factor
---	---	--	---	---------------------	---	---------------------	---	-----------------------	---	-------------------

Measure interactivity is also considered so as to prevent overstating (double-counting) of savings. To better illustrate this point, in the case of lighting, consider the upgrade of a T-12 fixture to a T-8, and then the installation of an occupancy control. In such a case, the occupancy control is only able to save the amount of energy left after the upgrade has taken place. Through functionality included within the GDS supply curve model, measures are ranked by benefit cost ratio (highest to lowest) as a proxy to determine the order by which measures are installed. Through a combination of the proper classification of the base case factors, and the rankings in the supply curve model, the potential for double-counting is methodically eliminated.

The supply curve model is designed in a manner that allows for each measure to have independent base, remaining, savings, and convertible factors for all of the nine (9) building types. In addition, every building type has its own energy consumption profile that defines how energy consumption within that building type is distributed among the end uses (e.g. lighting, water heating, appliances, etc) within the building type. This allows the model to run savings analyses on building specific energy consumption profiles and building specific energy savings profiles simultaneously in order to yield the most accurate and realistic savings potential estimates possible. In addition, individual models are run for commercial existing construction, and commercial new-construction for both electric and non-electric yielding a total of four unique (4) commercial supply curve models. The commercial electric models (existing and new

construction) were based on kWh sales in the year 2018, while the commercial non-electric model used 2018 MMBTu sales for natural gas, oil, and propane combined.⁴²

The measures within each building type are organized and grouped by the end use energy consumption pools that they have the ability to potentially save energy from. Lighting measures for instance are all working off of the lighting energy sales in the year 2018 as a basis or starting point for the energy savings potential within a particular building type. The ordering of the lighting related measures within this grouping is determined by benefit cost ratio. Measures with higher benefit cost ratios are assumed to be installed first, and then ranked in descending order on down the line. As a measure is installed, the model reduces the remaining sales left to be saved for the next measure (the actual algorithm for how this happens within the model on a measure to measure basis is more complex than what is being described here). So if a lighting fixture is upgraded, and then a control is installed, the control has less potential energy to save since the light it is controlling has already been upgraded to a more efficient version. This process is repeated until all measures within each end use are exhausted in order to yield the savings potential at the measure level, end-use level, and the building-type level.

The costs to achieve savings potential estimates within the commercial sector are calculated on a measure by measure basis using the levelized cost (\$/kWh in the electric model and \$/MMBTu within the non-electric model) for each measure. These levelized costs represent the cost to save a unit of energy. These levelized costs are then taken and multiplied (again at the measure level) by the 2018 annual savings associated with the potential level we are attempting to capture (technical potential, maximum achievable, etc.). A net present value (NPV) formula is then used in conjunction with each measure's measure life and an overall discount rate to determine the \$ cost per first year kWh (or MMBTu) saved for each measure. The cost per first year savings figure is then multiplied by the savings potential estimate being evaluated in order to yield the cost to achieve the savings potential being quoted in the year 2018 at the measure level. Each measure is then summed up at each potential level to yield the total cost to achieve savings level by the year 2018. This number can then be divided by the study length (10 years) in order to yield an estimate of annual spending needed to reach the potential level target in question.

In addition, the model includes a number of measures that save energy across multiple end-use categories. Examples include retrocommissioning which can saves heating, cooling, and ventilation energy, and insulation which can provide both heating and cooling savings. As a result, these types of measure are placed within the model in a manner so that they can claim their proper savings within each one of the appropriate end-uses. A complexity occurs when attempting to properly estimate the cost for these measures. In order to avoid overstating the cost to install a measure like retrocommissioning, the cost needs to be divided across the different end-uses it affects. To simplify the modeling, it is assumed that the costs would be divided by the number of end-uses the measure effects. If the full cost for each end-use is applied, it would be inaccurate (i.e., for retrocommissioning, if the end-user is only paying for an engineer to walk-through the facility and assess and assist with implementation of identified savings opportunities in a single visit; the end-user will typically receive a single invoice for the combined retrocommissioning service, as opposed to multiple invoices being sent for implementation of each type of savings identified by the engineer). This approach is also used

⁴² We were only provided actual sales forecasts through 2018 from the natural gas utilities. In order to determine the projected forecasts for oil and propane in MMBTu, we extrapolated based on the results of the commercial telephone survey (Question #16: What is the main energy source for heating?). The results of which yielded commercial customers in NH using natural gas to be 28%, oil at 46%, and bottled gas/propane at 26%. This allowed us to accurately estimate the year by year forecasts (particularly 2018) for all non-electric fuels combined.

in the model for many of the building envelope and HVAC controls measures, as they often affect more than one end-use when installed. This approach is due mainly to GDS's technical potential model's functionality. The description above, is provided to explain to readers how the model, within its existing framework, has been used to ensure that double counting of costs is avoided for these types of measures.

Table 48 and Figure 37 illustrate the commercial sector electricity sales based segmentation. This segmentation is based on 2009 commercial sales data by SIC code as provided by project sponsors.

5.4 Commercial Sector – Energy Efficiency Potential Results

One-hundred-twenty-five (125) commercial electric, and sixty seven (67) commercial nonelectric energy efficiency measures were included in the analysis for the commercial sector. In order to develop the list of energy efficiency measures to be examined, GDS worked closely

⁴³ Natural Gas Energy Efficiency Resource Development Potential in New York, Prepared for New York Energy Research and Development Authority, by OPTIMAL ENERGY, INC., AMERICAN COUNCIL FOR AN ENERGY-EFFICIENT ECONOMY, VERMONT ENERGY INVESTMENT CORPORATION, RESOURCE INSIGHT, INC., ENERGY AND ENVIRONMENTAL ANALYSIS, INC., October 31, 2006

with project sponsors and reviewed recent measure life, savings and cost assumption studies including a Measure Life Report prepared by GDS for the New England State Program Working Group in June 2007 and a GasNetworks measures assumptions update project completed by GDS during the summer 2008. In addition, GDS reviewed other related electric and non-electric commercial sector energy efficiency measure-specific data sources and technical potential studies that have been conducted recently in the US. Focus was for comprehensiveness on the electric and natural gas measures, less so for fuel oil and propane. Even within electric and natural gas some measure limitations were required (e.g., Data Center/IT, etc.).

The set of energy efficiency measures considered was pre-screened to mainly those measures that are currently commercially available (or were estimated to be cost effective within the ten year study period). Thus, emerging technologies not currently in the marketplace that had benefit cost ratios below 0.9 were not included in the analysis. The portfolio of measures includes retrofit and replace on burnout programmatic approaches to achieve energy efficiency savings.

5.2.1 Characteristics of Energy Efficiency Measures

GDS collected data on the energy savings, incremental costs, useful lives and other key "per unit" characteristics of each of the commercial electric and non-electric energy efficiency measures, this data is available in Appendix F for the commercial sector. Estimates of the size of the eligible market were also developed for each efficiency measure. For example, electric T-5 lighting efficiency measures are only applicable to those commercial building types in New Hampshire that have the potential to use that lighting technology in their building space.

The commercial sector analysis was based on the most recent sales forecasts for New Hampshire for the years 2009 to 2018.⁴⁴ For the commercial new construction market segment, GDS calculated a forecast of the new construction sales estimated to be built each year based on looking at the growth of the sector over the 10 year period, and making the assumption that half of that growth is from new construction, while the other half is coming from growth of existing buildings. This assumption was approved by the project sponsors, and has been used in previous technical potential projects around the US. The sizes of various end-use market segments were informed based on project primary data collection efforts.

Energy-efficiency measures were analyzed for the most important electric and non-electric consuming end uses in the Commercial sector including:

- Space heating
- Water heating
- Air conditioning
- Lighting
- Appliances
- Pools
- Cooking
- Motors
- Transformers
- Ventilation

GDS Associates, Inc.

⁴⁴ This Commercial sector load forecast was provided to GDS by project sponsors.

Tables⁴⁵ 52 through 55 below list the commercial sector electric and non-electric energy efficiency measures included in the technical (traditional), maximum achievable, maximum achievable cost effective, and potentially obtainable potential analyses. The portfolio of measures includes retrofit, and replace on burnout programmatic approaches to achieve energy efficiency savings. More information regarding measure-specific savings, cost and measure life assumptions can be found in Appendix F.

Table 52. Commercial <u>Electric</u> Savings Potential by Measure – <u>Existing Buildings</u>

Measure	Tech. Pot.	Max. Achievable	MACE	% of MACE	Potentially Obtainab
Retrocommissioning	101,979,593	101,979,593	101,979,593	10.3%	49,256,143

The distribution of commercial sector electric and non-electric savings by end use is shown below in Figure 39 through Figure 42 for existing and new buildings. On the electric side, for the commercial sector in New Hampshire, the electric lighting end use still represents the largest savings potential in absolute terms for both energy and peak demand, despite the significant adoption of high-efficiency lighting since the 1990's. Refrigeration represents the second largest end-use category for kWh savings and space heating and cooling makes up the third largest category for kWh savings. On the non-electric side, for the commercial sector in New Hampshire, the space-heating end use represents the largest savings potential (nearly 75%). Space heating is followed up by water heating, and the remainder is brought up by cooking, pools, and ventilation.

