Exhibit 7-22 provides a comparison of the Gas direct DRIPE and cross-fuel DRIPE 2013 for CT. AESC 2015 results are lower than AESC 2013, primarily due to the lower AESC 2015 estimate of basis DRIPE. The AESC 2015 results for other states are similarly lower than the AESC 2013 results.

7.7 Fuel DRIPE Effects from Electric Gas Efficiency on Retail Customers

7.7.1 Electric Efficiency Own Fuel DRIPE Effects

The gas supply DRIPE effect of a one MWh reduction in annual electric use is $\$2.55 \times 10^{-8}$/ per MWh saved. The basis DRIPE effect of that one MWh reduction is the reduction in electric energy (MWh) multiplied by the basis DRIPE multiplied by 7.2 MMBtu/MWh. Exhibit 7-23 shows the resulting electric efficiency gas supply and basis DRIPE effects by year.

Exhibit 7-23. Annual Electric-Gas-Electric Price Benefit per MWh Saved

Appendix A: Usage Instructions

Table of Exhibits

1.1 Introduction

This appendix provides instructions on how to apply the Base Case avoided costs of electricity, how to estimate avoided costs of electricity for the High Gas sensitivity case, and how to apply the Base Case avoided costs of natural gas.

1.2 Base Case Avoided Costs of Electricity

Appendix B of AESC 2015 provides detailed projections of avoided electricity costs for each New England state as well as for specific zones within Massachusetts whose energy prices differ from the statewide energy price. Appendix B provides tables in constant 2015$ for the following reporting regions:

- Connecticut
- Massachusetts : Northeast Massachusetts (NEMA), West Central Massachusetts (WCMA), Southeast Massachusetts (SEMA), MA statewide
- Maine
- New Hampshire
- Rhode Island
- Vermont

Appendix B also provides tables in nominal $ for Connecticut.

The projections are provided as two- page tables in Appendix B. The Excel workbooks used to develop these tables are provided to Program Administrators.

The Appendix B tables use the following costing periods:[1]

- Summer On-Peak: The 16-hour block 7 am–11 pm, Monday–Friday (except ISO holidays), in the months of June–September (1,390 Hours, 15.9 percent of 8,760).[2]
- Summer Off-Peak: All other hours–11 pm–7 am, Monday–Friday, weekends, and ISO holidays in the months of June–September (1,530 Hours, 17.5 percent of 8,760).
- Winter On-Peak: The 16-hour block 7 am–11 pm, Monday–Friday (except ISO holidays), in the eight months of January–May and October–December (2,781 Hours, 31.7 percent of 8,760).
- Winter Off-Peak: All other hours–11 pm-7 am, Monday–Friday, all day on weekends, and ISO holidays–in the months of January–May and October–December (3,059 Hours, 34.9 percent of 8,760)

The "all-hours" avoided electricity cost for a given year, or set of years, is equal to the hour-weighted average of avoided costs for each costing period of that year.

All-hours avoided electricity cost = (15.9 percent *summer on-peak) + (17.5 percent *summer off-peak) + (31.7 * winter on-peak) + (34.9 percent * winter off-peak)

Page one of each reporting region table provides the following avoided cost components:

1. Avoided unit cost of electric energy;
2. Avoided unit cost of electric capacity by demand reduction bidding strategy;
3. Intrastate energy DRIPE;
4. Cross-DRIPE; and
5. Avoided non-embedded costs.

Page two of each reporting region table provides:

1. Wholesale avoided costs of electricity (energy and capacity);
2. Avoided REC costs to load;
3. Rest-of-Pool Energy DRIPE values.

Each table provides illustrative levelized values for each category of avoided cost at the bottom of each cost column. These are computed using a real discount rate of 2.43 percent.

[1] AESC 2015 follows the ISO-NE defined on-peak and off-peak hours available at: http://www.iso-ne.com/support/training/glossary/index-p5.html.

[2] ISO-NE holidays are New Year's Day, Memorial Day, July 4, Labor Day, Thanksgiving Day, and Christmas.

1.3 Worksheet Structure and Terminology

For each reporting region/zone there is a two-page table of avoided electricity costs.

1.3.1 Page One—Avoided Cost of Electricity Results

Reading from left to right, the structure of page one of each table is as follows:

User-Defined Inputs

The tables have the following default values for the following three input assumptions:

1. Wholesale Risk Premium – 9 percent[3]
2. ISO Distribution Losses – 8 percent
3. Real Discount Rate – 2.43 percent
4. Percent of Capacity Bid into the FCM – 50 percent

Users may insert their own values for any or all of those input assumptions.

The columns in the tables are labeled a through al. **These column labels do NOT refer to xls cell coordinates.**

Avoided Unit Cost of Electric Energy ($/kWh) (Table columns a – d)

Avoided energy costs are presented by year for each of the four energy costing periods: Winter On-Peak, Winter Off-Peak, Summer-On Peak, and Summer Off-Peak.[4]

The generalized avoided energy cost in each period is calculated as: (modeled avoided wholesale energy cost + avoided renewable energy certificate cost) * (1 + wholesale risk premium).

Avoided Unit Cost of Electric Capacity ($/kW-yr) (Table columns e – g)

This section provides values for a PA to calculate the avoided capacity cost based on a simplified bidding strategy consisting of x percent of demand reductions from measures in each year bid into the FCA for that year and the remaining 1-x percent not bid into any FCA. The default value for x is 50 percent. Users

[3] The wholesale risk premium for Vermont is 11.1 percent per Vermont DPS.

[4] The avoided energy costs are computed for the aggregate load shape in each zone by costing period, and are applicable to DSM programs reducing load roughly in proportion to existing load. Other resources, such as load management and distributed generation, may have very different load shapes and significantly different avoided energy costs. Baseload resources, such as combined-heat-and-power (CHP) systems, would tend to have lower avoided costs per kWh. Peaking resources, such as most non-CHP distributed generation and load management, would tend to have higher avoided costs per kWh.

can insert their own input for that value in the user-defined inputs section of Table One. (See Chapter 5 for a discussion of energy efficiency and the capacity market).

The components of the avoided capacity cost are as follows:

- The Avoided Unit Cost of Capacity of a kW bid into the FCM in column e reflects an 8 percent adjustment to reflect losses from the customer meter to the ISO-NE delivery point.
- The Avoided Unit Cost of Capacity in column f for avoided capacity not bid into an FCA reflects upward adjustments for the wholesale risk premium, the reserve margin in that year, and also a 2.2 percent adjustment to reflect PTF losses. Because FCA auctions are set three years in advance of the actual delivery year, avoided capacity for measures installed in 2016 that is *not* bid into a FCA will not impact ISO-NE's determination of forecasted peak until 2020.
- The Weighted Average *Capacity Value* based on percent bid in column g is the *weighted average* avoided capacity of column e and f reflecting an individual PA's percent of capacity that is bid into the Forward Capacity Market. The column presents a weighted average of 50 percent bid default value that may be changed by PAs to reflect specific bidding strategies.

Under this approach the avoided capacity cost in each year is equal to the Weighted Average *Capacity Value* in column g for the relevant year multiplied by the demand reduction in that year.

Demand-Reduction-Induced Price Effects (Columns h – q)

Each table provides separate projections of intrastate energy DRIPE and capacity DRIPE for efficiency measures implemented in 2016 and in 2017, respectively.

AESC 2015 does not project any difference in electric energy DRIPE for efficiency measures implemented in 2016, 2017 or 2018. For example there are no differences by year due to differences in phase-in or decay. The only difference between the values applicable to reductions from measures of different vintages is the start year. A PA who wishes to evaluate an efficiency measure implemented in 2018 would use the energy DRIPE values for 2018 from columns m through p.

AESC 2015 does not project energy DRIPE from 2019 onward. AESC 2015 projects a zero capacity DRIPE value.

PAs should use energy DRIPE values that reflect the relevant state regulations governing treatment of energy DRIPE. For Massachusetts zones, the energy DRIPE values will be intrastate values only. For the remaining four states, the energy DRIPE values should reflect both intrastate and rest of pool values.

Avoided Non-Embedded Costs $/kWh (Columns r – u)

This section of the worksheet table provides the AESC 2015 estimates of non-embedded values fir CO_2. CO_2 non-embedded values are presented by year for each of the four energy costing periods.

1.3.2 Page Two—Inputs to Avoided Cost Calculations

Reading from left to right, the structure of page two is as follows:

Wholesale Avoided Costs of Electricity Energy, $ per kWh (Table columns v – y)

The wholesale electric energy prices are from the Base Case simulation modelling described in Chapter 5. Users should not normally need to use the input values directly, or modify these values.

Electric Cross DRIPE (Table columns z and aa)

These columns provide AESC 2015 projections of Electric own-fuel and Cross-fuel DRIPE as described in Chapter 7. Values are provided for the winter and the summer. PAs should use these own fuel and cross fuel DRIPE values to the extent allowed by the relevant state regulations governing treatment of energy DRIPE.

PAs would apply the winter values in column z to reductions in load which occur in winter on-peak or winter off-peak periods, and would apply summer values in column aa to z to reductions in load which occur in summer on-peak or winter off-peak periods.

AESC 2015 does not project any difference in electric cross DRIPE for efficiency measures implemented in 2016, 2017 or 2018. For example there are no differences by year due to differences in phase-in or decay. The only difference between the values applicable to reductions from measures of different vintages is the start year. A PA who wishes to evaluate an efficiency measure implemented in 2017 would use the cross DRIPE values starting 2017. A PA who wishes to evaluate an efficiency measure implemented in 2018 would use the cross DRIPE values starting 2018

Capacity, $ per kW-year (Table columns ab and ac)

The wholesale electric capacity prices and reserve margin requirements are from the relevant sections in Chapter 5 sections. Users should not normally need to use the input values directly or modify these values.

Avoided REC Costs to Load $/kWh (Table column ad)

The avoided REC costs are calculated based on REC prices and RPS requirements that are described in detail in Chapter 5. Users should not normally need to use the input values directly or to modify these values.

Rest-of-Pool Energy DRIPE Values $/kWh (Table columns ae – al)

The rest-of-pool energy DRIPE values are calculated based on energy DRIPE factors described in detail in Chapter 7. The Appendix B workbooks present both intrastate and rest of pool energy DRIPE values. Users should not normally need to use the input values directly or modify these values.

1.4 Guide to Applying the Avoided Costs

Users have the ability to specify certain inputs as well as to choose which of the avoided cost components to include in their analyses. .

1.4.1 User-Specified Inputs

The avoided cost results are based upon default values for three inputs that users can specify. They are 1) the wholesale risk premium of 9 percent (11.1 percent for Vermont), 2) the real discount rate of 2.43 percent, and 3) a percentage of capacity bid into the Forward Capacity Market of 50 percent. [5] The Excel workbook is designed to allow Program Administrators to specify their preferred values for those three inputs in the top left section of page one of each worksheet.

If a user wishes to specify a different value for any of the inputs, the user should enter the *new* value directly in the worksheet. The calculations in the worksheet are linked to these values and new avoided costs will be calculated automatically.

Program administrators are responsible for developing and applying estimates of avoided transmission and distribution costs for their own specific system that would be separate inputs to the values in the provided tables. An application of avoided transmission and distribution costs is described in section 1.4.6.

1.4.2 Avoided Costs of Energy

Calculating the quantity reduction benefits of energy reductions in a given year requires an estimate of losses from the ISO delivery points to the end use in addition to an estimate of the reduction at the meter. Each PA should obtain or calculate the losses applicable to its specific system as discussed in section 1.7.1.

These avoided costs should be estimated as follows:

- Reduction in winter peak energy at the end use
  × winter peak energy losses from the ISO delivery points to the end use
  × the *Winter Peak Energy* value for that year by costing period

- Reduction in winter off-peak energy at the end use
  × winter off-peak energy losses from the ISO delivery points to the end use
  × the *Winter Off-Peak Energy* value for that year by costing period

[5] For avoided capacity values, the Appendix B workbook includes ISO-NE distribution loss factor of 8%. This value should not need to be changed.

- Reduction in summer peak energy at the end use
  × summer peak energy losses from the ISO delivery points to the end use
  × the *Summer Peak Energy* value for that year by costing period

- Reduction in summer off-peak energy at the end use
  × summer off-peak energy losses from the ISO delivery points to the end use
  × the *Summer Off-Peak Energy* value for that year by costing period

1.4.3 Capacity Costs Avoided by Reductions in Peak Demand

A PA may achieve avoided capacity costs from reductions in peak demand through a range of approaches. At one extreme the PA could choose to bid 100 percent of the anticipated demand reduction from the program into the relevant FCAs, at the other extreme the PA could choose to bid zero percent of the anticipated reduction into any FCA. The range of approaches between those two extremes vary according to the portion of the reduction in peak demand from efficiency measures the PA chooses to bid into FCAs. These approaches are discussed in Chapter 5 as well as in section 1.9 of this Appendix.

The magnitude of the avoided capacity cost from the reduction in peak demand resulting from a particular measure in a given year will depend upon the approach the PA has taken and/or will take towards bidding the reduction in demand from that measure in that year into the applicable FCAs.

Following are descriptions of how a PA can calculate the avoided cost of reductions in peak demand for the two extreme approaches and the simplified user-specified bid strategy.

Value of 100 Percent Bid of Demand Reduction from First Program Year into the First Relevant FCA (Column e)

A PA will obtain the highest benefit for the reductions in peak demand from an energy efficiency program by bidding the full anticipated reduction into the FCA for the first power year in which that program would produce reductions. Thus, a PA responsible for an efficiency program that is expected to start January 2016 would have had to have bid 100 percent of the anticipated reduction in demand from that program into FCA 7, which was held in 2013 for the power year starting June 1, 2016. There is some financial risk associated with bidding in advance, in particular the potential a regulator may not approve the anticipated program budget and/or the possibility the program may fail to produce the anticipated level of demand reductions.

The benefit of a reduction in peak demand from either an On-Peak or a Seasonal Peak resource in a given year starting 2016 is estimated as the result of:

Average kW reduction at the meter for the relevant period in a given year

× the Avoided Unit Cost of Capacity bid if a kW bid into the FCM for that year.

Value of Zero Percent Bid of Demand Reduction into Any FCA (column f)

For an efficiency program that produces reductions starting in 2016, there is no benefit of a reduction in peak demand until 2020, at which point the annual benefit is calculated as follows:

> kW reduction at the meter during system peak in a given year× summer peak-hour losses from the ISO delivery points to the end use
> × the Avoided Unit Cost of Capacity for that year, which is the FCA price for that year adjusted upward by the reserve margin that ISO-NE requires for that year, distribution losses (user defined), by the PTF losses, and the wholesale risk premium.

Value of 50 Percent Bid of Demand Reduction into FCM (Column g)

The column reflects a 50 percent weighted average of demand reduction into Forward Capacity Market. A PA would therefore obtain 50 percent of the value of the capacity that is bid into the FCM (highest value) as described in section 1.9 and 50 percent of the market capacity value of a reduction in peak load (lowest value) based on the default percentage.

1.4.4 DRIPE

The workbook tables provide electricity DRIPE values by year.

AESC 2015 does not project any difference in electric cross DRIPE for efficiency measures implemented in 2016, 2017 or 2018. For example there are no differences by year due to differences in phase-in or decay. The only difference between the values applicable to reductions from measures of different vintages is the start year.

Avoided Cost of Energy DRIPE

The price benefits of energy reductions are energy DRIPE. A PA can estimate energy DRIPE for a measure as follows:

- Reduction in annual winter on peak energy at the end use
  × winter peak energy losses from ISO delivery to the end use
  × the Winter On-Peak Energy DRIPE;
- Reduction in annual winter off-peak energy at the end use
  × winter off-peak energy losses from ISO delivery to the end use
  × the Winter Off-Peak Energy DRIPE;
- Reduction in annual summer on peak energy at the end use
  × summer peak energy losses from ISO delivery to the end use
  × the Summer On-Peak Energy DRIPE;
- Reduction in annual summer off-peak energy at the end use
  × summer off-peak energy losses from ISO delivery to the end use
  × the Summer Off-Peak Energy DRIPE.

A PA who wishes to evaluate an efficiency measure implemented in 2016 would use the energy DRIPE values starting 2016. A PA who wishes to evaluate an efficiency measure implemented in 2017 would use the energy DRIPE values starting 2017. A PA who wishes to evaluate an efficiency measure implemented in 2018 would use the energy DRIPE values starting 2018

Cross DRIPE

A reduction in the quantity of electricity reduces gas consumption, which reduces electric prices. A PA can estimate the electric-gas-electric DRIPE value of a measure as follows:

- Reduction in summer energy (peak + off-peak periods) at the end use in the year × electric-gas-electric DRIPE for summer in that year
- Reduction in winter energy (peak + off-peak periods) at the end use in the year × electric-gas-electric DRIPE for winter in that year

A PA who wishes to evaluate an efficiency measure implemented in 2016 would use the cross DRIPE values starting 2016. A PA who wishes to evaluate an efficiency measure implemented in 2017 would use the cross DRIPE values starting 2017. A PA who wishes to evaluate an efficiency measure implemented in 2018 would use the cross DRIPE values starting 2018.

If desired, cross DRIPE values for a given season and time-period can be added to energy DRIPE values for the corresponding season and time period to simplify evaluations.

1.4.5 Avoided Non-Embedded Cost of Carbon

The non-embedded carbon costs can be calculated as follows:

- Reduction in winter peak energy at the end use
  × winter peak energy losses from the ISO delivery points to the end use
  × the *CO_2 Externality Winter On Peak Energy* value for that year,
- Reduction in winter off-peak energy at the end use
  × winter off-peak energy losses from the ISO delivery points to the end use
  × the *CO_2 Externality Winter Off-Peak Energy* value for that year,
- Reduction in summer peak energy at the end use
  × summer peak energy losses from the ISO delivery points to the end use
  × the *CO_2 Externality Summer On-Peak Energy* value for that year,
- Reduction in summer off-peak energy at the end use
  × summer off-peak energy losses from the ISO delivery points to the end use
  × the *CO_2 Externality Summer Off-Peak Energy* value for that year

1.4.6 Local T&D Capacity Costs Avoided by Reductions in Peak Demand

Although not part of the provided tables, the benefits of peak demand reductions of avoided local transmission and distribution costs, which should be based upon specific PA information, can be calculated as follows:

- Reduction in the peak demand used in estimating avoided transmission and distribution costs at the end use × the utility-specific estimate of avoided T&D costs in $/kW-year.[6]

1.5 Levelization Calculations

Illustrative levelized costs for each of the direct avoided costs are presented along the bottom of each table. These values are calculated for three periods (2016-2025, 2016-2030, and 2016-2045), using a 2.43 percent real discount rate assumed throughout this project.

For levelization calculations outside the three periods documented in the workbook, the following inputs are required:

- The real discount rate of 2.43 percent or other user specified discount rate
- The number or periods over the levelization time frame. For instance, the period 2014-2023 contains 10 periods
- The avoided costs within the levelization period

The Excel formula used to calculate levelized values in the workbook is:

$$\text{Present Value} = -PMT(Discount\_Rate, Period, (NPV(Discount\_Rate, Annual\_\cos ts\_within\_period)$$

1.6 Converting Constant 2015 Dollars to Nominal Dollars

Unless specifically noted, all dollar values in AESC 2015 are presented in 2015 constant dollars. To convert constant dollars into nominal (current) dollars, a user would follow the formula:

$$\text{Nominal Value} = \frac{\text{Constant Value}_{2015\$}}{Conversion\,Factor\,to\ 2015\$}$$

[6] Most demand-response and load-management programs will not avoid transmission and distribution costs, since they are as likely to shift local loads to new hours as to reduce local peak load.

For instance, in order to convert an AESC 2015 $1 in 2016 into nominal 2016 dollars, one would use the AESC 2015 conversion factor from 2016 to 2015 of 0.983. Inserting the conversion factor into the equation above (Nominal Value_{2016} = ($\$1_{2015\$}$/0.983)) results in a value of $1.02 in nominal dollars.

The AESC 2015 inflator and deflator conversion factors are presented in Appendix E.

1.7 Comparisons to AESC 2015 Reference Case Avoided Costs of Electricity

A PA can prepare a comparison of the 15-year levelized avoided costs of electricity from AESC 2015 for a given reporting location and costing period to the corresponding AESC 2015 results, such as the comparison presented in Exhibit 1-2, as follows:

- Identify the relevant reporting location and costing period
- For the relevant reporting location and costing period, obtain the yearly values of each component from AESC 2013 Appendix B.
- Convert the AESC 2013 yearly values for each component from $2013 to $2015
- Calculate the 15-year levelized values of each AESC 2013 component in 2015$ (AESC 2015 uses a default discount rate of 2.43 percent)
- For the relevant reporting location and costing period, obtain the fifteen year values of each component from AESC 2015 Appendix B.

1.8 Utility-Specific Costs to be Added/Considered by Program Administrators Not Included in Worksheets

This section details additional inputs that are not specifically included in the worksheet and not part of the AESC 2015 scope of work, but should be considered by program administrators.

1.8.1 Losses between the ISO Delivery Point and the End Use

The avoided energy and capacity costs and the estimates of DRIPE include energy and capacity losses on the ISO-administered PTF, from the generator to the delivery points at which the PTF system connects to local non-PTF transmission or to distribution substations.

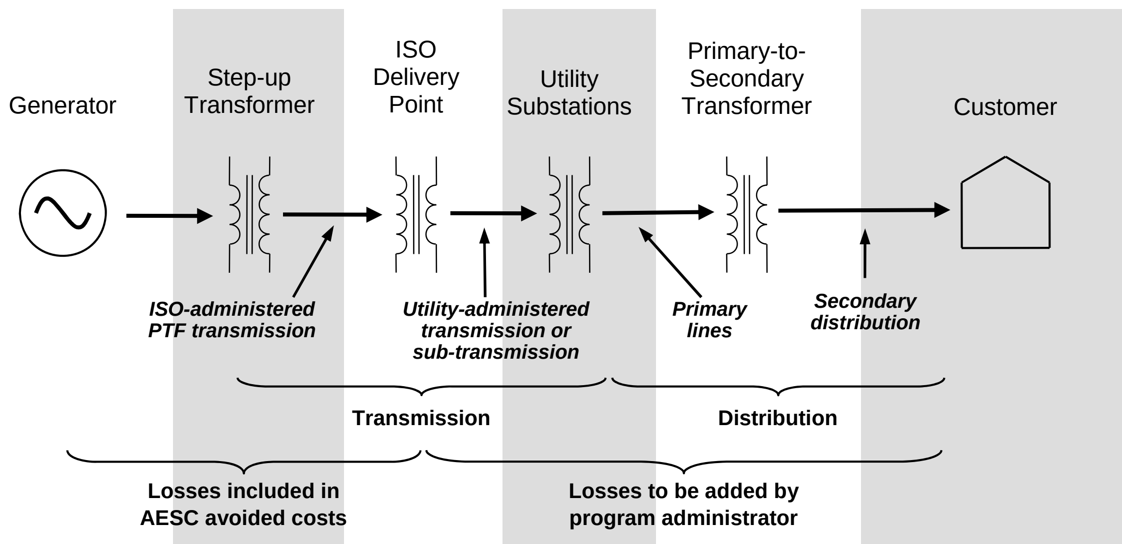
The presented values ***do not*** include the following losses:

- Losses over the non-PTF transmission substations and lines to distribution substations;
- Losses in distribution substations;

- Losses from the distribution substations to the line transformers on primary feeders and laterals;[7]
- Losses from the line transformers over the secondary lines and services to the customer meter;[8]
- Losses from the customer meter to the end use.

Exhibit A - 1 illustrates the sources of losses on transmission and distribution systems highlighted in the list above.

Exhibit A - 1. Delivery System Structure and Losses



In most cases, DSM program administrators measure demand savings from DSM programs at the end use. To be more comprehensive, the program administrator should estimate the losses from delivery points to the end uses. For example, if the energy delivered to the utility at the PTF is *a*, losses are *b*, and the customer received energy is *c*,

- Losses as a fraction of deliveries to the utility are $b \div a$,
- Losses as a fraction of deliveries to customers are $b \div c$.

[7] In some cases, this may involve multiple stages of transformers and distribution, as (for example) power is transformed from 115 kV transmission to 34 kV primary distribution and then to 14 kV primary distribution and then to 4 kV primary distribution, to which the line transformer is connected.

[8] Some customers receive their power from the utility at primary voltage. Since virtually all electricity is used at secondary voltages, these customers generally have line transformers on the customer side of the meter and secondary distribution within the customer facility.

Hence, each kilowatt or kilowatt-hour saved at the end use saves $1 + {}^{b}\!/_{c}$. The program administrator should estimate that ratio and multiply the end-use savings or benefits by that loss ratio. Loss ratios will be generally higher for higher-load periods than lower-load periods, since losses in wires (both within transformers and in lines) vary with the square of the load, for a given voltage and conductor type.

If the change in load does not change the capacity of the transmission and distribution system, then the losses should be computed as marginal losses, which are roughly twice the percentage as average line losses for the same load level.[9] Energy savings and/or growth do not generally result in changing the wire sizes. Hence, for energy avoided costs, losses are estimated on a marginal basis, so *a, b*, and *c* above are increments or derivatives, rather than total load values.

If the change in load results in a proportional change in transmission and distribution capacity, losses should be computed as the average losses for that load level. If the program administrator treats all load-carrying parts of the transmission and distribution as avoidable and varying with peak load, then only average losses should be applied to avoided capacity costs.

1.9 Energy Efficiency Programs and the Capacity Market

An energy efficiency program that produces a reduction in peak demand has the ability to avoid the wholesale capacity cost associated with that reduction. The capacity-cost amount that a particular reduction in peak demand will avoid in a given year will depend upon the approach that the program administrator responsible for that energy efficiency program takes towards bidding all, or some, of that reduction into the applicable FCAs.

A program administrator (PA) can choose an approach that ranges between bidding 100 percent of the anticipated demand reduction from the program into the relevant FCAs to bidding zero percent of the anticipated reduction into any FCA.

- A PA that wishes to bid 100 percent of the anticipated demand reduction from the program into the relevant FCA has to do so when that FCA is conducted, which can be up to three years in advance of the program implementation year. For example, a PA responsible for an efficiency program that will be implemented starting January 2016 would have had to have bid 100 percent of the forecast demand reduction for June 2016 onwards from that program into FCA 7, which was held in 2013. Since a bid is a firm financial commitment, there is an associated financial risk if the PA is unable to actually deliver the full demand reduction for whatever reason. The value of this approach is the compensation paid by ISO-NE, i.e., the quantity of peak reduction each year times the FCA price for the corresponding year.

[9] In this sense, "line losses" does not include the no-load losses that result from eddy currents in the cores of transformers. These are often called "iron" losses (since transformer cores were historically made of iron), in contrast to the load-related "copper" losses of the lines and transformer windings.

- If a PA does not bid any of the anticipated demand reduction into any FCA, the program can still avoid some capacity costs if it has a measure life longer than three years.[10] Under this approach, a PA responsible for an efficiency program starting January 2016 simply implements that program. The customers' contribution to the ISO peak load, whenever that occurs in the summer of 2016, would be lower due to the program. This PA's customers would see some benefit from a lower capacity share starting in June 2017 (the following year). The reduced capacity requirement will reduce the capacity acquired in future FCAs, starting as early as the reconfiguration auctions for the power year starting in June 2017 and affecting all the auctions for the power years from June 2020 onward; the entire region will benefit from the reduction of capacity purchases.

Exhibit A - 2 illustrates the various approaches that a program administrator could choose for avoiding wholesale capacity costs via a hypothetical energy efficiency measure that is implemented in 2012 and produces a 100 kW reduction for a five year period, 2014 to 2018. In this example, the PA considers three approaches.

The first approach is to bid 100 percent of the projected reduction, 100 kW, into each of the relevant FCAs. Under this approach the reduction avoids capacity costs roughly equals to its revenues from the FCM each year, i.e., l to 100 kW times the FCA price in each of the five years, 2014 through 2018.[11] However, the PA would have had to bid that 100-kW reduction, scheduled to start in 2014, into each FCA from FCA 5 onward.

The second approach is to bid none of the projected reductions into any FCA. Under this approach, the reduction avoids capacity costs equal to the value of the reduction in installed capacity it causes in 2018. That value is 100 kW increased by the reserve margin (17.2 percent for illustrative purposes) in 2018 and multiplied by the FCA price in 2018. The avoided capacity cost is limited to the impact in 2018 because ISO-NE sets the ICR to be acquired in each power year three years in advance of that year. Thus, in this approach, ISO-NE would first see the 100 kW reduction as a lower actual peak load in 2014. However, 2018 is the earliest power year for which ISO-NE could reflect the actual reduction in 2014 because, by July 2015 ISO-NE will have forecast peak load for 2018, set the ICR for 2018, and run the FCA for 2018.

The third illustrated approach is to bid 50 percent of the projected reduction, 50 kW, into each of the relevant FCAs.

Other approaches, not illustrated in Exhibit A - 2, would include bidding an increasing percentage of the 2014 load reduction into FCA 5 and future auctions, as the PA becomes more confident in its estimates of the demonstrable savings.

[10] In many cases, the PA is a utility; in other cases it is a state agency or other entity. In any case, the reduction in load benefits the customers served by the PA, whether they pay for generation supply through a utility standard-offer supply, an aggregator, or a competitive supplier.

[11] The price paid to a capacity resource in any year can vary from the price paid by load-serving entities by various factors, including PER deductions, availability penalties, multi-year prices for new resources, local reliability costs, etc.

Exhibit A - 2. Illustration of Alternative Approaches to Capturing Value from Reductions in Peak Demands

Hypothetical measure installed in 2012, reduces peak by 100 kw for 5 years								
ISO-NE sets NICR and Conducts FCA			Example 1—PA bids 100% of expected demand reduction into each corresponding FCA		Example 2—PA bids zero expected demand reduction into each corresponding FCA		Example 3—PA bids 50% of expected demand reduction into each corresponding FCA

1.10 High Gas Price Sensitivity Case Avoided Cost of Electricity

Chapter 6 provides avoided wholesale electric energy costs for a High Gas Price sensitivity case. Calculating the complete avoided cost of electricity under each of those sensitivity cases is not included in the AESC 2015 scope of work. However, a PA could use the results from those sensitivity cases to develop approximate estimates of the avoided costs of electricity for either or both sensitivity cases.

The estimates developed through th**e** approach described below will be approximate because they will not reflect the changes in various components, relative to Base Case values, that would occur with a change in wholesale electric energy costs. For example, an increase in wholesale electric energy costs under the High Gas Price would cause a decrease in the REC cost component.

A PA could develop an approximate estimate of the 15-year levelized avoided costs of electricity for the High Gas Price sensitivity case for a given reporting location by multiplying the wholesale avoided costs of electric energy for that location, on page two of the relevant Appendix B workbook, in each of the columns v, w, x, and y, by 1+ the percentage increase in electric energy prices in each year under the High Gas Case from column h in Exhibit A-3.

Exhibit A - 3. Avoided electric energy costs by year, WCMA, High Gas Case versus Base Case

Year	Annual Wholesale Gas Price, AGT hub (2015$/MMBtu)				Annual Energy Price, WCMA (2015$/MWh)			
	CASES		High Gas Case - Base Case		CASES		High Gas Case - Base Case	
	Base	High Gas	absolute difference	% change from Base Case	Base	High Gas	absolute difference	% change from Base Case
	a	b	c = b - a	d = c / a	e	f	g = f - e	h = g / e
2015	$ 6.96	$ 6.96	$0.00	0%	$57.59	$57.59	$0.00	0%

1.11 Guide to Applying Avoided Natural Gas Costs

Appendix C of AESC 2015 provides projections of avoided natural gas costs cost by end use by year as well as projections of natural gas supply and cross-fuel DRIPE by end use by year.

Avoided natural gas costs cost by end use

Exhibits C-1 through C-5 provide projections of avoided natural gas costs cost by end use by year for three sub-regions in New England, i.e. Southern New England (CT, RI, MA), Northern New England (NH, ME) and Vermont. The avoided cost by end use by is the sum of:

- the avoided cost of the gas sent out by the LDC (avoided city-gate cost) and
- the avoidable distribution cost, referred to as the avoidable LDC margin.

The Exhibits report avoided costs for Residential non-heating, water heating, heating and all; Commercial & Industrial non-heating, heating and all and all sectors.

- Non-heating value streams apply to year-round end uses whose gas use is generally constant over the year.
- Heating value streams apply to heating end uses where usage is high during winter months.
- For each program and/or measure, users should choose the appropriate value stream to determine the avoided cost benefit stream in evaluating cost-effectiveness.

Exhibits C-1 through C-5 provide two sets of avoided natural gas costs by end-use for each sub-region, one set assuming no avoided margin and one set assuming some level of avoided margins. PAs need to determine if their LDC does, or does not, have avoidable LDC margins.

Natural Gas Supply and Cross-Fuel DRIPE

Exhibits C-7 through C-13 provide projections of natural gas supply and cross-fuel DRIPE by end use / costing period by year by state, as well as for New England. PAs should use the natural gas supply and cross-fuel DRIPE values that reflect the relevant state regulations governing treatment of energy DRIPE. The values reported by state, Exhibits C-7 through C-12 are intrastate values. The values for New England, C-13, are essentially intrastate plus rest of pool vales.

A program administrator would apply these values regardless of whether or not the program administrator uses avoided costs including or excluding retail margin. If desired, a PA may add the natural gas supply and cross-fuel DRIPE values for a given year and end use / costing period to the avoided natural gas costs from Exhibits C-1 through C-6 for the corresponding year and end use / costing period.

AESC 2015 does not project any difference in natural gas supply or gas Cross-Fuel DRIPE for efficiency measures implemented in 2016, 2017 or 2018. For example there are no differences by year due to differences in phase-in or decay. The only difference between the values applicable to reductions from measures of different vintages is the start year. A PA who wishes to evaluate an efficiency measure implemented in 2016 would use the cross DRIPE values starting 2016. A PA who wishes to evaluate an efficiency measure implemented in 2017 would use the cross DRIPE values starting 2017. A PA who wishes to evaluate an efficiency measure implemented in 2018 would use the cross DRIPE values starting 2018.

The columns in Exhibits C-7 through C-13 are labeled 1 through 9. **These column labels do NOT refer to xls cell columns.**

Column 1 of Exhibits C-7 through C-13 provide gas supply DRIPE. PAs would apply the gas supply value in each year from Column 1 to every MMBtu of gas reduction from efficiency measures over the life of that measure. (As discussed in Chapter 7, a reduction in the quantity of gas used by retail gas customers reduces the demand for gas in producing regions and therefore reduce the market price for that gas supply. As discussed in detail in Chapter 7, we do not expect to see any significant decay in these natural gas supply DRIPE values.)

Columns 2 through 9 of Exhibits C-7 through C-13 provide gas cross-fuel c DRIPE by costing period / load segment. . PAs would apply the gas cross-fuel value in each year from each of these columns to the y MMBtu of gas reduction in the corresponding costing period / load segment in the corresponding year. (A reduction in gas use by retail gas customers reduces the gas production costs and gas basis components of the New England wholesale cost of gas incurred by gas-fired electric generators. These benefits accrue to gas programs for reducing natural gas prices to electric generators as a result of natural gas efficiency.)

Public Estimates of Price Suppression in Wholesale Electricity Markets

NOTES:

General — All Avoided Costs are in Year 2015 Dollars

ISO NE periods: Summer is June through September, Winter is all other months. Peak hours are: Monday through Friday 7 AM - 11 PM; Off-Peak Hours are all other hours

1 Avoided cost of electric energy = (wholesale energy avoided cost + REC cost to load) * risk premium, e.g. A = (v+ad) * (1+Wholesale Risk Premium)

2 Absolute value of avoided capacity costs and capacity DRIPE each year is function of quantity of kW reduction in year, PA strategy re bidding that reduction into applicable FCAs, and unit values in columns e and f. □

3 Proceeds from selling into the FCM also include the ISO-NE loss factor of 8%

4 PTF loss = 2.20%

5 Electric Cross -DRIPE is electric owen fuel DRIPE + Electric Cross-DRIPE

Revision: 4/3/2015

NOTES:

General — All Avoided Costs are in Year 2015 Dollars

ISO NE periods: Summer is June through September, Winter is all other months. Peak hours are: Monday through Friday 7 AM - 11 PM; Off-Peak Hours are all other hours

1. Avoided cost of electric energy = (wholesale energy avoided cost + REC cost to load) * risk premium, e.g. A = (v+ad) * (1+Wholesale Risk Premium)
2. Absolute value of avoided capacity costs and capacity DRIPE each year is function of quantity of kW reduction in year, PA strategy re bidding that reduction into applicable FCAs, and unit values in columns e and f. □
3. Proceeds from selling into the FCM also include the ISO-NE loss factor of 8%
4. PTF loss = 2.20%
5. Electric Cross -DRIPE is electric owen fuel DRIPE + Electric Cross-DRIPE

Revision: 4/3/2015

NOTES:

General — All Avoided Costs are in Year 2015 Dollars

ISO NE periods: Summer is June through September, Winter is all other months. Peak hours are: Monday through Friday 7 AM - 11 PM; Off-Peak Hours are all other hours

1. Avoided cost of electric energy = (wholesale energy avoided cost + REC cost to load) * risk premium, e.g. A = (v+ad) * (1+Wholesale Risk Premium)
2. Absolute value of avoided capacity costs and capacity DRIPE each year is function of quantity of kW reduction in year, PA strategy re bidding that reduction into applicable FCAs, and unit values in columns e and f. □
3. Proceeds from selling into the FCM also include the ISO-NE loss factor of 8%
4. PTF loss = 2.20%
5. Electric Cross -DRIPE is electric owen fuel DRIPE + Electric Cross-DRIPE

Revision: 4/3/2015

NOTES:

General All Avoided Costs are in Year 2015 Dollars

ISO NE periods: Summer is June through September, Winter is all other months. Peak hours are: Monday through Friday 7 AM - 11 PM; Off-Peak Hours are all other hours

1 Avoided cost of electric energy = (wholesale energy avoided cost + REC cost to load) * risk premium, e.g. A = (v+ad) * (1+Wholesale Risk Premium)

2 Absolute value of avoided capacity costs and capacity DRIPE each year is function of quantity of kW reduction in year, PA strategy re bidding that reduction into applicable FCAs, and unit values in columns e and f. □

3 Proceeds from selling into the FCM also include the ISO-NE loss factor of 8%

4 PTF loss = 2.20%

5 Electric Cross -DRIPE is electric owen fuel DRIPE + Electric Cross-DRIPE

Revision: 4/3/2015

NOTES:

General All Avoided Costs are in Year 2015 Dollars
ISO NE periods: Summer is June through September, Winter is all other months. Peak hours are: Monday through Friday 7 AM - 11 PM; Off-Peak Hours are all other hours

1 Avoided cost of electric energy = (wholesale energy avoided cost + REC cost to load) * risk premium, e.g. A = (v+ad) * (1+Wholesale Risk Premium)

2 Absolute value of avoided capacity costs and capacity DRIPE each year is function of quantity of kW reduction in year, PA strategy re bidding that reduction into applicable FCAs, and unit values in columns e and f.

3 Proceeds from selling into the FCM also include the ISO-NE loss factor of 8%

4 PTF loss = 2.20%

5 Electric Cross -DRIPE is electric owen fuel DRIPE + Electric Cross-DRIPE

Revision: 4/3/2015

NOTES:

General All Avoided Costs are in Year 2015 Dollars

ISO NE periods: Summer is June through September, Winter is all other months. Peak hours are: Monday through Friday 7 AM - 11 PM; Off-Peak Hours are all other hours

1 Avoided cost of electric energy = (wholesale energy avoided cost + REC cost to load) * risk premium, e.g. A = (v+ad) * (1+Wholesale Risk Premium)

2 Absolute value of avoided capacity costs and capacity DRIPE each year is function of quantity of kW reduction in year, PA strategy re bidding that reduction into applicable FCAs, and unit values in columns e and f. □

3 Proceeds from selling into the FCM also include the ISO-NE loss factor of 8%

4 PTF loss = 2.20%

5 Electric Cross -DRIPE is electric owen fuel DRIPE + Electric Cross-DRIPE

Revision: 4/3/2015

NOTES:

General All Avoided Costs are in Year 2015 Dollars

ISO NE periods: Summer is June through September, Winter is all other months. Peak hours are: Monday through Friday 7 AM - 11 PM; Off-Peak Hours are all other hours

1 Avoided cost of electric energy = (wholesale energy avoided cost + REC cost to load) * risk premium, e.g. A = (v+ad) * (1+Wholesale Risk Premium)

2 Absolute value of avoided capacity costs and capacity DRIPE each year is function of quantity of kW reduction in year, PA strategy re bidding that reduction into applicable FCAs, and unit values in columns e and f.

3 Proceeds from selling into the FCM also include the ISO-NE loss factor of 8%

4 PTF loss = 2.20%

5 Electric Cross -DRIPE is electric owen fuel DRIPE + Electric Cross-DRIPE

Revision: 4/3/2015

NOTES:

General All Avoided Costs are in Year 2015 Dollars
ISO NE periods: Summer is June through September, Winter is all other months. Peak hours are: Monday through Friday 7 AM - 11 PM; Off-Peak Hours are all other hours

1 Avoided cost of electric energy = (wholesale energy avoided cost + REC cost to load) * risk premium, e.g. A = (v+ad) * (1+Wholesale Risk Premium)
2 Absolute value of avoided capacity costs and capacity DRIPE each year is function of quantity of kW reduction in year, PA strategy re bidding that reduction into applicable FCAs, and unit values in columns e and f. □
3 Proceeds from selling into the FCM also include the ISO-NE loss factor of 8%
4 PTF loss = 2.20%
5 Electric Cross -DRIPE is electric owen fuel DRIPE + Electric Cross-DRIPE

Revision: 4/3/2015

NOTES:

General: All Avoided Costs are in Year 2015 Dollars
ISO NE periods: Summer is June through September, Winter is all other months. Peak hours are: Monday through Friday 7 AM - 11 PM; Off-Peak Hours are all other hours

1. Avoided cost of electric energy = (wholesale energy avoided cost + REC cost to load) * risk premium, e.g. A = (v+ad) * (1+Wholesale Risk Premium)
2. Absolute value of avoided capacity costs and capacity DRIPE each year is function of quantity of kW reduction in year, PA strategy re bidding that reduction into applicable FCAs, and unit values in columns e and f.
3. Proceeds from selling into the FCM also include the ISO-NE loss factor of 8%
4. PTF loss = 2.20%
5. Electric Cross -DRIPE is electric owen fuel DRIPE + Electric Cross-DRIPE

Revision: 4/3/2015

Financial Parameters for AESC 2015

1.1 Introduction

This appendix describes the assumptions and methods AESC 2015 used to develop the common financial parameters the TCR team used to prepare the study.

AESC 2015 requires that values be reported in constant 2015 dollars (2015$), which requires a set of inflators and deflators to convert values in other year dollars to 2015$. AESC 2015 also requires levelized avoided costs be calculated n 2015$ for three specific time periods: 10 years (2016-2025); 15 years (2016-2030); and 30 years (2016-2045). These levelized costs, which are used for summary reporting and comparison purposes, are to be calculated using an illustrative constant$ or "real" discount rate.

Exhibit E - 1 reports the long-term inflation rate and real discount rate used in AESC 2015. The inflation rate is consistent with the value used in prior AESC studies. The real discount rate is higher than the value used in AESC 2013 but consistent with the values used in AESC 2009 and AESC 2011 of 2.22% and 2.46% respectively.

Exhibit E - 1 Summary of Common Financial Parameters AESC 2015 versus AESC 2013.