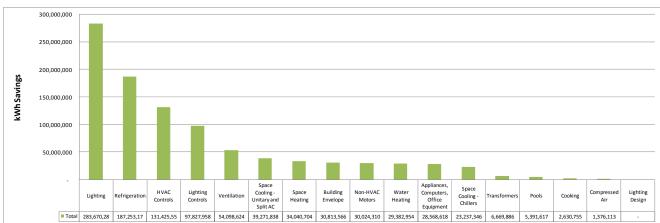

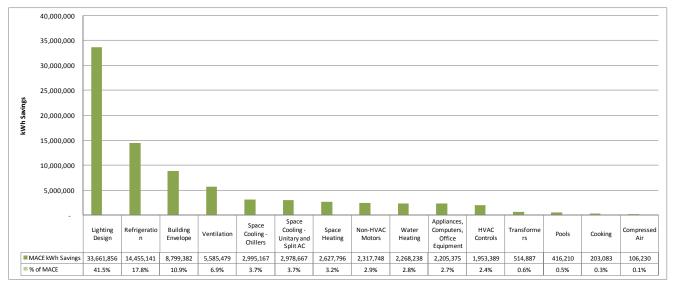

Figure 39. Commercial <u>Electric</u> Max. Achievable Cost Effective Savings By End Use - <u>Existing</u>

5.2.2 Commercial Energy Efficiency Measure Supply Curves

This report also presents results in the form of electric and non-electric energy efficiency supply curves. Figure 43 through Figure 48 present the electric existing and new construction supply curves under each scenario (technical potential, maximum achievable, maximum achievable cost effective). Figure 49 through Figure 54 present supply curves for the non-electric existing and new construction scenario (technical potential, maximum achievable, maximum achievable cost effective). As in the residential sector, these supply curves were built up across individual measures and were sorted on a lowest to highest cost basis per unit of energy saved.

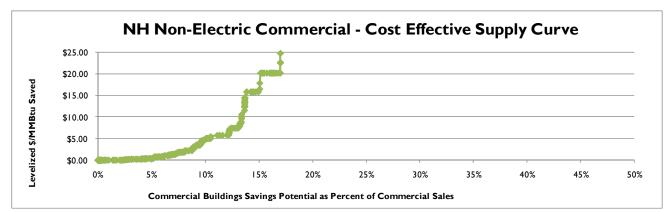

Figure 54. Commercial Non-Electric Supply Curve: New Buildings – Max. Achievable Cost Effective

Section 6: Industrial Sector Energy Efficiency Potential

This section of the report presents the estimates of electric and non-electric technical (traditional), maximum achievable, maximum achievable cost effective, and potentially obtainable energy efficiency potential for the existing and new construction market segments of the industrial sector in New Hampshire. More information regarding how these potentials were derived is also presented.

According to this analysis, there is still a large remaining potential for electric and non-electric energy efficiency savings in the industrial sector. Table 56 and Table 57 below summarize the savings by potential type by the year 2018. In addition, Table 56 presents peak demand savings for each potential level of savings associated with the electric energy efficiency measures.⁴⁵

On the electric side, the combined existing and new buildings maximum achievable cost effective potential in the industrial sector is over 440 million kWh, or 21 percent of the New Hampshire industrial sector sales forecast in 2018. With regard to non-electric potential, the maximum achievable cost effective potential in the industrial sector is 1.4 million MMBTu, or 9 percent of projected New Hampshire industrial sector natural gas, oil and propane sales in 2018.

The results on both the electric and non-electric tables below display the Maximum Achievable being equal to the Maximum Achievable Cost Effective potential. This is due to the end-uses being screened in a combined manner, rather than at the measure level. While there is a high likelihood that some measures within each of the end-uses would screen as not cost-effective, given that this analysis was done at the end-use level, modeling limitations prevented consideration of such measure-specific results.

		Estimated Annual Sales by 2018 (kWh)	Estimated Annual Savings by 2018 (kWh)	Savings in 2018 as % of Sector 2018 Electric Consumption	Savings in 2018 as % of Total 2018 Electric Consumption	Estimated Annual	Estimated Annual Demand Savings by 2018 By Sector (MW)	of Peak Sector		Estimated Costs to Achieve 2018 Annual Savings (10 Year Cumulative) (\$2008 NPV)	Total Estimated Annual Benefits Associated W/Combined Savings in 2018 (\$2008 NPV)	Simple Payback (NPV Total Costs / NPV Annual Savings)

 Table 56. Summary of Industrial Sector Electric Energy Efficiency Savings Potential

⁴⁵ For purposes of this study, a simplifying assumption was used to estimate peak demand savings. Percentage sector peak demand savings are calculated to show savings over the summer coincident peak demand period only and are not broken out separately for summer and winder peak periods.

6.1 Industrial Sector Savings Methodology Overview

The Industrial sector analysis was modeled using what is considered a "top-down approach". This methodology, shown visually in Figure 55 below:

Figure 55. Industrial Sector Savings Methodology – Top Down Approach

Industrial Energy Savings

Similar to the commercial sector, this top-down methodology starts with the total projected 2018 kWh sales for the industrial sector, and then splits those sales up by industry type using SIC codes of actual customer data (provided to GDS by project sponsors). After the sales are distributed across the industry types, they are broken down further to specific end-uses (e.g. lighting, space heating, appliances) within each of the building types. This was done using the 2002 Mechanical Energy Consumption Survey data (MECS)⁴⁶ for the New England Region. Given that the industrial sector equipment stock consists of highly specialized custom equipment, this sector was modeled at the end-use level as opposed to the detailed measure level. The end-uses being modeled in the Industrial sector include the following:

- Conventional Boiler Use
- CHP and/or Cogeneration Process
- Process Heating
- Process Cooling and Refrigeration
- Machine Drive
- Electro-Chemical Processes

⁴⁶ 2002 Manufacturing Energy Consumption Survey (MECS) Data (http://www.eia.doe.gov/emeu/mecs/mecs2002/)

- Other Process Use
- Facility HVAC
- Facility Lighting
- Other Facility Support
- Onsite Transportation
- Compressed Air
- Sensors & Controls
- End Use Not Reported

Once sales is applied to each of the end-uses in both the electric models and the non-electric models, an all-inclusive applicability factor is applied to each end-use within each of the industry types to determine industry specific savings by end-use. This all inclusive applicability factor is applied to the end-use sales by industry type and takes into account the four (4) factors that have been used throughout this study (i.e., the base case factor, remaining factor, savings factor, and convertible factor). Detailed measure end-use specific factors and related information can be found within Appendix G of this report.

The cost to achieve savings estimates within the industrial sector are calculated by multiplying the levelized cost per first year kWh or MMBTu savings within each measure category (e.g. machine drive, facility lighting, etc.) by the kWh or MMBTu savings in 2018 for the potential level being evaluated (e.g. technical potential, maximum achievable, etc.). The result of which is the cost to achieve the savings potential being quoted in the year 2018. This number can then be divided by the study length (10 years) in order to yield an estimate of annual spending needed to reach the potential level target in question.

New Hampshire-specific industry types identified and used in the industrial models included the following:

- Apparel And Other Finished Products Made From Fabrics And Similar Materials
- Chemicals And Allied Products
- Electronic And Other Electrical Equipment And Components, Except Computer Equipment
- Fabricated Metal Products, Except Machinery And Transportation Equipment
- Food And Kindred Products
- Furniture And Fixtures
- Industrial And Commercial Machinery And Computer Equipment
- Leather And Leather Products
- Lumber And Wood Products, Except Furniture
- Measuring, Analyzing, And Controlling Instruments; Photographic, Medical, And Optical Goods; Watches And Clocks
- Miscellaneous Manufacturing Industries
- Paper And Allied Products
- Petroleum Refining And Related Industries
- Primary Metal Industries
- Printing, Publishing, And Allied Industries
- Rubber And Miscellaneous Plastics Products
- Stone, Clay, Glass, And Concrete Products
- Textile Mill Products
- Tobacco Products
- Transportation Equipment

More information on the distribution of energy usage within each of these industrial building type categories is presented in the following section.

6.2 Industrial Sector Segmentation

Table 58 and Table 59 illustrate the industrial sector electricity and non-electric sales based segmentation. This segmentation is based on 2009 Industrial sales data by SIC code as provided by project sponsors.

 Table 58. Industrial Sector Segmentation by Industry Type - Electric

Industry	% Of Sales	2018 kWh Sales

6.4 Industrial Sector – Energy Efficiency Potential Results

Fourteen (14) industrial specific end-uses were included in the analysis for the industrial sector. In order to develop the list of energy efficiency end-uses examined, GDS worked closely with project sponsors as well reviewed other related electric and non-electric energy efficiency technical potential studies that have been conducted recently in the US.

Figure 56 and Figure 57 display a graphical comparison of the maximum achievable cost effective energy efficiency savings potential results by end use within the industrial sector (for electric and non-electric measures respectively). As shown in these figures, 40 percent of the electric savings comes from motors, followed by sensors and controls at 16 percent, facility lighting at 15 percent, and process heating at 13 percent. The remainder is made-up by compressed air and process cooling and refrigeration. With regard to savings from non-electric end-uses, process heating contributes the most at 52 percent of the savings, followed by conventional boiler use at 33 percent, facility HVAC at 13 percent, and the remaining 2 percent being classified as end-use not reported. Electric and non-electric savings allocations by building type are shown in Figure 58 and Figure 59 respectively.

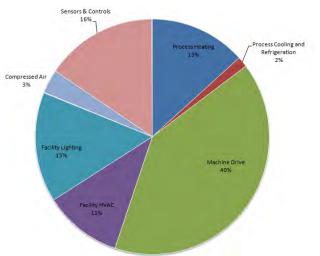

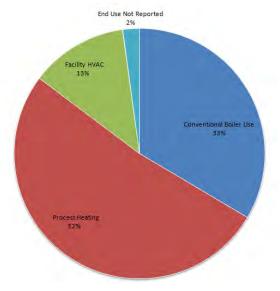

Figure 56. Industrial Max. Achievable Cost Effective <u>Electric</u> Savings by End Use

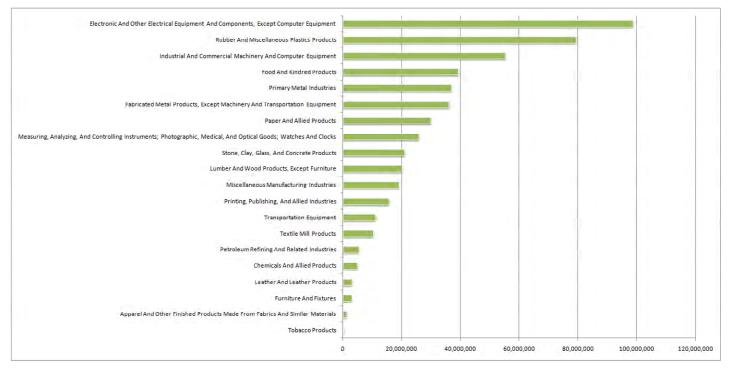

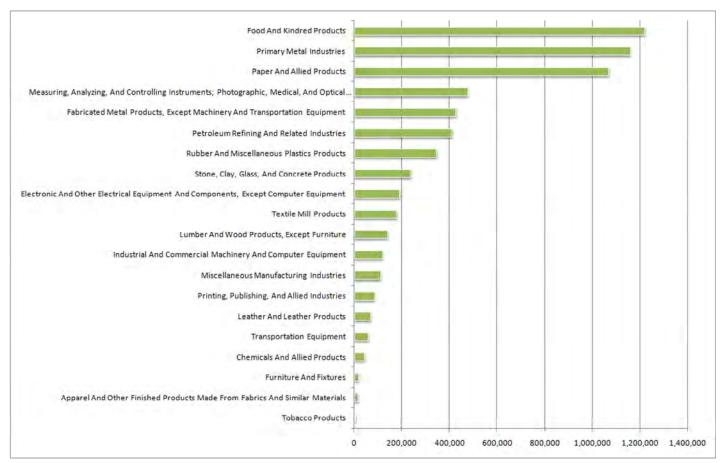

Figure 58. Industrial Max. Achievable Cost Effective Electric Savings by Building Type

Section 7: Primary Data Collection Highlights

This project included a major enhancement to most of the technical potential studies that have been conducted across the country in the past. Rather than relying on best available information from existing secondary sources to estimate current levels of energy using equipment saturations and penetration of energy efficiency measures, significant primary data collection efforts were undertaken to help inform and derive New Hampshire-specific values where possible. The focus of this Section is to provide information on how the results from this project's primary data collection efforts were used to help derive New Hampshire sector-specific estimates of energy using equipment saturations (base factors) and the penetration of energy efficiency measures (remaining factors). These factors were required inputs to the project's energy efficiency potential assessment models.

As highlighted below, a substantial amount of detailed information was gathered in the primary data collection efforts for this project. Although not all information collected was directly applied as model inputs, the data will serve as a valuable resource for future studies. The information obtained from the data collected includes the following:

<u>Ownership Characteristics</u>: The telephone surveys and site visits collected information on whether the facilities were owned or leased, the building type, the approximate age and size of the buildings, the number of employees, and building schedules (i.e. hours of operation). Results are summarized in Appendix J.

<u>Fuel Usage</u>: Information was collected on the primary types of fuel usage (i.e. oil, natural gas, etc.) as well as the specific gas and electric utility providers for each facility. This information was useful in developing cross tabulations of other data to determine trends within groups of customer types. The surveys were also used to determine whether any facilities had on-site power generation and to identify the capacity and uses of such on-site generation.

<u>Efficiency Attitudes</u>: Valuable information regarding customer attitudes towards energy efficiency and utility sponsored programs was collected, including primary motivations and barriers to participating in currently offered programs. Results were summarized in detail in Section 3.3 of this report.

<u>Heating and Cooling</u>: The surveys collected data on the types of heating and cooling systems employed in each facility. The site visits, in particular, collected detailed information on the systems including but not limited to run times, heating and cooling capacity, motor horsepower and efficiency, humidity control, presence of outside air economizers, presence of variable air volume control, heat recovery, fuel used, and the approximate age and condition of the systems.

<u>Building Envelope</u>: The site surveys gathered information on the general condition of building envelopes including wall types, insulation types, roof and floor construction, interior and exterior finish and color, and building fenestration (windows).

<u>Water Heating</u>: Much of the survey information regarding water heating was directly applicable to the energy efficiency assessment potential models. The site surveys also collected detailed information on the types of water heating storage and distribution systems, areas served, capacities, insulation, process heating, and the relative age and condition of the systems.

<u>Motors</u>: Substantial information regarding motors was collected including the total number of units, service, types of control, drive type, run hours per week, and the approximate age and condition of the motors.

<u>Refrigeration Equipment</u>: The surveys collected detailed information on the number and type of both commercial and non-commercial refrigeration equipment. Other valuable information collected included the amperage draw of commercial equipment, whether the equipment was ENERGY STAR, defrost control types, number, size and efficiency of compressors and condensers, and the relative condition of the systems in each facility.

<u>Compressed Air</u>: The site surveys gathered information on all compressed air systems, including the type and application of each compressor, the control type, size (horsepower), total number of units, nominal efficiencies, drive types, average age, run hours per week, and manufacturer and model numbers. The site surveys were also used to determine whether the facilities had a leak reduction maintenance program and to assess the overall condition of the compressed air systems.

<u>Process Heating</u>: The site surveys gathered information on all process heating systems, including the type of process, the products produced, the number of machines, rated heat inputs, whether waste heat recovery is utilized, primary fuel used, the average age of equipment, and the average run hours per week. The condition of process heating systems at each facility was also assessed.

<u>Cooking & Food Service Equipment</u>: Where applicable, the site surveys gathered information on cooking and food service equipment. Information gathered included the total number of both electric and gas fueled units and the average fuel usage for each type of equipment.

As discussed in more detail in Sections 7.1 and 7.2 below, where applicable, elements from this information were used to develop model-required base and remaining factors.

7.1 Data Summary and Analysis

The primary data collection efforts were summarized in Section 3.1 of this report, and included conducting 400 telephone surveys of residential customers, 200 telephone surveys of small commercial and industrial customers, and 200 site visits of large commercial and industrial customers. The methodologies utilized to create the survey instruments and sampling plans were outlined in detail in Sections 3.1.1 and 3.1.2, respectively. Data obtained from the surveys and site visits were coupled with secondary data collection and analysis where necessary, to develop New Hampshire-specific values for saturations and penetrations used in the GDS Team's sector-specific energy efficiency potential calculation models (referred to in the models as base and remaining factors). These primary data collection efforts were also used to assess customer attitudes towards energy efficiency programs and practices, including awareness, motivations and barriers, results of which were summarized earlier in Section 3.3 of this report.

Data collected from the residential and small commercial and industrial telephone surveys were analyzed by Research Into Action (RIA) using SPSS statistical software.⁴⁸ During this process, GDS worked with RIA to identify the specific survey questions and develop the cross tabulations needed to derive base and remaining factors for use in the models. Data collected from the large commercial and industrial site visits were recorded in paper files and entered manually into an analyzable Excel spreadsheet file. The data was organized and sorted by relevant

GDS Associates, Inc.

⁴⁸ Further information regarding the SPSS program can be found at <u>www.spss.com</u>

measure types, using pivot tables, to obtain information that helped inform the base and remaining values for specific efficiency measures needed for the models.

It is important to note that sample sizes were designed at project outset to ensure statistical validity at the aggregate residential, commercial and industrial sector levels only. However, attempts were made to mine the data, where possible, to support determination of base and remaining factors for specific measures at the building-type level as described in more detail below.

7.1.1 Residential Survey Data

Prior to the detailed evaluation of residential telephone survey data, responses were categorized as either single or multi-family homes. In total, 269 single family responses and 135 multi-family responses were recorded. Of those 404 total responses, the data collection effort focused on the 253 single family and 127 multi-family homes that were classified as permanent residences as opposed to seasonal residences. Separate evaluation of the survey data was then performed for each type of home. Based on a total population of approximately 600,000 housing units in New Hampshire, the margin of error for proportional results obtained from the single family surveys (253 total) was 6.2% with 95% confidence. The margin of error for proportional results obtained from the multi-family surveys (127 total) was 8.7% with 95% confidence.

7.1.2 Commercial and Industrial Survey Data

Data from the 200 small commercial and industrial phone surveys and the 200 large commercial and industrial site visits were analyzed on several levels. The most basic level of evaluation was to separate the commercial properties data from the industrial properties data. The breakdown of commercial versus industrial facilities for each survey is shown in Table 62 below.

	Small C/I Phone Surveys	Large C/I Site Surveys
Commercial	177	100
Industrial	23	100
Total	200	200

The small and large commercial properties were further categorized by model-defined building types, as shown below in Table 63.

 Table 63. Small Commercial vs. Large Commercial Surveys by Building Type

Model Building Type	Small Commercial Phone Surveys	Large Commercial Site Surveys
Warehouse	4	5
Retail	23	7
Grocery	13	7
Office	56	22
Lodging	6	14
Health	14	12
Restaurant	10	4
Education	5	16
Other - unclassified	46	13
Total	177	100

The GDS Team established a minimum sample size of 30 respondents as the threshold for collecting and reporting data at the building type-specific level for both small and large commercial buildings. This would ensure statistically valid results at a 15 percent margin of error and 90 percent confidence. As shown in the table above, based on this threshold, results from the small commercial phone surveys provided sufficient data to derive base and remaining factors for measures within both office (56) and other (46) building types. For the remaining building types, measure specific data was collected and reported based on the aggregate responses within the small commercial sector. Similarly in the large commercial sector, due to the limited number of responses within specific building types, a majority of the measurespecific base and remaining factors derived from the site visits were based on aggregate responses across the entire large commercial building stock. In some instances where a substantial amount of site visit data was available for a specific measure, base and remaining factors were determined at the building type level. An example is facility lighting, where a substantial volume of information was recorded during the site visits. It was the opinion of GDS that the data illuminated trends in lighting characteristics among the building types and warranted inclusion in the energy efficiency potential assessment models.