	AESC 2015	AESC 2013
Inflation Rate	1.88%	2.00%
Real Discount Rate	2.43%	1.36%

Exhibit E - 2 reports the resulting AESC 2015 inflator and deflator values by year.

Exhibit E - 2. Inflators and Deflators to Convert Nominal to 2015$

Year	GDP Chain-Type Price Index	Annual Inflation	Inflators/Deflators to convert nominal $ to 2015$
2000	81.89	2.28%	1.349
2001	83.75	2.28%	1.319
2002	85.04	1.53%	1.299
2003	86.74	1.99%	1.274
2004	89.12	2.75%	1.240
2005	91.99	3.22%	1.201
2006	94.81	3.07%	1.165
2007	97.34	2.66%	1.135
2008	99.25	1.96%	1.113
2009	100.00	0.76%	1.105
2010	101.22	1.22%	1.092
2011	103.31	2.06%	1.070
2012	105.17	1.80%	1.051
2013	106.73	1.49%	1.035
2014	108.55	1.70%	1.018
2015	110.50	1.80%	1.000
2016	112.38	1.70%	0.983
2017	114.52	1.90%	0.965
2018	116.81	2.00%	0.946
2019	119.14	2.00%	0.927
2020	121.52	2.00%	0.909
2021	123.95	2.00%	0.891
2022	126.43	2.00%	0.874
2023	128.96	2.00%	0.857
2024	131.54	2.00%	0.840
2025	134.01	1.72%	0.825
2026	136.53	1.73%	0.809
2027	139.10	1.75%	0.794
2028	141.72	1.77%	0.780
2029	144.38	1.83%	0.765
2030	147.09	1.88%	0.751

Data Sources:

1	Values through 2013 from Bureau of Economic Analysis, Table 1.1.9	
2	Values for 2014 through 2024 derived from *An Update to the Budget and Economic Outlook: 2014 to 2024*, Congressional Budget Office, August 2014, Table B-1	
3	Values for 2025 onward based on AEO 2014 inflation rate of	1.78%

1.2 Assumptions and Methodology Used to Develop Inflators and Deflators

AESC 2015 calculated the inflators to convert nominal dollars from prior years (i.e., pre-2015) into 2015$ from the Gross Domestic Product (GDP) chain-type price index published by the U.S. Department of Commerce's Bureau of Economic Analysis (BEA)[1].

AESC 2015 developed the deflators to convert nominal dollars from future years (i.e., post-2015) into 2015$ for 2015 through 2024 from the Congressional Budget Office (CBO) projection of inflation as of August 2014, the most recent available at the time it was developing these parameters[2] For the period 2025 to 2030 AESC 2015 use the projection of inflation from the Energy Information Administration (EIA) Annual Energy Outlook 2014 (AEO 2014), which was released May 2014. The resulting composite long-term inflation rate over the period 2015 through 2030 is 1.88%. That long-term rate is consistent with the 20-year annual average inflation rate from 1995 to 2014 of 1.95 percent implied by the Gross Domestic Product (GDP) chain-type price index.

1.3 Assumptions and Methodology Used to Develop Real Discount Rate

AESC 2015 uses a real discount rate of 2.43 percent for calculations of illustrative levelized costs. It calculated that illustrative real discount rate according to the formula used for each AESC study since 2007:

Real discount rate = ((1+ long-term nominal interest rate)/ (1+inflation rate)-1)

One input to that formula is the long-term projected inflation rate of 1.88 percent, discussed above. The other input is a projection of the long-term nominal interest rate, which AESC 2015 developed from two projections of the nominal rate of return for 10-year Treasury Bonds. Those two projections are the same as those AESC 2015 used for the long-term inflation rate, i.e., the CBO projection as of August 2014 for the period 2015 through 2024 and the EIA AEO 2014 for the period 2025 through 2030.

[1] Bureau of Economic Analysis, Table 1.1.9.

[2] *An Update to the Budget and Economic Outlook: 2014 to 2024*, Congressional Budget Office forecast, August 2014, Table B-1

Exhibit E - 3 presents a summary comparison of interest rates, inflation rates and real discount rates. The AESC 2015 real discount rate is higher than the value used in AESC 2013. However it is consistent with the values used in AESC 2009 and AESC 2011 of 2.22 percent and 2.46 percent respectively. The rate is also consistent with the real discount rate through 2040 of 2.36 percent implied in the macroeconomic forecasts for AEO 2014 and through 2024 of 2.42 percent implied in the CBO projections.[3] It is higher than the rate derived from the average of 30 year Treasury Bills issued to date in 2014. However, the 2014 average of 30 year Treasury Bill rates is a "snapshot" of current expectations regarding interest rates over the AESC study period, rather than a projection like that provided by the CBO and AEO 2014.

Assumptions:

1	RPS Targets for CT, ME, MA, NH & RI are based on state-specific legislation and regulation in effect as of December 31, 2015.
2	Vermont does not currently have an RPS. AESC 2015 assumes that Vermont resources can be counted toward other states' RPS obligations through 2016.
3	REC prices for 2015 and 2016 are based on those listed in Exhibit 5-39.
4	Prices beyond 2016 for MA Class I, CT Class I, NH Class I, and RI "New" based on supply curve analysis (2020 onward) and interpolation (2017-2019).
5	CT Class II, MA Class II-WTE, ME Class II, and RI "Existing" REC markets are in surplus. Therefore, REC prices in these markets are expected to remain relatively constant.
6	The MA Class II market has overlapping eligibility with CT Class I. In addition, while there is theoretically ample supply to meet MA Class II, fewer generators than expected have undertaken the steps necessary to comply with the eligibility criteria and become certified. Therefore, the MA Class II market has been in shortage, and the legislature directed the DOER to take measures necessary to bring the market into balance. Long-run MA Class II REC prices are therefore assumed to be the lesser of CT Class I REC prices and 50 percent of the MA Class II ACP rate.
7	Long-term REC prices for MA APS and NH Class 1 thermal are forecast at 90 percent of the ACP rate; CT Class III prices are expected to remain at about 86 percent of ACP (nominal terms) over the period.
8	Existing solar facilities across New England are eligible for NH Class II. As such, this market is expected to remain in balance at about 90 to 95 percent of ACP, as solar resources age out of solar carve outs and competing Class 1 prices drop.
9	The NH Class III and NH Class IV markets have overlapping eligibility with CT Class I, and in the near term, the markets face uncertainty. NH-III and NH-IV REC prices are assumed to be the lesser of CT Class I and 90% of their respective Alternative Compliance Payment (ACP) rates.

Appendix G: Survey of Transmission and Distribution Capacity Values

1.1 Introduction

The AESC 2015 project team issued a survey to the sponsoring electric utilities requesting the estimates of avoided Transmission and Distribution costs they use in their analyses of efficiency measure cost-effectiveness. The survey also requested a description of the methodology on which those estimates were based. Exhibit G-1 summarizes the results of the survey:

Exhibit G-1. Summary of Electric Utilities' T&D Cost Survey

Company	Year $	Transmission $kW-year	Distribution $kW-year	Total T&D $kW-year	Methodology
CL&P (CT)	2015	$1.25	$32.19	$33.44	ICF Tool
National Grid MA	2015	$23.01	$124.28	$147.29	ICF Tool
National Grid RI	2015	$37.86	$162.47	$200.33	ICF Tool
United Illuminating	2015	$2.74	$49.75	$52.49	B&V Report
Efficiency Maine	2015	NA	NA	$81.67	Historical (1)
Vermont	2015	$50.45	$113.51	$163.96	Historical

Notes
NA= Not applicable
ICF Tool = ICF workbook developed in 2009.
B&V Report = United Illuminating Avoided Transmission & Distribution Cost Study Report, Black & Veatch, September 2009.

Descriptions of the methodology used by respondents are detailed below.

1.2 ICF Tool

A complete description of the ICF model used by National Grid and other electric utilities was detailed in the AESC 2005 report. In summary, the ICF Tool is a workbook developed by ICF as part of the 2005 AESC Study. Inputs for the workbook are: 1) historical and budgeted future capital costs, 2) historical and future load, and 3) various accounting parameters from FERC Form 1 data.

Analysis period cost data is divided by analysis period load data to derive an average capital cost/kW. This is multiplied by a factor representing the percentage of capital costs that is avoidable by energy efficiency (another input variable). This avoidable $/kW is further modified by a carrying charge determined from the accounting inputs, to develop an annualized avoided capacity value in $/kW. Based on review of some of the carrying charge calculations in the AESC 2009 study, National Grid has updated this part of the workbook to create the updated ICF Tool. Other utilities have updated the workbook at other intervals.

1.3 Black and Veatch Report

United Illuminating's methodology is detailed in a Black and Veatch Report. Black and Veatch's methodology follows briefly:

- Identification of historical and future T&D capacity additions which could have been fully or partially avoided with additional energy efficiency programs.
- Collection of historical costs plus AFUDC associated with projects identified in the first step. Calculated project costs are then divided by each project's incremental MW load carrying capacity to derive a marginal capital cost for capacity per MW.
- Calculation of marginal O&M expenses.
- Converting marginal capital costs to annual costs adjusting for revenue requirements based on accounting inputs.
- Calculation of energy efficiency savings based on historical and projected load growth.
- Calculations of annual avoided cost based on annual costs and identified energy efficiency savings.

Appendix H: Pooled Transmission Losses Methodology

There is a loss of electricity between the generating unit and ISO-NE's delivery points, where power is delivered from the ISO-NE administered pooled transmission facilities (PTF) to the distribution utility local transmission and distribution systems. Therefore, a kilowatt load reduction at the ISO-NE's delivery points, as a result of DSM on a given distribution network, reduces the quantity of electricity that generators have to produce by one kilowatt plus the additional quantity that would have been required to compensate for losses. The energy prices forecast by pCA/PSO model reflect these losses. However, the forecast of capacity costs from the FCM do not and therefore, the forecast avoided capacity costs should be adjusted for transmission losses.

AESC 2015 estimated the PTF loss factor during the summer peak period by analyzing six summer-peak power flow cases ISO New England filed in its FERC Form 715. The summer peak loss factors for ISO New England in those six cases ranges from 2.14% to 2.34% with the average across these cases being 2.20%. Based on this analysis, AESC 2015 uses a marginal PTF demand loss factor of 2.20% for capacity costs. This is higher than the AESC 2013 factor of 1.5%

Exhibit H-1. PTF Losses vs. Non-PTF Demand for the Top 100 Summer Hours, 2010

Power Year summer	Peak Load (MW)	Losses (MW)	Loss Factor (%)	Loss Factor Averages (%)
2013/2013 (1)	27196.79	636.45	2.34%	
2013/2018 (1)	28671	638.71	2.23%	
2013/2023 (1)	29372	591.23	2.01%	
Three summer average				2.19%
2014/2014 (2)	27471	623.04	2.27%	
2014/2019 (2)	29057	637.35	2.19%	
2014/2024 (2)	30308	649.39	2.14%	
Three summer average				2.20%
Six summer average				2.20%

Table of Contents

Executive Summary

National Grid is investigating the influence of three key Wi-Fi thermostat features on its residential customers' energy usage, behavior, and satisfaction:

1. Integrated energy meters that provide whole-house energy consumption information.
2. HVAC control optimization.
3. A platform for participation in demand response (DR) events.

Working in partnership with Ecobee and Earth Networks, National Grid conducted a study to demonstrate the functionality of the Ecobee Smart Thermostat and integrated energy meter, and to evaluate the impact of Earth Networks' HVAC control optimization software and of four DR events on residential customers' natural gas and electric usage.

Objectives

National Grid engaged Cadmus to complete the following:

1. Assess the value and use of the Ecobee Smart Thermostat and integrated energy meter information to customers.
2. Determine the energy (natural gas and electric) impacts of the Ecobee thermostat with and without Earth Networks' HVAC optimization controls.
3. Verify the demand impacts of and participant experiences with each of the four DR events.

Technology

National Grid chose the Ecobee Smart Thermostat to represent a Wi-Fi thermostat in this study. The user could control their HVAC system settings at the thermostat itself, using a web portal or with a mobile application (app). In addition, each participant received an integrated home energy meter, which provided participants with information regarding energy usage and costs at their thermostats and web portals. This offered them access to viewing their whole-house electricity usage and costs, electricity bill projections, HVAC runtime histories, and weather-adjusted HVAC runtime histories.

As part of the evaluation, a portion of the participants' thermostats used HVAC control optimization software by Earth Networks (this report refers to this software as Automatic Temperature Control [ATC]). The software's algorithms use real-time, hyper-local weather data from WeatherBug weather stations, historical HVAC runtime data from the Ecobee Smart Thermostat, and historical energy usage data from the integrated energy meter to optimize HVAC runtimes, seeking to save energy while maintaining comfort.

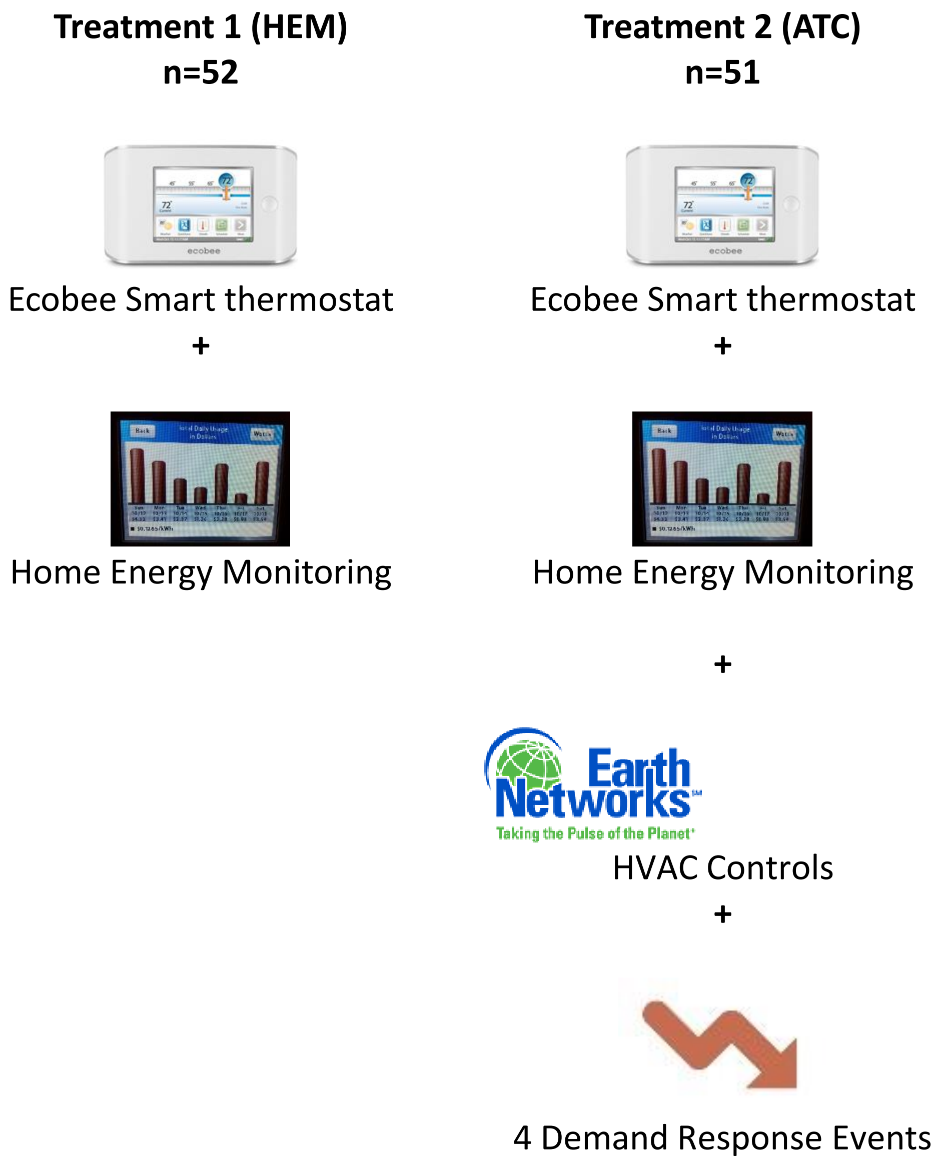
The implementer also tested a variety of DR event styles over the summer 2014, with the implementer choosing days forecast to be especially hot for running DR events. In total, the implementer ran three unique types of DR events across four days.

Methodology

National Grid administered the pilot using two treatment groups. Both groups received an Ecobee Smart thermostat and home energy monitoring capabilities via the integrated energy meter. In addition, one of the treatment groups' thermostats connected to Earth Networks' HVAC optimization controls, and they were invited to participate in the four DR events.

Figure 1 illustrates treatments for each group. This report references treatment group 1 as the Home Energy Monitoring (HEM) group and treatment group 2 as the ATC group.

Figure 1. Pilot Design



To accomplish the project objectives, Cadmus completed the following project tasks:

1. Collect and analyze smart thermostat and integrated energy meter data.
2. Conduct national gas billing analysis.
3. Conduct electric billing analysis.
4. Verify reported impacts from DR events.
5. Design, conduct, and analyze participant surveys.

Findings and Recommendations

Objective 1: Value of Ecobee Smart Thermostat and Integrated Energy Meter

Participants found having the ability to remotely control their thermostat using the smartphone app or the web portal as the most valuable feature of the Ecobee Smart Thermostat. Although some participants used the integrated energy meter features, including energy monitoring and bill estimation tools, interest in these features decreased significantly after two weeks.

Usefulness of Features

Participants found the Ecobee Smart Thermostat's basic functions more valuable than the integrated energy meter. Participants awarded the thermostat's temperature changing feature an average usefulness rating of 9.27/10.00, compared to 7.22/10.00 for the viewing energy usage feature and only 5.24/10.00 for the bill estimation feature.

Participants found remotely controlling and monitoring their thermostats as the thermostat's most valuable feature. Participants found flexible schedule programming, ease of use, and energy reports approximately one-half as valuable and considered convenience, checking outside temperatures, and the actual thermostats as the least valuable features/characteristics.

Persistence in Use of Features

Participants' interactions with their thermostats declined over time. During the program's first two weeks, participants reported viewing their energy usage more frequently, with the majority viewing their energy usage a couple of times each week. Several weeks into the program, the majority of customers viewed their energy usage only a few times each month. Use of the bill estimation feature also declined over time, with 10% of participants using the bill estimation feature multiple times per day for the first two weeks of the program, then losing interest after the initial period, with only 2% continuing to use the feature daily. All customers continued using the thermostat to change their home's temperature, with some additional activity occurring during the pilot's first two weeks.

Recommendations

An area for further research may address methods for keeping customers engaged with the energy usage and bill estimation information, perhaps by updating it regularly with new facts or comparisons to the past week's usage or to neighborhood averages.

Objective 2: Impact of HVAC Control Optimization

The HVAC optimization controls provided energy savings during the heating and cooling seasons, while regulating temperature setpoints more accurately than the comparison participant group without HVAC optimization controls. In terms of energy savings, the HVAC optimization controls outperformed the comparison group significantly in the cooling season, but provided similar savings in the heating season.

Temperature Regulation

During the heating and cooling seasons, HVAC systems with HVAC optimization controls more effectively regulated temperatures than HVAC systems without HVAC optimization controls. Indoor air temperatures for the group with HVAC optimization controls (the ATC group) more closely matched setpoints compared to the group without HVAC optimization controls (HEM group):

- In the heating season, indoor air temperatures (IAT) in the ATC group averaged 1.8 degrees warmer than setpoints, compared to 5.1 degrees warmer than setpoints in the HEM group.
- When cooling was required in the cooling season, IAT in the ATC group averaged 0.7 degrees warmer than the setpoint, compared to 2.4 degrees warmer than the setpoint in the HEM group.

Heating Season Energy Savings

Heating systems with HVAC optimization controls saved about the same in natural gas as heating systems without HVAC optimization controls. When comparing ATC and HEM participants with just one thermostat, Cadmus found natural gas savings to be about the same between the two groups. The HEM group performed slightly better when considering savings as a percentage of total gas usage, while the ATC group performed slightly better when considering savings as percentage of the disaggregated heating load and savings per square foot:

- As a percentage of total gas usage, the HEM group saved an average of 9.5%, compared to 9.1% for participants in the ATC group.
- As a percentage of the disaggregated heating load, the ATC group saved an average of 13.1% of heating gas usage, compared to 12.4% for participants in the HEM group.
- On a per-square-foot level, the ATC group saved 0.0480 therms/sqft compared to 0.0460 therms/sqft for the HEM group.

Cooling Season Energy Savings

Cooling systems with HVAC optimization controls saved significantly more electricity than cooling systems without HVAC optimization controls. When comparing ATC and HEM participants with just one thermostat, Cadmus found the ATC group outperformed the HEM by three times when considering the disaggregated cooling load and five times when considering savings per square foot:

- As a percentage of the disaggregated cooling load, the ATC group saved 16.5%, compared to 5.1% for the HEM group.

- On a per-square-foot level, the ATC group saved 0.1808 kWh/sqft, compared to 0.0358 kWh/sqft.

Recommendations

HVAC optimization controls show promise as an effective measure for reducing heating and cooling energy usage while improving temperature regulation, but energy savings calculations should be updated with larger sample sizes to improve the precision of estimates.

Objective 3: Impact of DR

Overall, DR events reduced participants' HVAC system runtimes without creating discomfort for participants.

Demand Impacts

DR events occurred and affected runtimes. The runtime impacts confirmed DR events occurred. Across all events, an average estimated runtime reduction of 7.9 minutes occurred in the first event hour and 3.6 minutes occurred in the second hour.

Evaluated kW impacts are likely overstated. Cadmus found statistically significant estimates of demand reductions were almost twice the value expected, given runtime reductions and the average tonnage of air conditioners (AC) in the program. This suggests a number of possible problems, some of which could indicate the study's demand impacts are overstated. Cadmus suspects this resulted from quality issues with the integrated energy meter dataset.

Smart cooling-style DR events had the largest impact on savings. During the two smart pre-cooling events, average estimated demand reductions of 0.847 kW and 0.267 kW resulted. Across all four events, average estimated demand reductions were 0.520 kW in the first hour and 0.472 kW in the second event hour.

Comfort

Participants in general did not find events uncomfortable. The majority of ATC participants (65% - 80%, depending on DR event) did not notice a change in comfort level during the DR events. Fourteen to 29% noticed the house was warmer but found the comfort level to be acceptable. Only 0-8% (depending on the DR event) found the house to be considerably less comfortable.

Recommendations

Cadmus recommends improving the estimated demand impacts by completing the actions that follow. However, if necessary to use this year's results for program planning, runtime impact results can be used with the average population EER and tonnage data to calculate estimated demand impacts.

To improve the estimated demand impacts:

- Improve the quality of the integrated energy meter data used to estimate DR impacts. For example, missing data should be clearly differentiated from true zeroes, and the source of high and low outliers should be investigated and corrected (for instance, readings over 40 kWh per hour).

- If possible, AC energy efficiency rating (EER) and tonnage data should be collected for new program participants at the time of thermostat installation. Better AMI data and a bigger sample of AC nameplate data will improve the accuracy of the DR program's demand impact estimates.

Introduction

Wi-Fi programmable thermostats (Wi-Fi thermostats) offer a broad range of features that could provide benefits to utilities and their customers. With the ability to communicate with utility program implementers and to collect and display historical performance data, Wi-Fi thermostats provide utilities with a platform from which to implement programs, while empowering customers with more HVAC control options than previously available.

National Grid is investigating the influence of three key Wi-Fi thermostat features on its residential customers' energy usage, behavior, and satisfaction:

1. Integrated energy meters that provide whole-house energy consumption information.
2. HVAC control optimization.
3. A platform for participation in demand response (DR) events.

Working in partnership with Ecobee and Earth Networks, National Grid conducted a study to demonstrate the functionality of the Ecobee Smart Thermostat and integrated energy meter, and to evaluate the impact of Earth Networks' HVAC control optimization software and of four DR events on residential customers' natural gas and electric usage.

Project Objectives and Scope

National Grid engaged Cadmus to evaluate the following:

1. Assess the value and use of the Ecobee Smart Thermostat and integrated energy meter information to customers.
2. Determine the energy (natural gas and electric) impacts of the Ecobee thermostat with and without Earth Networks' HVAC optimization controls.
3. Verify the demand impacts of and participant experience with each of the four DR events.

Wi-Fi Thermostat Features

This section describes the Wi-Fi thermostat features offered by Ecobee and Earth Networks and evaluated by Cadmus. These include the features of the Ecobee Smart Thermostat, the home energy monitoring system, Earth Networks' HVAC control optimization software (Automatic Temperature Control [ATC]), and the DR platform.

Ecobee Smart Thermostat

National Grid chose the Ecobee Smart Thermostat as a Wi-Fi thermostat in this study. Users can control their HVAC system settings at the thermostat, using a web portal, or via a mobile application (app). Descriptions follow of these three control platforms.

Thermostat

The Ecobee Smart Thermostat uses a color touch screen display. As shown in Figure 2, the Home screen displays the following: (1) the current space temperature; (2) the current setpoint (which can be adjusted by dragging the slider right or left); (3) the current operating mode; (4) the current date and time; (5) an Internet connection indicator; and (6) a Wi-Fi signal strength indication.

From the thermostat, the user can also access the following features: (7) check the current outdoor temperature; (8) put the HVAC system in an energy savings mode called QuickSave; (9) view system details, including humidity levels and fan settings; and (10) program setpoints for each day of the week. The user also can set up HVAC maintenance reminders, temperature alerts, and adjust display settings from the thermostat (11).

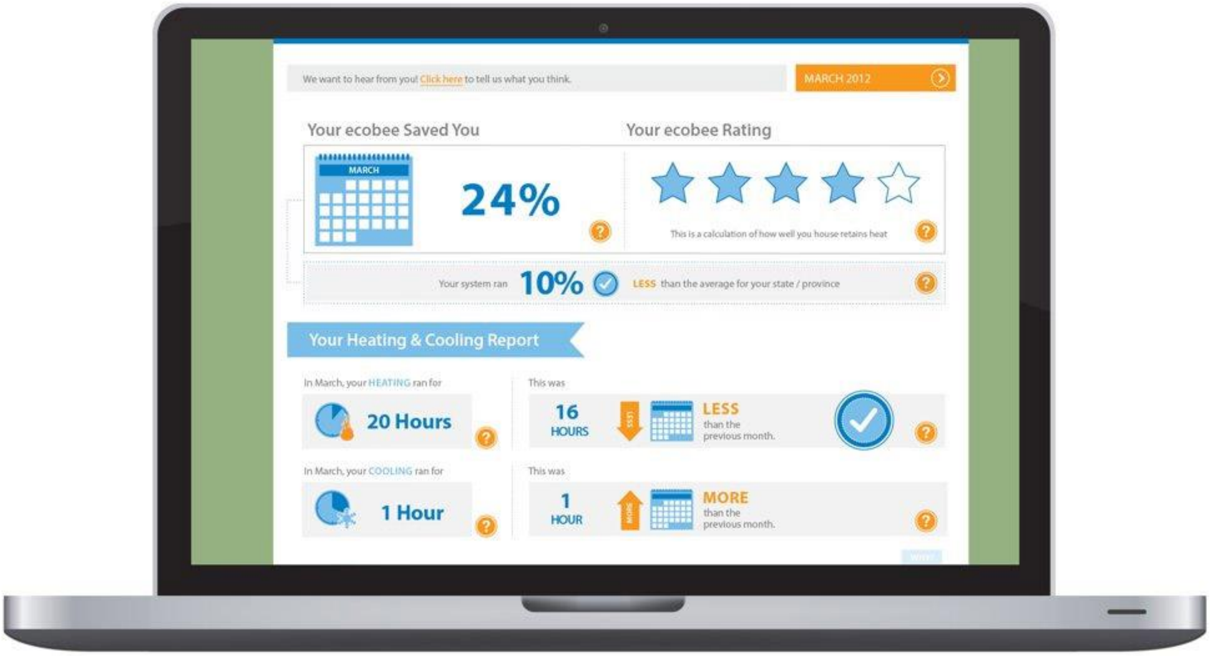
Figure 2. Ecobee Smart Thermostat

Web Portal

The Ecobee Smart Thermostat's web portal offers many of the same features as those available at the thermostat, including checking indoor and outdoor temperatures, adjusting setpoints, viewing and editing schedules, and setting up alerts. In addition, the web portal allows users to view and download HVAC system runtime histories and indoor temperature histories from the web portal, as shown in Figure 3.

CADMUS

Figure 3. Ecobee Smart Thermostat Web Portal



Mobile App

From the Ecobee Smart Thermostat mobile app, users can check indoor and outdoor temperatures, adjust setpoints, change operating modes, and set thermostats to vacation mode, as shown in Figure 4.

Figure 4. Ecobee Smart Thermostat Mobile App

HEM

Cadmus's evaluation objectives included assessing the value of the integrated home energy meter to participants. The energy meter provided participants with information on energy usage and costs via the thermostat and web portal. Participants could view their whole-house electricity usage and costs, electricity bill projections, HVAC runtime histories, and weather-adjusted HVAC runtime histories. Descriptions follow of each of these monitoring tools.

Whole-House Electricity Usage and Costs

Participants could monitor their whole-house electricity usage and costs via the thermostat and web portal. At the thermostat, participants could view their energy usage down to 20-minute increments, along with current electricity rates and costs-to-date for each day, as shown in Figure 5). They could also view electricity usage and cost totals on daily (Figure 6 and Figure 7) and weekly (Figure 8 and Figure 9) levels. As shown in Figure 10, the web portal offer participants similar information.

Figure 5. 20-minute Electricity Usage (Thermostat)

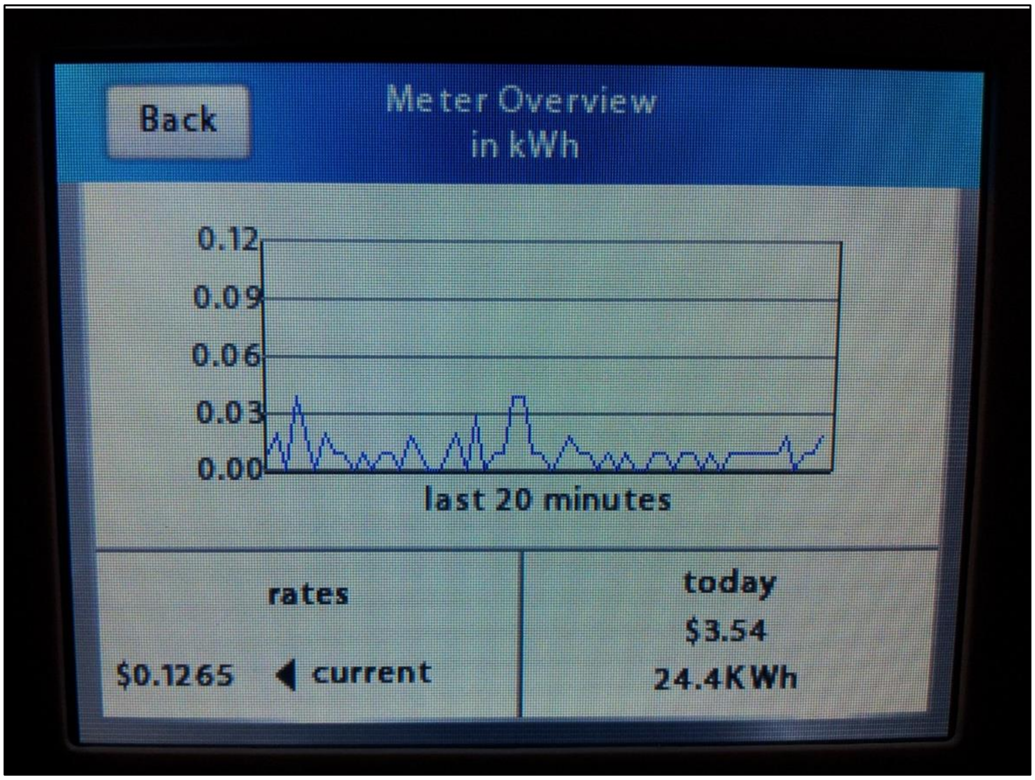


Figure 6. Daily Electricity Usage (Thermostat)

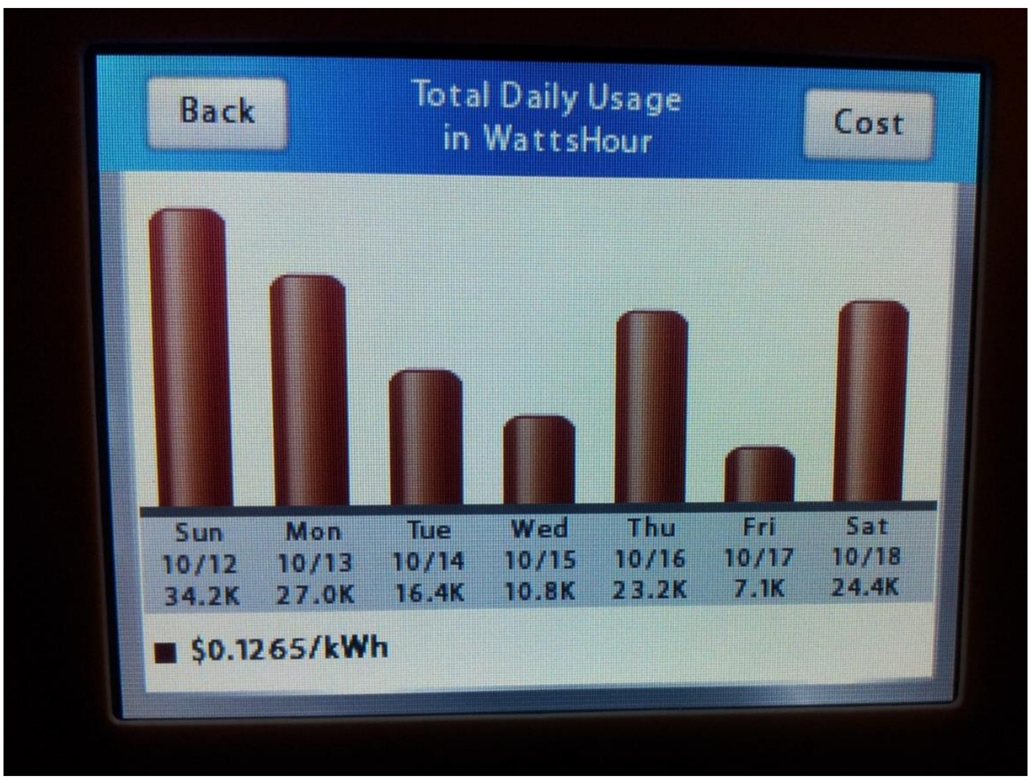

Figure 7. Daily Electricity Costs (Thermostat)

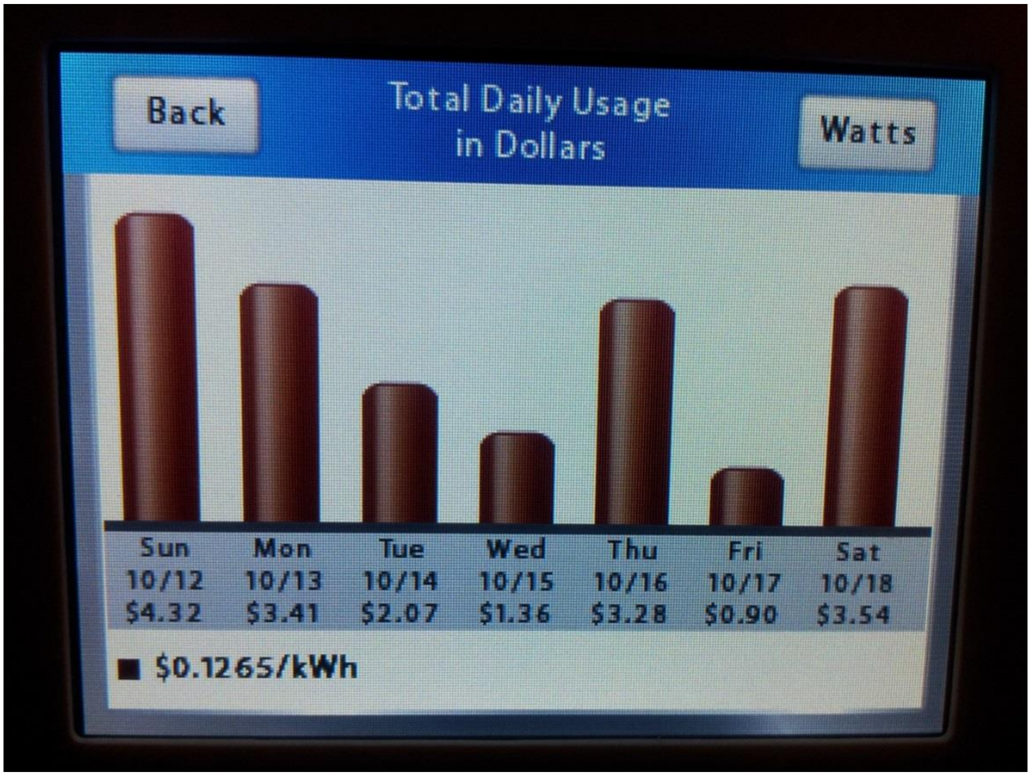

Figure 8. Weekly Electricity Usage (Thermostat)

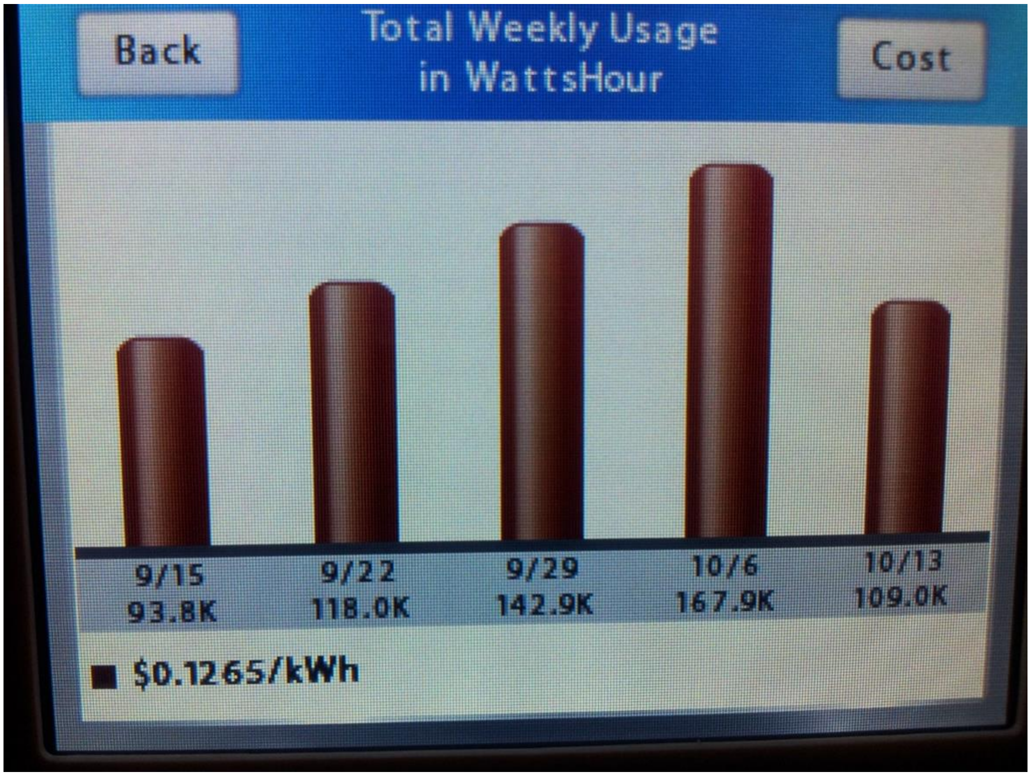

Figure 9. Weekly Electricity Costs (Thermostat)

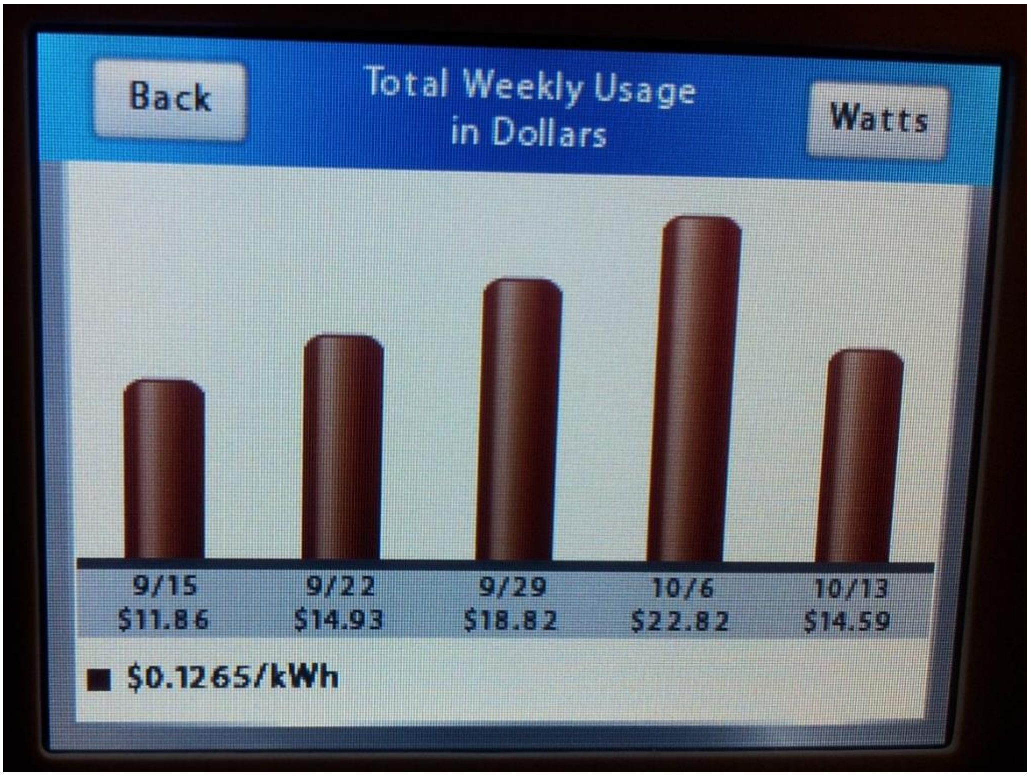

Figure 10. Hourly Electricity Usage (Web Portal)

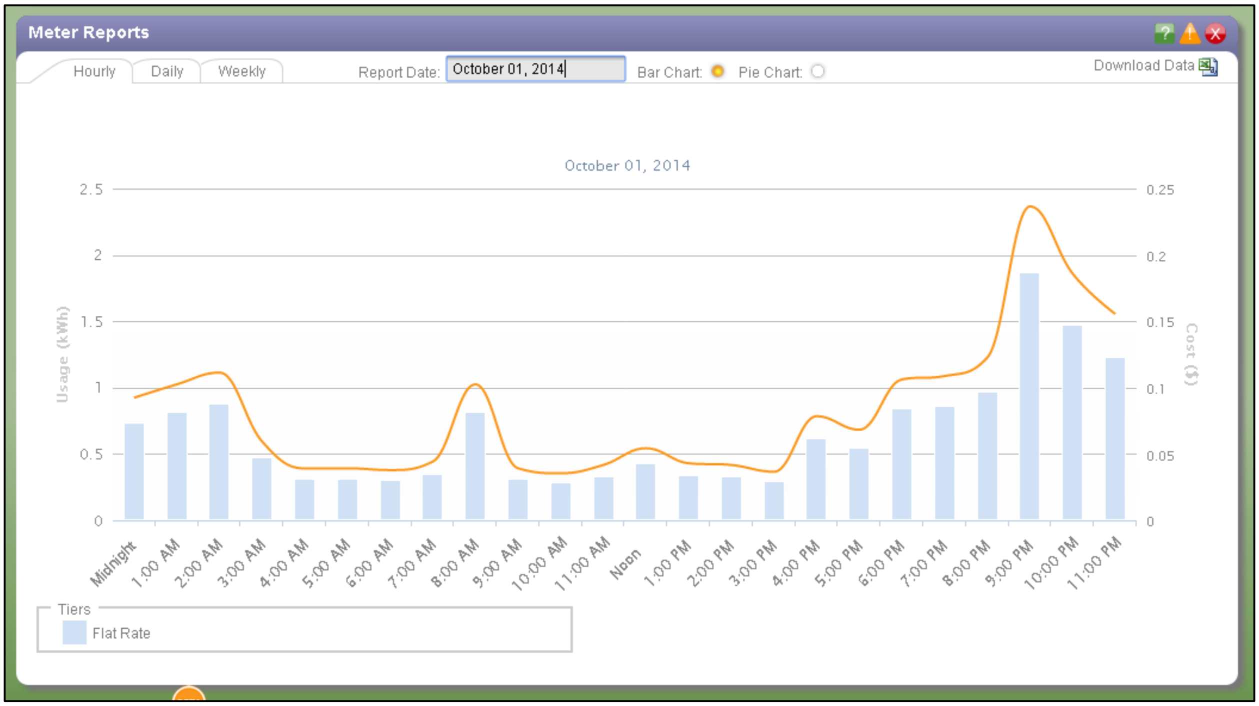

Bill Projection

In addition to monitoring current electricity usage and costs, participants had access to an electricity bill project tool, which allowed them to set a monthly electricity budget and define their budget's billing period. They could view their current bill and projected bill against their budget (Figure 11) and set up alerts for notifications if their current or projected usage exceeded their budget (Figure 12).