Industrial properties were also categorized by building type. The large industrial properties were broken down into ten specific building types as listed in Table 64 below. The small⁴⁹ industrial properties, where data was collected through a total of 23 phone surveys, were viewed as a single group (i.e., results were aggregated across all building types since the combined number of respondents was less than the 30 building type threshold required to ensure statistical validity).

Model Building Type	Small Industrial Phone Surveys	Large Industrial Site Surveys
Electronic and Other Electrical Equipment	-	15

Printing, Publishing and Allied Ind.	-	7
Rubber and Miscellaneous Plastics Production	-	9
Other – not classified	-	10
Total	23	100

 Table 64. Small Industrial vs. Large Industrial Surveys by Building Type

As described elsewhere in this report, the industrial supply model requires single savings factors for specific end uses (e.g., lighting, process heating, etc.) and recognizes that these factors can vary depending on the type of industry being assessed. Therefore, the information mined from the large industrial property site visits was analyzed to identify New Hampshire-specific equipment, system and process practices and trends that could be used to support adjustment of the original model assumptions which had initially been based only on secondary data sources from previous studies and prior experience.

⁴⁹ The 23 small industrial survey respondents consist of Seven (7) Industrial Metals Machining, Four (4) Industrial Parts Assembly, and Twelve (12) Industrial Other

7.1.3 Weighting of Small and Large Commercial Survey Data

In both the commercial electric and the commercial gas energy efficiency potential analysis models, small (less than 100 kW or 300,000 kWh annual consumption) and large (greater than 100 kW or 300,000 kWh annual consumption) commercial facilities have been treated as a single sector. Therefore, weighted averages were developed for the measure-specific base and remaining factors using results from both the small and large facilities data collection efforts.

The method used for calculating these weighted averages was based on 2007 total kWh consumption data provided by the utilities for their customers classified as small commercial/industrial and large commercial/industrial. In total, the small commercial customers consumed 2,100,349,654 cumulative kWh of energy in 2007 and the large commercial customers consumed a total of 2,643,763,935 kWh of energy. Based on these values, small commercial customers consumed 44.3 percent of commercial energy usage in 2007 and the large commercial customers consumed 55.7 percent. These ratios were used, where applicable, to derive weighted average commercial sector and building specific end-use measure saturation (base factor) and energy efficiency equipment penetration (remaining factor) values for use in the commercial models.

In several instances, survey data was available only from the small commercial facilities phone surveys, or from the large commercial facilities site visits, or from neither depending on the specific measure. If penetration and saturation values obtained from survey data were available for either the small commercial or large commercial facilities, but not both, an un-weighted survey value was utilized in the model. If values obtained from the surveys were not available for a specific measure, the original assumptions (based on existing secondary data) were utilized in the models and all applicable references that formed the basis for such assumptions were noted.

7.2 Application of Survey Data

As noted previously, a substantial amount of useful New Hampshire-specific information was collected on energy end use equipment saturations and energy efficiency measure penetrations for a number of residential, commercial, and industrial measures. In cases where such New Hampshire customer-specific information could not be collected from the phone surveys and site visits, the most prevalent barrier to obtaining that information tended to be the extremely specific nature of some measures and the time constraints existing for conducting the surveys and site visits. Wherever possible, when secondary sources were required to be used as the basis for base and remaining factors in the models, they were verified for reasonableness, or modified based on results obtained through the project's primary data collection activities.

The greatest percentage of model values that relied on primary survey data occurred in the residential sector, where nearly 70 percent of the model's required base and remaining factors for efficiency measures came directly from survey information. In the commercial electric model, 36 percent of the measures' base and remaining factors were also derived directly from this project's primary data collection activities. In the commercial non-electric model, 24 percent of the measures were based on survey information. This large variation between the percentages of survey data applicable in the residential (70%) versus commercial sectors (24 to 36%) is in part attributable to the complexity and specificity of the survey data application is provided in the following sections.

7.2.1 Residential Sector

The measure end-use categories that were most informed by the residential sector telephone surveys were appliances and water heating. Overall, customers appeared knowledgeable and

provided potentially useful information regarding the types of appliances they owned (i.e. refrigerators, ranges, water heaters, etc.) and whether the appliances were ENERGY STAR rated.⁵⁰ The total number of responses used to derive base and remaining factors for use in the residential models in these end use categories was also very high since these end uses are quite common in across all residences.

The measure end use categories of lighting and space conditioning were also fairly well informed by the surveys. Information on standard measures such as CFL bulbs, fixtures and programmable thermostats was readily available and was used to derive reliable base and remaining factors. Information on measures that were less well known to the general public, such as heat pumps, duct sealing, and photocell controlled outdoor lighting, proved to be less reliable (with little to no survey data responses) and were therefore supplemented in the model by secondary data sources.

A complete list of the base and remaining factors derived through information collected in this project's telephone surveys for each measure assessed within both single and multifamily homes is provided in Appendix K, along with links to specific survey questions and data sources.

7.2.1.1 Residential Sector Example

Programmable thermostats provide a good example as to how the base and remaining factors were derived from this project's telephone surveys. In the residential models, programmable thermostats are applied as energy efficiency measures within homes using electric heat, gas furnaces, gas boilers, and oil boilers. The measures are further categorized by systems for heating only and for systems with both heating and central air conditioning. In addition programmable thermostats are broken out by single family homes and multifamily homes and recognize that the savings associated with use of programmable thermostats will differ based on all of these factors. In the following example, the derivation of base and remaining factors for programmable thermostats is described within the context of single family homes without central air conditioning that heat with oil boilers.

The first step in the analysis was to derive the end use saturation (base case factor) for each sub-category of the measure. The end use saturation is defined as the percentage of total single family homes that contain the end use or measure. For this example, the end use saturation is the percentage of single family homes that have oil-fueled boiler heating (heating only, no central air conditioning) and was derived from survey questions SH2, SH3 and SC1. Question SC1 was used to determine whether homes had central air conditioning. As illustrated in the summary table below, a total of 214 respondents did not have central air conditioning.

	CON DO JOUT	ave benaral an bonaldoning. One		611			
				l	JTILITY		
			Granite State Electric	NH Elec CoOp	PSNH	Unitil	Total
SC1: Do you have central air conditioning?	Yes	Count	5	3	25	6	39
		% within UTILITY	17.9%	6.5%	18.5%	13.6%	15.4%
	No	Count	23	43	110	38	214
		% within UTILITY	82.1%	93.5%	81.5%	86.4%	84.6%
	Total	Count	28	46	135	44	253
		% within UTILITY	100.0%	100.0%	100.0%	100.0%	100.0%

SC1: Do you have central air conditioning? * UTILITY Crosstabulation

Of the 214 single family respondents who did not have air conditioning, a summary table was developed that combined the responses to questions SH2 and SH3. SH2 was used to identify

⁵⁰ It is important to note however, that past studies have shown as many people incorrectly identify products as being ENERGY STAR as do those that do not think their products are ENERGY STAR when in fact they are.

the primary type of heating fuel utilized and Question SH3 was used to identify the primary types of heating systems. The responses to Question SH2 (fuel type) were used as the cross-tab headings for the Question SH3 summary table shown below. A total of 36 responses are missing because they reported wood or electricity as the primary fuel used for heating and were excluded from this question.

				SH2: What is the	main fuel you use t	o heat this home?	
			Natural gas purchased from	Bottled gas or propane: [CONFIRM: DELIVERED BY TRUCK?]	Oil	Kerosene	Total

	Boiler + Radiator + Steam	Count	1	2	3	0	e
		% within SH2: What is the main fuel you use to heat this home?	3.8%	7.1%	2.5%	.0%	3.4%
	Radiator + DK (i.e., other components unknown)	Count	0	0	4	0	4
		% within SH2: What is the main fuel you use to heat this home?	.0%	.0%	3.3%	.0%	2.2%
	Could Identify Fuel, But Not Equipment	Count	1	0	1	1	3
		% within SH2: What is the main fuel you use to heat this home?	3.8%	.0%	.8%	50.0%	1.7%
	Other (please specify)	Count	2	1	1	0	4
		% within SH2: What is the main fuel you use to heat this home?	7.7%	3.6%	.8%	.0%	2.2%
	DON'T KNOW	Count	1	0	3	0	4
		% within SH2: What is the main fuel you use to heat this home?	3.8%	.0%	2.5%	.0%	2.2%
	REFUSAL	Count	2	2	0	0	4
		% within SH2: What is the main fuel you use to heat this home?	7.7%	7.1%	.0%	.0%	2.2%
	Total	Count	26	28	122	2	178
		% within SH2: What is the main fuel you use to heat this home?	100.0%	100.0%	100.0%	100.0%	100.0%

SH3: What type of heating system is your main source of heat? * SH2: What is the main fuel you use to heat this home? Crosstabulation

The end use saturation of homes with oil boilers, heating only, was calculated by summing the number of oil using respondents with boilers (28 + 34 + 3 + 4 = 69) and dividing it by the total number single family respondents (253). The total number of single family homes was used in the calculation because the end use saturation is defined as the percentage of all single family homes with oil boilers and no central air conditioning. The percentage of oil customers with boilers for heating only (i.e. end use saturation) was then 69/253 = 27.3%.

The next step was to derive the energy efficiency measure penetration for programmable thermostats. The penetration is defined as the fraction of the end use energy that is already energy efficient. For this example, the penetration is the percentage of homes that already have programmable thermostats and was derived from survey question SH14 which specifically asked whether the customers have a programmable thermostat. The cross tabulated responses, by primary fuel type (question SH2), are shown below for reference.

					Ma	iin heating fu	ıel		
			natural gas	electricity	propane	oil	kerosene	wood	Total
	Yes	Count	26	0	26	77	1	14	144
a programmable thermostat?		% within Main heating fuel	76.50%	0.00%	68.40%	51.00%	50.00%	35.00%	53.50%
	No	Count	8	4	12	73	1	26	124
		% within Main heating fuel	23.50%	100.00%	31.60%	48.30%	50.00%	65.00%	46.10%
	DON'T KNOW	Count	0	0	0	1	0	0	1
		% within Main heating fuel	0.00%	0.00%	0.00%	0.70%	0.00%	0.00%	0.40%
	Total	Count	34	4	38	151	2	40	269
		% within Main heating fuel	100.00%	100.00%	100.00%	100.00%	100.00%	100.00%	100.00%

As illustrated in the table above, 51.3% (77/150) of customers indicated that they have programmable thermostats after discounting the "Don't Know" response. Thus, the penetration for this measure is 51.3%. The remaining factor, defined as the percentage of homes in which this measure can be installed, is 1 minus the penetration, or 48.7% for this example. The resulting end use saturations (base case factors) and remaining factors were used in the residential model to calculate the potential for savings from this efficiency measure. Refer to Section 4.1 above for the actual equations used in the model to calculate potential savings.

7.2.2 Commercial Sector

Valuable information was gathered from both the telephone surveys and site visits to help derive base and remaining factors use in the commercial sector electric and gas models. In the commercial electric model, 36% of the measure remaining factors were directly attributable to the survey data. In the commercial gas model, 24% of the measure remaining factors were directly attributable to the survey data. The measure end-use categories that were most informed by the surveys and site visits were lighting, refrigeration, appliances, compressed air, motors and water heating. The measure end-use categories that were least influenced by the primary data collection activities were space cooling (chillers), space cooling (unitary and split AC), and cooking.

In the *Lighting* end use category for example, the base case factors were developed by first identifying sub-categories such as fluorescent tube lighting, screw-in incandescent/CFL lighting, high-bay lighting, exit signs and other specialty lighting. Then, the total number of fixtures reported in each sub-category from the site visits was tabulated and the relative percentages of each sub-category were calculated. Fixture counts were utilized to formulate the base case factors due to incomplete data on the wattage and run hours for all fixtures. These relative percentages, based on total fixture counts, were applied as base case factors for each building type to reflect the percentage of energy attributable to each sub-category. The site visits then provide useful information regarding the penetration of energy efficient lighting within each sub-category so remaining factors could be developed for each measure.

Substantial data was also compiled for the commercial non-electric model. Measure end use categories that were the most well informed by the phone surveys and site visits included water heating, pools, HVAC controls, and cooking. Measure end use categories that were least informed by the surveys were ventilation, building envelope, and space heating.

A complete list of base and remaining factors used in the commercial models is provided in Appendix L to this report. Factors that have been informed by data collected through the telephone and site visits conducted through primary data collection elements of this project have been highlighted for ease of reference. The survey instruments for the phone and site surveys are provided in Appendices B and C, respectively. Appendix L includes a summary sheet that identifies the questions used to derive the factors.

7.2.2.1 Commercial Sector Example

As with the residential sector, programmable thermostats provide a good example of how base and remaining factors were derived from survey data collected in the small commercial sector. To start, nearly all commercial customers were found to have thermostat-controlled heating systems as shown in the cross tabulation for Question 20 below. 90% of respondents indicated that they had control over the heating, while 10% did not have control, or did not know.

							Building t	pe_recoded2					
			Warehouse	Retail	Grocery	Office	Lodging	Health	Education	Industrial	Restaurant	Other	Total
Q20: Do you have control		Count	2	22	12	50	6	14	4	19	8	43	180
over the temperature of the heating?		% within Building type recoded2	50.0%	95.7%	92.3%	89.3%	100.0%	100.0%	80.0%	82.6%	80.0%	93.5%	90.0%

Q20: Do you have control over the temperature of the heating? * Building type_recoded2 Crosstabulation

It was assumed that the percentage of respondents without control of the temperature of the heating is largely attributable to tenant or landlord circumstances, thus the base case factor for this end use was determined to be 100 percent. For the small commercial phone surveys, Question 21 specifically asked whether respondents had a programmable thermostat. The cross tabulated summary table is provided below for reference.

Q21: Do you have a programmable thermostat? * Building type_recoded2 Crosstabulation

				Building type_recoded2									
			Warehouse	Retail	Grocery	Office	Lodging	Health	Education	Industrial	Restaurant	Other	Total
	Yes	Count	1	11	6	31	3	7	3	8	5	20	95
programmable thermostat?		% within Building type_recoded2	50.0%	50.0%	50.0%	62.0%	50.0%	50.0%	75.0%	42.1%	62.5%	46.5%	52.8%
	No	Count	1	10	6	18	3	6	1	11	3	21	80
		% within Building type_recoded2	50.0%	45.5%	50.0%	36.0%	50.0%	42.9%	25.0%	57.9%	37.5%	48.8%	44.4%
	DON'T KNOW	Count	0	1	0	1	0	1	0	0	0	2	5
	% within Building type recoded2	.0%	4.5%	.0%	2.0%	.0%	7.1%	.0%	.0%	.0%	4.7%	2.8%	
	Total	Count	2	22	12	50	6	14	4	19	8	43	180
		% within Building	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%

The energy efficient measure penetration, defined as the percentage that is already efficient, was calculated by dividing the total number of positive responses among non-industrial building types (95 total "yes" responses minus 8 "yes responses from the "industrial" building type = 87 commercial "yes" responses) by the total number of non-industrial respondents, excluding "don't know" responses (156). The average penetration for this measure was thus determined to be 55.8%. The remaining factor was simply calculated as 1 minus the penetration, or 44.2% for this example.

As can be seen from the cross tabulation table above, more than 30 total responses were received in both the *Office* and *Other* building type categories. Therefore, the remaining factors for programmable thermostats were derived at the building-specific level for each of these two building types. For example, the remaining factor for programmable thermostats in the *Office* building type was 36.7% and 51.2% for the *Other* building type category. For all remaining commercial building types, the 44.2% remaining factor (calculated in aggregate across all building types) was applied to maintain statistical validity in the data with reasonable confidence.

Programmable thermostats were not included in the survey for the large commercial surveys due to a larger prevalence of EMS systems as the primary means for temperature controls in these facilities and because larger facilities that use thermostatic control often have a large number of thermostats, or a mix of programmable and manual thermostats. This makes the quantification of programmable thermostats in larger commercial facilities very difficult. Since no large commercial data was available for programmable thermostats, the data from the small commercial surveys was applied without weighting. It is important to note that once the weightings were completed, the remaining factor for each measure was qualitatively assessed for reasonableness and adjusted if necessary. It was felt that applying the small commercial remaining factor overall was reasonable for this application based on industry experience.

7.2.3 Industrial Sector

The industrial model varies from the residential and commercial models in that energy end-use areas are assessed from a top-down (end-use category) perspective vs. bottom-up (a measure specific assessment approach). Therefore, the base case, remaining and other factors that were considered independently (by measure) in the residential and commercial models, are combined into a single savings factor in the industrial model. Initial values for each industrial end-use category savings factor were based upon secondary data that was developed previously by the American Council for an Energy Efficient Economy (ACEEE)⁵¹ and used in other GDS technical potential studies in the region. These factors were then adjusted, where appropriate, based upon the New Hampshire industrial sector-specific survey results. Adjustments to the savings factor based upon this project's primary data collection efforts are summarized in Table 65 and Table 66 below.

Industry	End Use Area	Adjustment
Electronic and Other Electrical Equipment	Process Heating	The savings factor was raised 10% to 30% total because this industry type had the largest number of process heat machines and lower MECS data percentage than other industry types with fewer machines (19%)
Electronic and Other Electrical Equipment	Process Cooling and Refrigeration	The savings factor was raised 5% to 10% total because this industry type had the largest number of both commercial and non-commercial refrigeration units and a low relative MECS percentage (4%)
Electronic and Other Electrical Equipment	Facility Lighting	The savings factor was raised 9% due to the disproportional ratio of T12 to T8 lighting in this industry type.
Fabricated Metals	Process Cooling and Refrigeration	The savings factor was increased 2% to 7% total because this industry type had the second highest total of both commercial and non-commercial refrigeration units and a low relative MECS percentage (3%)
Fabricated Metals	Machine Drive	The savings factor was increased 7% to 26% total because this industry type had the 2 nd highest number of motors, and the most number of motors that run for 40 hours per week or more. The MECS percentage for this industry type (44%) was also at the low range for this measure category (36% - 82%)
Measuring, Analyzing, and Controlling Instruments	Facility Lighting	The savings factor was increased 9% to 49% total due to a disproportionally high percentage of incandescent lighting fixtures in this industry type compared to other types
Paper and Allied Products	Machine Drive	The savings factor was decreased 9% to 17% total due to the low number of machine drive processes compared to other industry types. The MECS data for this industry type was also high (82%) compared to other industry types
Printing, Publishing and Allied Industries	Process Heating	The savings factor was reduced 10% to 20% total. This industry type had a 50^{th} percentile number of process heating applications so the savings factor was adjusted to represent the 50^{th} percentile of factors for this end use area. The MECS data for this industry type was also the lowest of any industry type (2%)
Rubber and Miscellaneous Plastics Products	Machine Drive	The savings factor was increased 6% to 23% total due to an average number of machine driven equipment, but a relatively high number of motors that run more than 40 hours per week. The MECS data for this industry type was also lower than average (52%) for this measure category
Rubber and Miscellaneous Plastics Products	Facility Lighting	The savings factor was decreased 5% to 35% total due to a large percentage (97%) of fluorescent tube lighting already being T8 fixtures. Fluorescent

⁵¹ Sources: Connecticut Efficiency Potential Analysis (GDS), EPRI Potential Study Webinar, Resource Assessment for Energy Trust of Oregon, California Industrial Energy Efficiency Potential (Ernest Orlando Lawrence, Berkeley National Laboratory), ACEEE Potential Studies (Vermont, Florida, Texas and Fan & Pump Analyses), Reading Industrial Tech Potential Analysis (GDS), Vermont Electric Energy Efficiency Potential Study (GDS).