Figure 11. Bill Projection Tool (Thermostat)

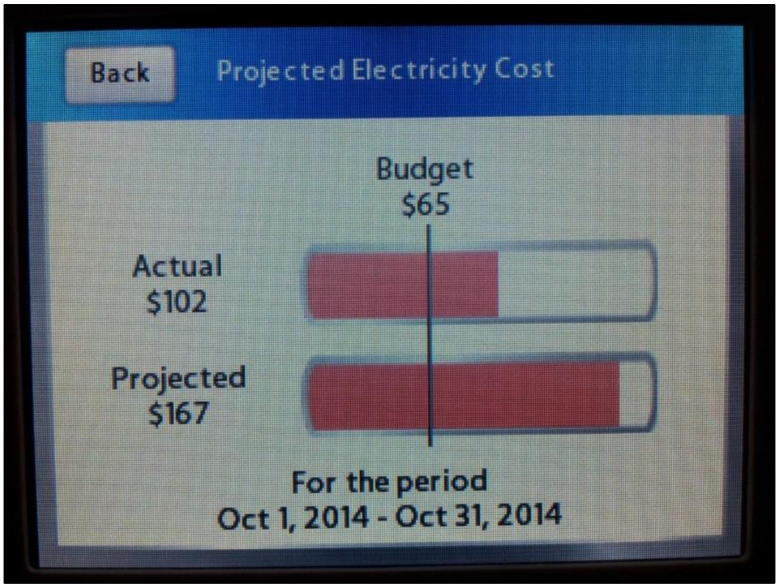

Figure 12. Bill Projection Tool (Web Portal)

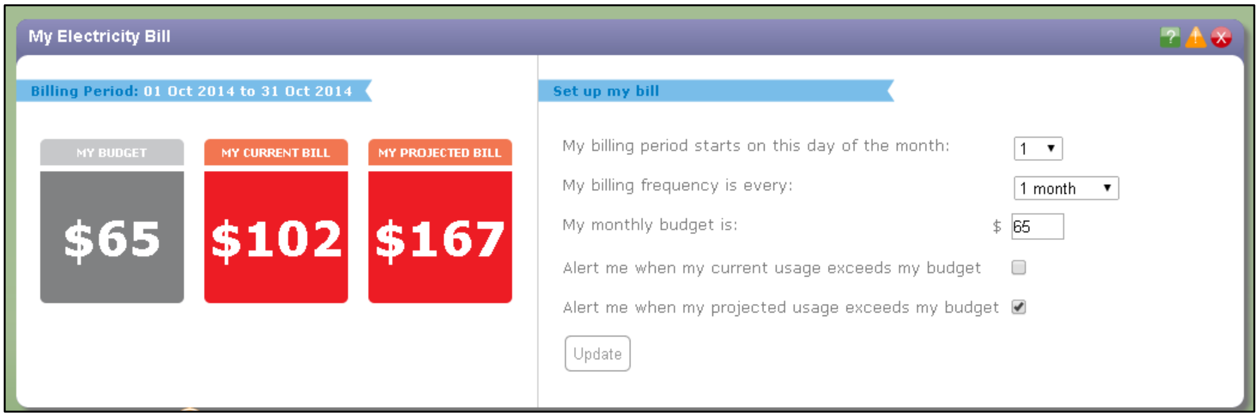

Runtime History

Via the web portal, participants could access their HVAC system's total raw runtimes (Figure 13) and weather-normalized runtimes (Figure 14) by month, and compare this to previous years' runtimes. For each month, they also could view the average indoor and outdoor air temperatures (OAT) for each month.

CADMUS

Figure 13. HVAC Runtime Comparison

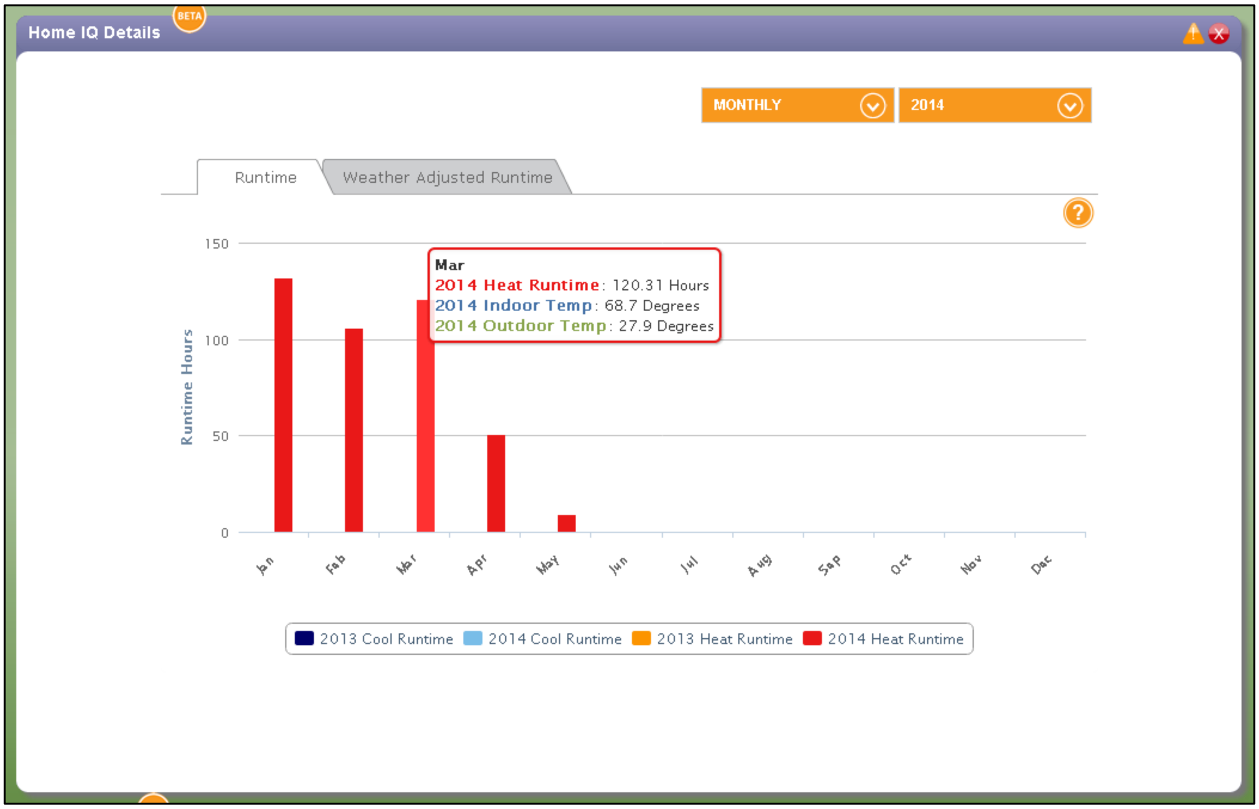

Figure 14. Weather-Normalized HVAC Runtime

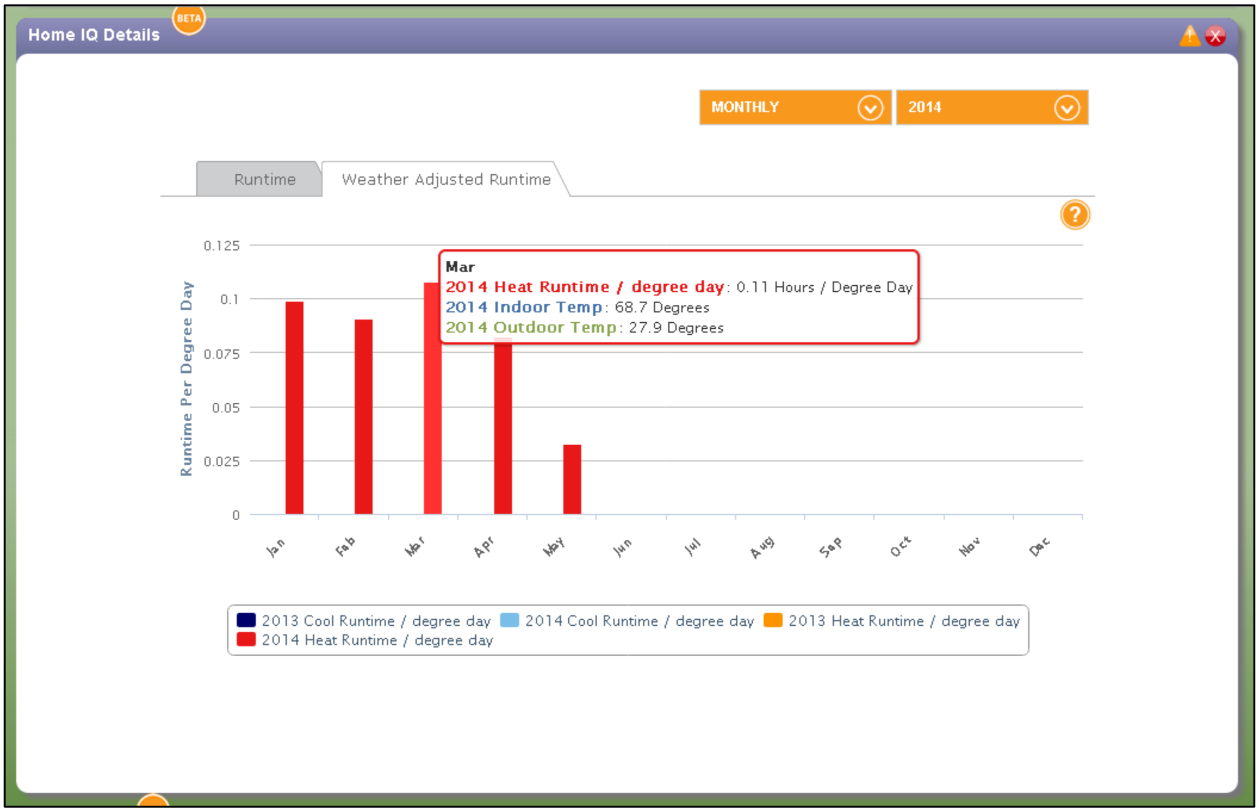
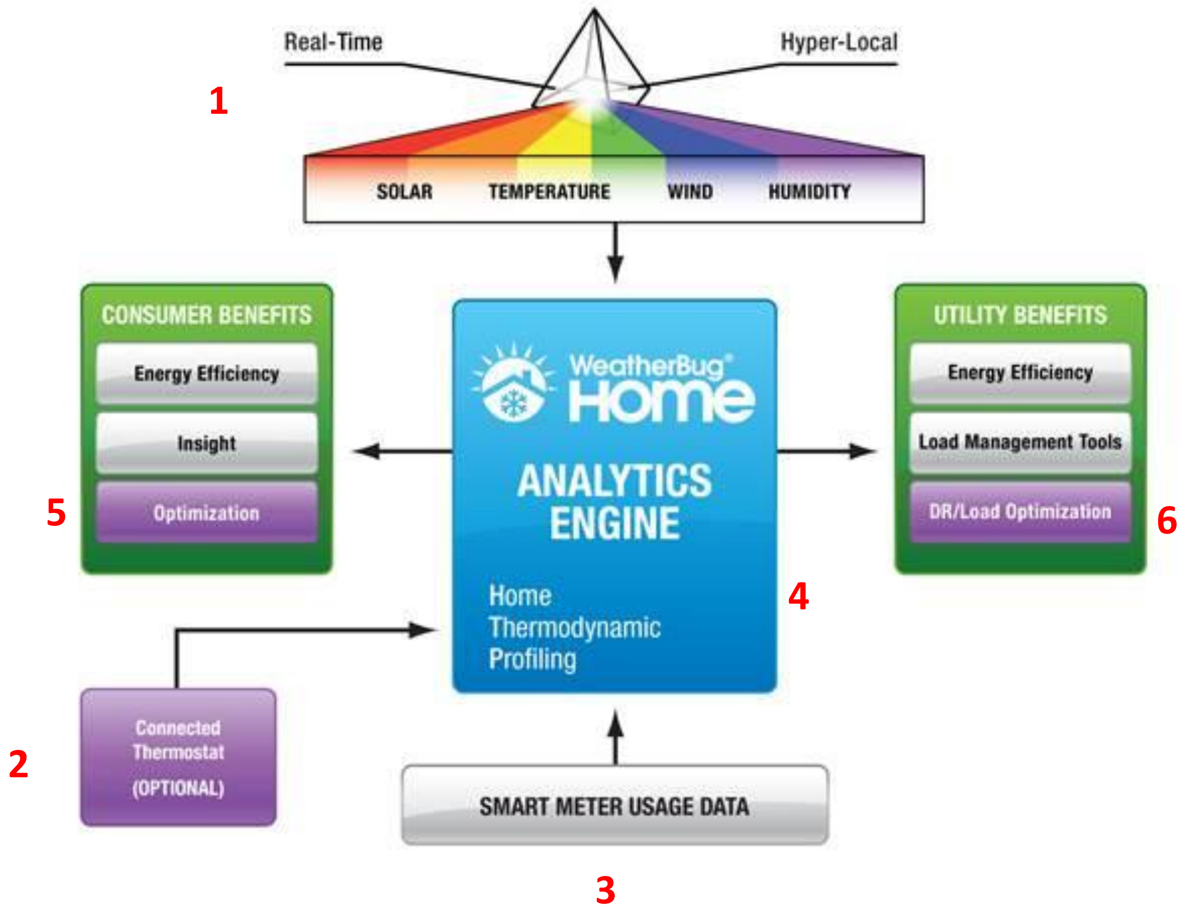


ATC

As part of the evaluation, a portion of participants had Earth Networks' HVAC control optimization software on their thermostats (i.e., ATC). The software's algorithms use real-time, hyper-local weather data from participants' local WeatherBug weather stations, historical HVAC runtime data from the Ecobee Smart Thermostat, and historical energy usage data from the integrated energy meter to optimize HVAC runtimes, seeking to save energy while maintaining comfort. Figure 15 outlines ATC model inputs and outputs.

Figure 15. Earth Networks' ATC Model



The ATC model algorithms use three inputs to optimize HVAC control: (1) real-time, hyper-local weather data, including solar irradiance, outdoor temperature, wind speed, and humidity from WeatherBug stations; (2) one-minute interval data on HVAC runtimes, indoor temperatures, and setpoints from the Ecobee smart thermostat; and (3) integrated energy meter data on electricity consumption. Algorithms in the analytics engine (4) use the inputs to optimize the time required to heat or cool a home to meet a setpoint at a particular time (5). In addition to optimizing HVAC control, National Grid used the Earth Networks system as a platform for implementing a DR pilot (6).

DR

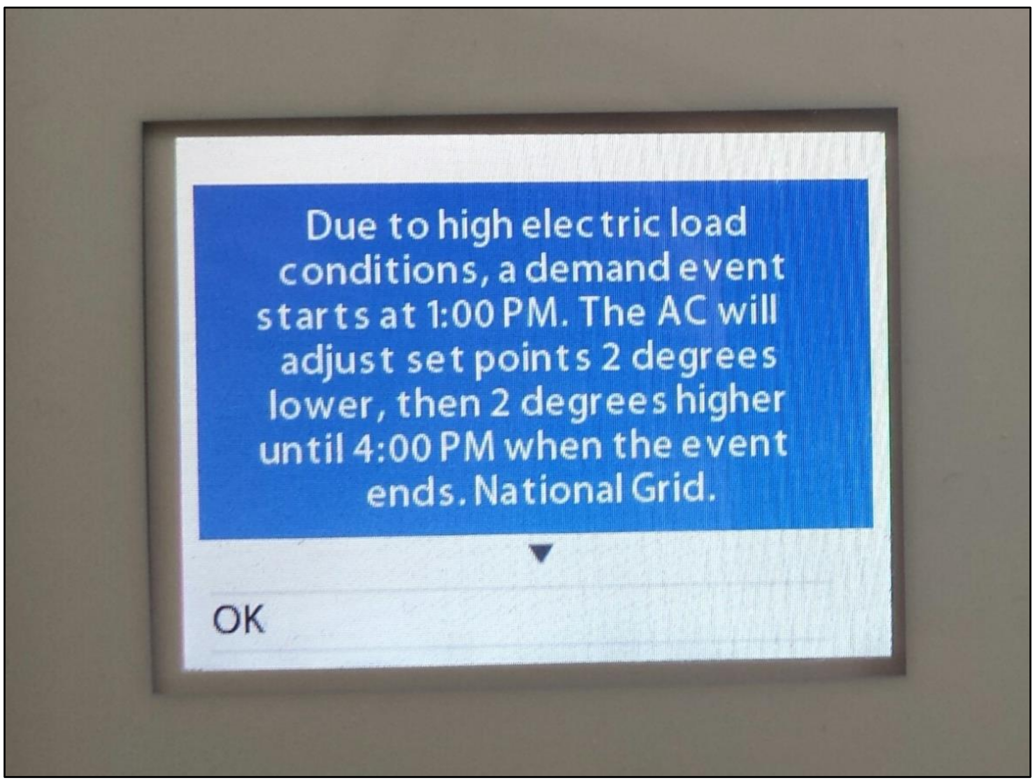
The implementer tested a variety of styles of DR events over summer 2014, running the events on days forecast as especially hot. In total, the implementer ran three unique types of DR events across four days. Table 1 summarizes the date, duration, type, and description of each event.

Table 1. Summary of DR Events

Date of Event	Duration	Event Type	Event Description
7/9/2014	1:00–3:00 pm	No pre-cooling	Raise all participants' setpoints by 2 °F.
8/26/2014	1:00–4:00 pm	Standard pre-cooling	Reduce all participants' setpoints by 2 °F for the hour prior to desired load reduction (1:00–2:00 pm), then raise setpoints by 2 °F (2:00–3:00 pm).
8/27/2014	1:00–4:00 pm	Smart pre-cooling	Use thermodynamic models to reduce all participants' setpoints by 2 °F for a minimum required time prior to desired load reduction, then raise setpoints by 2 °F.
9/5/2014	1:00–4:00 pm	Smart pre-cooling	Use thermodynamic models to reduce all participants' setpoints by 2 °F for a minimum required time prior to desired load reduction, then raise setpoints by 2 °F.

National Grid sent notifications to participants about each DR event 24 hours before events took place, via messages on participants' thermostats (shown in Figure 16) and e-mails (included as Appendix A).

Figure 16. Thermostat Notification of DR Event



During each DR event, the thermostat home screen displayed a message indicating the event was in progress (shown in Figure 17). At any time, participants could opt-out of each event (shown in Figure 18).

Figure 17. DR Event in Progress

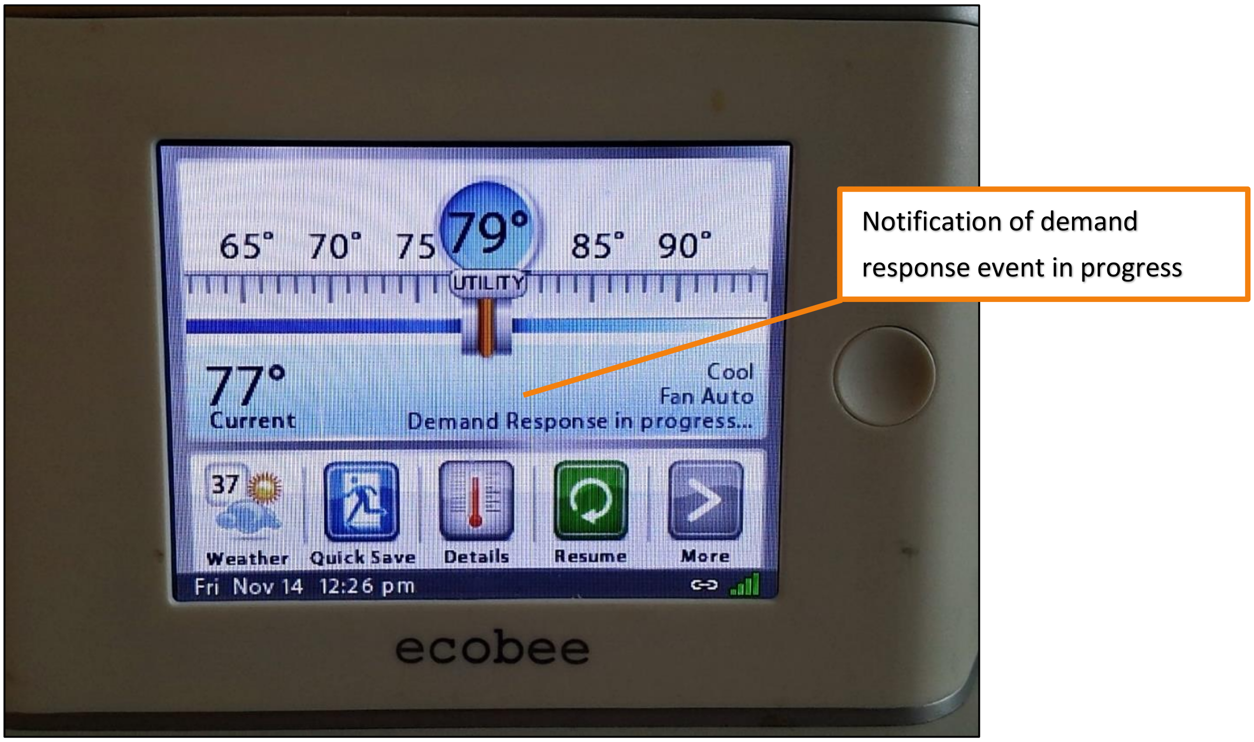


Figure 18. Opt-out Notification

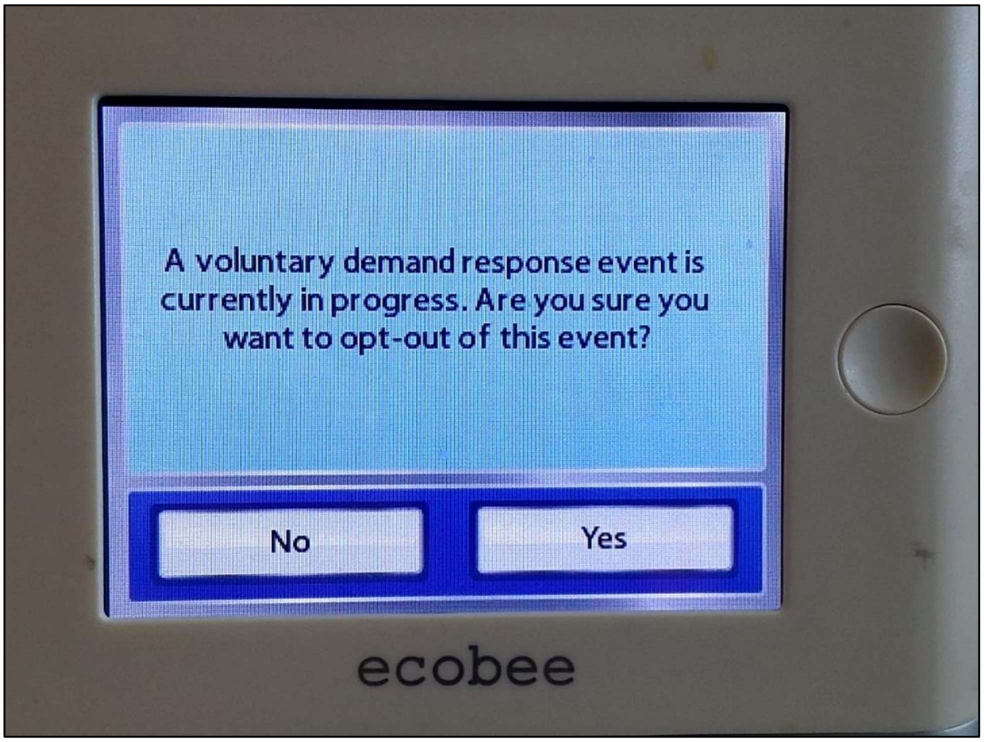
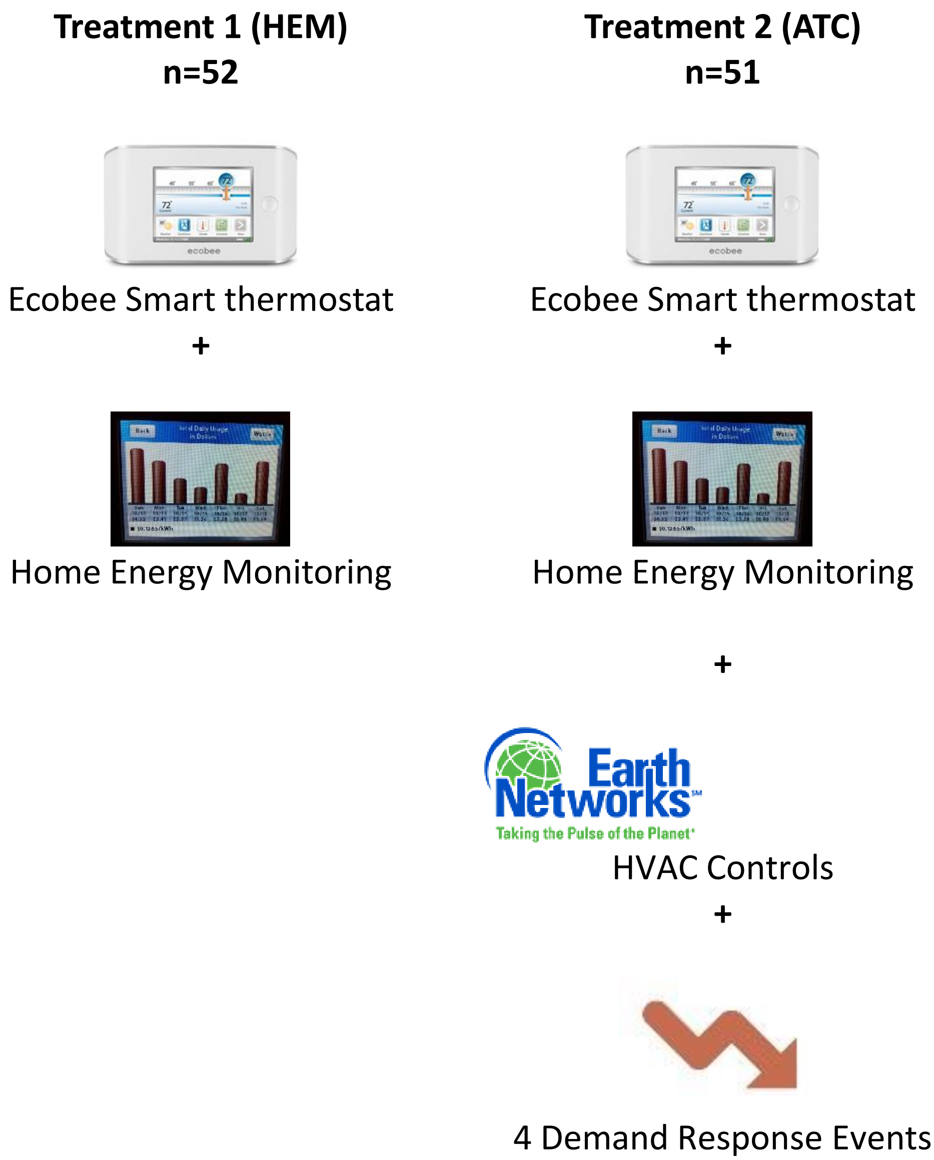


Methodology

National Grid administered the pilot using two treatment groups. Both received an Ecobee Smart thermostat and home energy monitoring capabilities via integrated energy meters. In addition, one groups' thermostats connected to Earth Networks' HVAC optimization controls, and they were invited to participate in the four DR events. Figure 19 shows treatments for each group. The study refers to Treatment Group 1 as the Home Energy Monitoring (HEM) group, and Treatment Group 2 as the ATC group.

Figure 19. Pilot Design



To achieve project objectives, Cadmus completed the following tasks:

1. Collect and analyze smart thermostat and integrated energy meter data.
2. Conduct national gas billing analysis.
3. Conduct electric billing analysis.
4. Verify reported impacts from DR events.
5. Design, conduct, and analyze participant surveys.

Descriptions of these tasks follow.

Task 1. Collect and Analyze Thermostat Meter Data

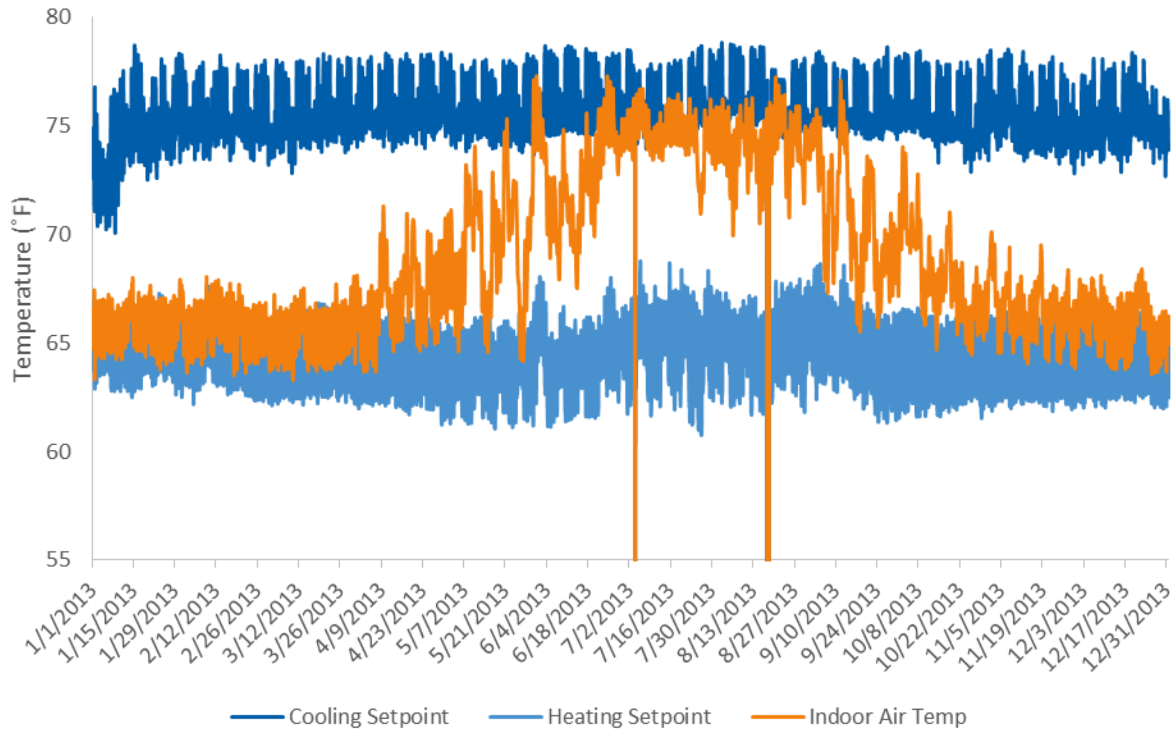
Cadmus used a combination of integrated energy meter and smart thermostat data to understand how participants set their thermostats and to compare participants with HVAC optimization controls and DR event participation (ATC group) and without (HEM group).

Defining Heating and Cooling Seasons

To analyze the smart thermostat data, Cadmus first defined the heating and cooling seasons, plotting heating and cooling setpoints against the measured indoor air temperature (IAT) for the year. Cadmus determined the heating season based on when the IAT most closely aligned with heating setpoints and the cooling season based on when the IAT most closely aligned with the cooling setpoints.

As shown in Figure 20, the evaluation team determined the heating season spanned November through March and the cooling season spanned June through August. The remaining time periods, classified as shoulder months, were not analyzed due to the lower HVAC usage rate in these months.

Figure 20. Determination of Heating and Cooling Seasons (N=103)



Task 2. Conduct Natural Gas Billing Analysis

Cadmus performed a natural gas billing analysis to determine smart thermostat impacts with and without HVAC controls on gas usage. The evaluation team requested one year of pre-installation and one year of post-installation gas billing data (from March 2012 to September 2014), and evaluated gas savings attributable to the program by conducting a billing analysis, following the steps below:

1. Matched thermostat installation dates and customer information to billing data.
2. Used participant zip codes to map to the nearest weather stations.
3. Obtained daily average temperature weather data from March 2012 through September 2014 for eight National Oceanic and Atmospheric Administration (NOAA) weather stations, representing all participant zip codes.
4. Used daily temperatures to determine base 45–85 heating degree days (HDDs) and cooling degree days (CDDs) for each weather station; and mapped the typical meteorological year series (TMY3) normal HDDs and CDDs by zip code for each home.[1]
5. Matched billing data periods with the CDDs and HDDs from associated stations.

[1] Cadmus used the PRISM models to select the best base temperature for each home.

Gas Billing Analysis Model

Cadmus estimated savings from each customer using a PRInceton Scorekeeping Method (PRISM) specification, using pre- and post-installation billing data for each participant in the HEM and ATC treatment groups. These models provided weather-normalized, pre- and post-installation annual usage for each participant and nonparticipant.

Through this regression model approach, the evaluation team obtained estimates of energy savings for each group and each participant, estimating heating-only PRISM models for each participant in the pre- and post-installation periods to weather-normalize raw billing data. Each model allowed heating reference temperatures to range from 45 degrees to 85 degrees.

The evaluation used the following PRISM model specification:

$$ADC_{it} = \alpha_i + \beta_1 HDD_{it} + \varepsilon_{it}$$

Where for each customer 'i' and month 't':

ADC_{it}	=	Average daily gas consumption in the pre- or post-installation program period
α_i	=	The participant intercept representing the average daily base load
β_1	=	The model space heating slope
HDD_{it}	=	The base 45-85 average daily HDDs for the specific location
ε_{it}	=	The error term

Using this model, Cadmus computed weather-normalized annual consumption (NAC) for each heating reference temperature as follows:

$$NAC_i = \alpha_i * 365 + \beta_1 LRHDD_{it} + \varepsilon_{it}$$

Where:

NAC_i	=	The normalized annual consumption
α_i	=	An intercept representing the average daily base load for each participant
$\alpha_i * 365$	=	The annual base load consumption (non-weather sensitive)
β_1	=	The heating slope (usage per HDD from the model above)
$LRHDD_{it}$	=	Annual, long-term HDDs of a typical meteorological year (TMY3) in the 1991–2005 series from NOAA for the specific location
$\beta_1 LRHDD_{it}$	=	The weather-normalized, weather-sensitive, annual heating usage (HEATNAC)
ε_{it}	=	The error term

Cadmus screened and removed accounts yielding negative heating NACs from the analysis. From the models with correct signs on all parameters, the team chose the best model of each participant's pre- and post-installation periods, based on those with the highest R-squared value.

Task 3. Conduct Electric Billing Analysis

Cadmus evaluated electric savings from the disaggregated cooling load, using one year of pre-installation and one year of post-installation electric billing data (from March 2012 to September 2014). To weather-normalize savings, Cadmus also collected daily temperature weather data from the National Climatic Data Center for weather stations corresponding to the participants' zip codes.

As thermostats' impact on cooling energy typically constitutes a small fraction of total electric energy consumption and can be difficult to disaggregate, the evaluation team crosschecked the billing analysis results with results from a regression analysis of the daily AC runtimes versus total usage.

Electric Billing Analysis Model

Cadmus estimated savings for each customer using a PRISM specification, which utilized pre- and post-installation billing data for each participant in HEM and ATC groups. These models provided weather-normalized, pre- and post-installation, annual usage for each participant.

Through this regression model approach, the team obtained estimates of energy savings for each group and each customer. For each participant and control home, the team estimated heating-only PRISM models in pre- and post-installation periods to weather-normalize raw billing data. Each model allowed heating reference temperatures to range from 45 degrees to 85 degrees and cooling reference temperatures to range from the heating reference temperature to 85 degrees.

The evaluation used the following PRISM model specification:

$$ADC_{it} = \alpha_i + \beta_1 HDD_{it} + \beta_2 CDD_{it} + \varepsilon_{it}$$

Where for each customer 'i' and month 't':

ADC_{it} = Average daily electric consumption in the pre- or post-installation program period

α_i = The participant intercept representing the average daily base load

β_1 = The model space heating slope

HDD_{it} = The base 45–85 average daily HDDs for the specific location

β_2 = The model space cooling slope

HDD_{it} = The base 45–85 average daily CDDs for the specific location

ε_{it} = The error term

Using this model, Cadmus computed weather-NAC for each heating and cooling reference temperature as follows:

$$NAC_i = \alpha_i * 365 + \beta_1 LRHDD_{it} + \beta_2 LRCDD_{it} + \varepsilon_{it}$$

Where:

NAC_i	=	The normalized annual consumption
α_i	=	An intercept representing the average daily base load for each participant
$\alpha_i * 365$	=	The annual base load consumption (non-weather sensitive)
β_1	=	The heating slope (usage per HDD from the model above)
$LRHDD_{it}$	=	Annual, long-term HDDs of a typical meteorological year (TMY3) in the 1991–2005 series from NOAA for specific location
$\beta_1 LRHDD_{it}$	=	The weather-normalized, weather-sensitive, annual heating usage (HEATNAC)
β_2	=	The cooling slope (usage per CDD from the model above)
$LRCDD_{it}$	=	Annual, long-term CDDs of a typical meteorological year (TMY3) in the 1991–2005 series from NOAA for the specific location
$\beta_2 LRCDD_{it}$	=	The weather-normalized, weather-sensitive annual cooling usage (COOLNAC)
ε_{it}	=	The error term

Cadmus screened and removed any accounts from the analysis that yielded negative cooling NACs and negative base loads. If a model produced a negative heating slope, the team estimated a cooling-only PRISM model. From the various models with correct signs on all parameters, the team chose the best model of each participant's pre- and post-installation periods based, on the model with the highest R-squared value.

Task 4. Verify Reported Impacts from DR Events

Before analyzing the AMI data, Cadmus performed extensive data quality checks and data cleaning. During this process, the team identified widespread errors in the data, including sites with over 5% zero kWh readings and sites with hourly readings over 100 kWh. Extensive hourly zero kWh datapoints could result from unoccupied houses or missing data, and extremely large datapoints (over 38 kWh per hour) could result from measurement error. To address these problems, the team flagged customers with zero readings at least 5% of the time, and customers with kWh readings greater than 38 kWh 5% of the time. Finally, Cadmus included only meters marked by Earth Networks as containing valid data, removing all these observations from the dataset used for analysis.

Cadmus estimated demand savings using a panel regression of hourly kWh for dates from June 15, 2014, to September 15, 2014. The model controlled for day of the week (weekend vs. weekday), the hour of day, weather (cooling degree hours), and event hours. Standard errors were clustered on homes to account for energy consumption correlations over time.

The evaluation team also ran the same model with AC runtimes as the dependent variable. Sufficient model data (e.g., EER, age, tonnage) were unavailable for all units in the DR sample; so the team could not convert AC runtimes to kW. Runtime analysis results served as comparison to results obtained from the kWh regression.

Task 5. Design, Conduct, and Analyze Participant Surveys

Cadmus designed surveys for both HEM and ATC participant groups to collect household demographics and to assess participants' use of thermostats and integrated energy meter information.

The survey primarily sought to increase an understanding of program participants' motivations, previous thermostat usage and behaviors, behaviors during the program (including features participants found valuable), and overall comfort during the pilot (including behavior shifting). The survey included satisfaction and willingness-to-pay questions. DR group participants were asked further questions about comfort and about opt-out or temperature-changing behaviors. Survey results also informed the billing analysis.

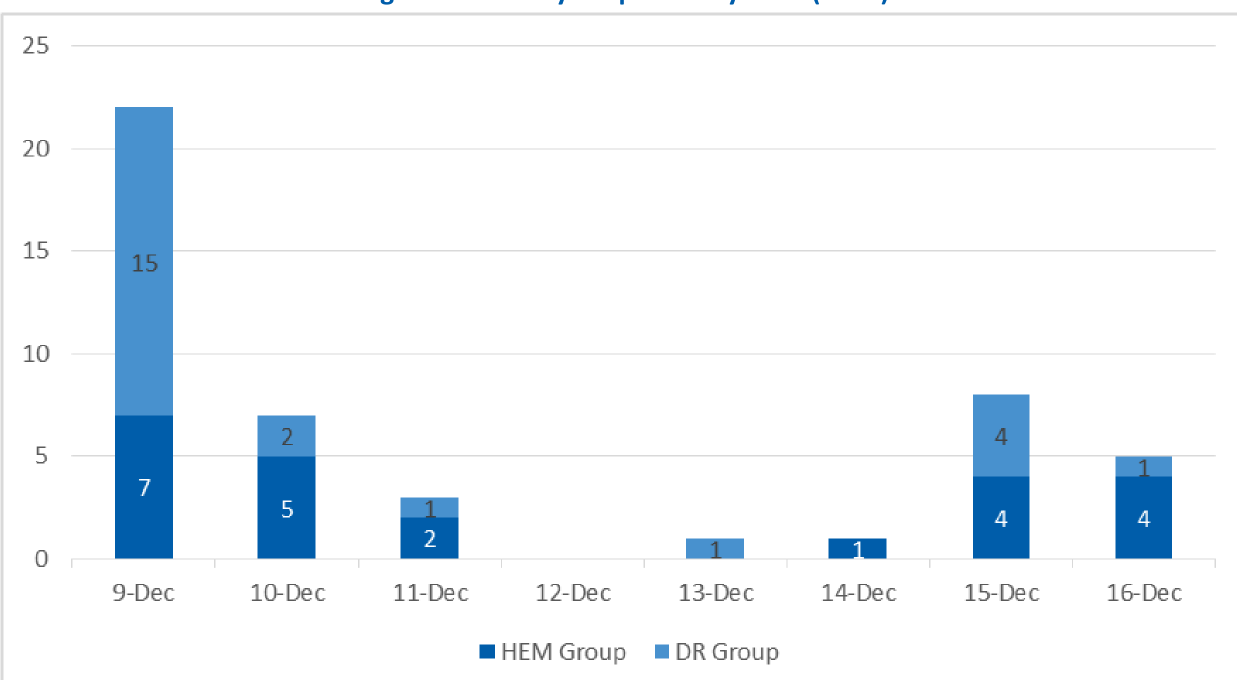
Cadmus fielded a web-based survey to pilot program participants from December 9–16, 2014, for all 103 program participants. Participants received an e-mail invitation to the survey, which included a link. Upon completion, participants could include contact information to enroll in two $100 gift card drawings.