		lighting comprised over 60% of all lighting in this industry type
All	Sensors and Controls	The savings factors were increased uniformly 3% to 4% total to account for the low number of occupancy sensors currently in place, and the low number of reported energy management systems

Table 66. Industrial Non-Electric End-Uses Informed by Primary Data

Industry	End Use Area	Adjustment
Electronic and Other Electrical Equipment	Conventional Boiler Use	The savings factor was raised 4% to 20% total because this industry type reported the largest number of conventional boilers and a low MECS percentage (12%) relative to other industry types
Electronic and Other Electrical Equipment	Facility HVAC	The savings factor was decreased 2% to 11% total due to a high reported incidence of outside air economizers and EMS systems in this industry type
Fabricated Metals	Facility HVAC	The savings factor was increased 4% to 17% total due to a lower than average number of outside air economizers, EMS systems, and heat recovery systems
Lumber and Wood Products	Facility HVAC	The savings factor was increased 7% to 20% total due to the lowest reported number of outside air economizers, EMS systems, and heat recovery systems. This industry type also had a lower than average MECS percentage (14%)
Petroleum Refining and Related Industries	Process Heating	The savings factor was decreased 2% to 11% total due to the lowest number of reported gas-fired process heating applications. This industry type also had a higher than average MECS percentage (60% in this measure category
Petroleum Refining and Related Industries	Facility HVAC	The savings factor was increased 3% to 16% total due to a lower than average number of outside air economizers, EMS systems, and heat recovery systems. This industry type also had the lowest MECS percentage (2%) in this measure category

The adjustments summarized above were made by compiling all relevant data for each end-use area by industry type and looking for trends in the data. As examples, industry types that were found to have disproportionate amounts of processes (i.e. process heating applications), or fixtures (i.e. T8 fluorescent tubes versus T12 fluorescent tubes) were adjusted to reflect the trends noted within that industry type. Trends noted from the surveys were also reviewed with respect to the MECS data. The MECS data was used to determine energy distribution among various processes in each facility. Using the example above, the industry type Electronics and Other Electrical Equipment had the highest number of process heating machines but a lower MECS percentage for process heating than other industry types. In this example, the savings factor for this industry type was increased to reflect the trend noted in the site surveys. In some instances, such as the end use area *Sensors and Controls*, a uniform adjustment was made to reflect what appeared to be increased potential for savings beyond the initial assumptions.

A complete list of savings factors for all end use categories and industry types is provided in Appendix M. In the electric model, 10 of 180 (5.5%) of the factors were adjusted based on survey results. In the non-electric model, 6 of 80 (7.5%) were adjusted. Specific factors that have been amended based on survey data are highlighted for reference.

7.3 Summary and Recommendations

The primary data collection effort for this project gathered an abundance of information relating to the saturation of electric and non-electric (natural gas, oil and propane) energy end uses and the penetration of energy efficiency measures across New Hampshire's residential, commercial, and industrial sectors. These data were used, where applicable, to help derive base and remaining factors applied to the energy efficiency potential assessment models employed for this specific study and will serve as a valuable starting reference for New Hampshire-specific energy end use saturations and efficient equipment penetrations going forward.

Beyond survey information used to derive critical model inputs, a wealth of additional customer and energy usage data was obtained through the telephone surveys and site visits conducted as part of this project. Considerable information regarding customer attitudes towards energy efficiency concepts and programs was acquired, as well as the main motivations and barriers considered by customers with respect to their participation in efficiency programs. Other data such as the distribution of heating fuel usage, facility information, and process information was also collected and will be a valuable resource for future studies.

A number of lessons have been learned through this initial primary data collection effort which might help to increase the effectiveness and value of subsequent efforts. Following is a brief listing of the top three recommendations:

- Begin with the end in mind Documenting and communicating a clear vision of the required results from the data collection effort and how those results will be used is a vital first step to ensuring success. This is especially important given the large number of project sponsors, consultant team data collection/evaluation staff, and other parties interested and involved in the process and outcomes from a project of this magnitude. For this current project, written work scopes were developed, discussed, refined and shared with all project participants.
- 2. Set realistic expectations It is important to set realistic expectations regarding the amount of measure-specific information that can be collected through a phone survey or site visit. Prioritizing measures and consolidating multiple measures within common end-use categories, up front, will help to maximize survey instrument effectiveness. For this project, multiple discussions and drafts of survey and site visit instruments were developed for this purpose. Results from this report identify measures within each sector that have the greatest potential for savings. Going forward, review of the base and remaining factors associated with these measures will identify clear areas where refined New Hampshire-specific information would be most valuable.
- 3. Allot sufficient time for data collection and analysis When large amounts of data are being collected, it is critical that sufficient time be made available, not only for the data collection phase of the project, but more importantly for data analysis. Time to enter, verify, clean and analyze data results is needed to ensure that the most value is mined out of the efforts expended. For this project, as discussed throughout this section of the report, substantial information from this primary data collection effort was used to help inform development of base and remaining factors and to identify customer behaviors and barriers. Going forward, additional review of the data collected through this project could yield further insights and value to the project sponsors.

Past Program Capture and Recommendations Section 8:

This section summarizes results from evaluation of the penetration of energy efficiency savings (electric and natural gas) associated with past and current utility-sponsored program activities. A review of the utilities' annual Core New Hampshire Program Highlights reports formed the basis for this evaluation, along with estimated savings for prior years not posted on the New Hampshire Public Utilities Commission website⁵². Results are presented from both a cumulative savings as a percent of sales perspective, and on a number of customers served as a percent of population basis. Recommendations for potential modifications to program and measure offerings that could increase the likelihood of achieving identified potentials are made and have been developed mainly through information on barriers collected directly from New Hampshire utility customers (through this project's telephone surveys and site visits) and supplemented by the GDS Team's experience with looking at programs from a logic-modeling perspective, and extensive knowledge of other local, regional and national programs and best practices.⁵³

Energy efficiency programs offered in New Hampshire include both electric and gas efficiency measures and serve all customer sectors; residential (including low income), commercial and industrial. The electric efficiency programs are comprised of CORE programs offered jointly by the four electric utility providers, and additional efficiency programs offered by the individual utilities. The gas efficiency programs are offered through the individual utility providers.

The CORE programs were formally launched in June 2002, although efficiency programs have been offered by the utilities for quite some time prior. As shown in Table 67, since the formal inception of the CORE programs in June 2002, an estimated total of 557,274 MWh (annual) have been saved.⁵⁴ This savings value is based on the estimated annual savings for each year since 2002 added together. In other words, this savings value is calculated by adding the annual savings from the 2003 programs to the annual savings from the 2004 programs to the annual savings from the 2005 programs and so on. This value does not consider the fact that the annual savings from the programs are actually realized every year over the lifetime of the The total annual savings were calculated in this manner to provide a useful measures. comparison to the forecast sales in 2008.

This total savings represents five percent of the total forecasted electric usage for New Hampshire in 2008. Nearly four percent of this savings has been achieved within the commercial industrial sector, with slightly more than one percent of the savings coming from the residential sector.

⁵² http://www.puc.state.nh.us/Electric/coreenergyefficiencyprograms.htm

⁵³ Assessments based on a logic-modeling perspective recognize current program resources (dollars, staffing, etc.) and activities (measure installations, promotional rebates/incentives, marketing/outreach, education/training, etc.) and seek to identify their causal links to anticipated outputs (measures installed, in-program energy and capacity savings, # of customers served, market actors trained, etc.), short-, intermediate- and long-term outcomes (changes in awareness and behavior, market-wide/sustainable energy, economic and environmental benefits, etc.). In addition, logic models recognize the existence and potential impacts of external influences (price of energy, state of the local and regional economy, federal tax incentives, other non-program sponsored activities, etc.). ⁵⁴ Estimate is based on reported lifetime savings from 2005-2008 available on NHPUC website, GDS estimates for

program measure lives, and extrapolated kWh savings estimates for 2002-2004

Sector	Total Annual Savings Since 2002 (MWh)		Cummulative Annual Savings as a Percent of 2008 Sector Sales	Cummulative Annual Savings as a Percent of 2008 Total Sales
Residential	120,064	4,537,480	2.6%	1.1%
Commercial/Industrial	437,210	6,650,732	6.6%	3.9%
Total	557,274	11,188,212		5.0%

Table 67	Energy	Efficiency	Program	Savings as	Percent	of 2008 Sales	2002-2008 -	- Electric Utilities
Lable 07.	Energy	Lincichey	rivgram	Davings as	, i ci cent	of 2000 Bales.	2002-2000 -	- Little Oundes

It is important to note that the above figure is conservative in several ways. First, the utility providers have been actively offering efficiency programs since well before 2002 so the total amount of energy saved since the inception of efficiency programs is much higher. Second, this figure considers only a single year of annual savings. In reality, annual savings are realized every year over the assumed measure life of the programs. The data was reported in the above manner to provide an appropriate comparison to the forecast 2008 usage.

New Hampshire's natural gas utilities offered energy efficiency programs from 1993 through 1999, at which time the programs were suspended in light of gas industry restructuring and investigation of the electric industry's development of energy efficiency programs. The natural gas utilities began offering the energy efficiency programs again on January 1, 2003, and since that time have saved an estimated total of nearly 250,000 decatherms (annual).⁵⁵ This value was again calculated by adding the estimated annual savings for each year since 2003. This value does not consider the cumulative savings over the life of the measures installed in the programs each year (i.e. only one annual year of savings from 2003 programs). As shown in Table 68, this savings represents 1.1 percent of the total forecasted therm sales for New Hampshire in 2008.