Surveys achieved excellent response rates, for a total of 47 completes (i.e., 46% response rate). Program groups produced the following response rates:

- 24 of 51 DR Group (47%)
- 23 of 52 HEM Group (44%)

Figure 21 shows survey response rates over time.

Figure 21. Survey Responses by Date (n=47)



Results

This section presents results for each of the five project tasks.

Task 1. Analysis of Thermostat Data

For the heating and cooling seasons, Cadmus assessed setpoints, IAT, and HVAC runtimes by hour and by day of week.

Heating Season Setpoints

Setpoint data represent temperatures that participants chose for their homes. Figure 22 and Figure 23 show average hourly weekday and weekend heating setpoints programmed by participants.

Figure 22. Weekday Heating Setpoints, by Hour (n_{ATC}=51, n_{HEM}=52)

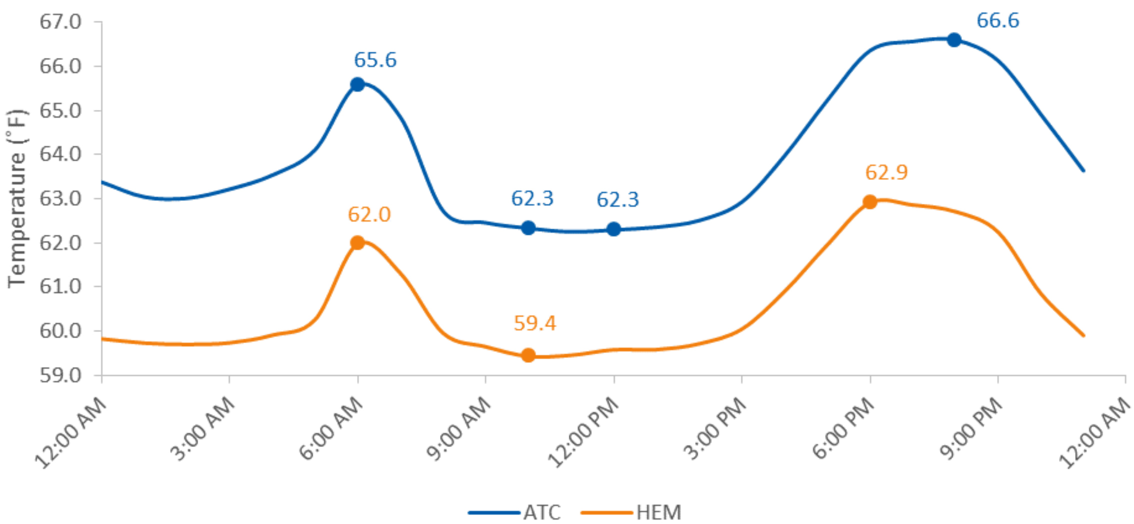


Figure 23. Weekend Heating Setpoints, by Hour (n_{ATC}=51, n_{HEM}=52)

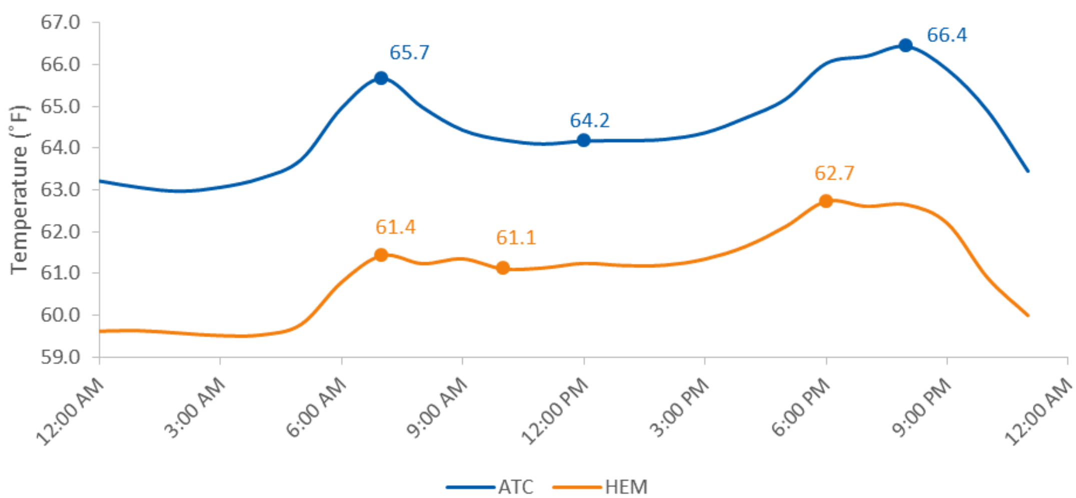

Figure 22 shows a very similar schedule of setbacks between the two groups. Generally, a peak occurred at approximately 6:00 a.m. on weekdays and 7:00 a.m. on weekends, followed by a setback in the middle of the day. The setpoint increased in the evening, peaking between 6:00 p.m. and 9:00 p.m., followed by another setback at night, lasting until the early morning. These patterns are consistent with energy-efficient usage, whereby tenants turn down their heating systems when not at home or when sleeping.

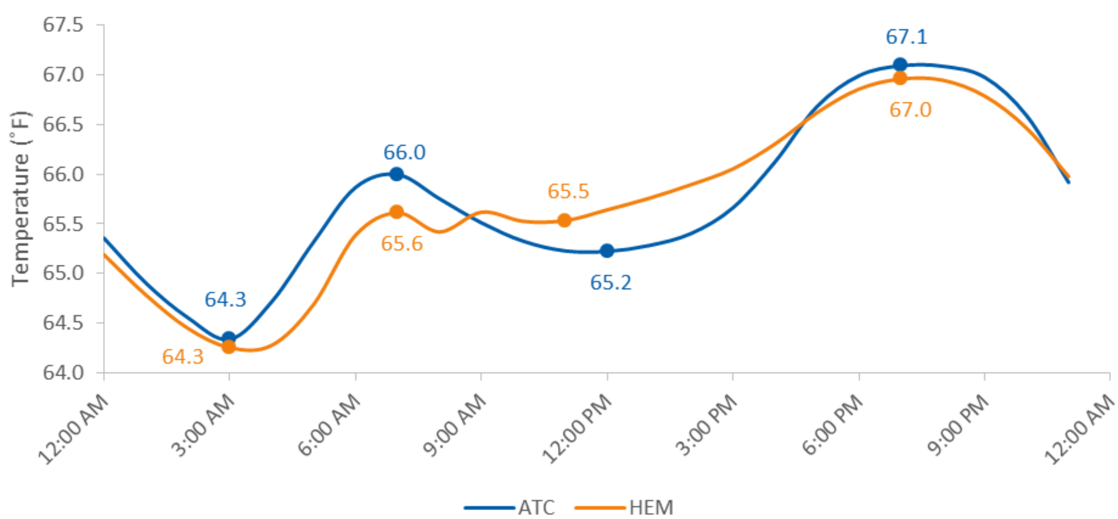
A key difference emerged between the groups: the HEM group used lower setpoints than the ATC group, averaging three to four degrees lower than the ATC group. The ATC group also exhibited a deeper daytime setback compared to the HEM group, with an average setback of 3.3 on weekdays (the setpoint dropping from 65.6 degrees to 62.3 degrees) and 1.5 degrees on weekends. The HEM group used a daytime setback of 2.6 degrees on weekdays and 0.3 degrees on the weekends.

Heating Season Indoor Air Temperatures

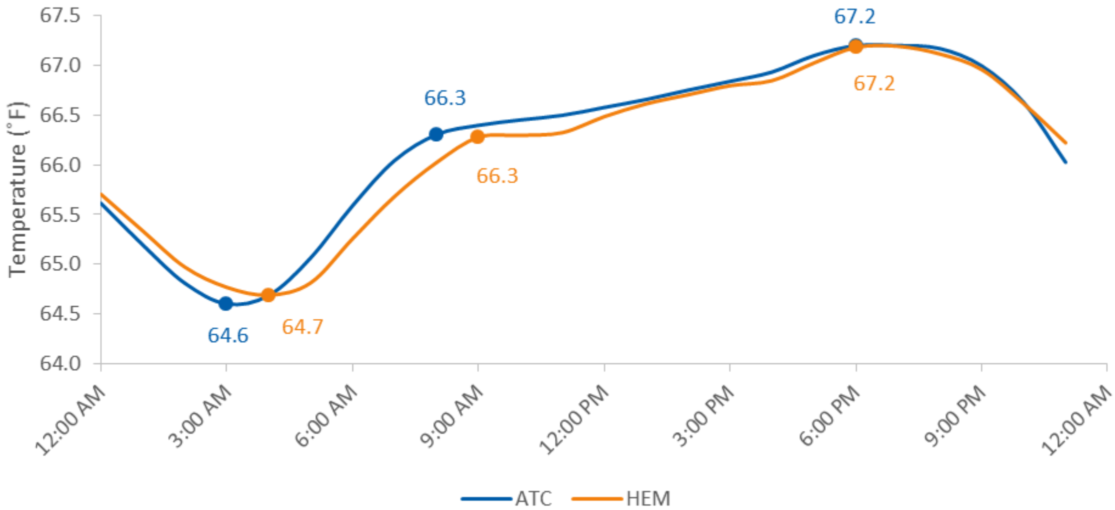
In addition to thermostat setpoint data, Cadmus assessed actual IAT data. The evaluation team used these data to develop trends showing average air temperatures for each hour of the day during weekdays and weekends. Figure 24 shows weekday trends (including hourly IAT during the week for ATC and HEM groups), and Figure 25 shows weekend trends for the heating season.

Figure 24. Weekday IAT, by Hour (n_{ATC}=51, n_{HEM}=52)



CADMUS

Figure 25. Weekend Indoor Air Temperature, by Hour (n_{ATC}=51, n_{HEM}=52)



The two groups exhibited similar profiles: a peak in the morning; a second peak in the evening; and a deep valley at night. The two groups show a large difference, however, in the middle of the day (roughly from 9:00 a.m. to 3:00 p.m.). During this period, average indoor temperatures in the ATC group dropped from 66 degrees during the morning peak to 65.2 degrees around midday. The HEM group exhibited a short dip immediately following the morning peak, before temperatures increased gradually throughout the day, eventually hitting the evening peak. The evaluation team found it notable that, despite a significantly lower weekday setpoint (62.0 degrees vs. 65.6 degrees), the HEM group had nearly the same IAT as the ATC group during the morning peak.

Cadmus believes the difference in IAT load shapes largely resulted from the magnitude of the setback programmed by each group. The ATC group programmed a setback of 3.3 degrees, with a resulting IAT drop of 0.8 degrees. The HEM group used a setback of 2.6 degrees, with a resulting IAT drop of 0.1 degrees. Both groups showed a 2.5-degree difference between the degree of the setback and the actual drop in IAT. Assuming the homes in the two groups otherwise share the same qualities, this finding makes intuitive sense: heat transfer rates from the interior of a home to the outdoors would be nearly the same as temperature differentials were very nearly the same.

Figure 25 shows hourly IAT during weekends for both participant groups, with load shapes essentially identical. The weekend profiles do exhibit a striking detail: the IAT did not drop during the middle of the day, as on weekdays. This largely results from the lower setback degree occurring during weekends. This lower setback degree, coupled with a higher occupancy rate, resulted in an IAT that actually increased throughout the day. Data from both participant groups indicated a very linear increase in IAT from the morning peak to the evening peak. This likely resulted from increased activity within the home, a lower setback degree, and solar heat gains throughout the day.

Heating Season Setpoint and Indoor Temperature Comparisons

Cadmus compared participants' average heating season setpoints to actual IAT for each hour of the day to assess how effectively the HVAC controls met setpoints. In interpreting these results, readers should note: it is normal for space temperatures to vary up to three degrees above and below thermostat setpoints (termed the temperature differential); and a variety of factors impact how well a thermostat regulates space temperatures, including home insulation types, level of solar heat gains, and HVAC system types.

Figure 26. HEM Average Heating Season Setpoints and IAT, by Hour (n_{HEM}=52)

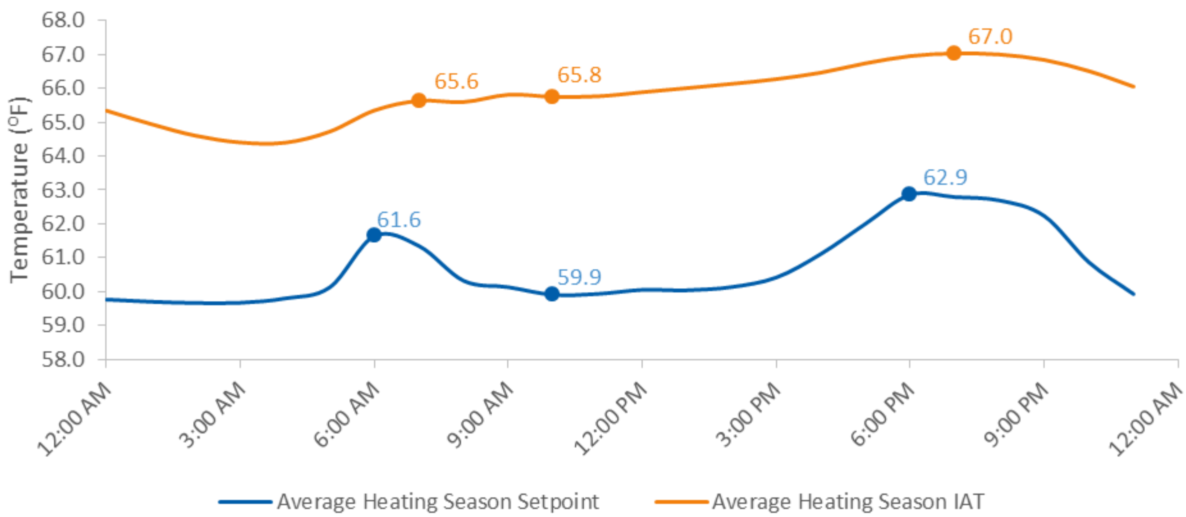


Figure 27. ATC Average Heating Season Setpoints and IAT, by Hour (n_{ATC}=51)

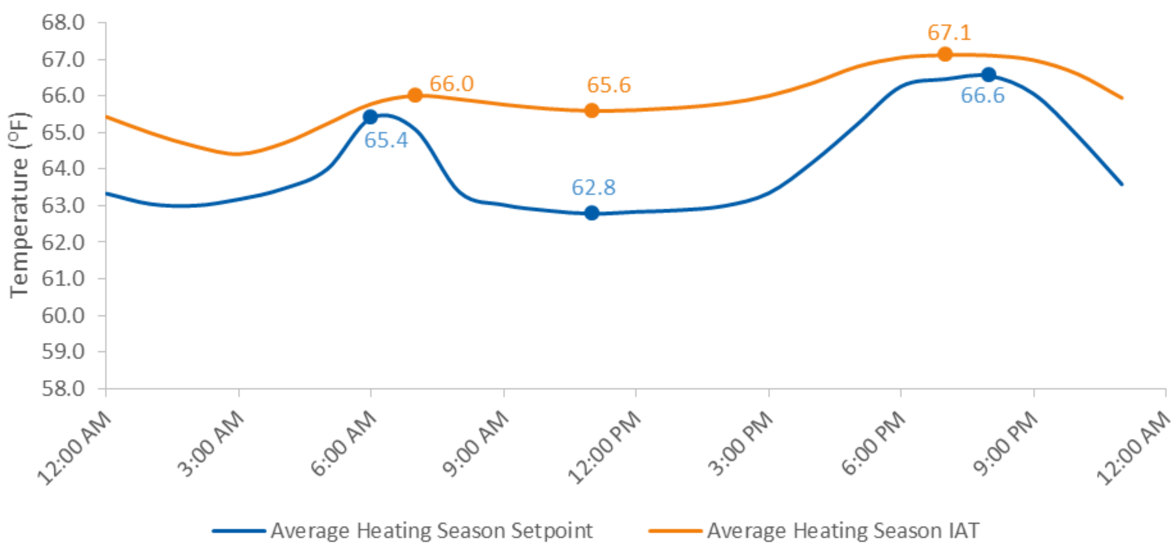

In the heating season, the IAT in the ATC group more closely matched setpoints than in the HEM group, where the IAT averaged 1.8 degrees warmer than setpoints, compared to 5.1 degrees warmer in the HEM group.

For both groups, the IAT came the closest to matching setpoints during non-setback periods. Cadmus expected this result as, during setbacks, it takes time for homes to lose heat and temperatures to drift down to setpoints. In the HEM group, the IAT came within 3.7 degrees of the setpoint at 6:00 a.m. and 4.1 degrees of the setpoint at 6:00 p.m. In the ATC group, the IAT came within 0.4 degrees of the setpoint at 6:00 a.m. and 0.6 degrees at 8:00 p.m. Although many factors can impact how well a thermostat regulates temperature, sample results indicated heating systems with HVAC optimization controls (the ATC group) performed better at meeting setpoints than heating systems without HVAC optimization controls.

Heating Season HVAC Runtimes

Cadmus assessed HVAC system runtimes by overlaying average hourly runtimes with the average hourly IAT and setpoint data, as shown in Figure 28 and Figure 29.

Figure 28. HEM Heating Season HVAC Runtime, Setpoints, and IAT, by Hour (n_{HEM}=52)

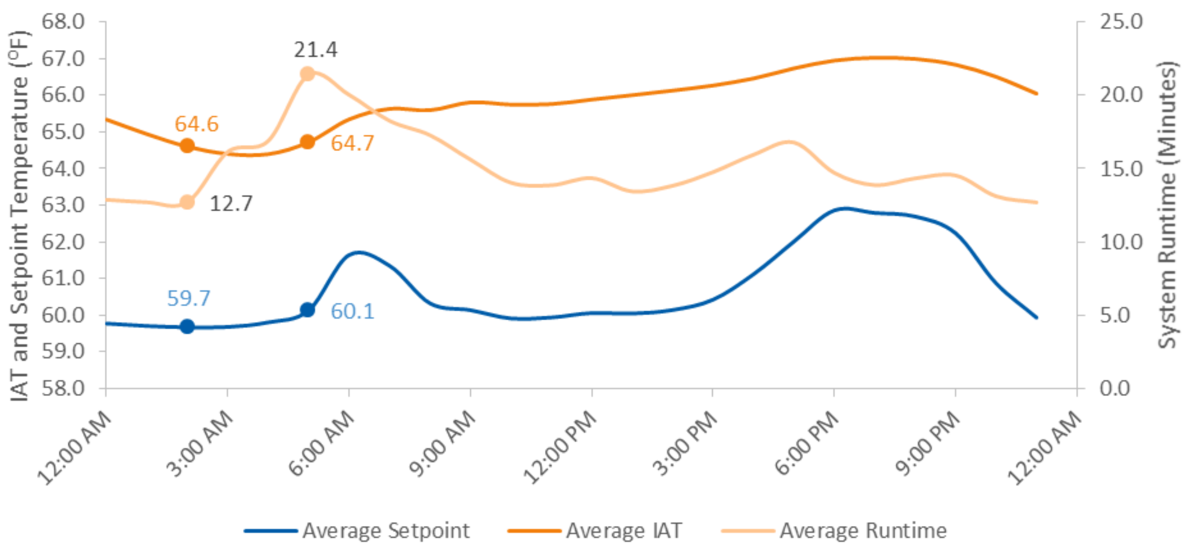

Figure 29. ATC Heating Season HVAC Runtime, Setpoints, and IAT, but Hour (n_{ATC}=51)

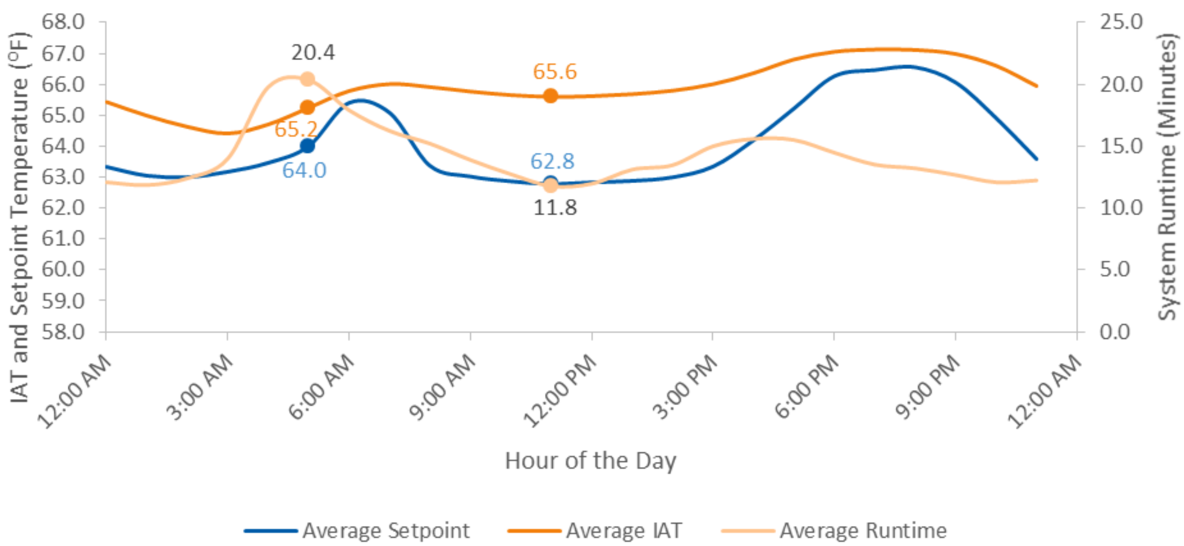

In both groups, average hourly heating system runtimes peaked at 5:00 a.m., when systems sought to meet increased setpoints at 6:00 a.m. HEM group runtimes last one minute longer than those of the ATC group (e.g., 21.4 minutes compared to 20.4 minutes). For the rest of the day, average hourly runtimes remained around 13–14 minutes per hour for the HEM group and 12–13 minutes per hour for the ATC group. Both had slight increases in runtimes from approximately 4:00 p.m. to 5:00 p.m., when runtimes increases to 16–17 minutes per hour for HEM and 15–16 minutes per hour for HEM.

Cooling Season Setpoints

Setpoints represent temperatures that participants chose for their homes. Figure 30 and Figure 31 show weekday and weekend cooling setpoints programmed by the participants, by hour.

CADMUS

Figure 30 Weekday Cooling Setpoints, by Hour (n_{ATC}=51, n_{HEM}=52)

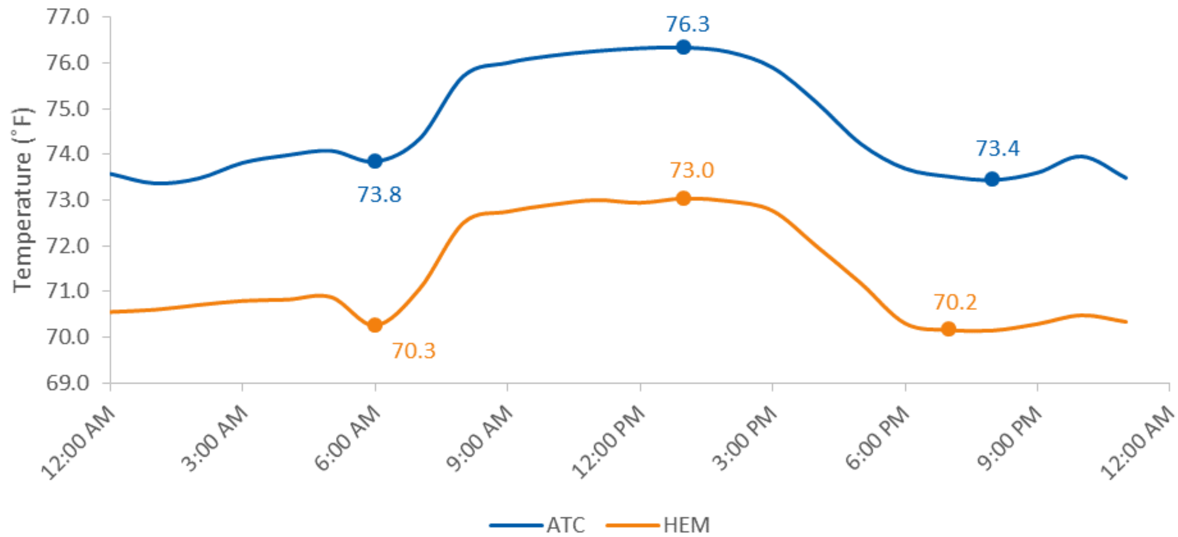

Figure 31. Weekend Cooling Setpoints, by Hour (n_{ATC}=51, n_{HEM}=52)

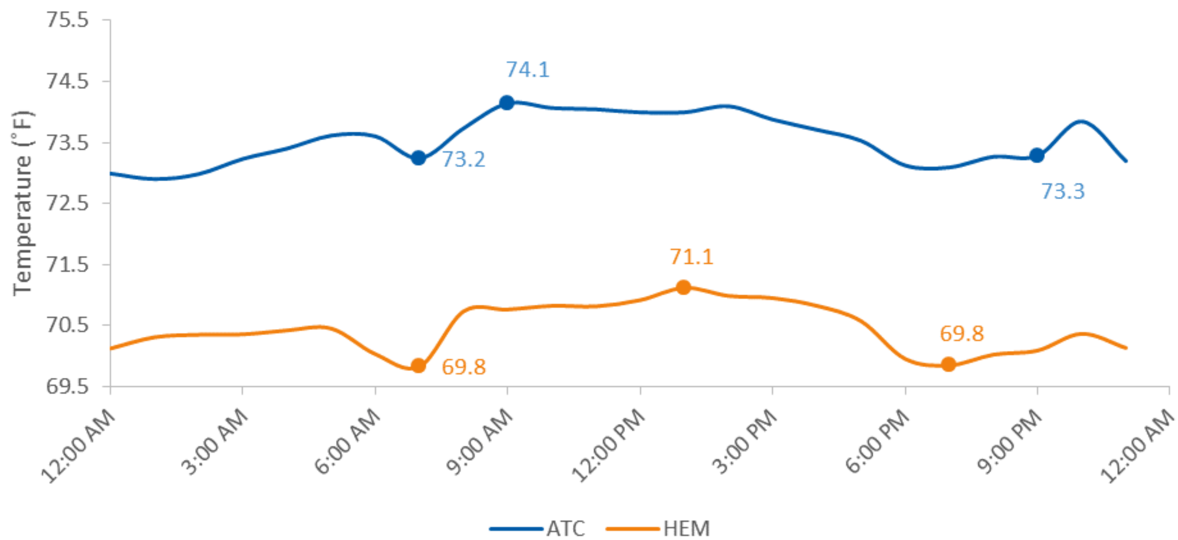

Figure 30 shows weekday setpoint schedules very similar between the groups. Generally, a valley occurred between 6:00 a.m. and 7:00 a.m. in the morning, followed by a long peak in midday. Setpoints dropped again in evenings, bottoming out between 6:00 p.m. and 9:00 p.m. Temperature remained fairly constant until the morning. This produced patterns consistent with energy-efficient cooling season usage, whereby tenants turn up temperatures while not at home.

During the week, the two groups primarily differed in temperature setpoints for various peaks and valleys throughout the day. The ATC group turned their ACs down to approximately 73.8 degrees at night, turned them up to 76.3 degrees while away during the day, and then lowered temperatures to approximately 73.4 degrees when returning home in the evening. As in the heating season, the HEM group and the ATC group followed the same general pattern: both exhibited a valley in the early morning, peaked during the day, dipped in the evening, and remained fairly constant throughout the night. The HEM group, however, used lower setpoints, typically between 3 and 6 degrees lower than the ATC group. Assuming all else remained equal, the HEM groups' lower setpoints suggested they would consume more energy than the ATC group.

Similar to Figure 30, Figure 31 shows setpoint schedule load shapes similar between the groups on weekends. The load shape followed the same peak-valley pattern seen during the week, but the magnitude of the shift between peaks and valleys was much smaller. For instance, the ATC group had a weekday setback of 2.5 degrees (from 73.8 degrees to 76.3 degrees), but this setback more than halved on the weekends, to 0.9 degrees—a finding consistent with the HEM group, which exhibited setbacks of 2.7 degrees during the week, but only 1.3 degrees on the weekend.

The smaller setback largely can be explained by participants' presence within their homes during the day on weekends. As participants would be home more often on weekends, they preferred to keep household temperatures at comfortable levels at that time. A small setback occurred on the weekends, but was not as extreme as during the week. Following the slight setback during the day, a valley again occurred in the evenings, likely due to increased occupancy during that time.

Cooling Season Indoor Temperatures

In addition to thermostat setpoint data, Cadmus looked at IAT data recorded by the thermostat. The evaluation team used these data to develop trends showing average air temperatures for each hour of the day during weekdays and weekends. Figure 32 shows weekday trends and Figure 33 shows weekend trends during the cooling season.

Figure 32. Weekday IAT, by Hour (n_{ATC}=51, n_{HEM}=52)

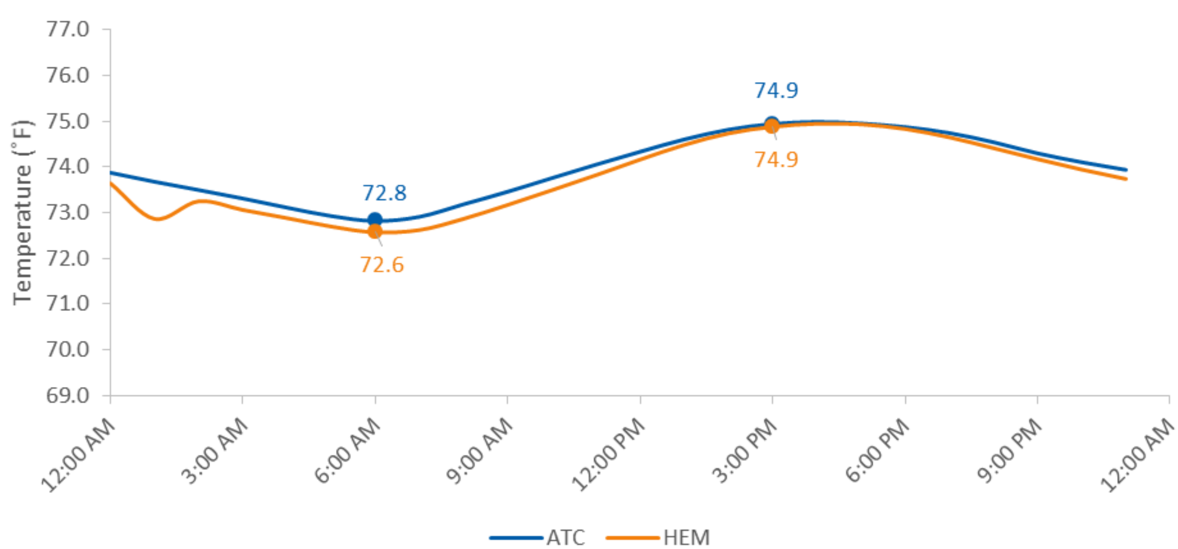

Figure 33. Weekend IAT, by Hour (n_{ATC}=51, n_{HEM}=52)

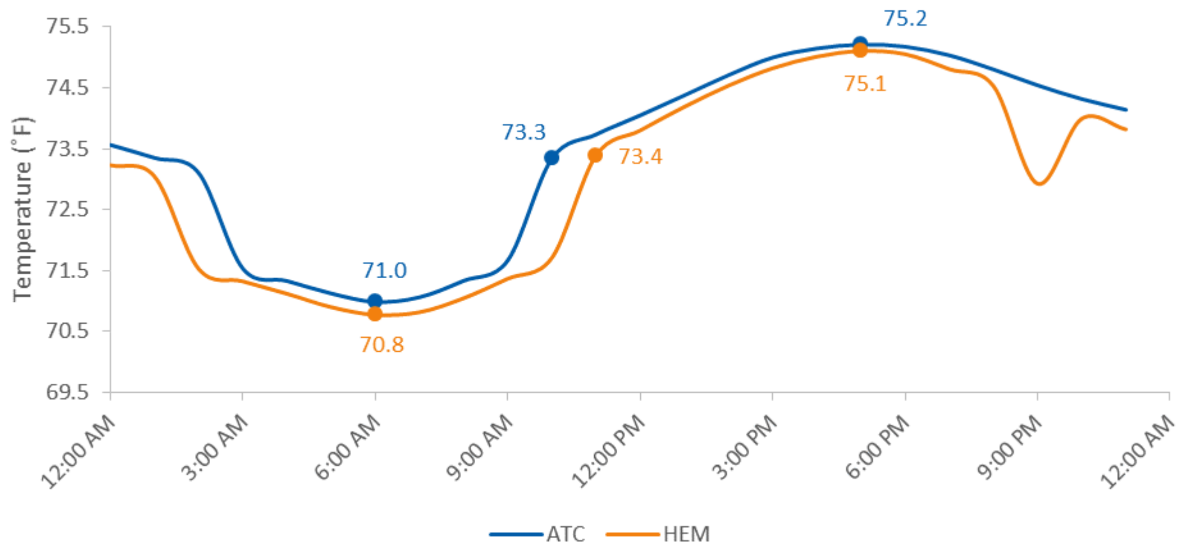

Figure 32 shows the hourly IAT during the week for both groups; both groups exhibit a similar, nearly sinusoidal general shape, with lowest temperatures in the morning and highest temperatures in the midafternoon.

Cadmus noted that, despite a significantly lower setpoint (70.3 degrees vs. 73.8 degrees), the HEM group had nearly the same IAT as the ATC group throughout the entire day—a finding consistent with trends seen in the heating season, where a discrepancy also occurred between the HEM group's IAT and the hourly setpoints.

Figure 33 shows hourly IAT during the weekend for both participant groups, resulting in similar profiles similar, with the curves following a rough sinusoidal waveform, with a dip in the early morning and a peak in the evening. The two primarily differed in that the HEM curve experienced an uncharacteristic dip around 9:00 p.m.

Most striking, Figure 33 shows the ATC group's IAT dropped to nearly the same level as the HEM group's IAT overnight, despite having a significantly higher setpoint. This indicates the heating load for ATC group's homes decreased at night. Intuitively, this makes sense as there would not be thermal gain from the sun, and the building's occupants sleep; so the internal heat gain would significantly decrease. This also may indicate the point at which buildings no longer store thermal energy absorbed during the day.

Cooling Season Setpoints and Indoor Temperature Comparisons

Cadmus compared participants' average cooling season setpoints to actual the IAT for each hour of the day to assess how effectively HVAC controls met setpoints. When interpreting these results, readers should note that space temperatures normally vary up to three degrees above and below the thermostat setpoint (i.e., the temperature differential), and a variety of factors impact how well a thermostat regulates space temperatures, including home insulation types, levels of solar heat gain, and HVAC system types.

Figure 34. HEM Average Cooling Season Setpoints and IAT, by Hour (n_{HEM}=52)

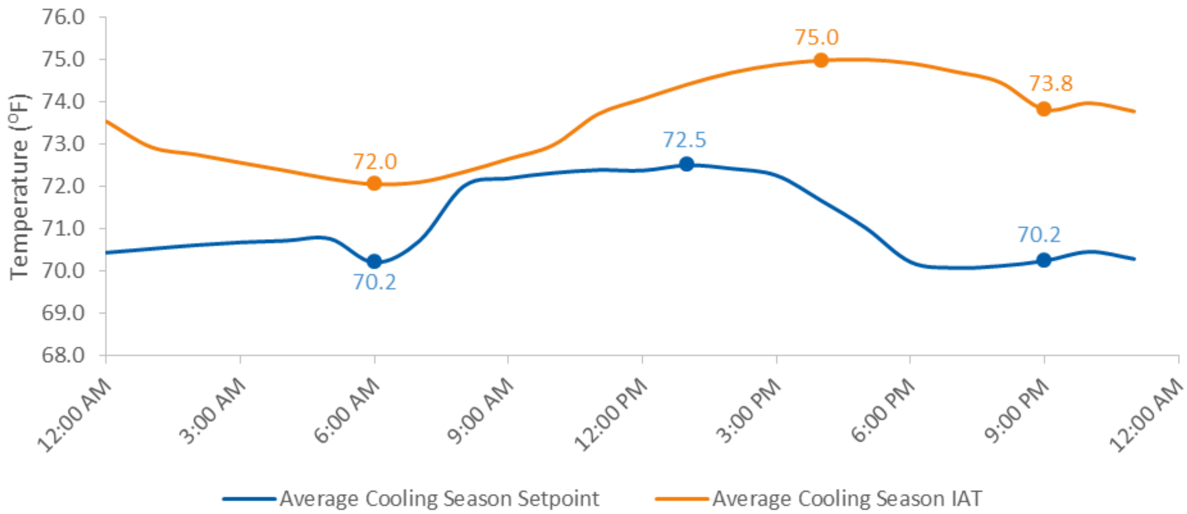

Figure 35. ATC Average Cooling Season Setpoints and IAT, by Hour (n_{ATC}=51)

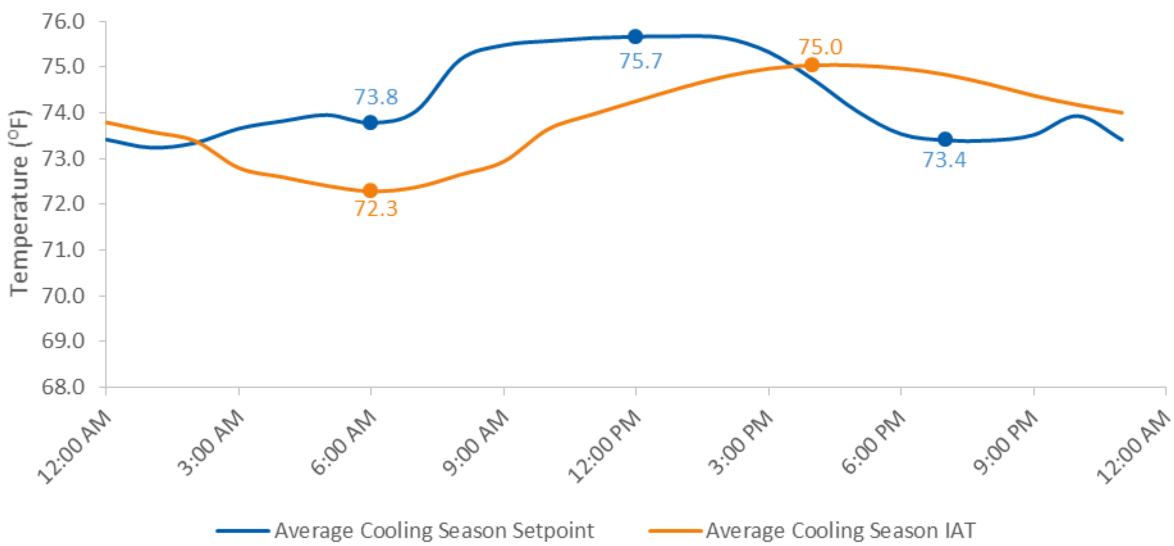

In the cooling season, the ATC group IAT more closely matched setpoints than did the HEM group: the latter group exhibited an IAT on average 2.4 degrees warmer than the setpoint, compared to 0.5 degrees cooler in the ATC group. For both groups, cooling systems had the most difficulty in meeting setpoints at 6:00 p.m., when cooling setpoints had recently dropped and impacts from solar heat gained throughout the day continued to taper off. At this time, the IAT for the HEM group was 4.7 degrees warmer than its setpoint and 1.4 degrees warmer than the setpoint in the ATC group.

Unlike in the HEM group, the ATC group exhibited IATs below the setpoint for some parts of the day. From 3:00 a.m. to 3:00 p.m., the group's IAT was cooler than the setpoint by as much as 2.5 degrees. This can be explained by outdoor air temperature (OAT) conditions. Figure 36 and Figure 37 show average hourly setpoints and IATs, overlaid with average hourly OATs.

Figure 36. HEM Average Cooling Season Setpoints, IAT, OAT by Hour (n_{HEM}=52)

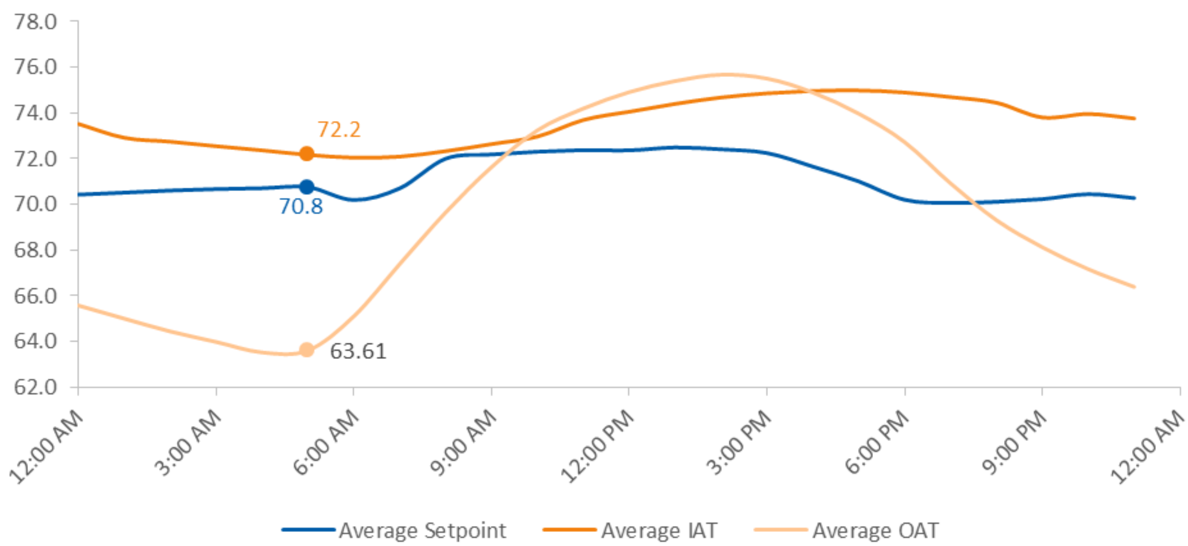

Figure 37. ATC Average Cooling Season Setpoints, IAT, OAT by Hour (n_{ATC}=51)

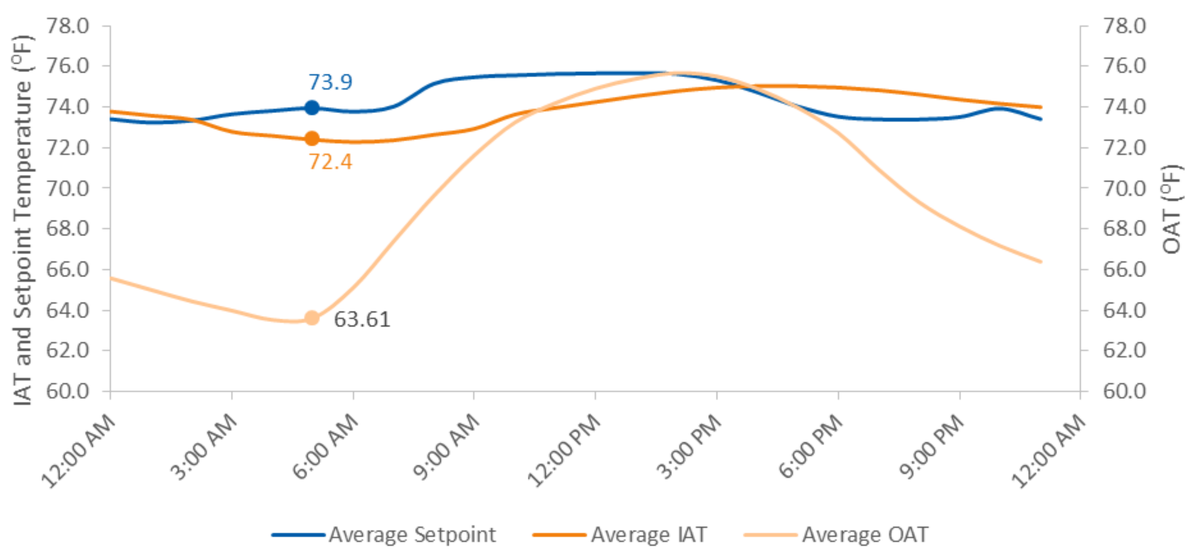

As OAT dropped at night, so did IAT: for the study sample, the average OAT fell to a low of 63.61 degrees at 5:00 a.m. For both groups, home temperatures dropped to approximately 72 degrees by 5:00 a.m. This IAT still remained higher than the setpoint for the HEM group, but was lower than the setpoint for the ATC group (which generally used higher setpoints in the cooling season). As this occurred during the cooling season, the heating system did not turn on to raise the IAT to the setpoint. Rather, rising OAT and solar heat gains increased the ATC group's IAT until it met the setpoint at 3:00 p.m., at which time the cooling system helped maintain the setpoint.

If solely considering hours when the cooling system was needed (4:00 p.m. to 2:00 a.m.), the ATC group's IAT averaged 0.7 degrees warmer than the setpoint (compared to 2.4 degrees for the HEM group). Although many factors can affect how well a thermostat regulates temperatures, sample results indicated cooling systems with HVAC optimization controls (i.e., the ATC group) performed better at meeting setpoints than cooling systems without HVAC optimization controls.

Cooling Season HVAC Runtimes

Cadmus assessed HVAC system runtimes by overlaying average hourly runtimes with average hourly IAT and setpoint data, as shown in Figure 38 and Figure 39.

Figure 38. HEM Cooling Season HVAC Runtime, Setpoints, IAT, by Hour (n_{HEM}=52)

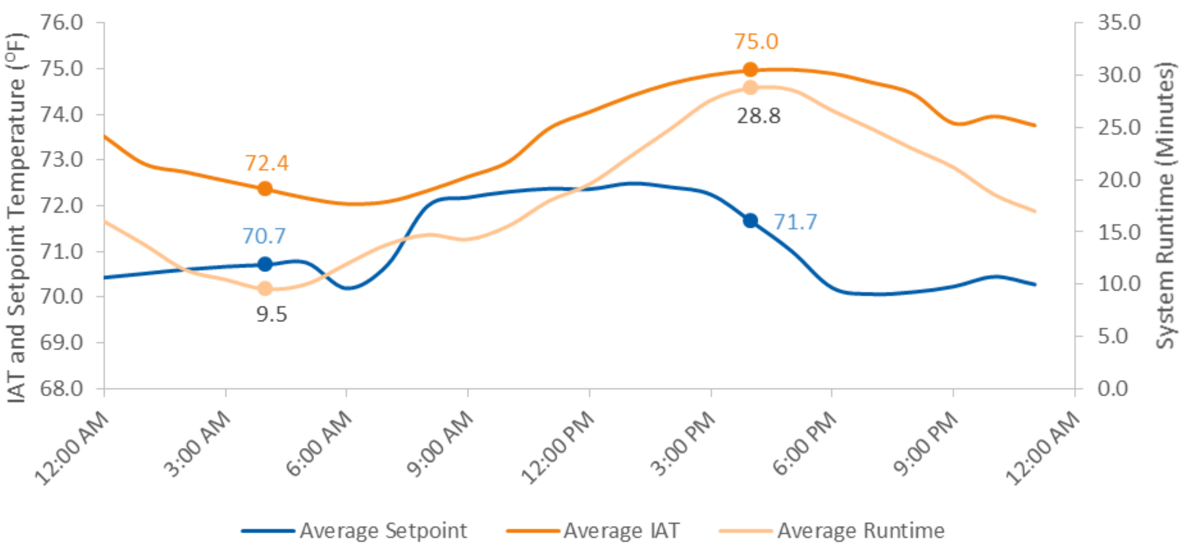

Figure 39. ATC Cooling Season HVAC Runtime, Setpoints, IAT, by Hour (n_{ATC}=51)

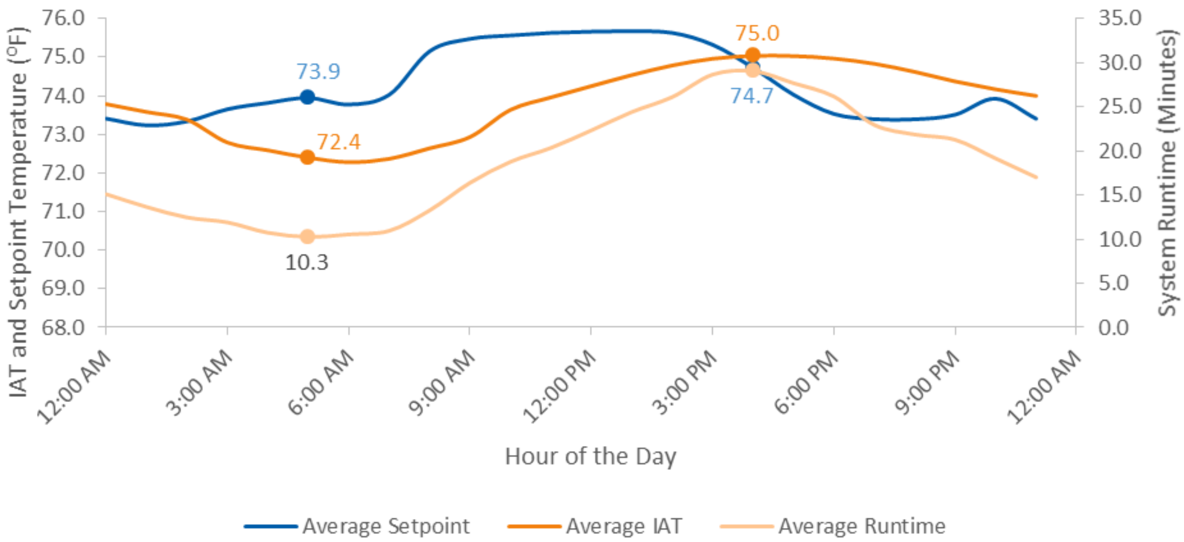

For both groups, daily runtimes had a pattern similar to the IAT profile—lower at night and higher during the day. This likely resulted from IAT increases due to increasing OAT and solar heat gain during the day, when cooling systems must run longer to maintain the setpoints. Alternatively, at night, when OAT drops and no solar heat gain occurs, IAT drops, and cooling systems need not work as hard.

Both groups experienced average hourly cooling system runtime peaks at 4:00 p.m., when setpoints decreased but impacts remained from solar heat gain. At this hour, both groups had average runtimes of approximately 29 minutes. Both groups experienced the lowest runtimes in the early morning (4:00 a.m. for HEM and 5:00 a.m. for ATC), when the average hourly runtime dropped to 9.5 minutes for HEM and 10.3 minutes for ATC.

Task 2. Natural Gas Billing Analysis

Cadmus received gas billing data for 52 of the 54 participants with National Grid gas accounts. Table 2 shows gas savings as a percentage of total gas usage, and Table 3 shows gas savings as a percentage of disaggregated heating gas usage for participants with available data. The evaluation team provided results for four sets of comparison groups:

- Manual vs. programmable baseline
- One thermostat vs. multiple thermostats
- ATC group vs. HEM group
- ATC participants with one thermostat vs. HEM participants with one thermostat

Table 2. Gas Savings as Percentage of Total Gas Usage

Group	Sample Size	Savings Per Customer (therms)	Average Number of Thermostats	Pre Usage (therms)	Savings Per Thermostat (therms)	% Savings Per Thermostat	Lower 90% Savings	Upper 90% Savings	Precision at 90% Confidence	Sqft	Thermostat Savings Per Sqft
Manual Baseline	9	100	2.22	1164	45	3.9%	25	65	44%	2,345	0.0192

CADMUS

Table 3. Gas Savings as a Percentage of Heating Gas Usage

Group	Sample Size	Savings Per Customer (Therms)	Average Number of Thermostats	Pre Heating Usage (Therms)	Savings Per Thermostat (Therms)	% Heating Savings Per Thermostat	Lower 90% Savings	Upper 90% Savings	Precision	Sqft	Thermost at Savings Per Sqft
Manual Baseline	9	100	2.22	810	45	5.6%	25	65	44%	2,345	0.0192
Programmable Baseline	26	76	1.38	720	55	7.6%	40	70	28%	2,016	0.0272
1 Thermostat	19	95	1.00	743	95	12.8%	69	121	27%	2,021	0.0470
Multiple Thermostats	16	67	2.31	742	29	3.9%	17	41	42%	2,194	0.0132
ATC	19	81	1.58	671	51	7.6%	39	63	24%	2,035	0.0252
HEM	16	84	1.63	828	52	6.2%	30	74	42%	2,178	0.0237
ATC 1 Thermostat	10	95	1	724	95	13.1%	71	120	26%	1,984	0.0480
HEM 1 Thermostat	9	95	1	765	95	12.4%	46	144	51%	2,062	0.0460
Overall	**35**	**82**	**1.60**	**743**	**51**	**6.9%**	**39**	**63**	**23%**	**2,100**	**0.0245**

Notably, participants with programmable thermostats as baselines had slightly higher savings than participants with manual thermostats as baselines (e.g., 5.5% compared to 3.9% of total gas usage; 7.6% compared to 5.6% for heating gas usage). These data suggest participants with programmable thermostats might not have used efficient setback schedules, compared to participants controlling their thermostats manually.

When considering savings from participants in both treatment groups, a large discrepancy appeared in savings between participants with one thermostat compared to those with multiple thermostats: participants with one thermostat saved 9.2% on total gas usage (12.8% of heating has usage), compared to 2.8% (3.9%) for multiple thermostats. Consequently, the comparison of ATC and HEM participants with one thermostat provided the most appropriate set of results for to consideration. Figure 40 shows a visual comparison of total gas savings results and the precision for the ATC and HEM participants with one thermostat.

Figure 40. Total Gas Savings, ATC 1 Thermostat and HEM 1 Thermostat (n_{ATC}=10, n_{HEM}=9)

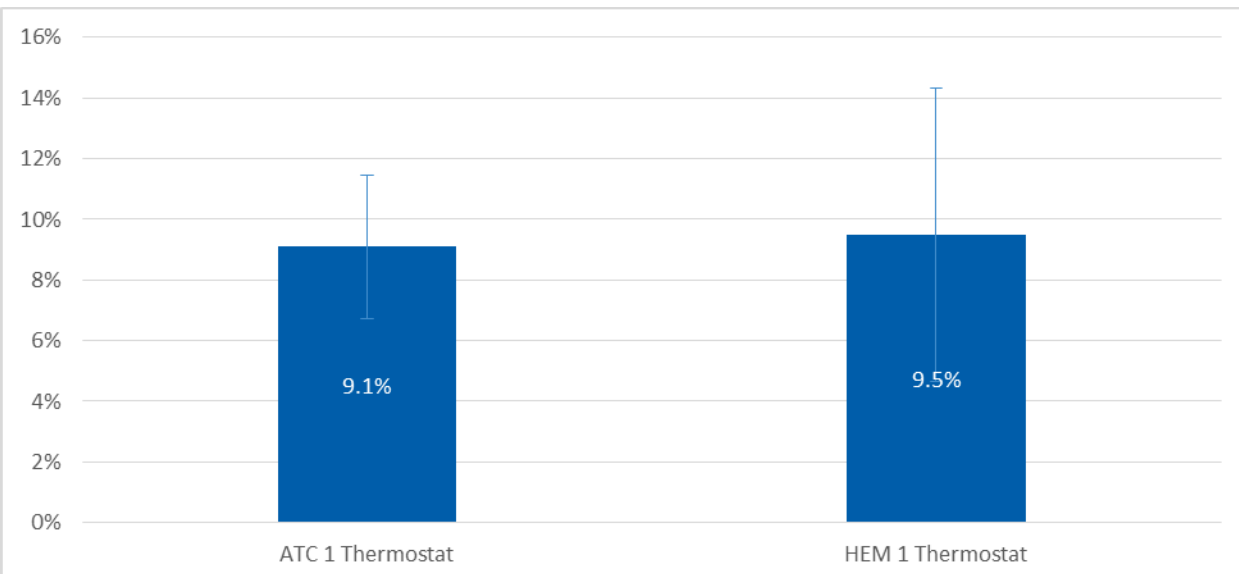

Figure 41. Heating Gas Savings, ATC 1 Thermostat and HEM 1 Thermostat (n_{ATC}=10, n_{HEM}=9)

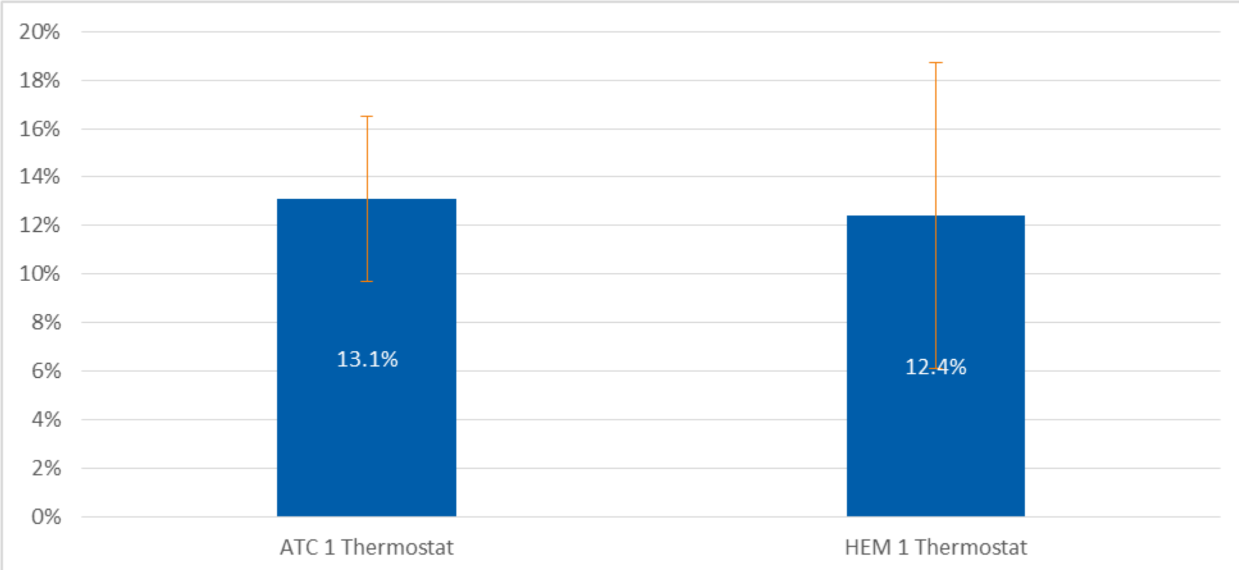

When comparing ATC and HEM participants with just one thermostat, Cadmus found the two groups achieved about the same savings: HEM performed slightly better when considering savings as percentage of total gas usage while ATC performed slightly better when considering savings as percentage of the disaggregated heating load. As a percentage of total gas usage, the ATC group saved an average of 9.1% (compared to 9.5% for participants in the HEM group). For the disaggregated heating load, the ATC group saved an average of 13.1% of heating gas usage (compared to 12.4% for participants in the HEM group). The ATC group had slightly higher savings per square foot (0.0480 therms per square foot compared to 0.0460 therms per square foot for HEM).

Task 3. Electric Billing Analysis

Cadmus analyzed billing data for 102 participants with National Grid electric accounts. Table 4 shows electric savings as percentage of the disaggregated cooling load. Similarly the natural gas billing analysis, the evaluation team provided results in four sets of comparison groups:

- Manual vs. programmable baseline
- One thermostat vs. multiple thermostats
- ATC group vs. HEM group
- ATC participants with one thermostat vs. HEM participants with one thermostat

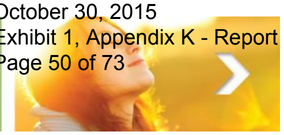

Table 4. Electric Savings as Percentage of Cooling Usage

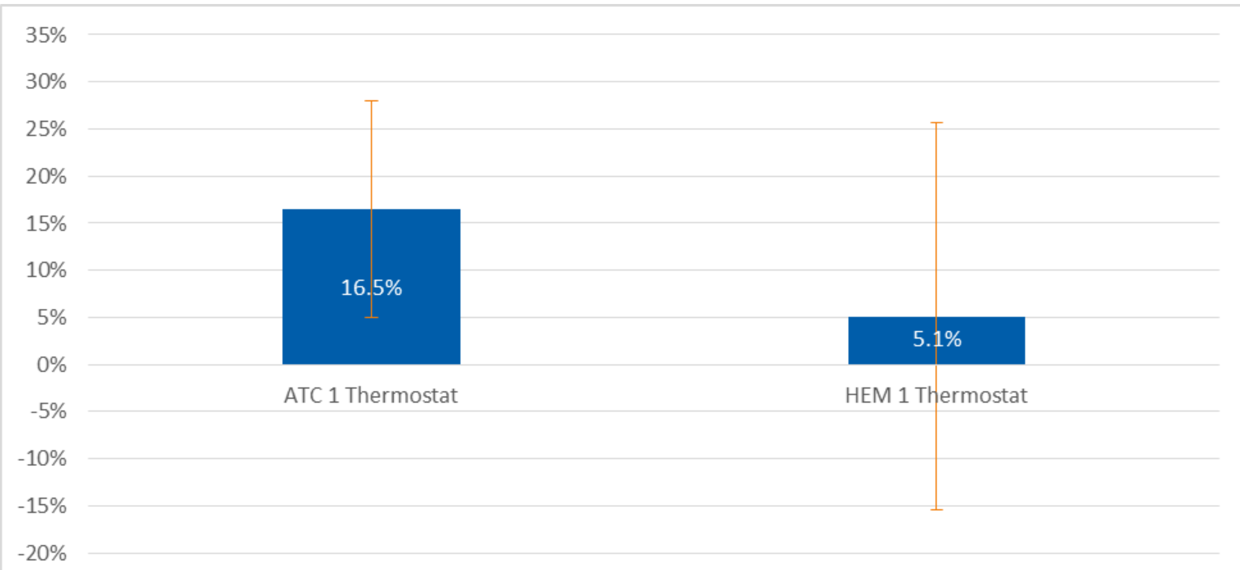
Group	Sample Size	Savings Per Customer (kWh)	Average Number of Thermostats	Pre Cooling Usage (kWh)	Savings Per Thermostat (kWh)	% Cooling Savings Per Thermostat	Lower 90% Savings	Upper 90% Savings	Precision	Sqft	Thermostat Savings Per Sqft
Manual Baseline	15	491	2.27	2,161	217	10.0%	63	370	71%	2,314	0.09136
Programmable Baseline	48	198	1.42	1,896	140	7.4%	23	257	84%	2,093	0.0669
1 Thermostat	34	215	1.00	1,755	215	12.2%	115	314	46%	1,946	0.1102
Multiple Thermostats	29	331	2.34	2,199	141	6.4%	80	203	44%	2,378	0.0593
ATC	29	384	1.45	2,379	265	11.1%	103	426	61%	2,100	0.1261
HEM	34	170	1.76	1,601	96	6.0%	-16	208	117%	2,184	0.0440
ATC 1 Thermostat	18	341	1.00	2,066	341	16.5%	104	579	70%	1,888	0.1808
HEM 1 Thermostat	16	72	1.00	1,405	72	5.1%	-218	362	403%	2,013	0.0358
Overall	**63**	**268**	**1.62**	**1,959**	**166**	**8.5%**	**72**	**260**	**57%**	**2,145**	**0.0772**

Unlike gas savings results, participants with manual thermostats as baselines had slightly better savings (10.0% compared to 7.4%), which may indicate participants with manual thermostats operated them more efficiently than those with programmable thermostats during the heating season, but not during the cooling season.

As with the gas savings analysis, a large savings discrepancy occurred between participants with one thermostat compared to those with multiple thermostats: participants with one thermostat saved 12.2% of cooling electric usage, compared to 6.4% of cooling electric usage for participants with multiple thermostats.

The ATC group reduced almost twice the electric usage for the cooling load compared to the HEM group, saving an average of 11.1%, compared to 6.0% for all group participants. When comparing ATC and HEM participants with just one thermostat, the ATC group outperformed the HEM group by more than three times, as shown in Figure 42. The ATC group saved 16.5%, compared to 5.1% for the HEM group. On a per-square-foot level, the ATC group achieved approximately five times the savings than the HEM group (0.1808 compared to 0.0358 kWh/sqft).

Figure 42. Cooling Electric Savings, ATC 1 Thermostat and HEM 1 Thermostat (n_{ATC}=18, n_{HEM}=16)



Task 4. Verification of DR Impacts

Cadmus analyzed participants' integrated energy meter data to assess the DR event impacts, with the regression analysis results shown in Table 5. The table flags statistically significant results in red. Figure 43 and Figure 44 show the runtime and demand impacts of the DR events, respectively. Bars with data labels indicated statistically significant results.

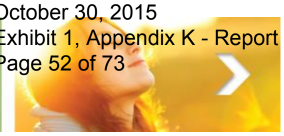


Table 5. DR Impacts: Runtime and Demand (n=30)

Event	Parameter	Runtime Analysis (Dependent Variable: Minutes of Cooling Runtime Per Hour)		Demand Analysis (Dependent Variable: kWh-Per-Hour or Average Hourly Demand in kW)	
		Change in Runtime (Minutes)	Significance (Pr > ChiSq)	Change in Demand (kW)	Significance (Pr > ChiSq)
Event 1: No pre-cooling	event1hour1	**-8.2118**	**0.0003**	0.0024	0.9973

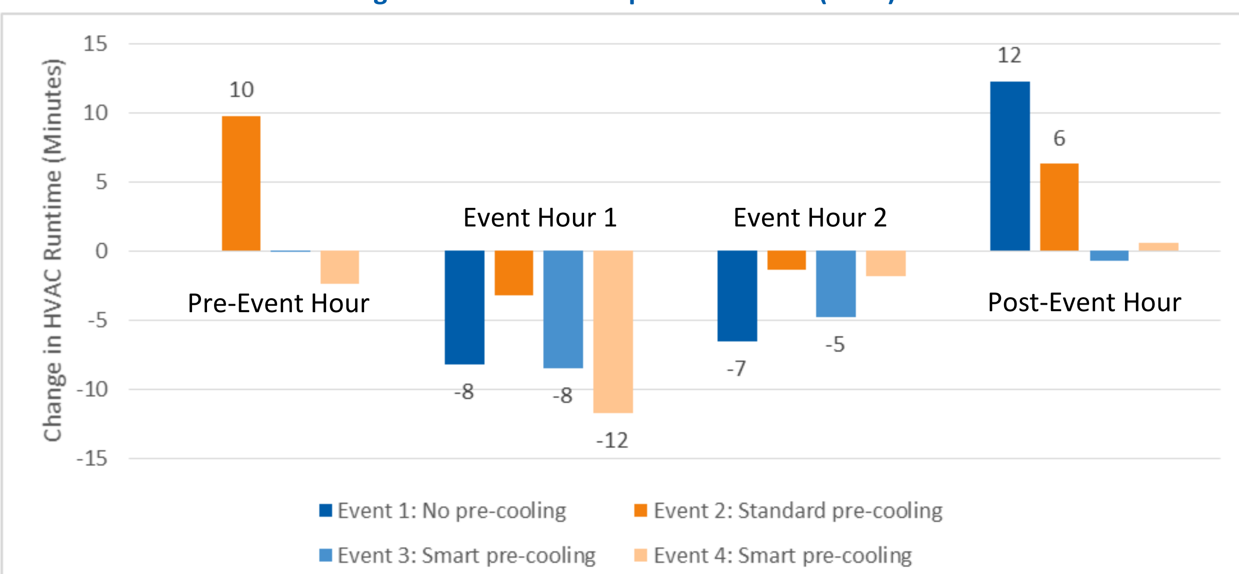
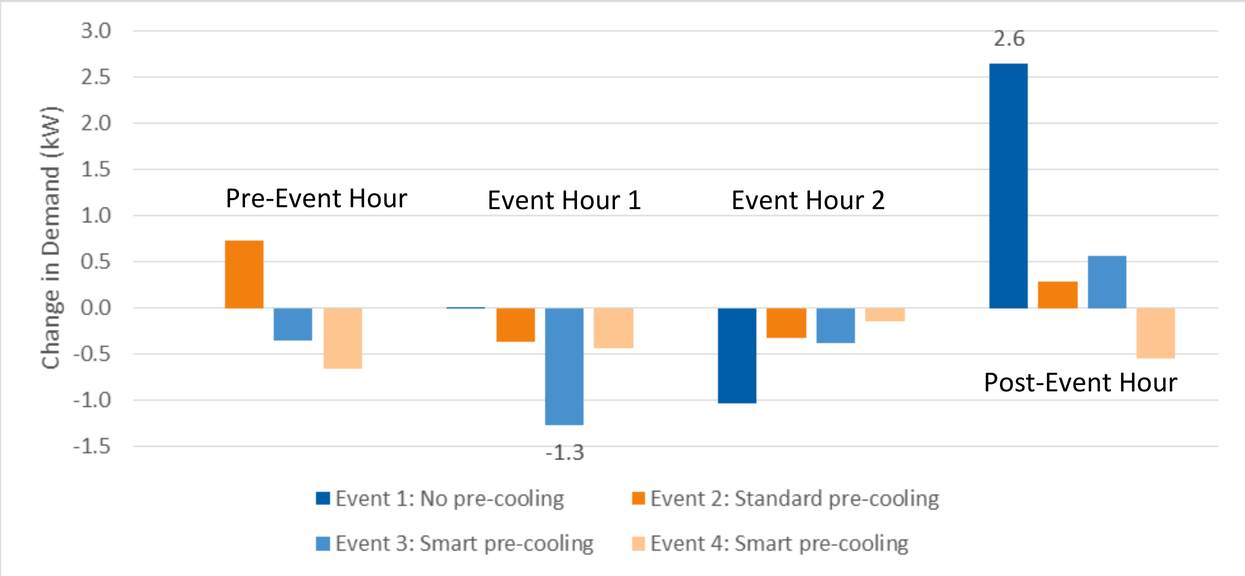
Figure 43. DR Event Impacts: Runtime (n=30)



CADMUS

Figure 44. DR Event Impacts: Demand (n=30)



Across all four events, Cadmus found average estimated demand reductions of 0.520 kW in the first event hour and 0.472 kW in the second event hour. During smart pre-cooling events, average estimated demand reductions were 0.847 kW and 0.267 kW, respectively. The largest estimated impact—1.264 kW per home—was achieved in the first hour of the third event: an estimate statistically significant at the 10% level. None of the other event hour impact estimates, however, differed statistically from zero at the 10% significance level.

In the first hour after the DR events (eventposthour1), an average estimated increase in demand of 0.736 kW occurred. During smart pre-cooling events, an average estimated demand increase of 0.009 kW occurred due to the opposite effects estimated between Event 3 and Event 4 (both with approximately 0.5 kW, but opposite signs). Cadmus expected to observe an *increase* in demand during the first hour after a DR event (as in Event 3), but Event 4 demand decreased during that hour. Neither result, however, proved statistically different from zero. The only statistically significant post-event impact that Cadmus estimated followed Event 1 (no pre-cooling), where demand increased by 2.646 kW after the DR event.

Cadmus also estimated the same regression model using AC runtimes for comparison against whole-home demand impacts. As expected, runtime impacts were more precisely estimated than demand impacts due to the absence of all other residential end uses in the data. Across all events, an average estimated runtime reduction of 7.9 minutes occurred in the first event hour and 3.6 minutes in the second hour. The average increased runtime in the first hour after the event was 4.5 minutes. No statistically significant increase in runtime occurred after the smart pre-cooling events (Events 3 and 4). Before all three pre-cooling events, a 2.4-minute average estimated runtime increase resulted from pre-cooling, though no statistically significant impact occurred for the smart pre-cooling events, and point estimates were negative (i.e., a *reduction* in runtime during the pre-cooling hour).

Given the wide variation in the magnitude and statistical significance of Cadmus' runtime and demand impact estimates, the evaluation team sought to compare runtime impacts with demand impacts to determine if they were consistent with one another. When the EER and tonnage of an AC is known, the hourly runtime of that AC (minutes) can be approximately converted to average hourly demand (kW) using a simple engineering equation.[2]

To this end, Cadmus requested nameplate data for smart thermostat program participants. National Grid provided the evaluation team with AC makes, models, ages, and tonnage for 60 AC units in the program. Though EER was not available in these data, among these the 60 ACs averaged 4 tons, much more than Cadmus expected. (In other DR programs the average tonnage was closer to 2.5 tons. In addition, 4 tons is large for the average size of homes reported in the survey).

Assuming an average EER of 11, the average demand of each unit while running would be 4.36 kW. During the first hour of Event 3, Cadmus' estimated a runtime reduction of 8.4825 minutes and demand reduction of 1.2641 kW, as shown in Table 5. Using the average tonnage of 4 and an assumed average EER of 11, the expected kW reduction associated with an 8.4825 minute runtime reduction was approximately 0.617 kW.

However, Cadmus' statistically significant estimate of the demand reduction in this hour was 1.2641 kW, or almost twice the value expected, given the runtime reduction and the average tonnage of ACs in the program. Similarly, in the first hour after Event 1, the expected kW reduction, given the runtime reduction of 12.2605 minutes, was 0.892 kW, yet Cadmus' estimated demand reduction was 2.6463 kW—almost three times larger than expected. This suggests a number of possible problems, some of which could indicate the evaluated demand impacts are overstated.

First, the selection of AC nameplate data that National Grid provided to Cadmus may not reflect average characteristics of the true DR program population, or Cadmus' assumption of an average EER of 11 may be incorrect. This conclusion, however, suggests actual program populations ACs were even larger than 4 tons or extremely inefficient. If true, Cadmus' estimated event impacts may not be overstated, but the evaluation team finds this scenario unlikely, given observations of average AC characteristics in other DR programs.

Rather, Cadmus suspects measurement or data management errors occurred in the energy consumption data, and these errors resulted in demand impact estimates much larger than expected from the runtime impacts. As noted in the DR methods section, Cadmus identified and removed many suspicious outliers from the energy consumption data before performing the regression analysis. These outliers, however, may suggest widespread measurement error resulted in overstated demand impacts.

2 $Average\ kW = \frac{12*tonnage}{EER} * (\frac{Hourly\ Runtime\ in\ Minutes}{60\ Minutes})$

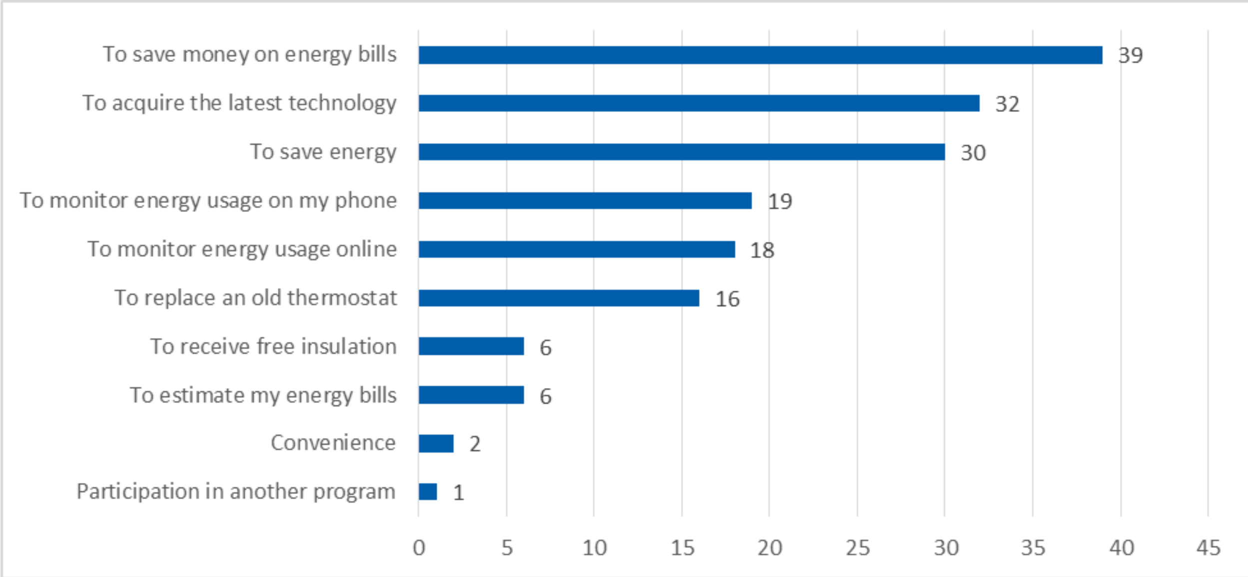
CADMUS

Task 5. Analysis of Participant Surveys

Motivations and Previous Thermostat Usage

Cadmus asked participants their motivations for signing up for the pilot program, with responses shown Figure 45.

Figure 45. Motivations for Signing up for the Pilot Program (n=47; multiple responses permitted)

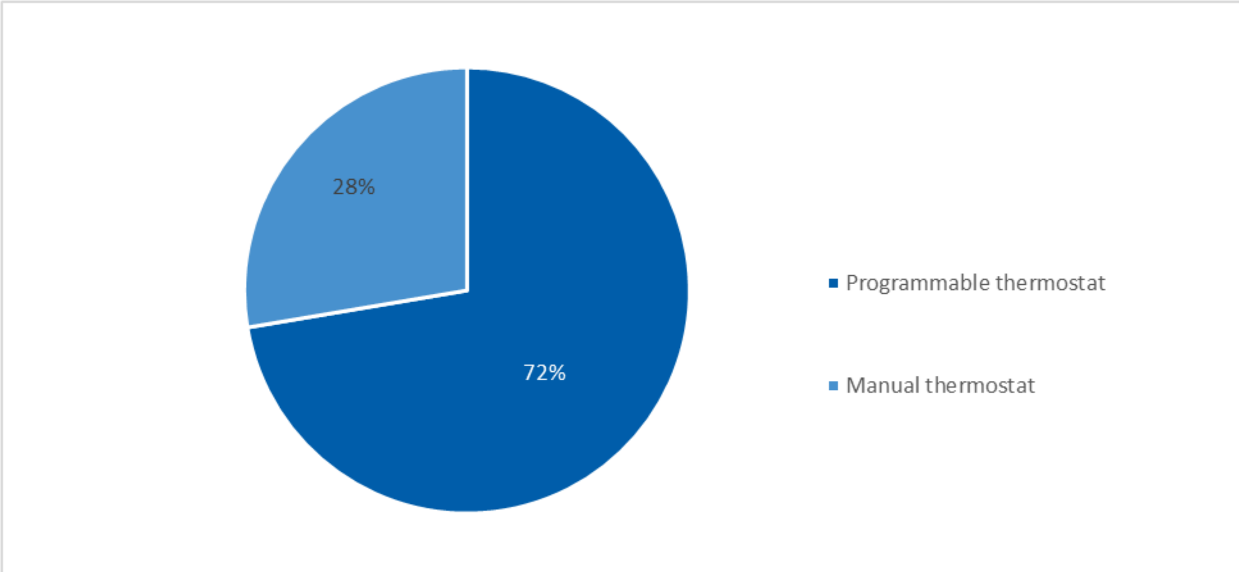


Source: 2014 Ecobee Thermostat Pilot Program Survey

The majority of participants (39 of 49) reported signing up for the pilot program to save money on electric bills. Participants cited acquiring the latest technology as their second most common motivation (32 of 49), followed by saving energy (30 of 49). Nineteen participants cited monitoring energy usage on their phones as a motivating factor, and 18 participants cited monitoring their energy usage online as a motivation. Respondents also found obtaining a new thermostat also highly motivating, with 16 citing this. When asked about the single most important factor in their decision-making process, saving money on energy bills remained the most important factor, followed by acquiring the latest technology.

Cadmus also asked participants to confirm their baseline thermostat type, with responses shown in Figure 46.

Figure 46. Participants' Previous Thermostat (n=47)

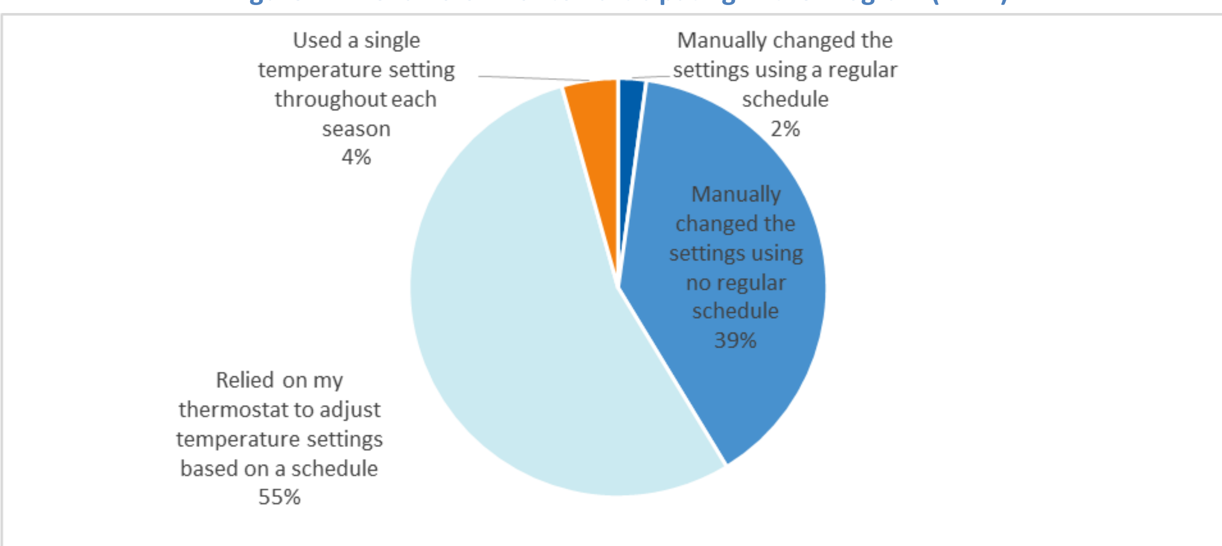


Source: 2014 Ecobee Thermostat Pilot Program Survey

A majority of participants used a programmable thermostat prior to participating in the program (72%). None of the program participants reported using an Internet-connected or smart thermostat prior to participation.

To understand participants' baseline behavior, Cadmus asked participants to describe how they operated their previous thermostats, with results shown in Figure 47.

Figure 47. Behaviors Prior to Participating in the Program (n=47)



Source: 2014 Ecobee Thermostat Pilot Program Survey

The majority of program participants (53%) set their thermostat to a schedule prior to participating in the program; 39% manually changed their thermostat settings without using a regular schedule; 4% manually changed their settings using a regular schedule; and 4% used a single temperature setting throughout each season.

Post-installation Behavior

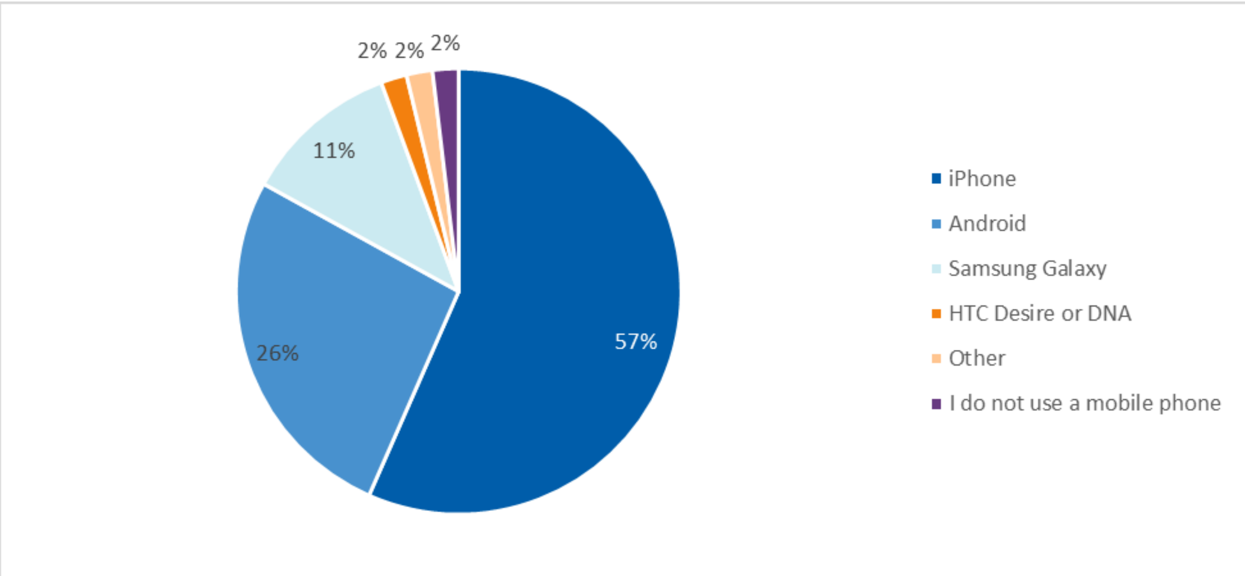
During the program, participants could access the following features:

1. Change the temperature
2. View energy usage
3. Estimate their bill by using three technologies:
    a. The thermostat itself
    b. A web portal from a computer
    c. A smartphone app

All program participants used the thermostat itself (100%) for at least one of these tasks, followed by the smartphone app (72%) and the web portal (70%).

Notably, smartphone app usage was slightly higher than web portal usage. This may be explained, as discussed further in the *Satisfaction and Willingness to Pay* section, through the appeal of mobile access through a smartphone, opposed to more stationary access afforded by web portals. Figure 48 shows participants' types of smartphones.

Figure 48. Customer Type of Phone (n=47; multiple responses allowed)



Source: 2014 Ecobee Thermostat Pilot Program Survey

The majority of participants used an iPhone (57%), followed by an Android phone (26%), and a Samsung Galaxy (11%). Only 2% of customers did not use a smartphone (Other), and only 2% of customers did not use a mobile phone. An app running on iPhone, Android, and the Samsung Galaxy worked for 94% of the pilot program population. As the pilot program population may have been more motivated by having the "latest" technology than the general population, these percentages may not apply to the general population, but the high percentage of iPhone and Android users provides a smartphone platform baseline on which to base future planning.

Cadmus asked participants to rank the usefulness of the three key features, with results shown in Table 6.