Sector	Total Annual Savings Since 2003 (decatherms)		Cummulative Annual Savings as a Percent of 2008 Sector Sales	Cummulative Annual Savings as a Percent of 2008 Total Sales
Residential	95,387	8,435,900	1.1%	0.4%
Commercial/Industrial	150,248	14,267,000	1.1%	0.7%
Total	245,635	22,702,900		1.1%

 Table 68. Energy Efficiency Program Savings as Percent of 2008 Sales:
 2003-2008 – Natural Gas Utilities

Overall since 2003, a substantial amount of energy has been saved in both the residential and commercial/industrial sectors. The values presented above are also conservative as they do not reflect the efficiency efforts of the utility providers prior to 2003, nor do they consider the cumulative annual savings of the programs since 2003. The following sections discuss the programs in more detail, including customer participation, benefit cost ratios, and expansion potential.

8.1 Electric Utility Energy Efficiency Programs

The electric utility energy efficiency programs assessed in this section include the CORE programs and other utility-specific programs being offered by National Grid, the New Hampshire Electric Cooperative, Public Service Company of New Hampshire, and Unitil Energy Systems. Any programs being offered by New Hampshire's municipal electric utilities or through conservation and educational programs that do not have reportable energy savings have not been included in this summary. Table 69 presents a listing of the programs and sponsoring

⁵⁵ Estimate based on reported savings from 2003-2007 and GDS estimates for program measure lives

utilities included in this past and current electric utility energy efficiency program savings capture assessment. More detailed information on these programs can be found on the NHPUC website at <u>http://www.puc.state.nh.us/Electric/coreenergyefficiencyprograms.htm</u>.

Program Name	Utility Sponsor	
ENERGY STAR Home Program	CORE Program – NH Electric Providers	
Home Energy Solutions	CORE Program – NH Electric Providers	
Home Energy Assistance Program	CORE Program – NH Electric Providers	
ENERGY STAR Lighting Program	CORE Program – NH Electric Providers	
ENERGY STAR Appliance Program	CORE Program – NH Electric Providers	
Small Business Energy Solutions	CORE Program – NH Electric Providers	
Large Business Energy Solutions	CORE Program – NH Electric Providers	
New Equipment and Construction	CORE Program – NH Electric Providers	
NHEC High Efficiency Heat Pump Program	New Hampshire Electric Cooperative (NHEC)	
PSNH ENERGY STAR Homes - geothermal	Public Service Company of New Hampshire (PSNH)	
PSNH C&I RFP Pilot Program	Public Service Company of New Hampshire (PSNH)	

 Table 69. New Hampshire Electric Utility Core and Additional Programs

8.1.1 Program Participation

The number of customers participating in the CORE programs has remained relatively constant since 2005. Some programs, such as the Home Energy Solutions and the Home Energy Assistance programs have decreased slightly in participation since 2005. Participation in these programs is somewhat limited under current program design, as they serve limited markets (i.e., homes with electric heat and low income homes, respectively). Homes with electric heat as the main fuel source represent approximately 4 percent of all residences in the state.⁵⁶ Low-income homes represent approximately 5.5 percent of all residences in New Hampshire. Since 2005, the total customer participation in the Home Energy Solutions and Home Energy Assistance programs is summarized in Table 70 below:

	Table 70.	Customer Served	Through Utility	HES and HEA	Programs: 2005-2008
--	-----------	------------------------	------------------------	-------------	---------------------

	Customers Served (2005-2008)	Total Population	Saturation
Home Energy Solutions	5,087	20,849	24.3%
Home Energy Assistance Program	4,143	28,668	14.5%

Given that the CORE programs have been in effect since June 2002, the actual saturation of these two markets is likely greater than the totals shown above. It is important to note however, that there are over 16,000 households on the waiting list for the Home Energy Assistance programs that serves low-income households⁵⁷ – therefore, there remains substantial demand for this program for the foreseeable future.,

⁵⁶ Figure based on residential phone survey data for both single family and multi-family

⁵⁷ Based on recent testimony by PSNH in CORE docket hearings (DE 08-120). Also, the low-income subgroup of the CORE docket produced an estimate that there are about 87,000 low-income households in New Hampshire, almost one-fifth of the total housing stick, that still need energy efficiency services (Low Income Report entered as Appendix B to the CORE Settlement Agreement filed on December 11, 2008 in DE 08-120.

Participation in the ENERGY STAR lighting and appliance programs has remained mostly steady since 2005, with spikes in participation in the lighting program in 2007 and the highest participation rate for the appliance program in 2006. These two programs have consistently maintained a good return of lifetime kWh saved per unit of cost. Since these programs target individual appliances and fixtures, and not individual homes per se, it is difficult to assess the extent to which the available market for these programs has diminished since the inception of the programs.

Participation in the ENERGY STAR Homes program has remained relatively stable since 2006 likely due to an overall downturn in the real estate market. In 2007, 524 builders (i.e. 524 homes) participated in New Hampshire's ENERGY STAR Homes programs out of a total of 3,772 single-family residential building permits⁵⁸. This represents a saturation of 13.9 percent of ENERGY STAR homes among the residential new construction market in 2007.

Since 2005, a total of 3,110 small businesses have participated in the Small Business Energy Solutions program and a total of 1,008 large businesses have participated in the Large C&I Retrofit Program. These participation rates cannot be directly correlated to program saturation rates because many of the large businesses may have participated more than once. It is clear from this data, however, that the saturation of the large business programs has been much greater than in the small business programs.

In 2007, 194 builders or clients participated in the New Equipment and Construction program representing 24.6 percent of commercial/industrial building permits.

With respect to the three utility specific programs reviewed⁵⁹, total number of participants and total expenditures are far less than the CORE programs.

8.1.2 Program Awareness

Customer attitudes towards energy efficiency practices and programs were obtained from sector-specific site visits and phone surveys and were summarized in detail in Section 3.3 of this report. It seems relevant to this discussion to reiterate the findings relative to customer awareness of existing energy efficiency programs offered by the utilities. From the site and phone surveys, the percentages of customers who reported being aware of the programs offered are summarized in Table 71. As shown in this table New Hampshire's large commercial and industrial customers reported being most aware utility efficiency programs (over 85%). Residential customers were the least aware, at less than 50 percent. Nearly 60 percent of small commercial/industrial customers were aware of the utilities' programs.

	% Aware of Efficiency Programs Offered
Residential	49.4%
Small Commercial/Industrial	59.6%
Large Commercial/Industrial	85.9%

Table 71.	Percent of Customers	Aware of Utility	Efficiency Programs
1 4010 / 11	I citcult of Customers	i wai e or e unity	Enterency i rograms

Although less than half of the 400 residential customers surveyed were aware that their utility providers offered energy efficiency programs, over 90 percent of all residential survey

⁵⁸ http://www.bos.frb.org/

⁵⁹ NHEC's High Efficiency Heat Pump Program, PSNH's Energy Star Homes Geothermal Program, and PSNH's C&I RFP Pilot Program

respondents indicated that they would incorporate energy efficient features in future renovations. This data indicates the potential for much greater participation in the residential marketplace with increased awareness. Similar opportunities exist with small commercial/industrial customers, although these customers are often the most hard to reach and to encourage to take action.

8.1.3 Efficiency Measures Not Included in Current Programs

This New Hampshire Additional Energy Efficiency Opportunities Potential Assessment study identified an abundance of energy efficiency measures that were cost effective and represent potential energy savings for New Hampshire in the next 10 years. Many of the most cost effective measures such as lighting, programmable thermostats and ENERGY STAR appliances are already included in the current energy efficiency programs sponsored by the electric and natural gas utilities. The efficiency measures discussed in Table 72 below are not included in the current programs and may represent opportunities for program expansion upon further review. It is important to note that the table below is by no means comprehensive, it is intended to be illustrative of areas with potential for expansion.

Efficiency Measure	Measure End Use	Comments
Programmable thermostat	Space heating and cooling	For homes with Oil or Propane heating. Programmable thermostats are included in the Home Energy Solutions (HES) program for homes with electric heat and offered by the gas utilities for homes with gas heat. The Home Energy Assistance (HEA) offers them for low income customers
Energy Efficient Windows	Space heating and cooling	For homes with Oil or Propane heating. The HEA low income program offers windows replacement for all fuels when cost-effective. The gas utilities offer a rebate for high efficiency window replacement for customers with gas heat.
Duct Sealing	Space heating and cooling	For homes with Oil or Propane heating. Duct sealing is included in the Home Energy Solutions program for homes with electric heat and the Weatherization program for homes with gas heat.
High efficiency heat pumps	Space heating and cooling	This measure is included in NHEC's specific program but not in the CORE programs for existing residential homes
Ground source heat pumps	Space heating and cooling	This measure is included in NHEC's specific program but not in the CORE programs for existing residential homes. PSNH offers this measure for residential new construction
Low flow shower heads/faucets	Water heating	For homes with Oil or Propane heating. Low flow shower heads and faucets are included in the Home Energy Solutions program for homes with electric heating (and also in the gas utility efficiency programs)
Water Heating measures	Water heating	For homes with Oil or Propane heating. Low flow shower heads and faucets are included in the Home Energy Solutions program for homes with electric heating, HES for all fuels and in the gas Weatherization program. Water heater wraps are offered for older water heaters in the HES program.
New water heater (efficient, tank less, heat pump)	Water heating	For all homes. Incentives are offered by the gas utilities
ENERGY STAR Refrigerator	Appliances	For all homes, not currently included in ENERGY STAR Appliances program. Available in HEA & HES programs if qualification criterion are met.
ENERGY STAR Freezer	Appliances	For all homes, not currently included in ENERGY STAR Appliances program. Available in HEA & HES programs if qualification criterion are met.
ENERGY STAR Dehumidifier	Appliances	For all homes, not currently included in ENERGY STAR Appliances program. Available in HEA if qualification criterion are met but none have been done.
ENERGY STAR Dishwasher	Appliances	For all homes, not currently included in ENERGY STAR Appliances program. Available in HEA if qualification criterion are met but none have been done.