Table 6. Ranking of Usefulness by Feature (n=47)

#	Answer	Min Value	Max Value	Average Value	Responses
1	Change the temperature feature	5	10	9.27	45
2	View energy usage	1	10	7.22	37
3	Bill estimation feature	1	10	5.24	30

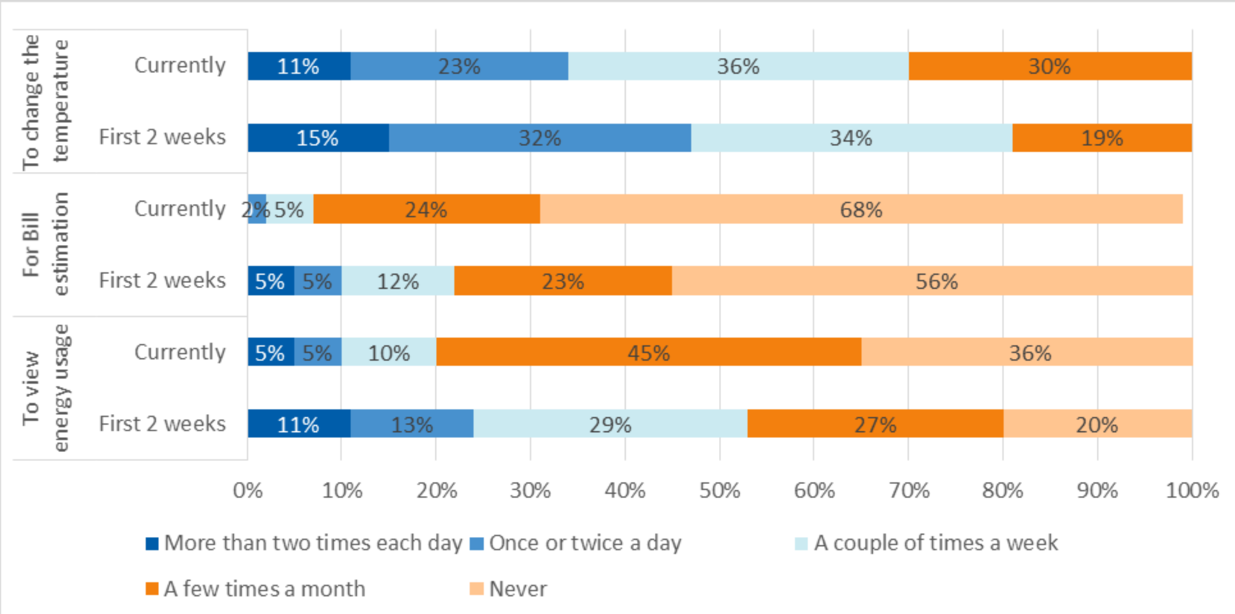
Respondents cited the top ranked feature as the ability to change temperatures: an average, participants ranked this feature a 9.27/10.00. Viewing energy usage was ranked a 6.84/10.00, and bill estimation a 4.75/10.00.

Twelve respondents offered verbatim responses received for the question: "Do you have any suggestions for any of the features above?" Three customers suggested a simpler user interface. Other comments and suggestions included the following:

> "Maybe an alert when the usage is higher and lower than your normal use."
>
> "Bill estimation and View energy usage features stopped working after installing Net Meter (for Solar)."
>
> "I don't think that the energy usage includes gas used for heat, that would be more helpful if it did!"
>
> "[I] never really got any initial instructions or feedback from National Grid on how to make the most of the unit's features."
>
> "Ability to change the schedule from the phone."

To assess these features' usefulness, Cadmus asked participants to rate their frequency of use for the first two weeks of the program, compared to the present. Figure 49 shows the results.

Figure 49. Thermostat Usage Frequency Phases (n=47)



Source: 2014 Ecobee Thermostat Pilot Program Survey

Customer interactions with their thermostats changed over time. During the first two weeks of the program, customers reported viewing their energy usage more frequently, with the majority viewing energy usage a couple times each week. Several weeks in, the majority of customers viewed their energy usage a few times each month.

Use of the bill estimation feature also declined over time, with 10% of participants using the bill estimation feature multiple times per day in the first two weeks of the program, then losing interest after the initial period, with only 2% continuing to use the feature daily.

All customers continued using the thermostats to change their home temperatures, with some additional activity occurring in the first two weeks of the pilot.

Comfort

Customers reported maintaining average home temperatures of 72.3°F during the summer cooling season, with a minimum value of 65 degrees and a maximum of 81°F. Cadmus asked participants to rate their comfort levels during the cooling season. Table 7 shows results for the HEM group.

Table 7. Summer Cooling Season Comfort Ratings (HEM Group)

Answer	Responses	%
Did not notice a change in comfort level	14	61%
The house is warmer but the comfort level is acceptable	6	26%
The house is considerably less comfortable	2	9%
Other: "House was more comfortable"	1	4%
Total	23	100%

The majority of participants (61%) did not notice changes in comfort levels. One respondent found levels more comfortable. Approximately one-quarter (26%) found the house was warmer but acceptably comfortable. Only two respondents found the house considerably less comfortable. Overall, the program's curtailment settings proved acceptable to 91% of participants.

All 47 participants were asked if they had done taken different actions to manage comfort levels in their homes during the program, with 57% using a ceiling fan or other fan to manage their comfort, 49% percent shutting blinds, 13% not taking different actions, one participant (2%) turning on a window-unit AC, and one participant (2%) leaving their house more frequently.

Participants reported the average temperature settings of 67.7°F for the 47 homes during the heating season, with a minimum value of 58°F and a maximum value of 78°F. Table 8 shows winter season comfort ratings during program participation, as compared with the season before participation.

Table 8. Heating Season Comfort Ratings (Both DR and HEM Groups)

Answer	HEM Participants		ATC Participants	
	Responses	%	Responses	%
Did not notice a change in comfort level	13	57%	15	65%
The house is cooler but the comfort level is acceptable	6	26%	5	22%
The house is considerably less comfortable	1	4%	2	9%
Other	3	13%	1	4%

The majority of participants in both groups (57% of HEM and 65% of ATC) did not notice changes in comfort levels, while 26% of HEM and 22% of ATC found their homes cooler but acceptably comfortable. Only one HEM participant (4%) and two ATC participants (9%) found their homes considerably less comfortable. These findings mirror those of summer cooling comfort levels, with most participants acceptably comfortable during the program.

Actions participants took to manage comfort levels included: 26% closing off unused rooms, 19% using a woodstove or fireplace, 11% turning on a space heater, 4% wearing extra layers of clothing, one participants (2%) using a door draft stopper, and one participant (2%) leaving their house more frequently, indicating discomfort.

DR Events

Cadmus asked DR participants an additional battery of survey questions specific to their experiences with DR events. Understanding DR events for a larger population requires determining how many participants remained home in respect to event timing. In the pilot program, 14 to 16 of 24 participants (about two-thirds) reported staying home for each of the four events. Cadmus asked these participants additional questions about comfort, as discussed further below. All participants reported receiving an e-mail notification of the events beforehand; 71% preferred to receive notification 24-hours in advance.

Notably, 17% reported that advance notification was not important for them. The remaining 13% preferred receiving notification the evening before.

If participants' records indicated they had opted-out of events, they were asked: "What was the main reason for deciding to opt-out of this event?" (for each event they opted out of). Of four opt-out respondents, only one respondent offered a clear reason for their choice: they had family visiting. Two participants reported they "don't know" or one respondent thought they had not opted out of that event.

Cadmus asked respondents if they changed their temperature setting during a DR event, and, if so, why. The majority did not change their temperature settings; the one respondent who did said it became too warm in the home. Table 9 shows overall comfort level ratings for each event.

Table 9. DR Event Comfort Ratings

Date	Did not Notice a Change in Comfort Level	The House is Warmer but the Comfort Level is Acceptable	The House is Considerably Less Comfortable	Total Responses
August 26th	79%	14%	7%	14
August 27th	77%	15%	8%	13
July 9th	64%	29%	7%	14
September 5th	80%	20%	0%	15

The majority of participants who remained home for the event did not notice a change in comfort levels (64% to 80%, depending on the event date). Between 14% and 29% found the home warmer, but still acceptably comfortable. Less than 9% in each event found the home "considerably less comfortable" during DR events.

When asked if they had taken actions to manage comfort *during* events, nine of 24 participants reported turning on ceiling fans or other fans, and eight of 24 participants reported shutting the blinds. One "other" response explained that the respondent ran the furnace fan to move air around the house during the events. When asked for additional comments on the events, the nine responses ranged from "they were fine, barely noticed," to "my wife was not happy that someone else was controlling her comfort level...." Some verbatim responses follow:

> "I didn't notice a big change which has led me to not having the AC on quite as much."
>
> "I am very happy with the thermostat. It is very convenient to adjust the temp from my smart phone and tablet."
>
> "Was prepared to adjust temperature if required, but it was not necessary."
>
> "The e-mail notifications were very informative. I had questions about the events and customer service was very prompt in answering my questions and responding to my concerns."

Behaviors and Attitudes

Cadmus asked participants if they participated in any other National Grid program in the past year. Twelve respondents had participated in another program. Two specifically reported participating in MassSave, five mentioned an insulation program, three mentioned lighting rebates, and three mentioned rebates for measures such as a new boiler, a dehumidifier, and a Nest Thermostat. The majority of respondents (73%) had not participated in another program.

Cadmus also asked participants for their agreement levels regarding a series of statements designed to better understand participant attitudes towards energy conservation, saving money, trust in the utility, and preferences for having the latest technology. Table 10 shows the results.

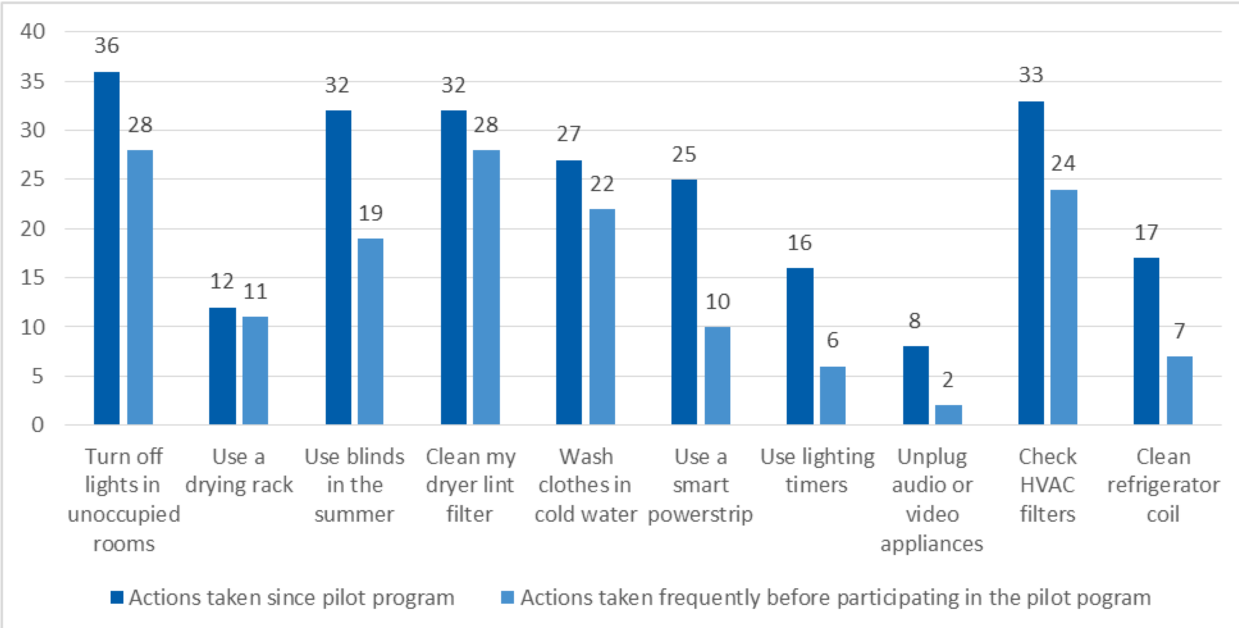
Table 10. Attitude Statements and Level of Agreement

	Strongly Disagree	Disagree	Neither Agree nor Disagree	Agree	Strongly Agree	Total Responses	Mean
Conserving energy is important to me	2%	0%	4%	23%	70%	47	4.6
I like to have the latest technology	2%	4%	11%	28%	55%	47	4.3
Saving money is important to me	2%	0%	0%	15%	83%	46	4.76
In general, I trust my utility company as an expert in energy-saving opportunities	2%	2%	15%	62%	19%	47	3.94

Most participants strongly agreed with statements such as “conserving energy is important to me” and “saving money is important to me.” The majority of program participants also considered having the latest technology important. While most participants strongly agreed that saving energy and money were important, trust in the utility showed more ambivalence, with seven participants neither agreeing nor disagreeing, and the majority (29/47) expressing agreement, but not strong agreement. This finding may be a useful in planning future program messaging focused on the convenience and value of personal control over temperature settings.

The majority of participants took additional actions or changed the frequency in which they performed behaviors since participating in the program. Figure 50 shows these actions.

Figure 50. Comparison of Participants' Current Actions as Compared to Before Program (n=46; multiple responses allowed)



Source: 2014 Ecobee Thermostat Pilot Program Survey

The greatest changes from pre-program participation to post-program participation regarding using a smart powerstrip, cleaning refrigerator coils, using lighting timers, using blinds in the summer, and checking HVAC filters. While use of smart power strips showed a large increase post-participation, other behaviors may have been influenced by monitoring electricity consumption, as these had not been practiced prior to program participation.

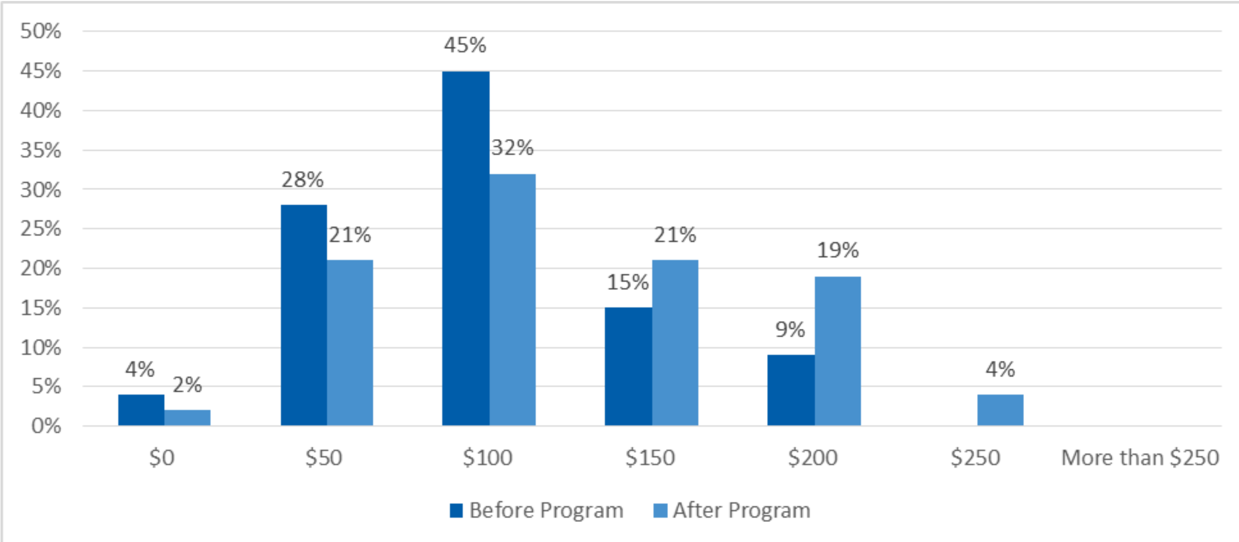
Participants also made home improvements to save energy after participating in the program, with 42% percent of respondents (19 of 45) making improvements. Such improvements included insulation, exterior door improvements, draft stopping tape, new boilers, furnaces, windows, installing a solar PV system, and lighting improvements or LED purchases.

Satisfaction and Willingness to Pay

Participants expressed overall satisfaction with National Grid, awarding an average satisfaction ratings of 7.87/10.00, with a 10 as "very satisfied." On the same scale, participants rated the Ecobee thermostat an average of 8.72/10.00. Participants also were asked: "Given the opportunity, how likely would you be to recommend this program to a friend?" Respondents rated this question an average of 9.02/10.00, or very likely to recommend the program. Participants also were asked how likely they would be to recommend the thermostat to a friend, with an average value of 8.65/10.00. These findings indicate the program was well received.

Respondents also indicated if they were inclined to pay an average of 25% more for a smart thermostat after participation in the study. When asked how much they would be willing to pay before and after the study, the average amount before was $98 and the average amount after was $123. Figure 51 shows the distribution of responses.

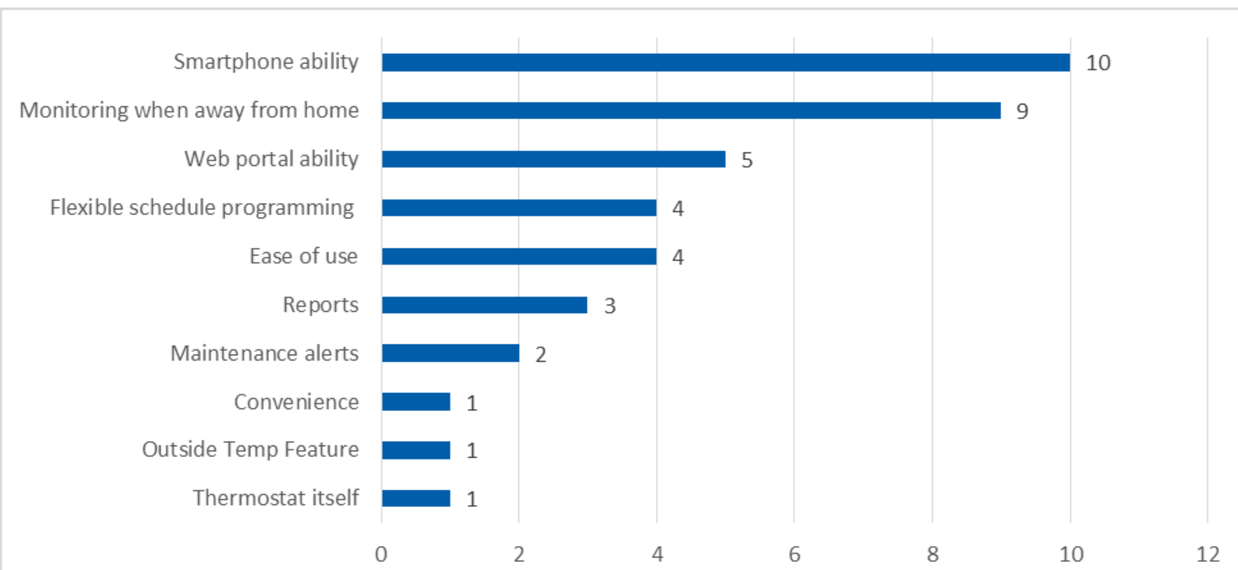
Figure 51. Willingness to Pay (n=47)



Source: 2014 Ecobee Thermostat Pilot Program Survey

Cadmus asked participants what they liked the most about the program. Figure 52 shows their responses.

Figure 52. What Program Features Did You Find Most Valuable? (n=47; multiple responses allowed)



Source: 2014 Ecobee Thermostat Pilot Program Survey

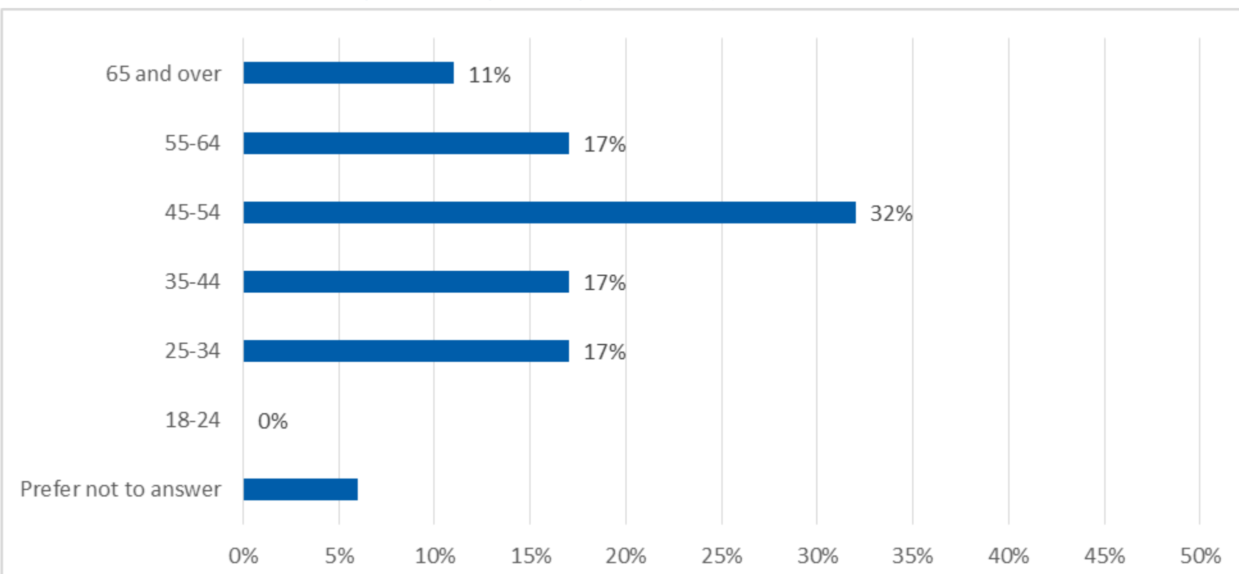
Many respondents found the smartphone app the most valuable aspect of the program. Comments included: "the ability to adjust my temp from my smartphone" and "access from my iPhone." Many participants also found the ability to monitor their home while away valuable. Comments included: "checking on the heat while out of town" and "loved the remote access and ability to monitor the home while away." Five participants cited the web portal as valuable. Some verbatim comments follow:

> "I liked the online features and details the website provided regarding usage rates and trends."
>
> "The ability to check status on a smartphone as well as set maintenance alerts (i.e. changing the filter)"
>
> "Remote and mobile controls worked out awesome when I was not home."
>
> "With my old thermostat, I could only program 3 changes per day. With Ecobee, I could program many more, and thus could be more efficient. I also really liked the ability to change temperature from my phone in case I needed to change it after leaving the house."

Demographics

Cadmus collected demographics regarding participant age, home square footage, education, and income. The following figures detail their responses.

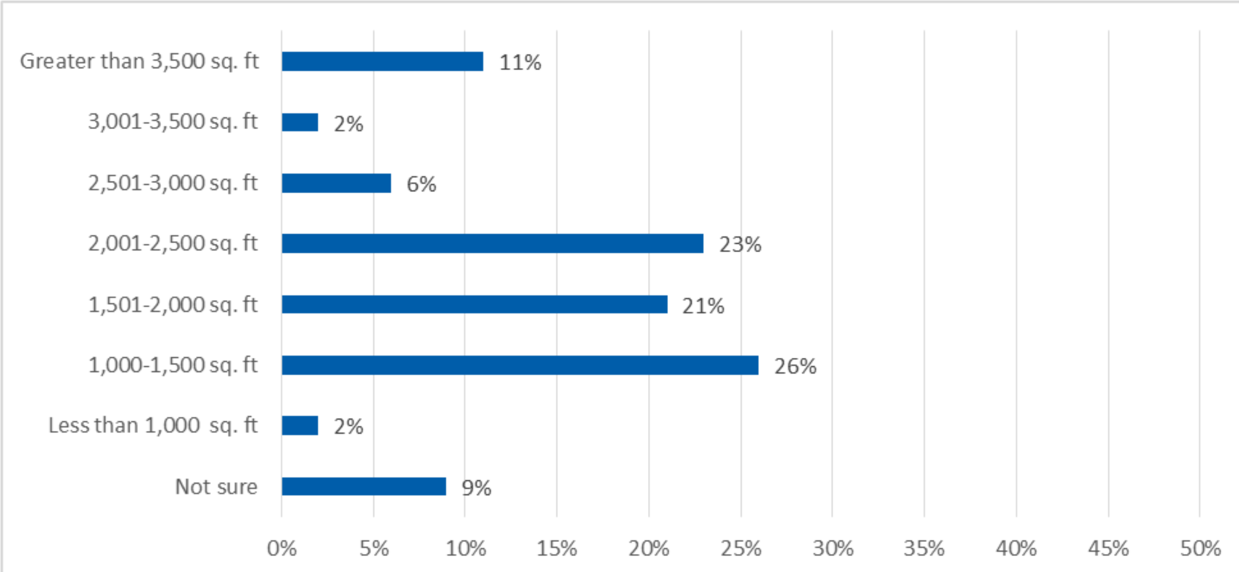
Figure 53. Age Category of Respondents (n=47)



Source: 2014 Ecobee Thermostat Pilot Program Survey

The majority of survey respondents were male (66%). Most survey respondents were in the 45 to 54 age category (32%), with 17% in the 25 to 34 age category, 17% in the 35 to 44 age category, 17% in the 55 to 64 age category, and 11% in the 65 and older category. No survey respondents were in the 18 to 24 age category (possibly due to lower homeownership rates in that age category).

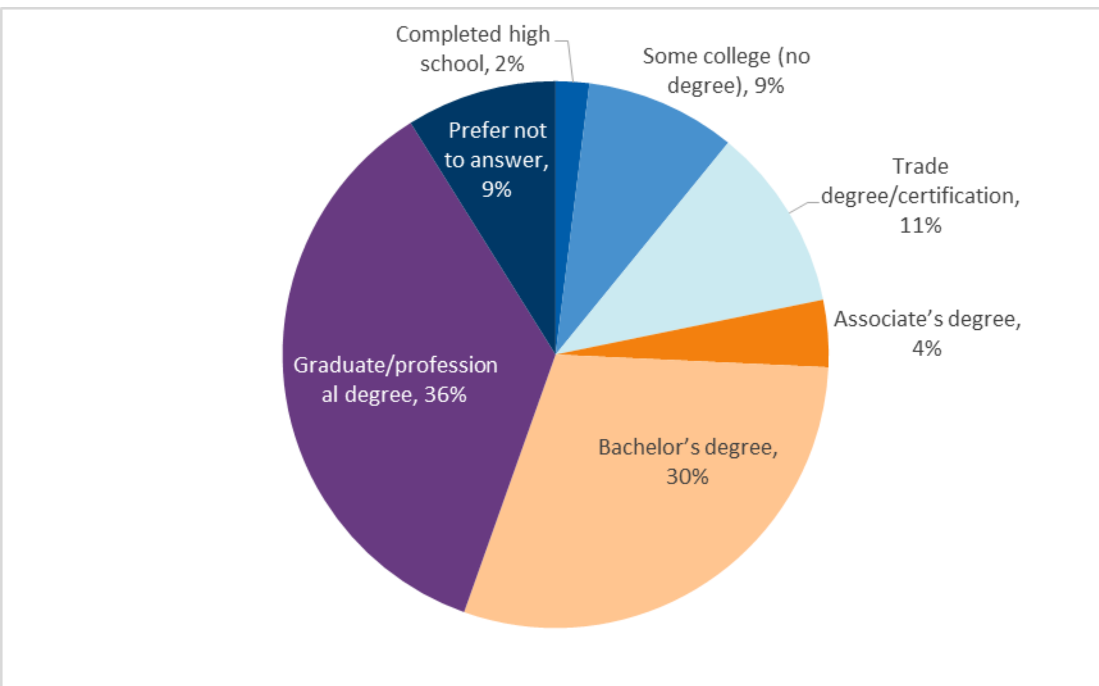
Figure 54. Home Size, in Square Feet (n=47)



Source: 2014 Ecobee Thermostat Pilot Program Survey

Most survey respondents live in a home between 1,000 to 2,500 square feet, with the majority (26%) falling into the 1,000 to 1,500 square foot home category. Specific categories are detailed below.

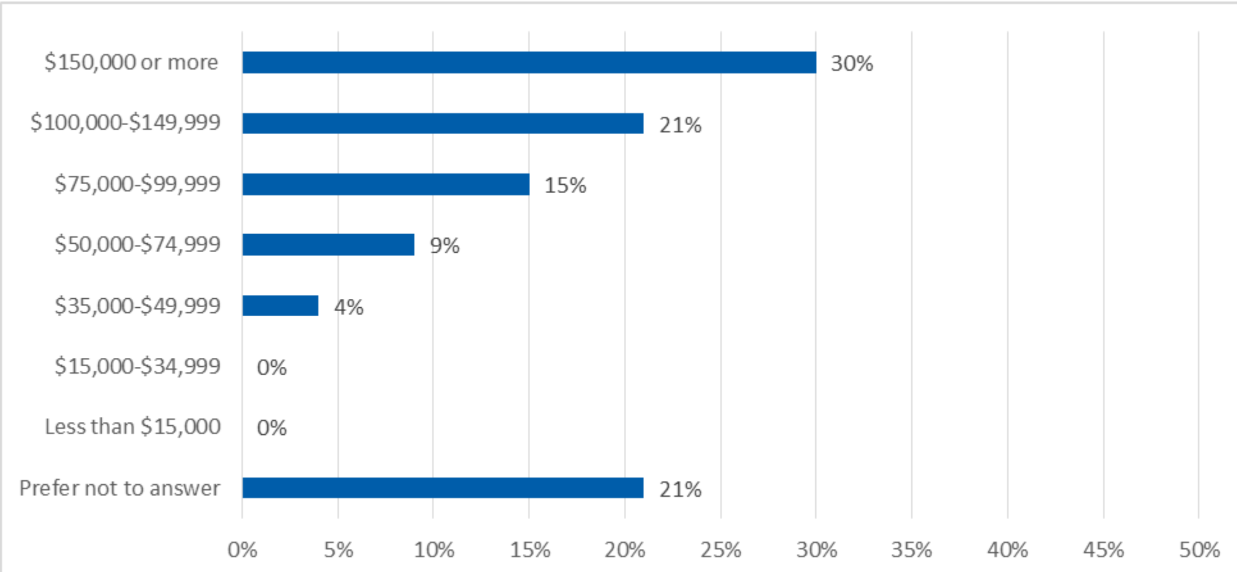
Figure 55. Education Levels (n=47)



Source: 2014 Ecobee Thermostat Pilot Program Survey

The majority of survey respondents have a graduate or professional degree (36%), followed by those with a bachelor's degree (30%). See below for the breakout by education level.

Figure 56. Income Categories (n=47)



Source: 2014 Ecobee Thermostat Pilot Program Survey

While a large percentage preferred not to answer, most survey respondents were in the $150,000 or more income category. Overall, survey respondents were highly educated and financially well off, which likely extends to the program population as a whole. The program reaches multiple income groups.

Findings and Recommendations

Objective 1: Value of Ecobee Smart Thermostat and Integrated Energy Meter

Participants found having the ability to remotely control their thermostat using the smartphone app or the web portal as the most valuable feature of the Ecobee Smart Thermostat. Although some participants used the integrated energy meter features, including energy monitoring and bill estimation tools, interest in these features decreased significantly after two weeks.

Usefulness of Features

Participants found the Ecobee Smart Thermostat's basic functions more valuable than the integrated energy meter. Participants awarded the thermostat's temperature changing feature an average usefulness rating of 9.27/10.00, compared to 7.22/10.00 for the viewing energy usage feature and only 5.24/10.00 for the bill estimation feature.

Participants found the ability to remotely control and monitor their thermostats to be the most valuable feature of the thermostat. Flexible schedule programming, ease of use, and energy reports were considered about one-half as valuable. Participants found convenience, checking the outside temperature, and the thermostat itself to be the least valuable features/characteristics.

Persistence in Use of Features

Participants' interactions with their thermostats declined over time. During the program's first two weeks, participants reported viewing their energy usage more frequently, with the majority viewing their energy usage a couple of times each week. Several weeks into the program, the majority of customers viewed their energy usage only a few times each month. Use of the bill estimation feature also declined over time, with 10% of participants using the bill estimation feature multiple times per day for the first two weeks of the program, then losing interest after the initial period, with only 2% continuing to use the feature daily. All customers continued using the thermostat to change their home's temperature, with some additional activity occurring during the pilot's first two weeks.

Recommendations

An area for further research may address methods for keeping customers engaged with the energy usage and bill estimation information, perhaps by updating it regularly with new facts or comparisons to the past week's usage or to neighborhood averages.

Objective 2: Impact of HVAC Control Optimization

The HVAC optimization controls provided energy savings during the heating and cooling seasons, while regulating temperature setpoints more accurately than the comparison participant group without HVAC optimization controls. In terms of energy savings, the HVAC optimization controls outperformed the comparison group significantly in the cooling season, but provided similar savings in the heating season.

Temperature Regulation

During the heating and cooling seasons, HVAC systems with HVAC optimization controls more effectively regulated temperatures than HVAC systems without HVAC optimization controls. Indoor air temperatures for the group with HVAC optimization controls (the ATC group) more closely matched setpoints compared to the group without HVAC optimization controls (HEM group):

- In the heating season, indoor air temperatures (IAT) in the ATC group averaged 1.8 degrees warmer than setpoints, compared to 5.1 degrees warmer than setpoints in the HEM group.
- When cooling was required in the cooling season, IAT in the ATC group averaged 0.7 degrees warmer than the setpoint, compared to 2.4 degrees warmer than the setpoint in the HEM group.

Heating Season Energy Savings

Heating systems with HVAC optimization controls saved about the same in natural gas as heating systems without HVAC optimization controls. When comparing ATC and HEM participants with just one thermostat, Cadmus found natural gas savings to be about the same between the two groups. The HEM group performed slightly better when considering savings as a percentage of total gas usage, while the ATC group performed slightly better when considering savings as percentage of the disaggregated heating load and savings per square foot:

- As a percentage of total gas usage, the HEM group saved an average of 9.5%, compared to 9.1% for participants in the ATC group.
- As a percentage of the disaggregated heating load, the ATC group saved an average of 13.1% of heating gas usage, compared to 12.4% for participants in the HEM group.
- On a per-square-foot level, the ATC group saved 0.0480 therms/sqft compared to 0.0460 therms/sqft for the HEM group.

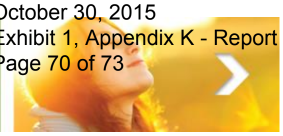
Cooling Season Energy Savings

Cooling systems with HVAC optimization controls saved significantly more electricity than cooling systems without HVAC optimization controls. When comparing ATC and HEM participants with just one thermostat, Cadmus found the ATC group outperformed the HEM by three times when considering the disaggregated cooling load and five times when considering savings per square foot:

- As a percentage of the disaggregated cooling load, the ATC group saved 16.5%, compared to 5.1% for the HEM group.
- On a per-square-foot level, the ATC group saved 0.1808 kWh/sqft, compared to 0.0358 kWh/sqft.

Recommendations

HVAC optimization controls show promise as an effective measure for reducing heating and cooling energy usage while improving temperature regulation, but energy savings calculations should be updated with larger sample sizes to improve the precision of estimates.



Objective 3: Impact of DR

Overall, DR events reduced participants' HVAC system runtimes without creating discomfort for participants.

Demand Impacts

DR events occurred and affected runtimes. The runtime impacts confirmed DR events occurred. Across all events, an average estimated runtime reduction of 7.9 minutes occurred in the first event hour and 3.6 minutes occurred in the second hour.

Evaluated kW impacts are likely overstated. Cadmus found statistically significant estimates of demand reductions were almost twice the value expected, given runtime reductions and the average tonnage of air conditioners (AC) in the program. This suggests a number of possible problems, some of which could indicate the study's demand impacts are overstated. Cadmus suspects this resulted from quality issues with the integrated energy meter dataset.

Smart cooling-style DR events had the largest impact on savings. During the two smart pre-cooling events, average estimated demand reductions of 0.847 kW and 0.267 kW resulted. Across all four events, average estimated demand reductions were 0.520 kW in the first hour and 0.472 kW in the second event hour.

Comfort

Participants in general did not find events uncomfortable. The majority of ATC participants (65% - 80%, depending on DR event) did not notice a change in comfort level during the DR events. Fourteen to 29% noticed the house was warmer but found the comfort level to be acceptable. Only 0-8% (depending on the DR event) found the house to be considerably less comfortable.

Recommendations

Cadmus recommends improving the estimated demand impacts by completing the actions that follow. However, if necessary to use this year's results for program planning, runtime impact results can be used with the average population EER and tonnage data to calculate estimated demand impacts.

To improve the estimated demand impacts:

- Improve the quality of the integrated energy meter data used to estimate DR impacts. For example, missing data should be clearly differentiated from true zeroes, and the source of high and low outliers should be investigated and corrected (for instance, readings over 40 kWh per hour).
- If possible, AC energy efficiency rating (EER) and tonnage data should be collected for new program participants at the time of thermostat installation. Better AMI data and a bigger sample of AC nameplate data will improve the accuracy of the DR program's demand impact estimates.

Introduction

Heat pump dryers (HPDs) are a plug-and-play alternative to conventional electric resistance dryers (ERDs) and can reduce clothes dryer energy consumption and electrical demand without changing consumer habits. A heat pump dryer reduces energy consumption by recycling the warm air that it produces. Rather than venting heat and moisture to the outside of the house like a conventional electric resistance dryer, the HPD extracts heat and moisture from the air leaving the dryer drum and adds that heat to the airstream entering the drum.

National Grid and Eversource Energy (the Companies) contracted Cadmus to examine HPDs as a potential product offering for their energy-efficiency programs. Cadmus conducted a technology demonstration to achieve these objectives:

1. Measure the energy consumption and performance of the heat pump dryer in participant single-family households;
2. Estimate the energy and demand impacts of the heat pump dryer compared to various baseline scenarios;
3. Examine the interactive impacts of the heat pump dryer on cooling and heating energy consumption;
4. Survey participants regarding their experience and satisfaction with the new dryer; and
5. Identify the energy impacts of different user settings to support educational material about optimizing equipment performance.

Between November 2014 and January 2015, Cadmus conducted data collection and analysis on six *in situ* heat pump dryer installations in Massachusetts and Rhode Island and two *ex-situ* installations in Cadmus' testing laboratory. Cadmus then performed additional *ex situ* performance testing on a second HPD model. In total, Cadmus analyzed 102 *in situ* loads of laundry to establish the baseline (pre-replacement) conditions, 191 *in situ* loads of laundry to establish the technological impact (post-replacement) conditions, and 36 to 40 *ex situ* loads of laundry for each of the two HPD models to establish the lab testing segment of this demonstration. Cadmus also conducted surveys for the *in situ* participants to examine the user experience and satisfaction with the HPD technology.

This report describes the methods, results, and Cadmus' findings and recommendations from this HPD technology demonstration.

Methods

To examine the energy performance of heat pump dryers (HPDs), potential energy and demand savings compared to electric resistance dryers, and customer satisfaction, Cadmus completed pre- and post-installation *in situ* metering at six single-family households, *ex situ* or laboratory testing on two HPD models, and surveys with the six *in situ* participants.

In this report, we refer to the original HPD model, for which we performed both *in situ* and *ex situ* testing, as "Model A" or "HPD-A" and to the second HPD model, for which we performed *ex situ* testing only, as "Model B" or "HPD-B."

In Situ Pre/Post Data Collection

Cadmus completed pre-installation and post-installation *in situ* metering at six single-family households (participants) in Massachusetts and Rhode Island to (1) examine and compare the energy performance of existing electric resistance dryers (ERD) and new HPDs and (2) collect information on the typical laundry load characteristics and user settings.

Figure 1 describes the *in situ* data collection process for each participant. All six participants were recruited by National Grid and received a new front-loading washing machine and HPD for their participation in six weeks of performance testing. To maintain the comparability of post-installation performance, we used the same washer and HPD models for all participants.

Figure 1. Process for *In Situ* Data Collection

Install Metering Equipment

To start the *in situ* activities, Cadmus visited each participant home to collect information on the existing appliances, install our data collection equipment, and instruct participants on the pre-installation data collection process. We provided each participant with a laundry basket, scale, and a pre-installation data collection form (Appendix A).

Table 1 lists the information Cadmus collected for each appliance.

Table 1. Data Collection Points – Equipment Specifications

Equipment	Clothes Washer	Clothes Dryer	Water Heater
Make/Model	X	X	X
Age or Manufacture Date	X	X	X
Vented to Outside (Y or N)	n/a	X	n/a
ENERGY STAR® Label (Y or N)	X	n/a	X
Front- or Top-Loading	X	n/a	n/a
Fuel	X	X	X

Table 2 lists the data collection points and metering equipment that Cadmus installed for each home. Figure 2 (page 11) shows the metering equipment installed on the new clothes washer and HPD.

Table 2. Data Collection Points – Metering

Collect Pre-Installation Data

Over two weeks in October and November, our installed data loggers recorded data on the homeowners' existing clothes washer and ERD. During this period, the participants recorded laundry weights (dirty, wet, and dry), machine settings, and date/time of load using Cadmus' laundry log.

One site (Newton) did not operate its existing washer or dryer during this period so we could not collect pre-installation data at this site.

Install New Washer and Heat Pump Dryer

At the end of the pre-installation period, the HPD manufacturer's technicians installed a new clothes washer and new HPD at each participant household. A Cadmus technician accompanied the manufacturer technician to download the pre-installation data and ensure correct placement and operation of the logging equipment on the new appliances. Figure 2 displays the metering equipment installed on the new washer and heat pump dryer.

Figure 2. Metering Equipment with New Washer and Heat Pump Dryer

We observed several installation or user requirements unique to the HPD installation and use:

- **HPD condensate line:** The HPD contains a condensate line to purge the moisture removed from the dryer air. The condensate line is typically connected to the same drain used by the clothes washer discharge or a nearby utility sink. For two sites with the appliances located in the basement, the existing drain was higher than allowed by the design of the HPD condensate pump. To solve this issue at one site, the manufacture used a pedestal to increase the height of the machine relative to the existing plumbing (Figure 2). At the second site, the manufacturer temporarily used a five-gallon bucket to receive the HPD condensate with a submersible booster pump to connect to the existing plumbing drain. For a permanent solution, the manufacture installed an elevated condensate pump to receive the HPD condensate and pump it to the existing drain plumbing.
- **Ventless model**: Because the HPD recycles the dryer air, it does not require a vent like standard ERDs. Removing the need for a dryer vent allows for more flexibility in the location of the dryer. However, as discussed in later in this report, the location of the dryer in an open or enclosed space may have a substantial impact on the HPD energy performance.
- **Secondary lint filter**. The HPD model includes a secondary lint filter, in addition to the lint screen, located below the main dryer door. The appliance manual recommends that the user clear this additional filter after every fifth cycle or as prompted by an indicator light.

Collect Post-Installation Data

For a minimum of four weeks, our installed data loggers recorded performance data on the new washer and HPD. During the post-installation period, participants documented laundry weights, machine settings, and satisfaction ratings using an online form provided by the appliance manufacturer.

At the end of the post-installation period, Cadmus returned to each site to remove and download the data loggers. We also collected the post-installation laundry data from the manufacturer's online forms.

Conduct Participant Survey

Cadmus developed a survey to examine participant experiences with the dryer technology and to inform program design recommendations for a HPD rebate program. (The survey instrument is included in Appendix B.) At the end of the post-installation period, we e-mailed each participant a link to the online survey and asked participants to complete the survey within seven days.

Ex Situ (Laboratory) Testing for HPD-A

To supplement the *in situ* data and examine the HPD performance under controlled conditions, we performed a series of *ex situ* tests on HPD-A, the same washer and HPD equipment used in the *in situ* post-installation testing.

We installed HPD-A and the new clothes washer in our Waltham, Massachusetts laboratory and designed a testing protocol to demonstrate the impact of various parameters – such as dryness level, termination, and textile type – on dryer performance and energy consumption.

Figure 3 describes the key steps in our laboratory testing.

Figure 3. Laboratory Testing Procedure

Install Metering Equipment

We installed the same metering equipment that we used for the *in situ* testing (Table 2) on the new washer and heat pump dryer in our laboratory.

Define Control Conditions

We compiled a uniform load of laundry for the laboratory test runs, basing the load composition on the AHAM/ANSI HLD-1-2010 standard *Household Tumble Type Clothes Dryers* and the Department of Energy (DOE) Appendix D2 *Uniform Test Method for Measuring the Energy Consumption of Clothes Dryers*, with supporting information gathered from a review of publicly available literature. Our literature review included documents published in the ACEEE Summer Study on Energy Efficiency in Buildings (2014) and by the National Resources Defense Council (2011).

Condition Laundry Load

We pre-conditioned and normalized the test load based on the AHAM/ANSI HLD-1-2010 standard procedure. We then performed the subsequent bone-drying procedure within an electric resistance clothes dryer under both the AHAM/ANSI HLD-1-2010 and DOE Appendix D2 standards.

CADMUS

Define Test Load Procedure

To identify the performance and energy impacts of different load characteristics or user settings, we designed a series of test runs to modulate various parameters while holding other parameters constant. Based on guidelines in the previously noted literature, we toggled the following options on the laboratory heat pump dryer to examine performance and help guide our customer recommendations for dryer energy use minimization:

- Weight of Clothing: 4.5, 8.45, and 15 pounds;
- Cycle Type: *Normal* and *Timed Dry*;
- Energy Options: *Eco*, *Balanced*, and *Speed*;
- Temperature Options: *Extra Low*, *Low*, *Medium*, and *High*;
- Dryness Level: *Less*, *Normal*, and *More*; and
- Termination: *Auto* and *Monitored* (based on DOE Appendix D2, Section 3.3.1).

Table 3 describes the combinations of parameters we designed for this testing.

Table 3. Test Run Specifications for *Ex Situ* Testing (HPD-A)

Load Size	Cloth Dimension		Cycle Type		Energy Options			Temp				Dryness Level			Termination	
	2D	3D	Normal	Timed Dry	Eco	Balanced	Speed	Extra Low	Low	Medium	High	Less	Normal	More	Auto	Timed / Monitored

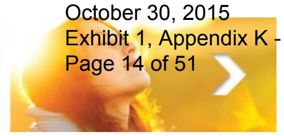
		■	■			■				■			■		■	
15	■		■			■				■			■		■	

Conduct Iterative Test Loads

We ran each test three times to decrease the impact of external variation and with a single test load to decrease variations in cloth composition. In total, Cadmus analyzed 36 test laundry loads for HPD-A and 40 test laundry loads for HPD-B.

HVAC Interaction

We examined primary and secondary data to estimate the interactive impacts of the HPD on household cooling and heating energy consumption. We examined the measured ambient temperature at each participant's home to determine typical ambient temperatures and used laboratory air flow values to estimate expected makeup air requirements for a vented dryer.



We compared the typical ambient temperatures inside participant homes to the typical meteorological year (TMY) weather data to estimate the energy needed to condition the makeup air for a vented dryer, then used heating and cooling periods of to estimate impacts of ventless dryers on household HVAC consumption compared to typical vented dryers.

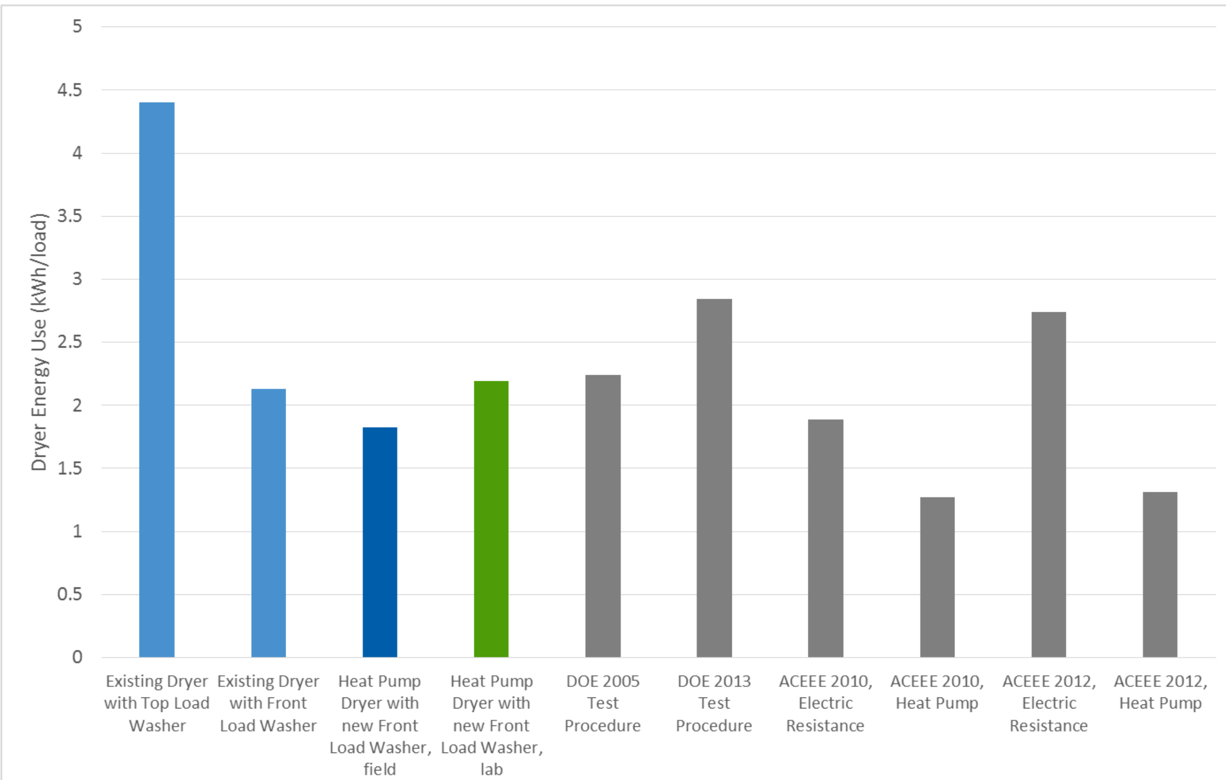
Based on this analysis, there is no significant change in the HVAC load within vented clothes dryers. The data gathered for this study confirms a marginal (2%) savings of the ventless dryer on household annual HVAC energy consumption. While heat pump clothes dryers do increase the local temperature and humidity during and shortly after a load of laundry, these effects have little impact on the home's energy use due to the duration of the laundry cycle and the variation in outside temperatures. Overall, the net of the additional heat rendered by the ventless heat pump dryer is beneficial to the household due to the offset of heating required during the winter in a heating dominated climate.

Results

In this section we compare the average *in situ* performance to the results from other studies or specifications, examine the energy and savings performance of the heat pump dryer (HPD) installations at each participant home, and discuss results of the participant satisfaction surveys.

Figure 4 compares the overall dryer performance results from this study (left four columns) to other HPD performance values available in literature (right six columns). In this figure and throughout the report, a light blue color denotes field testing of existing ERDs, a dark blue denotes field testing of HPDs, a dark green color denotes laboratory testing of the HPD, and a gray color denotes information from the literature review.

Figure 4. Comparison of Average HPD Energy Performance



Estimated Annual Energy Performance

In this study, we estimate the annual energy savings potential for heat pump dryers by comparing the per-load energy consumption of the baseline and HPD, estimating the number of dryer loads performed each year, and comparing the annual standby energy required for each model.

We calculate the annual savings using the following formula:

$$\Delta kWh = (kWh_{ERD} - kWh_{HPD}) \times Loads + (SBE_{BASE} - SBE_{HPD})$$

where:

kWh_{ERD}	= the average per-load energy consumption of the baseline ERD (kWh/load)
kWh_{HPD}	= the average per-load energy consumption of the HPD (kWh/load)
$Loads$	= the estimated total number of dryer loads performed each year (loads/year)
SBE_{BASE}	= the total annual standby energy of the baseline dryer (kWh/year)
SBE_{HPD}	= the total annual standby energy of the heat pump dryer (kWh/year)

Baseline Energy Consumption

To determine the energy savings for various replacement scenarios, we examined multiple baseline conditions. Table 4 presents baseline values from this study and literature for average ERD per-load energy consumption.

Table 4. ERD Energy Consumption

Baseline Condition (Source)	kWh_{ERD} (kWh/load)	Average Power (kW)	Max Power (kW)
This Study			
Existing ERD with top-loading (vertical axis) washer (n=2)	4.46	4.12	5.43
Existing ERD with front-loading (horizontal axis) washer (n=3)	2.17	2.07	4.76
Weighted average existing ERD in MA (n=5) [1]	3.84	3.63	5.27
Literature Review

Federal minimum requirement for ERD (2015)	2.27	UNK	UNK
ENERGY STAR® minimum requirement for ERD (2014)	2.15	UNK	UNK

Note: These consumption results do not include standby power
[1] Weighted based on percentage of front-loading (24.75%) and top-loading (75.25%) clothes washers in MA

We calculated a weighted average energy consumption for the *in situ* existing dryers using market share information about the percentage of top-loading washers and front-loading washers from the Massachusetts Residential Appliance Saturation Survey and the Massachusetts data given in the US Residential Energy Consumption Survey.

To compare the values using consistent units (average kWh per load), we modified some values via a load-based average using the DOE's currently accepted value of 283 loads per year or converted values from an Energy Factor (pounds per kWh) using the DOE's standard weight of 8.45 lbs.

Heat Pump Dryer Energy Consumption

Table 5 shows the average HPD per-load energy consumption from this study and other sources.

[1] We provide an average performance value excluding Newton due to the enclosure issues discussed on page 23.
[2] ENERGY STAR® QPL lists these ratings for HPD-A: CEF = 4.5; Annual consumption = 531 kWh/year; and average cycle time = 71 minutes. We estimated kWh/load and average kWh using 1.89 W of standby power (see page 31) and the DOE standard of 283 loads/year.
[3] ENERGY STAR® QPL lists these ratings for HPD-B: CEF = 4.3; annual consumption = 556 kWh/year; and average cycle time = 58 minutes. We estimated kWh/load and average kWh using 0.76 W of standby power (see page 31) and the DOE standard of 283 loads/year.

Annual Loads

Table 6 provides values to estimate the annual dryer loads per year. Although the six participants in this study completed an average 0.95 loads per day (346 loads per year), the DOE protocol for estimating annual energy consumption specifies 283 loads per year.

Table 6. Dryer Annual Loads

Source	Annual Loads (loads/year)
This study	**346**
DOE	283
ACEEE 2010	285

In Situ Dryer Performance

Over six weeks of *in situ* data collection, Cadmus measured the performance of 293 ERD (pre-installation) loads and HPD (post-installation) loads. Table 7 shows the ERD existing washer type and install location for the clothes dryer for each site.

Table 7. *In Situ* Testing Locations and Notable Characteristics

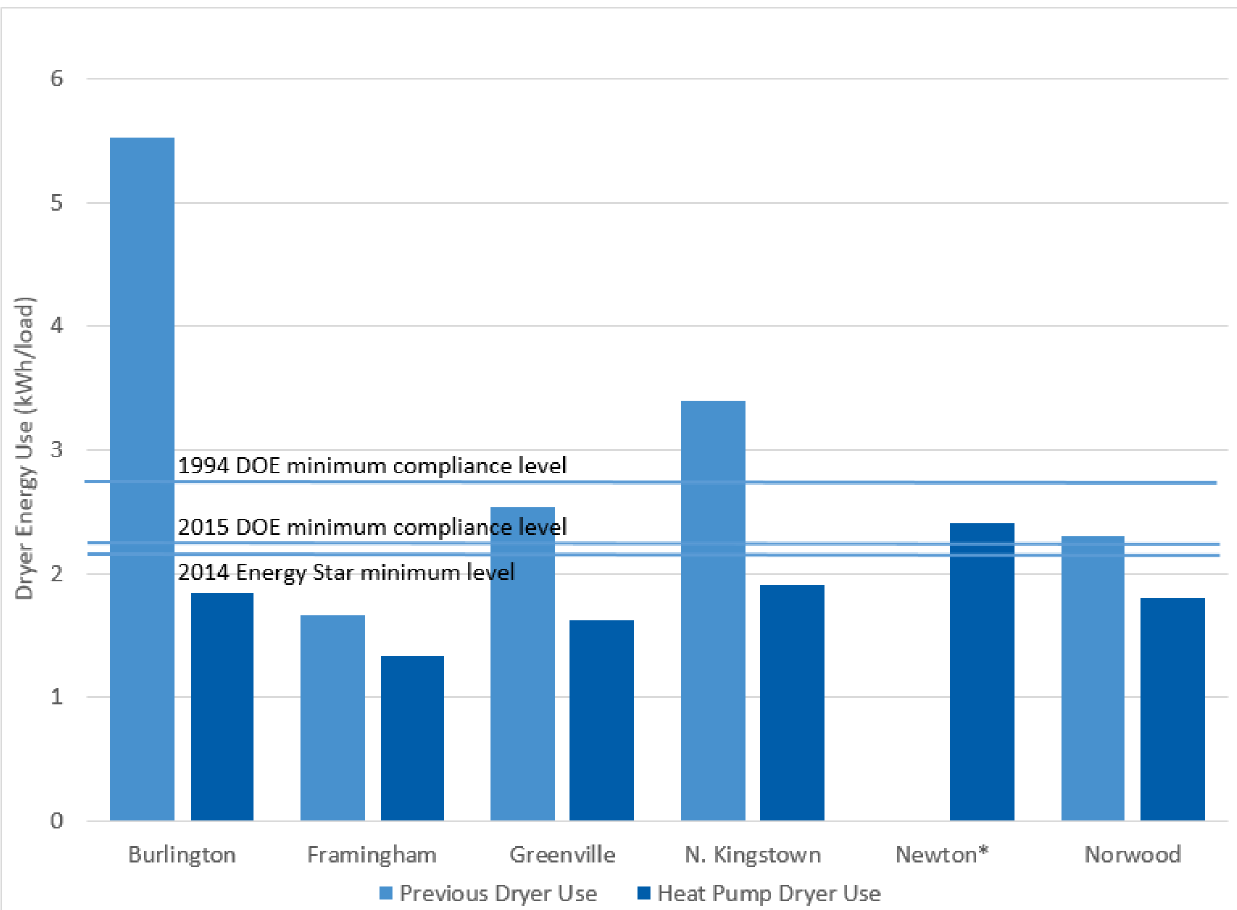
Site	Existing Washer Type	Clothes Dryer Location
Burlington, MA	Top-Loading	Open Area
Framingham, MA	Front-Loading	Open Area
Greenville, RI	Front-Loading	Open area
N. Kingstown, RI	Top-Loading	Open Area
Newton, MA [1]	Front-Loading	Closed Area
Norwood, MA	Front-Loading	Open Area

[1] The participant did not operate the washer or dryer during the pre-installation period, so we do not have baseline ERD measurements for this site.

Average Load Performance per Site

Figure 5 shows the average per-load kWh consumption and savings for each participant site.

Figure 5. Average Per-Load Dryer Energy Use and Savings



* The participant did not operate the washer or dryer during the pre-installation period.

All sites demonstrated a reduction in dryer energy consumption between the existing ERD and the new HPD, but the magnitude of the savings varied.

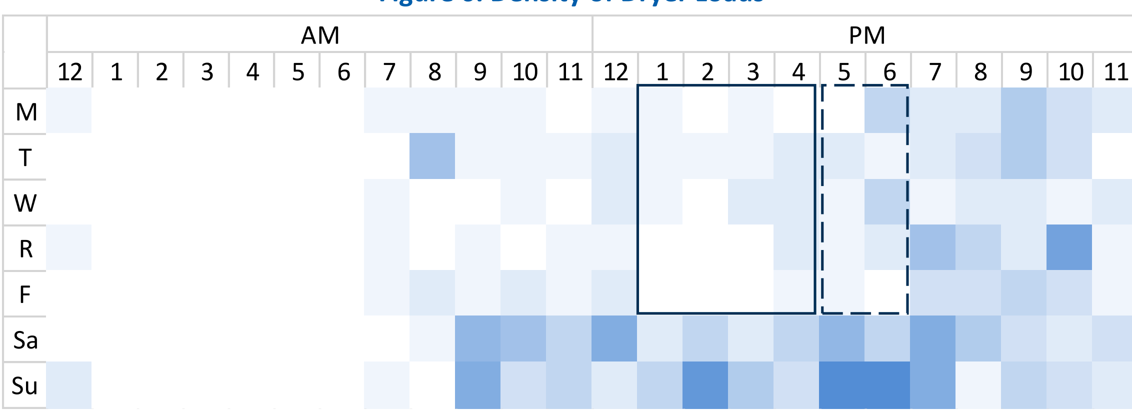
We observed the largest reductions in dryer energy consumption at the Burlington and N. Kingstown sites, the two households with top-loading, vertical-axis clothes washers. Although the HPDs at these sites performed similarly to the other sites, the Burlington and N. Kingstown ERDs demonstrated the highest average ERD consumption and operated above the 1994 DOE minimum compliance level. The high ERD consumption is likely due to high moisture content in the loads washed with the existing top-loading clothes washers. Similarly, the large reduction in dryer energy use (compared to other sites) is likely due to the replacement of the existing top-loading washer with the new front-loading washer.

At all sites except for the Newton site, the HPD performance exceeded 2014 ENERGY STAR® compliance levels. (We discuss possible reasons for the higher average HPD consumption observed at the Newton site on page 23.) The average HPD consumption ranged from 1.34 kWh/load (Framingham) to 2.41 kWh/load (Newton) with the varied performance due to varied load conditions (e.g., load material and weight) and operating settings (e.g., dryer modes and dryness setting) at participant homes.

Time of Day Operation

Figure 6 shows a frequency map illustrating the time-of-day operation of the *in situ* clothes dryers. The darker colors indicate more frequent dryer operation during that hour.

Figure 6. Density of Dryer Loads



Note: Data include dryer operation during both the pre-installation and post-installation periods. Solid line box is summer peak period (1-5 p.m. M-F). Dash line box is winter peak period (5-7 p.m. M-F).

Participants completed more than half of all dryer loads (152 of the 293 recorded loads) on Saturdays and Sundays, with the most frequent operation between 5:00 and 7:00 p.m. on Sundays. During the weekdays, Thursday evening had the most loads (23 of the 293 loads).

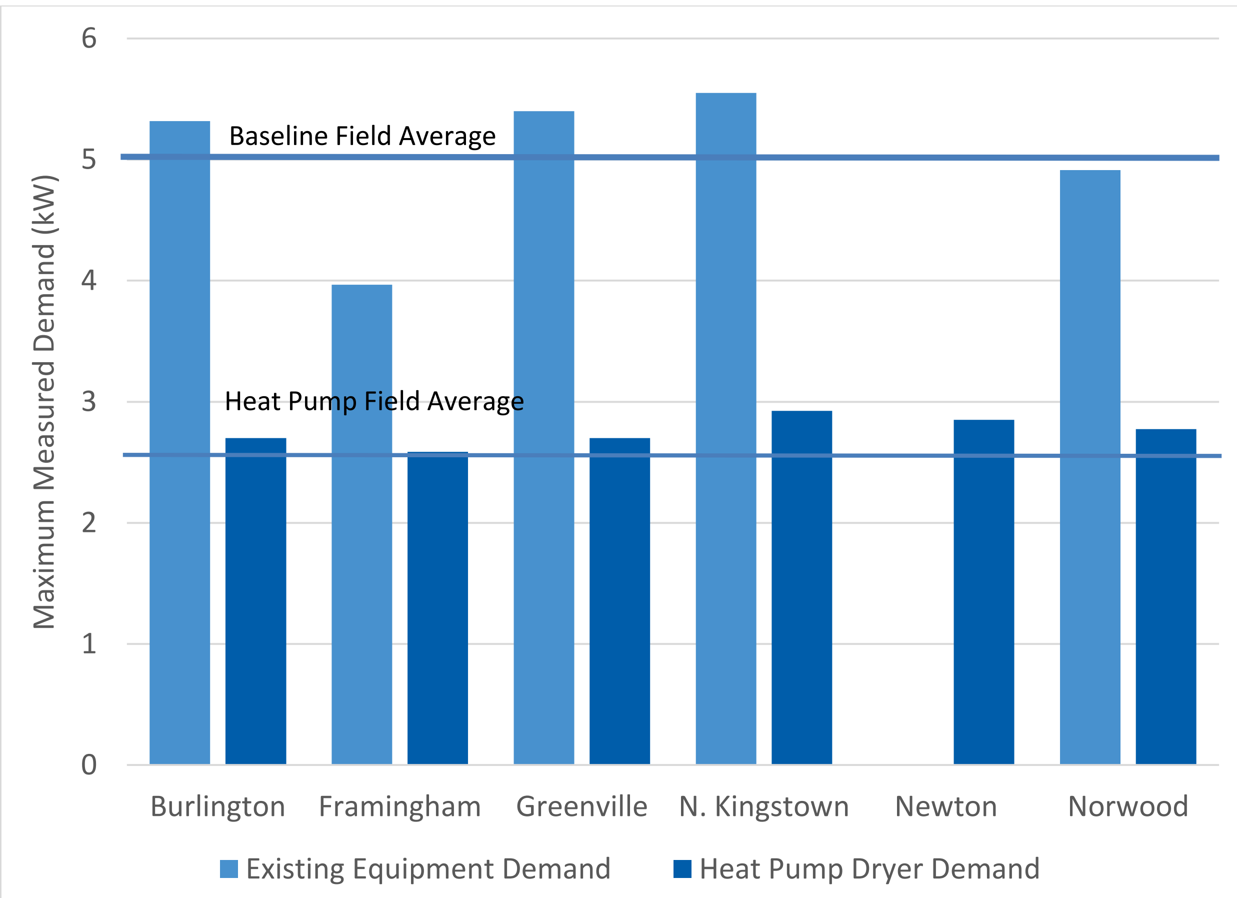
For the purposes of energy-efficiency program reporting in Massachusetts and Rhode Island, the summer on-peak period is defined as 1:00 to 5:00 p.m. Monday through Friday during summer months. The winter on-peak period is defined as 5:00 to 7:00 p.m. Monday through Friday during winter months. Assuming the use pattern measured does not change throughout the year, the data show infrequent operation during the summer and winter on-peak periods. Most loads occur on the weekends outside of both the summer and winter peak periods.

These frequency and coincidence data are based on the usage of the six program participants, all of whom work at National Grid and may not represent a future energy-efficiency program population. Still, the low coincidence results are consistent with previous research studies that indicate low usage during system peak periods.

Maximum Power Demand

Figure 7 illustrates the maximum measured demand for both the existing ERDs and the new HPDs at each site.

Figure 7. Maximum Measured Demand (kW)



Note: The Newton site did not operate its ERD during the pre-installation period.

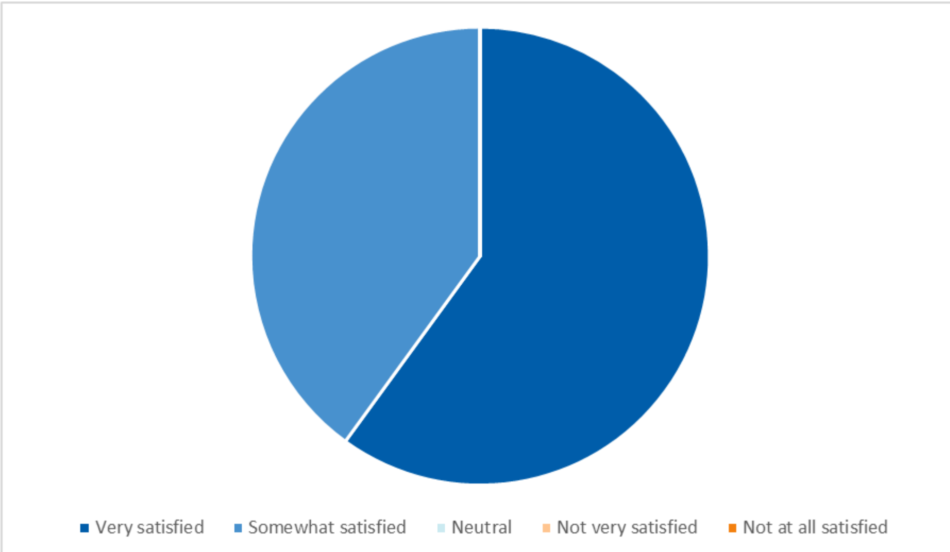
Compared to the existing electric resistence dryers, the *in situ* HPDs achieved an average maximum measured demand reduction of 2.79 per unit (up to a 50% reduction).

Customer Satisfaction

Cadmus examined the survey data from Cadmus' post-installation online survey (see Appendix B) and the manufacture's laundry logs to assess the participant experience and satisfaction with the new heat pump dryer. Five of the six participants responded to our survey.

All survey participants indicated that they were satisfied with their heat pump clothes dryer (Figure 8).

Figure 8. Participant Satisfaction Levels



The survey also assessed participant satisfaction with differences between both of the technologies (old electric and new HPDs) in areas relating to functionality, ease of use, and additional characteristics of HPDs.

Principal complaints arise from the presence and perceived integrity of the secondary lint filter. One participant also noted concerns regarding the durability of the external condensate water pump required in some installations, particularly in basements.

Despite these concerns, participants' overall satisfaction with the new HPD outweighed that of any changes in drying duration, dryness levels, or ergonomics from participants' previous models.

Factors Influencing Energy Savings

In this section, we describe the factors that influence dryer energy use based on findings from the *in situ* and laboratory testing of the same HPD model. The next chapter presents the results of laboratory testing on a different HPD model (not included in the *in situ* testing) and compares the laboratory results of the two lab-testing HPD models.

Clothes Washer Axis

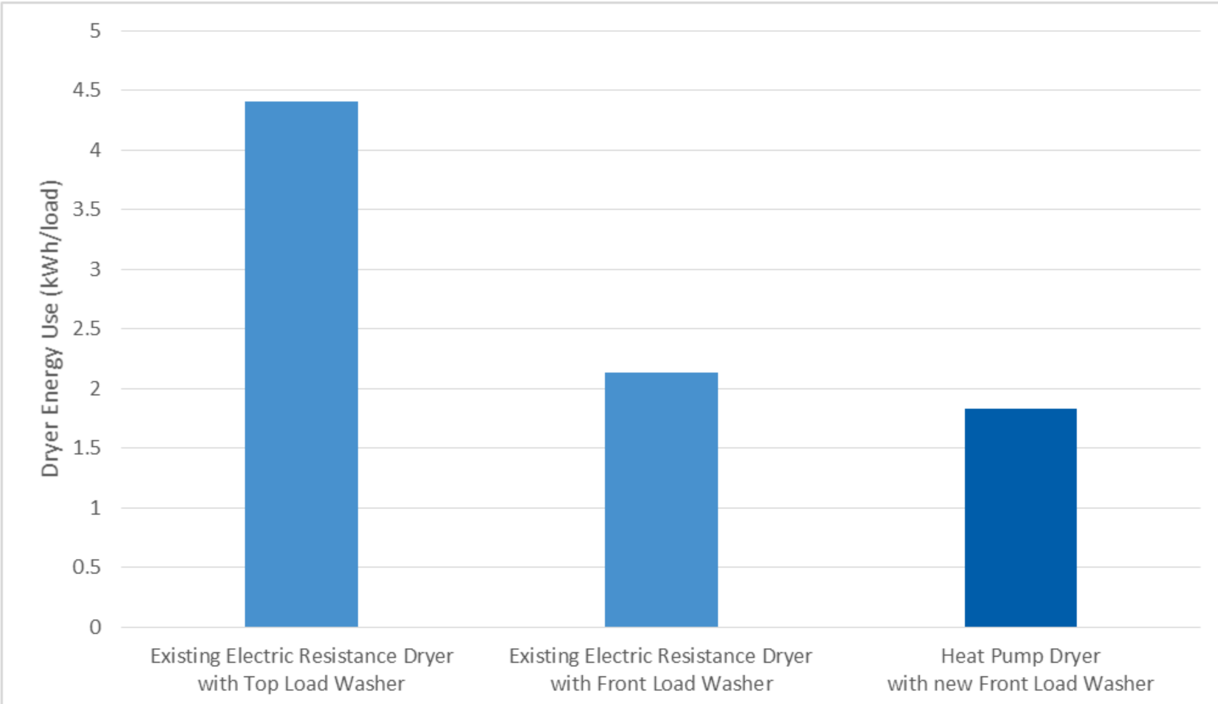
A majority of the dryer energy savings may be attributable to a change in washer orientation. A top-loading or vertical-axis clothes washer historically has been the dominant design in the United States. However, a front-loading or horizontal-axis clothes washer design is more common for commercial washers and today's high-performance residential washers. A horizontal-axis washer has higher spin speeds than a vertical-axis machine, removing more residual water from the clothes.

Figure 9 illustrates the impact of the clothes washer axis on clothes dryer energy consumption by showing the average dryer energy use in the three categories:

1. The existing ERD with the existing top-loading washer,
2. The existing ERD with the existing front-loading washer, and
3. The new HPD with a new front-loading washer.

The first and second columns show the impact of a change in clothes washer orientation on dryer energy use. Comparing the second and third columns demonstrates the energy savings attributable to the change in clothes dryer technologies.

Figure 9. Impact of Washer Axis on Dryer Energy Use



The average energy savings achieved by the HPD with a new front-load washer is 2.63 kWh per load compared to an existing ERD with top-load washer, but only 0.34 kWh per load compared to an existing ERD with a front-load washer. Although the sample size for this comparison is small (293 loads of laundry at six *in situ* test sites), Cadmus' previous clothes washer studies and available literature also emphasize the influence of clothes washer axis on the energy required to dry the load.

The difference between the two washer groups used in this study comes down to the fact that a horizontal-axis, front-loading washer is able to spin more water from the clothes than a vertical-axis, top-loading washer. Furthermore, Tomlinson et al. documents that the conversion from a vertical-axis washing machine to a horizontal-axis washing machine will save, on average, 1.3 kWh per load of washer energy (58%).[1] The combination of lower water use and a higher spin rates in horizontal-axis washing machines also yields clothing with less moisture, leaving the clothes dryer to do less work (energy) on the clothes.

Dryer Location

The *in situ* HPD performance data indicate that the position of the clothes dryer within an enclosed area may degrade the performance of the HPD. The Newton participant located its dryer in an enclosed closet and, due to noise levels, operated the dryer with the closet doors closed. This placement was not in compliance with the manufacturer's installation instructions for minimum ventilation openings for a

---

[1] Tomlinson, J.J. and Rizy, D.T. "Bern Clothes Washer Study." Final Report. 1998. Available online: http://dc.doi.org/10.2172/633967

closet installation. This type of operation places the unit in an enclosed operating environment, which taxes the dryer due to the non-vented nature of the appliance.

The Newton HPD averaged 2.41 kWh per load, or 41% more energy than the 1.71 kWh per load average used at the households that located the dryers in open spaces. We used load weight data to examine the impact of moisture content on dryer energy consumption and found that the Newton site used 52% more energy per weight of water removed (kWh/lb-H_2O) than the five other sites. This result indicates that higher energy use of the Newton dryer was not due higher levels of moisture removed during the dryer cycle. Because the Newton home was unoccupied during the pre-installation period, no data were available to examine the Newton baseline dryer performance.

Despite the poorest performance among other heat pump dryers, the Newton HPD (paired with the new front-load washer) still performed better than the average existing ERDs with top-load washers.

Load Weight

Figure 10 compares the frequency distribution of the *in situ* load weights (293 total loads) to the laboratory testing weights. Based on participant records, the median load weight (8.8 pounds) was similar to the main testing weight (8.45 pounds). The average participant load weight was 9.31 pounds.

Figure 10. Load Weight Frequency Distribution

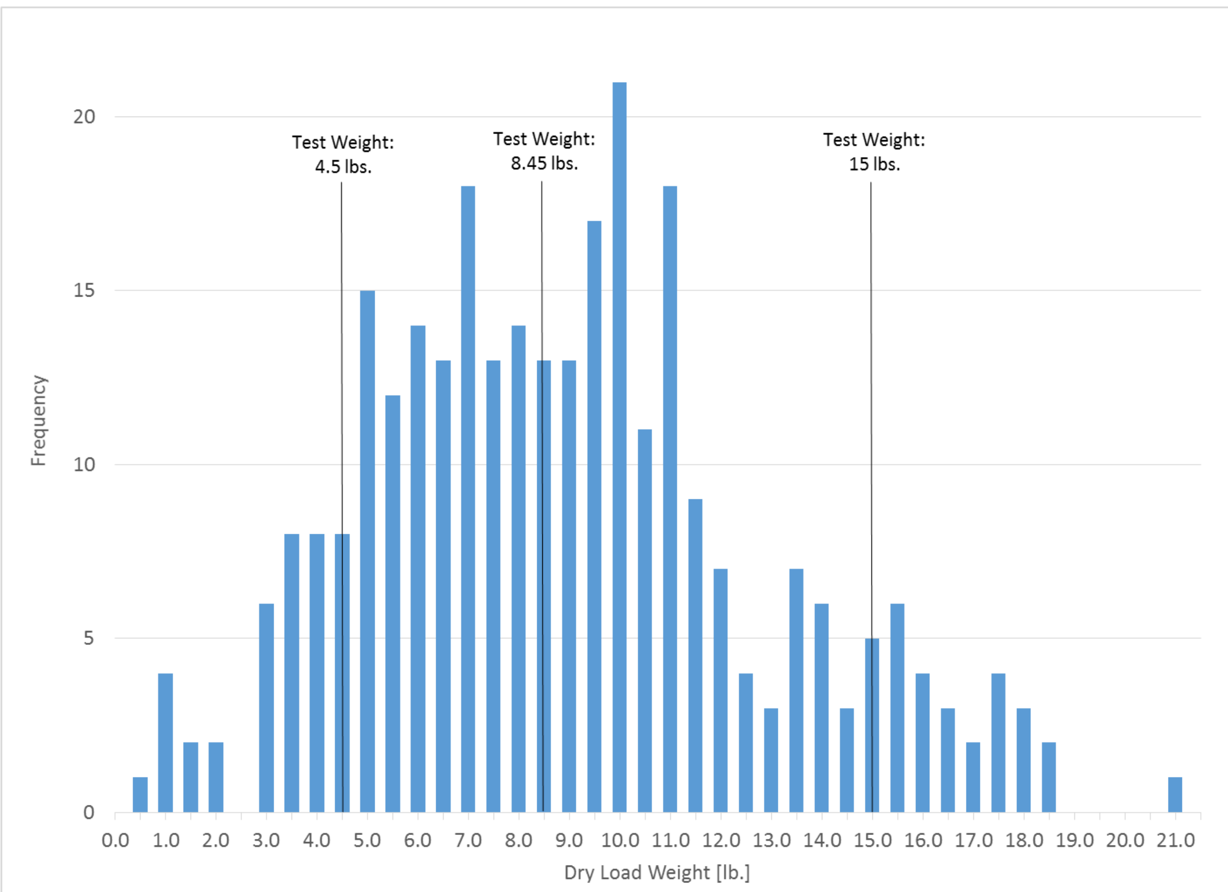


Figure 11 plots the dry load weight against the dryer energy use for the loads monitored during the *in situ* data collection period. The data indicate a wide variety of load weights and a loose correlation between load weight and dryer energy consumption.

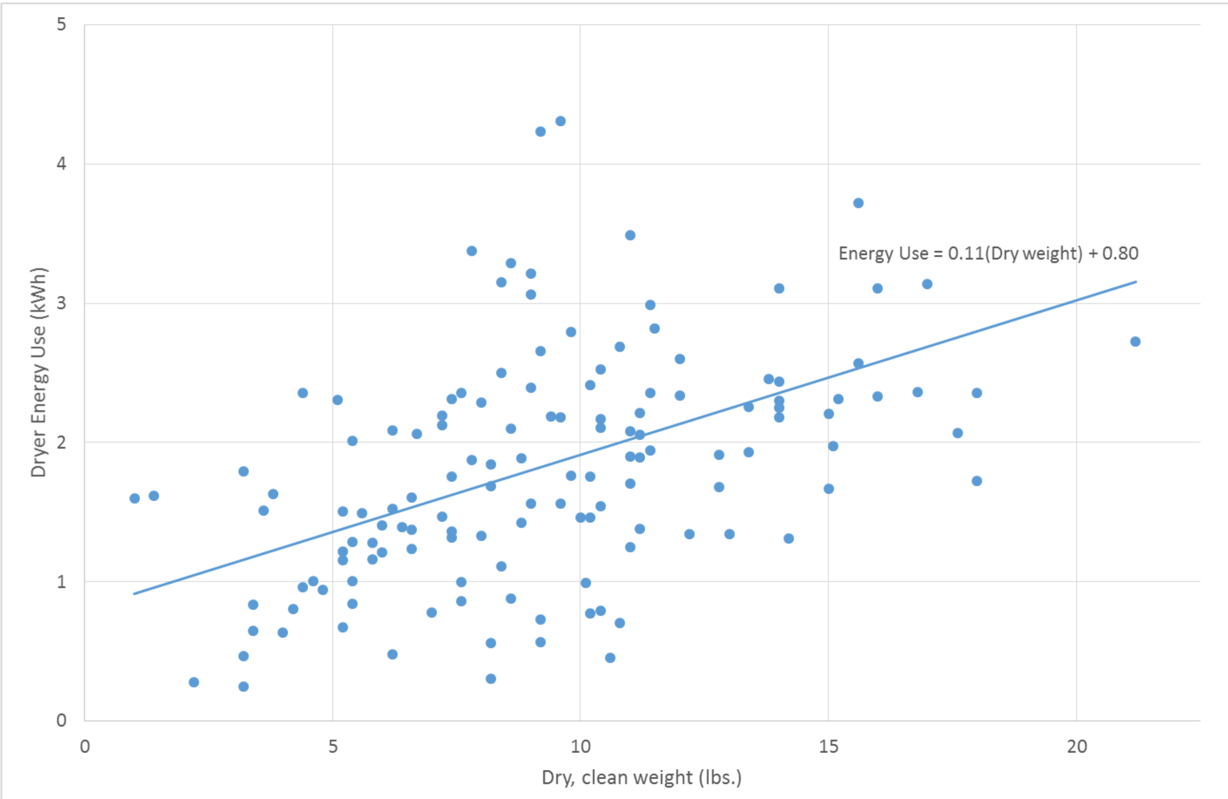
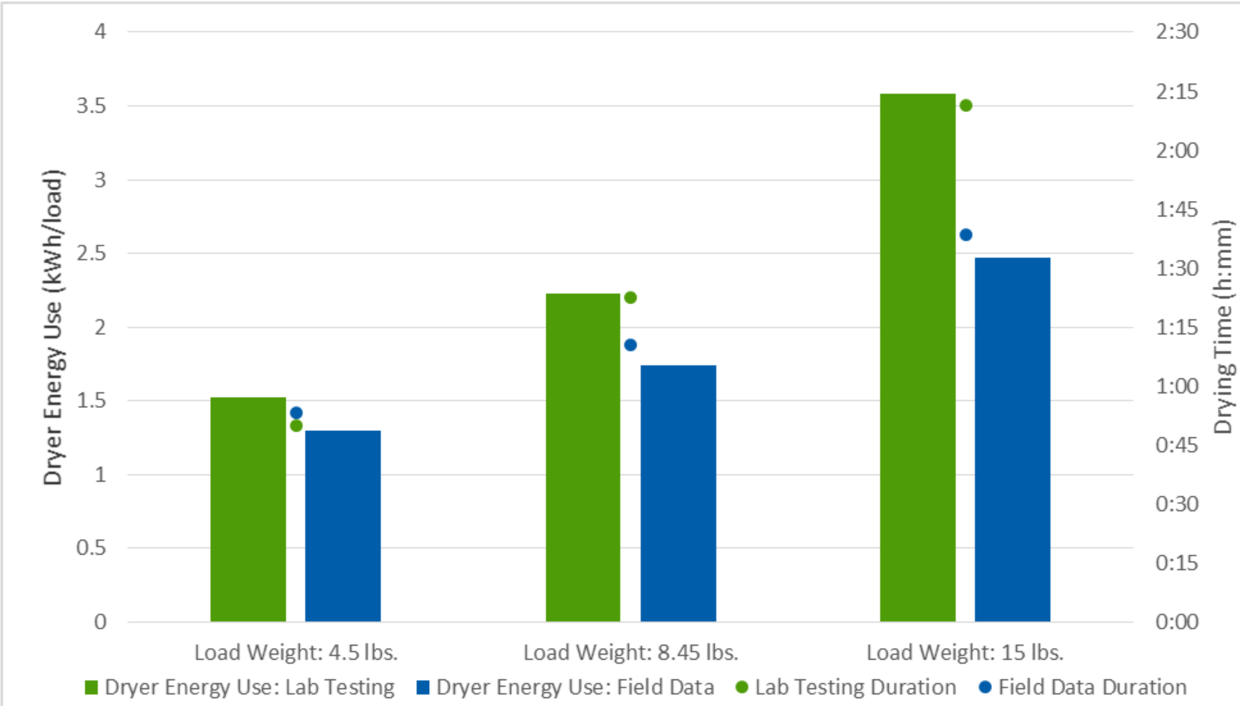
Figure 11. Dry Load Weight vs. Dryer Energy Use



Despite the scatter, the load data demonstrate that heavier laundry loads require more energy. The scatter is due to other factors that influence dryer energy consumption and are not controlled in the *in situ* environment. The data reveal that, on average and in a typical household environment, the incremental additional energy required to dry each additional pound of laundry is roughly 0.11 kWh per pound of dry load.

Figure 12 compares the average *in situ* results with the lab testing results.

Figure 12. Dryer Performance vs. Load Weight



The laboratory loads (green bars) consistently used more energy than the *in situ* loads (blue bars), with an increasing differential as the weight of the load increased. It is likely that the relative dominance of cotton towels in the test load contributed to this increasing variance. The conformity of the data at lower load weights suggests the amount of energy required to simply operate the cycle, independent of the weight of the laundry load. The linear relationship of Figure 11 suggests this amount of 0.80 kWh.

Dryness Level Setting

The HPD test model offers three dryness level settings: *Less*, *Normal*, and *More*. The *Less* setting would have a higher remaining moisture content in the clothes than the *Normal* setting. The *More* setting would have a lower remaining moisture content in the clothes than the *Normal* setting. When using automatic cycles, the dryness level can be selected. The automatic cycles are the equivalent of a macro which, given the cycle category, specifies default values such as drying temperature or energy options. The manufacturer defines automatic cycles as *Normal*, *Bulky*, *Heavy Duty*, *Towels*, *Delicates*, and *Casual*. The *Normal* setting is the default dryness level for five out of the six automatic cycles, although the user can override the dryness level to other settings.

Figure 13 shows the participant-reported values for the dryness setting selection. For the majority of the time, participants used the default *Normal* setting. Although the average load under this option takes longer than the existing equipment, none of the survey respondents stated that they were dissatisfied with the drying time of their new heat pump clothes dryer.

Figure 13. *In Situ* Dryness Level Setting Selection

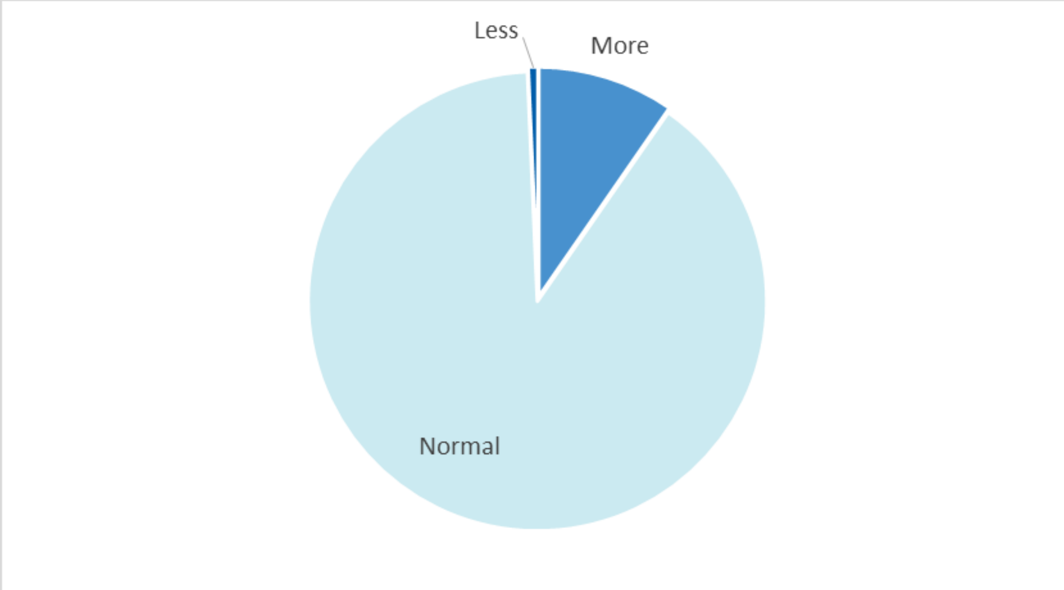


Figure 14 shows the impact of the dryness setting on dryer performance based on laboratory test loads. In each group, the left column shows the results of lab testing, and the right column shows the results of cross-referencing the field data with the participant self-reported drying logs. For comparison, the rightmost bar shows the average energy use and drying time for the *in situ* electric resistance dryers. The small circles indicate the drying time.