Table 72.	. Residential Measures Not Included in	Current Programs
I GOIC / II	i itebiaennai inicabai eb i (or inclaaca in	Current rograms

Many of the efficiency measures identified above are efficiency measures that are cost effective and to date have been included only in programs serving homes with electric or natural gas heating. Homes with electric heat comprise approximately 4 percent of all residences based on the survey data whereas homes with natural gas, propane or oil heat comprise approximately 84 percent of homes. The appliances noted consume a significant amount of electricity and are not currently included in the ENERGY STAR appliances program for existing residences. Table 73 provides similar information regarding measures not currently included in the utilities' commercial/industrial programs.

Efficiency Measure	Measure End Use	Comments
Dishwasher, clothes washers, refrigeration, etc.	Appliances	Energy efficient appliances represents a potential for small and large businesses to conserve energy with small incremental costs, but is currently included only in the Small Business Energy Solutions Program
Ground source heat pumps	Space heating and cooling	Ground source heat pumps represent both a significant initial cost as well as a significant payback in terms of energy savings
General water heating measures Water heating Water heating Water heating Program but represe		Water heating measures such as low flow faucets and shower heads, efficient water heaters, water heater blankets, and similar water heating measures are only included in the Small Business Energy Solutions Program but represent a potential for energy savings in other facilities using electric hot water heating

8.2 Gas Efficiency Programs

Gas efficiency programs are offered independently in New Hampshire by the two gas utilities, National Grid and Northern Utilities. The gas efficiency programs were offered from 1993 through 1999, at which time the programs were suspended in light of gas industry restructuring and investigation of the electric industry's development of energy efficiency programs. The natural gas utilities began offering the energy efficiency programs again on January 1, 2003. The programs offered since 2003 are the programs evaluated in this analysis, and include the following (Table 74).

Program Name	Utility Sponsor	
Residential custom measures	Northern Utilities (Gas)	
Residential Low Income custom measures	Northern Utilities (Gas)	
residential high efficiency heating equipment	Northern Utilities (Gas)	
High efficiency water heating	Northern Utilities (Gas)	
ENERGY STAR homes	Northern Utilities (Gas)	
ENERGY STAR Programmable thermostats	Northern Utilities (Gas)	
ENERGY STAR Windows	Northern Utilities (Gas)	
Weatherization	Northern Utilities (Gas)	
Multifamily custom measures	Northern Utilities (Gas)	
Small commercial and Industrial Custom Measures	Northern Utilities (Gas)	
Med and large C/I custom measures	Northern Utilities (Gas)	
Commercial high efficiency heating program	Northern Utilities (Gas)	
Infrared heating program	Northern Utilities (Gas)	
Commercial ENERGY STAR Thermostats	Northern Utilities (Gas)	

Program Name	Utility Sponsor
Low Income	National Grid (Gas)
Residential High Efficiency heating	National Grid (Gas)
ENERGY STAR Windows	National Grid (Gas)
Residential Weatherization	National Grid (Gas)
ENERGY STAR Thermostats	National Grid (Gas)
Residential High Efficiency Water Heating	National Grid (Gas)
ENERGY STAR Homes	National Grid (Gas)
Commercial Energy Efficiency Program	National Grid (Gas)
Economic Redevelopment	National Grid (Gas)
Commercial High Efficiency Heating	National Grid (Gas)
Multifamily Housing	National Grid (Gas)

Programs that do not have reportable therm savings such as the online audit and educational programs have been excluded from this list. A complete list of efficiency programs offered by the New Hampshire natural gas utilities may be found on the NHPUC website.⁶⁰

8.2.1 Program Participation

Program summary sheets reviewed for the gas efficiency programs did not report the total number of actual participants for each program on a yearly basis. Based on the design goals for each program, the total number of participants has increased each year since 2003 with the largest increase in targeted users occurring between 2005 and 2006.

The design goal participation in several programs has increased steadily since 2003. Efficiency programs with notable increases in design goal participations since 2003 include the following:

- ENERGY STAR Homes
- ENERGY STAR Programmable Thermostats
- ENERGY STAR Windows
- Residential Weatherization
- Commercial High Efficiency Heating

GDS estimated the saturation of natural gas efficiency programs in the residential and commercial/industrial marketplace by calculating the cumulative number of design goal participants for each program since 2003 and comparing that number to the total number of potential users. The number of actual participants was not available from the documents posted to the NHPUC website. Potential users were determined by applying the percentage of natural gas users from the phone surveys, to the overall number of end use customers in each sector. For the purpose of estimating saturations, participation in programs offered by both utilities has been added together. The saturations presented in Table 75 below do not account for homes and facilities already equipped with the efficiency measure (i.e. homes already with programmable thermostats) and are intended only to reflect the percentage of the marketplace reached by the individual programs⁶¹.

⁶⁰ http://www.puc.state.nh.us/Gas-Steam/energyefficiencyprograms.htm

⁶¹ It is also important to note that many of the programs are time of replacement, so the saturations may be misleading because the total population is actually the number of customers in need of a heating system replacement and that number is constantly changing.

	Customers Served (2005-2008)	Total Population ⁶²	Saturation
Residential Conservation Services	2,245	45,279	5.0%
Residential Custom Measures	580	45,279	1.3%
Residential Low Income Custom Measures	621	2,402	25.9%
Residential High Efficiency Heating Equipment	2,912	45,279	6.4%
ENERGY STAR Homes	307	15,088 ⁶³	2.0%
ENERGY STAR Programmable Thermostats	2,054	45,279	4.5%
Multi-Family Custom Measures	56	84,989	0.1%
C&I Custom Measures	375	33,481	1.1%
Commercial High Efficiency Heating Program	437	34,400	1.3%
Infrared Heating Program	28	34,440	0.1%
Commercial ENERGY STAR Thermostats	220	34,440	0.6%
Commercial Food Service Program	18	3,851	0.5%

 Table 75. Customer Served Through Natural Gas Utility Programs: 2005-2008

The summary table above indicates that the gas efficiency programs since 2003 have penetrated the residential market to a greater extent than the commercial and industrial market. It appears that there is substantial opportunity for further penetration in all customer sectors.

8.2.2 Program Awareness

Customer awareness of utility sponsored efficiency programs is summarized in Sections 3.3 and 8.1.2 of this report. Of importance to this discussion of gas efficiency programs is the finding that less than half of residential customers are aware that programs are offered by their utility providers. More than 40 percent of small commercial and industrial customers are not aware of the programs offered by the utility providers. Increasing customer awareness will be an important barrier to overcome.

8.2.3 Efficiency Measures Not Included in Current Programs

A significant majority of the efficiency measures identified in the technical potential study have already been incorporated in the programs offered by the natural gas utilities. Several measures that are cost effective and are not currently included in the efficiency programs offered by the utility providers are summarized in Table 76 below. It is important to note that the current program designs do not permit the utility providers to pay for programs for oil/propane measures because the programs are funded by electric and gas ratepayers.

 ⁶² Total population estimates are based on the total number of available properties by program type, times the percentage of facilities reporting the usage of natural gas from the site and phone surveys
 ⁶³ Estimate is number of 2007 single family building permits (3,772) times four years

Efficiency Measure	Measure End Use	Comments
ENERGY STAR Dishwashers	Appliances / Water heating	In homes with natural gas water heating
ENERGY STAR Clothes Washers	Appliances / Water heating	In homes with natural gas water heating
Boiler Tune up	Water Heating	In homes with natural gas supplied boilers
High efficiency cooking equipment Cooking		High efficiency cooking equipment represents a potential for substantial savings. Northern Utilities and National Grid currently offer rebates for high-efficiency fryers and steamers.

Both of New Hampshire's natural gas utilities offer basic or prescriptive rebates for incorporating general energy efficiency products such as space heating equipment and water heaters. For small and large commercial and industrial customers, both utilities offer energy audit services and the potential for custom energy efficiency programs tailored to the specific facility. The audit and custom approach to efficiency programs in the commercial and industrial sector incorporate the potential for a wealth of energy efficiency measures to be incorporated at a specific facility.

8.3 Summary and Recommendations

To date, the efficiency programs offered in New Hampshire by the state's four largest electric utilities and two natural gas distribution companies have been successful and have saved a substantial amount of energy. Many of the programs have and are continuing to perform quite well in terms of cost per unit of energy saved and customer participation. Several other programs have shown positive trends becoming more cost effective on a yearly basis.

For all programs, but most notably in the electric market, the cost per kWh saved in the commercial and industrial sectors has been better than in the residential market. This might explain why in general, commercial and industrial customers have indicated a higher awareness of the utilities' efficiency programs available to them as well as an increased likelihood of participation compared to residential customers. Given the scale of energy consumption in the commercial and industrial sectors, these customers continue to represent a substantial area for potential energy savings in the upcoming years. Additional penetration can be achieved through increased outreach to small commercial/industrial customers and by expanding current program offerings to include other cost effective measures not currently included in the companies' CORE and utility-specific programs.

Residential customer participation in the state's electric and natural gas energy efficiency programs has met or exceeded program expectations on a yearly basis. However, in the phone surveys more than half of respondents indicated that they were not aware of the programs offered by their utilities, or that they were even eligible. Of the customers who were aware of the programs, a high percentage participated and indicated they would participate in the future. This data underscores the importance of increasing consumer education on the programs available to residential customers and of the associated benefits.

One final finding from the study is that nearly all of the most cost effective energy efficiency measures are included in current programs in some manner. In several programs, however, the cost effective measures are targeted to a small percentage of consumers. The best example of this is the *Home Energy Solutions* program which targets consumers with 65 percent or greater electric heating. Customers with primarily electric heat represent approximately 4 percent of the total population based on the phone surveys. Customers with 65% or more electric heat likely

represent a larger percentage of the total population but are nonetheless a small percentage of all customers. Adding more comprehensive programs and expanding the depth, breadth and promotion of the current programs to include a larger number of potential participants may lead to increased overall energy savings. It is important to recognize that such expansion would require providing services to customers that heat with fuels other than electric or natural gas. Issues regarding who would pay for the provision of services to such customers would need to be addressed.