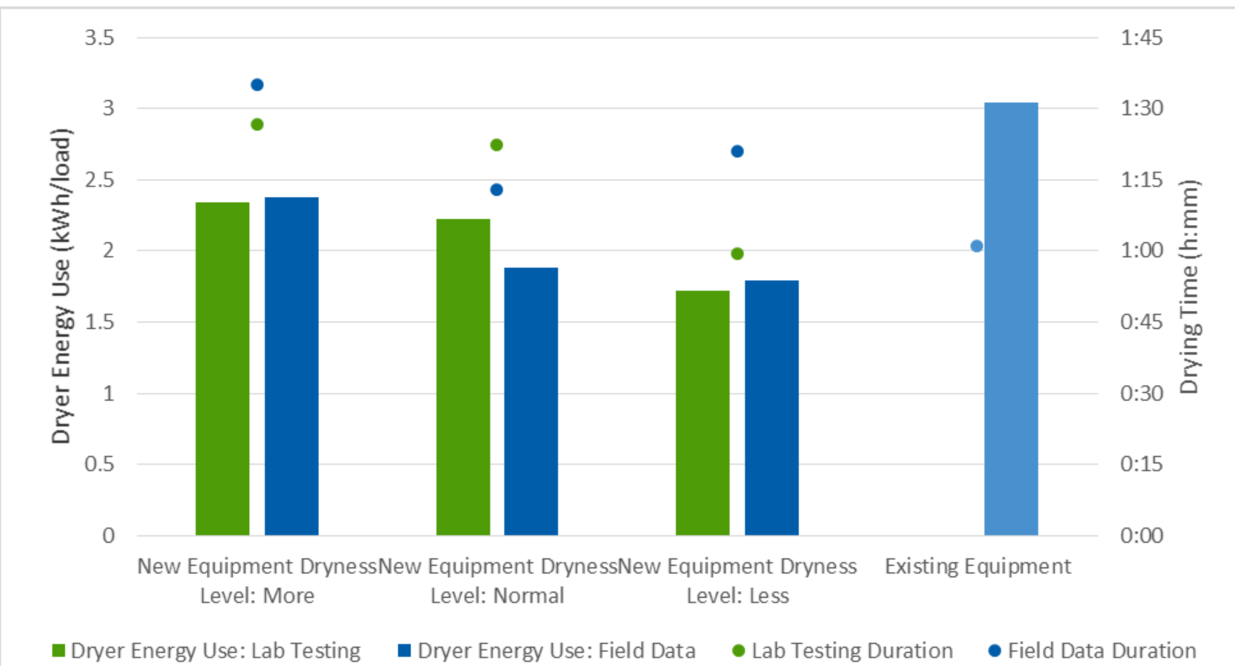
Figure 14. Dryer Performance vs. Dryness Level Setting



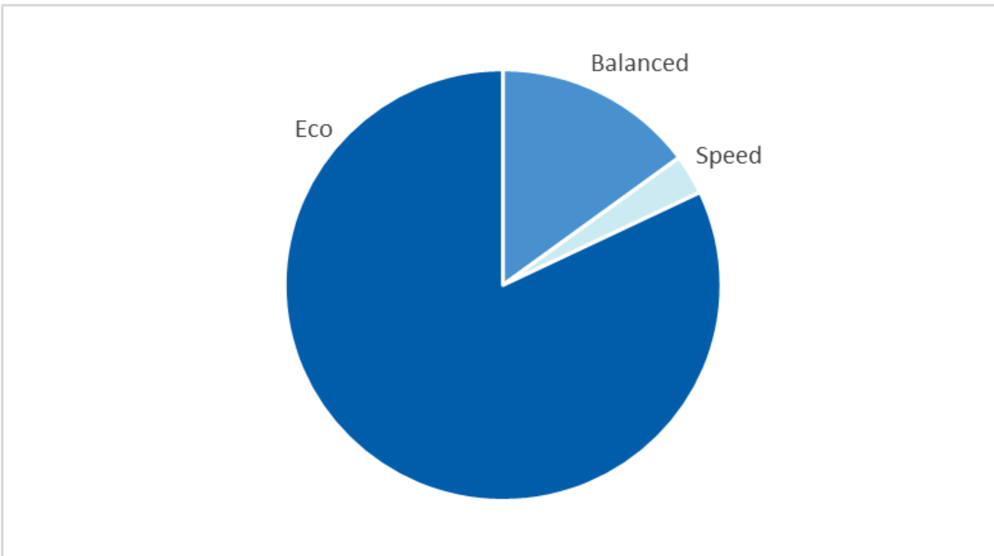
Decreasing the dryness level (i.e., decreasing the required moisture removal) reduces dryer energy use. The *More* setting consumed 3.7% (0.083 kWh) more energy and took 5.5% (four minutes) longer than the *Normal* setting, but resulted in similar residual moisture content to the *Normal* setting. In contrast, the *Less* setting saved 22.3% (0.498 kWh) of energy and 28% of drying time compared to the *Normal* setting, with an increase of 2.8% in the residual moisture content. For all tests, we used the auto-termination function of the machine.

Energy Option Setting

The HPD test model offers three energy option settings: *Eco*, *Balanced*, and *Speed*.

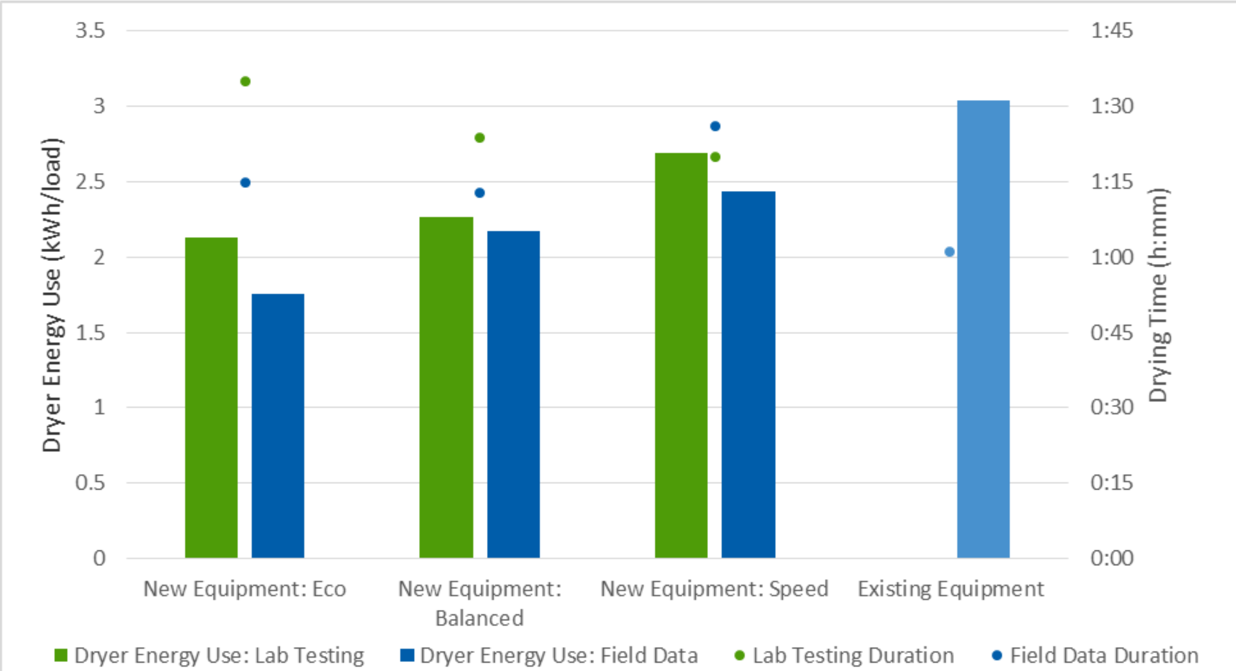
Figure 15 shows the distribution of participant-reported energy option selections. Participants reported using the *Eco* mode often (82%), followed by the *Balanced* mode (15%), and then the *Speed* mode (3%).

Figure 15. Economy Mode Selection



Cadmus ran several tests to evaluate the energy use and duration of different loads. We ran all loads with the 8.45-lb test load. Figure 16 shows the energy use and dryer times of the different economy settings both in the field and in the laboratory.

Figure 16. Dryer Performance vs. Energy Option Setting



The laboratory tests confirmed that the *Eco* mode is the most efficient in terms of kWh used per load (2.13 kWh per load), followed by the *Balanced* mode (2.27 kWh per load), and then *Speed* mode (2.69 kWh per load). With the energy option lab tests all run with the same weight load, we confirmed the inverse relationship between drying time and energy use.

The high use of the *Eco* mode selection a good indicator of overall consumer settings that influence the duration of the drying time per load. Even though the *Eco* mode requires 25% more time than the homeowners' existing ERDs, participants favored it over the faster energy options. Since it is the manufacturer's default setting, its high *in situ* use is influenced by it being positively programmed into the design.

Cloth Dimension: 2D vs. 3D

Unlike simple fabrics, clothing is multi-dimensional. With pockets, hoods, collars, and sleeves, both sides of the fabric used in clothing are unlikely to be exposed to the rotating drum of the clothes dryer. However, the AHAM/ANSI load composition includes bed linens, pillowcases, and towels; these items are largely two-dimensional, heavily water-absorbent, and not representative of most consumers' laundry loads. The multi-dimensional aspect of consumer laundry loads has been noted in the literature, but there is not a uniform testing methodology known to the authors at the writing of this report.

To fill this gap, Cadmus conducted laboratory tests using a mix of heavyweight short-sleeved polo shirts with embroidery and long-sleeved shirts without buttons or embellishment. When we compared the results of these tests, we found the three-dimensional loads consumed 0.27 kWh (11%) less energy and took 5 minutes longer to dry the load. This helps to explain why *in situ* loads (composed of complex, 3D fabrics) consistently use less energy than the lab loads (based on a 2D load).

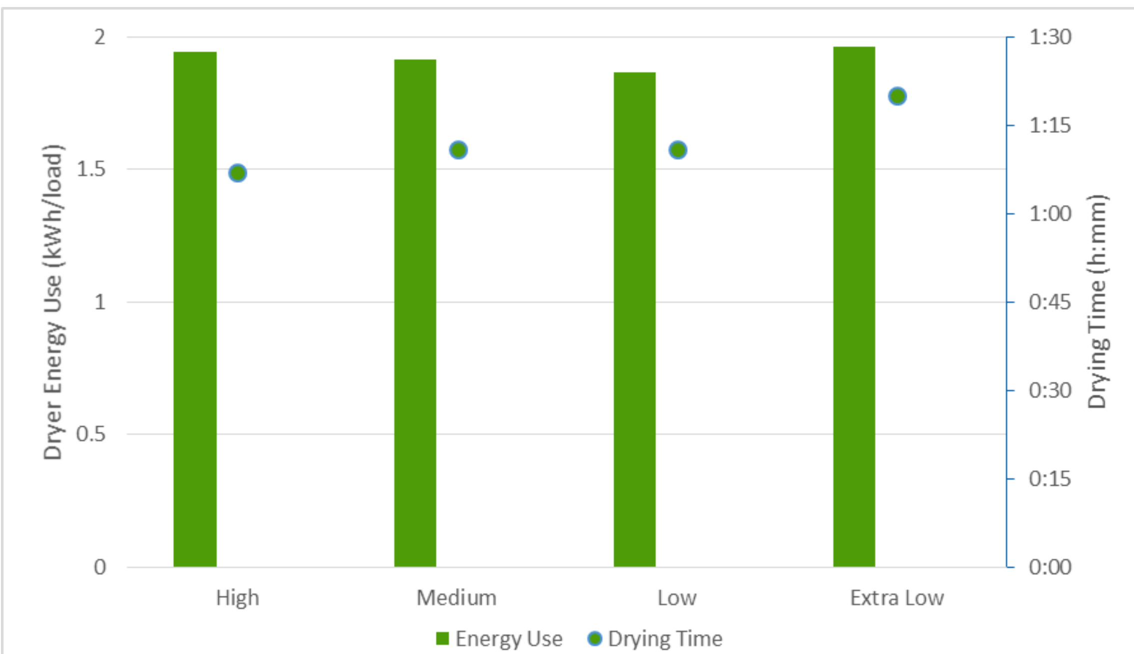
Dryer Temperature Setting

The HPD test model offers four dryer temperature settings: *High*, *Medium*, *Low,* and *Extra Low*. The owner's manual recommends using the warmest setting safe for the items in the load per the garment label instructions.

It is not immediately intuitive how the dryer temperature setting impacts dryer energy use. At a first glance, a higher temperature would seemingly require more energy, but the auto-termination feature allows for a reduced drying time. To look into this further, our lab tests varied the dryer temperature, keeping the final moisture content as a constant.

Figure 17 shows the impact of the dryer temperature setting on dryer energy use based on laboratory test loads.

Figure 17. Dryer Performance vs. Temperature Setting



The data indicate that the dryer temperature setting has little impact on dryer energy use. Switching from the *High* to *Low* temperature setting saved 0.08 kWh (or about 4%) per load. However, savings due to lower temperature settings are offset by the increased drying time. The *Extra Low* temperature setting resulted in the highest energy consumption due to the longer drying time.

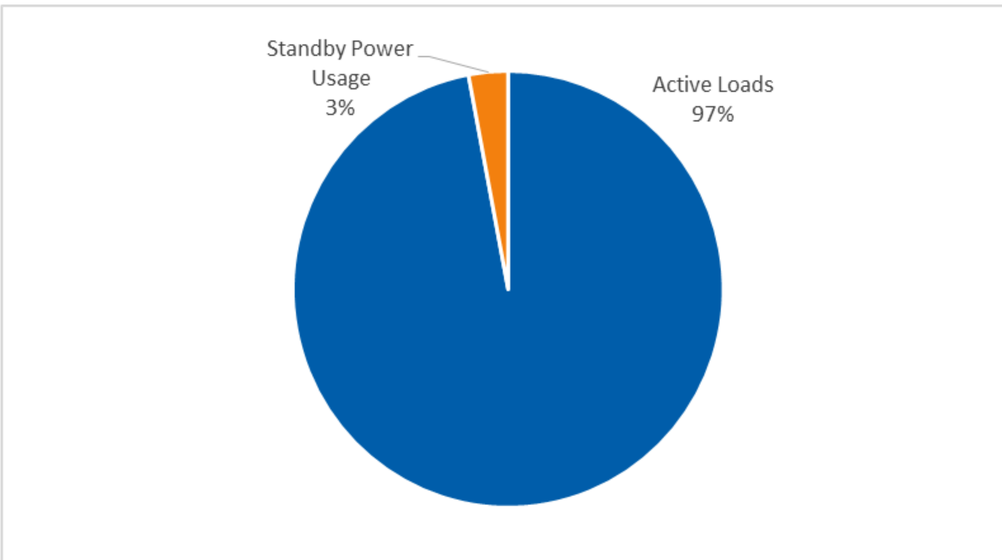
The temperature setting from the *in situ* data is more a reflection of the types of clothing in a household and is driven by participants following the garment labels instructions to "tumble dry low". It is not an opportunity to save additional energy by choosing one setting over the other as shown by our laboratory testing. An interesting finding is that the switch from *Medium* to *Low* setting saved 0.05 kWh per load, achieved the same residual moisture level in the dried load, and did not increase drying time.

Standby Energy Usage

Unlike mechanically controlled dryers with dials, electronically controlled dryers with touch pad settings consume a small amount of additional energy for the electronics. Unless the user unplugs the dryer before and after use, the electronic controls draw power even when the dryer is not operating.

Cadmus measured 1.89 Watts of standby power from the tested heat pump dryer, equal to 16 kWh per year. Figure 18 shows the portion of energy consumed by the dryer merely to provide power to the controls.

Figure 18. Standby Electric Usage Impacts



Combined Energy Factor

To include the influence of standby energy on the performance of clothes dryers, ENERGY STAR uses a metric called the Combined Energy Factor (CEF). The CEF is given in pounds per kWh and is the weight of the load divided by the average per-load energy use (including both standby and operational energy). A higher CEF represents a more energy-efficient dryer.

$$CEF = \frac{Load\ Weight\ (lbs)}{Energy_{Operation} + Energy_{Standby}}$$

The CEF of the heat pump dryer is 4.94 pounds per kWh, exceeding the ENERGY STAR® minimum criteria of 3.93 lb/kWh for a standard size, ventless electric clothes dryer.[2]

The ENERGY STAR®-rated performance for this clothes dryer lists the CEF as 4.5, yielding an energy consumption of 531 kWh per year.[3] While the energy use per load and standby usage from this demonstration are in agreement with that with the ENERGY STAR® CEF, the average weight of participants' loads was 9.31 pounds, greater than the 8.45 pound DOE assumption and increasing the resultant CEF. The annualized result of the CEF via our field data is then 533 kWh/year, very close to that from the details from ENERGY STAR®.

Laboratory Testing Results on HPD-B (Second Model)

Cadmus performed a second round of laboratory testing on a different heat pump dryer (HPD) model provided by the Companies. Although we did not repeat the *in situ* testing with the second HPD model, we designed the laboratory test procedure similar to the procedure used for the first HPD model.

Ex Situ *(Laboratory) Testing Procedure for HPD-B*

To conduct performance testing for HPD-B, we followed the same laboratory testing procedure described in Figure 3 on page 12. We installed the same metering equipment (Step 1), defined the same control conditions (Step 2), and used the same conditioned laundry load materials (Step 3). We also used the same clothes washer for testing both HPD-A and HPD-B so that any differences in the dryer performance should not be attributable to the clothes washer performance. Although the clothes washer is from the same manufacturer and designed to be paired with HPD-A, using the same clothes washer model ensures that key factors influencing dryer energy performance—load weight and moisture content—remain constant for similar tests on both dryer models.

Because the HPD models have different operating options, we designed a unique test load procedure (Step 4) for HPD-B. The HPD-B procedure is similar to the procedure for HPD-A (shown in

on page 13) but uses the unique options available on the HPD-B equipment:

- Cycle Type: *Normal* and *Timed Dry*;
- Energy Options: *EcoHybrid* and *Normal*;
- Temperature Options: *Ultra Low*, *Low*, *Medium*, *Mid High*, and *High*;
- Dryness Level: *Damp Dry*, *Less Dry*, *Normal*, *More Dry*, and *Very Dry*; and
- Termination: *Auto* and *Monitored*.

We used information from the *in situ* participant survey to determine the combinations of dryer settings most likely to occur in customer households. For example, we did not include the *Damp Dry* option and designed only one test each with the *Less Dry, More Dry,* and *Very Dry* options due to participants' frequent use of the Normal dryness setting with HPD-A (Figure 13).

Table 8 describes the thirteen combinations of parameters we designed for testing HPD-B. As we did for HPD-A, we ran each HPD-B test combination three times for a total of 40 test loads (including a fourth run for test #13, which exhibited high variation) and used the average performance in our analysis.

Table 8. Test Run Specifications for *Ex Situ* Testing (HPD-B)

Results for HPD-B

The following sections describe how the various load characteristics or dryer settings impact dryer performance, based on the results of 40 loads of *ex situ* testing. In each figure, we provide three performance metrics:

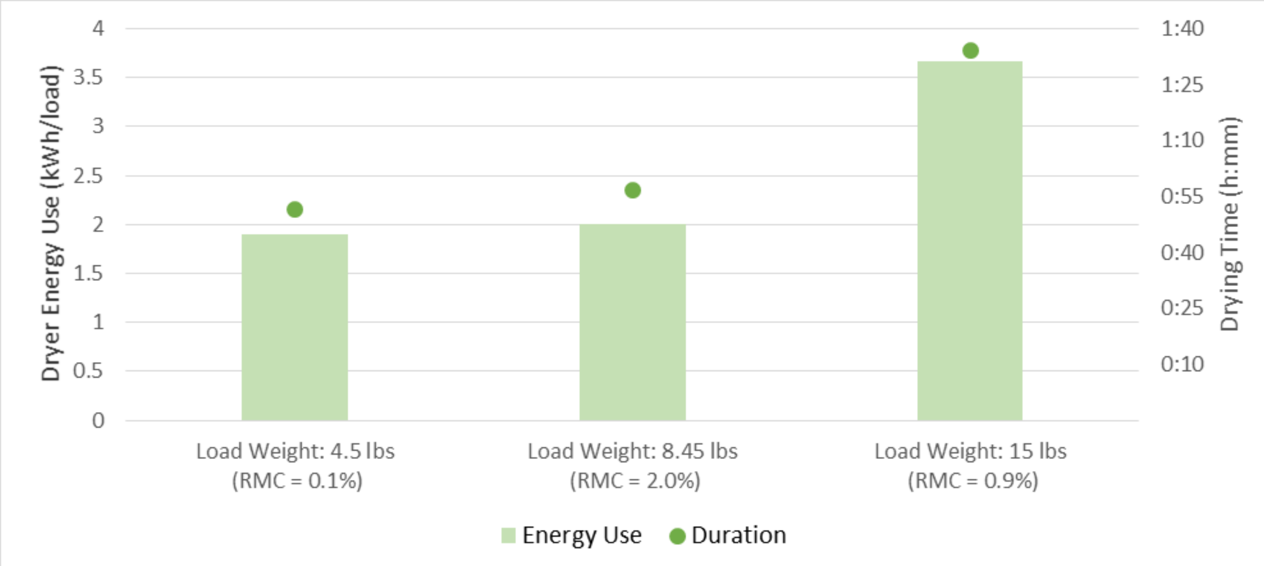
- Dryer energy use is the total electric energy consumed for the load (kWh/load);
- Drying time is the total time required for the dryer to dry the load (minutes/load); and
- Remaining moisture content (RMC) indicates the final dryness level of the load.

Load Weight

Figure 19 shows the impact of load weight on dryer energy performance.

CADMUS

Figure 19. Dryer Performance vs. Load Weight (HPD-B)



The HPD performs similarly to dry the 4.5-lb load (1.90 kWh and 52 minutes per load) and the 8.45-lb load (2.00 kWh and 57 minutes per load) but requires significantly more energy and time to dry the 15-lb load (3.66 kWh and 1 hour, 35 minutes per load).

However, when normalized by pound of laundry, the dryer is more efficient serving the 8.45-lb and 15-lb loads (0.24 kWh/lb) than the smaller 4.5-lb load (0.42 kWh/lb).

Dryness Level Setting

HPD-B offers five dryness level settings: *Damp Dry*, *Less Dry*, *Normal*, *More Dry*, and *Very Dry*.

Figure 20 shows the impact of dryness level setting on dryer energy performance. (Due to the tendencies of participants to use the *Normal* dryness setting, we did not include the *Damp Dry* option in our testing).

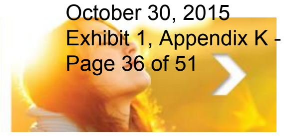


Figure 20. Dryer Performance vs. Dryness Level Setting (HPD-B)

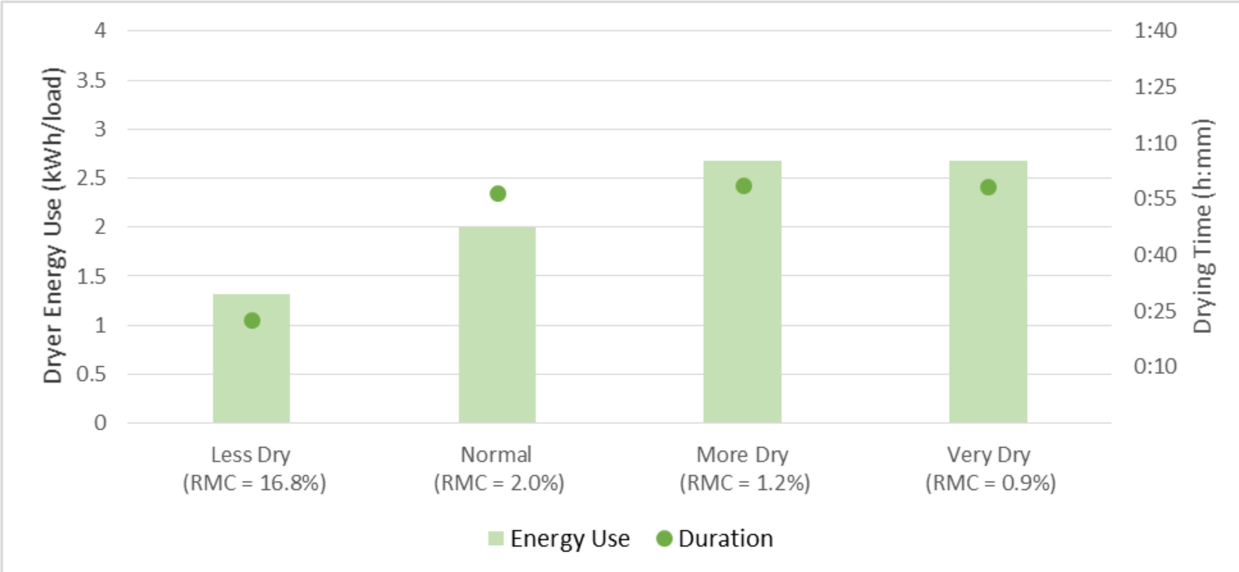


As expected, increasing the dryness level setting increased both the dryer energy consumption and the drying time. The *Less Dry* option used much less energy than the other options (1.31 kWh per load) but, with a remaining moisture content of 16.8%, is unlikely to satisfy most customers.

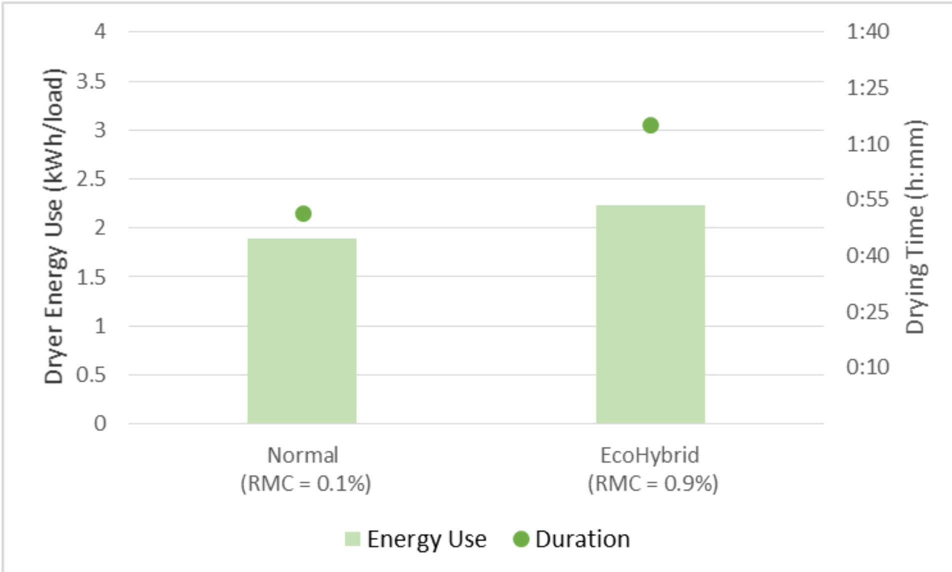
The *Normal* setting most efficiently achieves a satisfactory RMC value. The *More Dry* and *Very Dry* settings use 34% more energy compared to the *Normal* setting to produce dryer loads with insignificant drying time penalties.

Energy Option Setting

HPD-B offers two energy options: *Normal* and *EcoHybrid*.

Figure 21 shows the impact of the energy option setting on dryer performance.

Figure 21. Dryer Performance vs. Energy Option Setting (HPD-B)

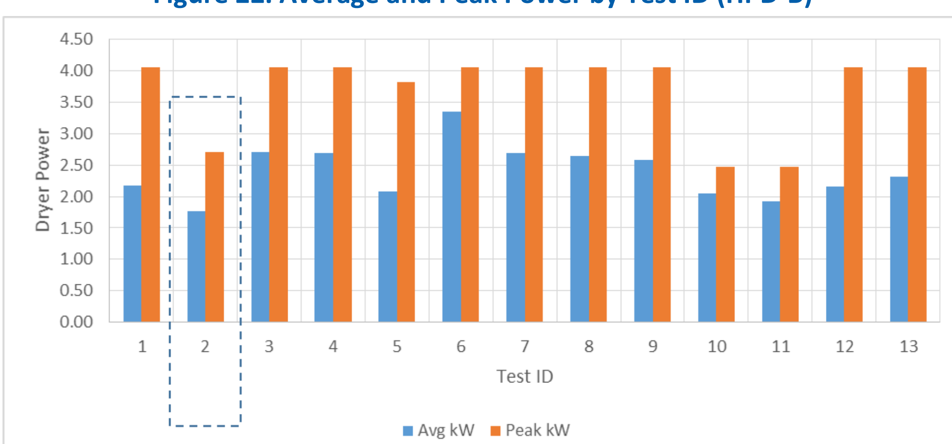


The data suggest that there are no advantages to the customer for selecting the *EcoHybrid* option. Compared to the *Normal* setting, the *EcoHybrid* setting used 18% more energy, took 23 minutes longer, and had a higher RMC in the finished load.

The benefit of the *EcoHybrid* option is to reduce both maximum and average power to complete the dryer cycle. Compared to the *Normal* setting, the *EcoHybrid* setting reduces average power by 18% and reduced maximum power by 33%.

As shown in Figure 22, the *EcoHybrid* option (Test ID #2) offers the lowest average demand compared to all other test runs and the lowest peak demand compared to all but two test runs. (Tests 10 and 11 use the *Ultra Low* and *Low* temperature settings and result in the lowest peak power values.)

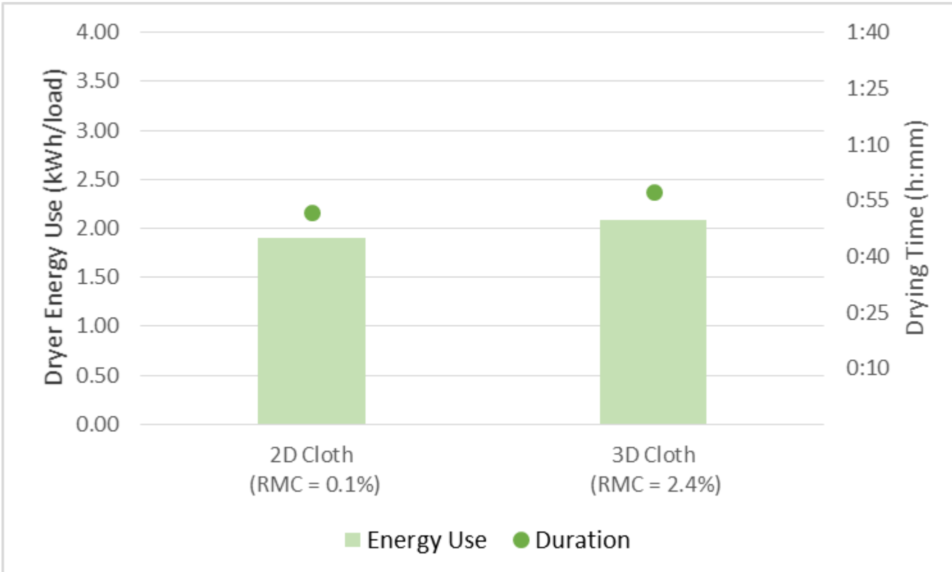
Figure 22. Average and Peak Power by Test ID (HPD-B)



Cloth Dimension: 2D vs. 3D

Figure 23 shows the impact of the cloth dimension on dryer performance by comparing two test runs with the same dryer settings but different laundry load compositions.

Figure 23. Dryer Performance vs. Cloth Dimension (HPD-B)



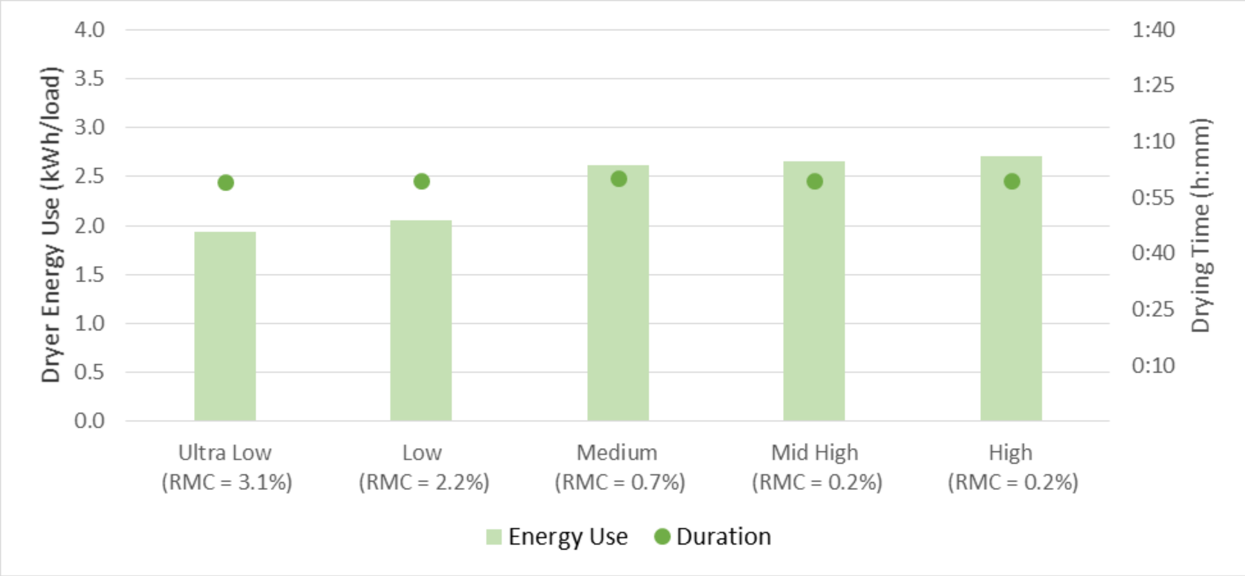
The data indicate only a marginal increase in energy use and drying time with the more complex load. However, the dryer also left the 3D load less dry than the 2D load. (Both test runs used the auto termination feature).

Dryer Temperature Setting

HPD-B offers five dryer temperature settings: *Ultra Low*, *Low*, *Medium*, *Mid High*, and *High*.

Figure 24 shows the impact of the dryness setting on dryer performance.

Figure 24. Dryer Performance vs. Temperature Setting (HPD-B)



As expected, increasing the dryer temperature setting increases the dryer energy consumption. The data indicate modest energy differences between to two lower settings and among the three medium and high settings, with a significant energy different between the two groups. Although a user can save 27% energy consumption by using the *Low* setting instead of the *Medium* setting, the user sacrifices final dryness, with remaining moisture content (RMC) values above 2% for the low energy loads.

The data also demonstrate that changes in the dryer temperature setting had no impact on the drying time. All test loads at all settings averaged exactly one hour in duration.

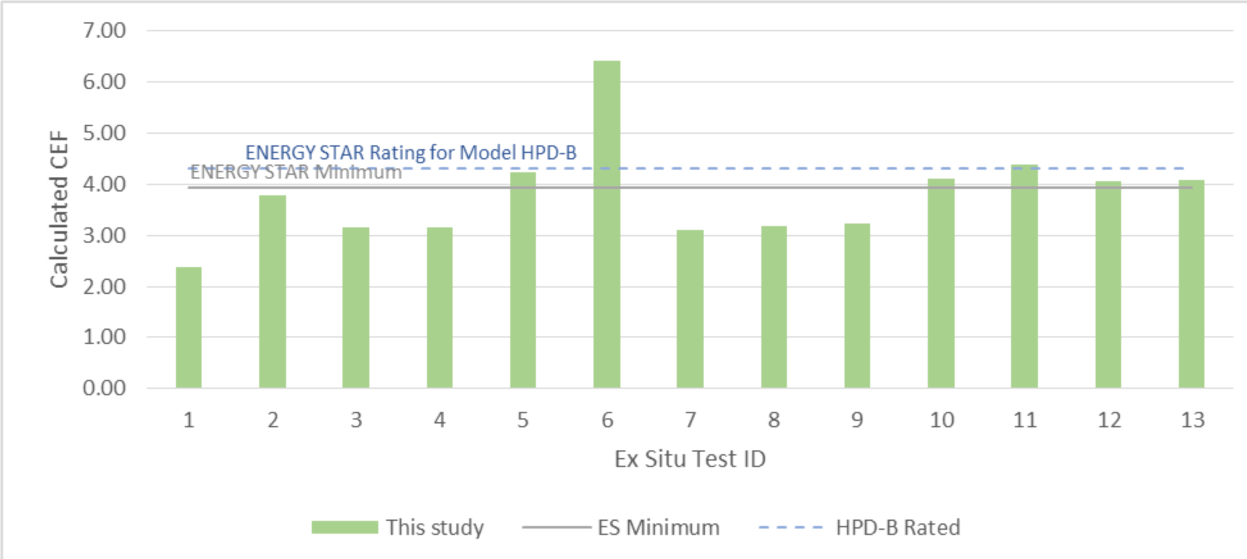
Standby Energy Usage

Cadmus measured 76 Watts of standby power from HPD-B, less than half of the 1.89 Watts of standby power measured for HPD-A. Assuming the dryer operates at one hour per load and served 283 loads per year, the annual standby energy for HPD-B is 6.5 kWh when the dryer is not operating.

Combined Energy Factor

HPD-B has a rated combined energy factor (CEF, defined on page 31) of 4.3. Cadmus' testing (which does not strictly follow the standard test procedures) found the CEF for HPD-B ranges from 2.37 (Test 1) to 6.43 (Test 6) for the tested combinations of load characteristics and dryer settings (Figure 25).

Figure 25. Calculated CEF Values for HPD-B



Only six of the thirteen ten runs exceed the ENERGY STAR® minimum performance value of 3.93 pounds per kWh for electric clothes dryers, and only two of the test runs exceed the rated CEF for the specific make and model of HPD-B. However there are differences in the laboratory performance conditions for this study and the conditions through which the ENERGY STAR® ratings are measured.

Recommendations

Cadmus offers the following recommendations based on the findings from this study:

- **Encourage replacement of top-load (vertical axis) clothes washers with front-load (horizontal axis) clothes washers.** The moisture content of the laundry entering the clothes dryer has a major impact on energy use, and literature confirms that the rotation of the washer drum extracts moisture more efficiently than evaporation in the clothes dryer. This study confirmed that the majority of energy savings achieved at each participant site is attributable the change in washer axis configuration.
- **Discourage customers from installing non-vented heat pump dryers enclosed areas (e.g., a closet).** Although it still performed better than the average existing ERD, the HPD located and operated in an enclosed closet consumed 41% more energy per load than the other *in situ* HPDs, illustrating the impact of enclosure on energy performance.
- **Encourage users to operate appliances with full loads to optimize energy performance, and educate customers on the inverse relationship between energy and drying time.** Heavier loads were more energy efficient per pound of dry laundry, but also took longer to dry. Increasing the load weight from 4.5 pounds to 8.45 pounds decreased the energy consumption from 0.30 kWh per pound to 0.26 kWh per pound (13.3% reduction), but required an additional 32 minutes over the 50 minutes required for 4.5-pound load (total drying time of 82 minutes).
- For the HPD model in this study:
  - The most common user settings—the *Eco* energy mode and the *Normal* dryness level—are efficient and practical. The laboratory data showed that using the *Eco* energy option setting and the *Less* dryness level setting results in the most energy-efficient dryer performance; however, compared to the user-preferred *Normal* setting, the *Low* dryness level results in a higher residual moisture content. Compare to *Eco* and *Normal*, the *Speed* mode increases energy but only reduced drying time by 3 minutes and the *More* dryness setting increases energy but does not impact residual moisture content.
  - With the exception of the *Extra Low* option, temperature settings had little impact on the energy use and drying time. Users should avoid the *Extra Low* setting, which consumed more energy and resulted in longer drying cycles compared to other options.

Appendix A. Pre-Installation Participant Laundry Log

Instructions: For each load of laundry please record start data/time, laundry weight before wash, laundry weight after wash/before dryer, and laundry weight after dry. Also please circle washer and dryer settings that best match your machine.

Cycle #	Date	Start Time	Dirty Laundry Weight (w/basket)	Washer: Please Circle All That Apply						Wet, Clean Laundry Weight (w/ basket)	Dryer: Please Circle One				Dry, Clean Laundry Weight (w/ basket)

Appendix B. Participant Survey

CADMUS

National Grid Heat Pump Dryer Program: Participant Survey

This survey consists of one group of participants:

- National Grid Heat Pump Dryer Group (6 participants)

The group received a new Whirlpool heat pump clothes dryer and a new matching Whirlpool front-loading clothes washer. The purpose of this survey is to use participant feedback to examine participant experiences with the dryer technology and to inform program design recommendations for a heat pump dryer rebate program. Cadmus will administer the survey online by e-mailing each participant link to the survey website. We will ask participants to complete the survey within seven days. Cadmus will follow up by phone with any participants who have not completed the survey.

Researchable Questions
• What was the participant's experience with the new technology? • Were participants satisfied with the heat pump dryer? • Would participants recommend the heat pump dryer? • What would participants be willing to pay for a heat pump dryer?

Thank you for your participation in this survey. This survey will ask questions about the new heat pump clothes dryer and matching clothes washer you received. The survey should take approximately 10 minutes to complete.

A. *Equipment Performance: Clothing Washer*

The first five questions will ask about your old and new **clothes washer**s.

A1. How old was your previous clothes washer? (in years) [Record: ________________]

A2. Compared to your previous clothes washer, would you say that the performance of your new **clothes washer** is:

1. Much better
2. Somewhat better
3. About the same
4. Somewhat worse
5. Much worse

-98. Don't know

A3. Do you operate your new washer or do you wash loads differently in any way compared to your previous dryer? **[Record: ________________]**

A4. Overall, how satisfied are you with the **clothes washer** you received?

1. Very satisfied
2. Somewhat satisfied
3. Neutral
4. Not very satisfied
5. Not at all satisfied

-98. Don't know

A5. Please provide any additional comments on the **clothes washer** you received in the space below: [Record: ________________]

CADMUS

B. Equipment Performance: Heat Pump Dryer

The next set of questions will ask about your old dryer and new **heat pump dryer**.

B1. How old was your previous clothes **dryer**? (in years) **[Record: ________________]**

B2. Compared to your previous clothes **dryer**, would you say that the performance of your new **dryer** is:

1. Much better
2. Somewhat better
3. About the same
4. Somewhat worse
5. Much worse

-98. Don't know

B3. Do you operate your new dryer or do you dry loads differently in any way compared to your previous dryer? **[Record: ________________]**

B4. Overall, how satisfied are you with the heat pump dryer you received?

1. Very satisfied
2. Somewhat satisfied
3. Neutral
4. Not very satisfied
5. Not at all satisfied

-98. Don’t know

B5. **[If “Not very satisfied” or “Not at all satisfied]** Why are you dissatisfied with the heat pump dryer you received? **[Record: _______________]**

B6. In the table below, please rate your level of satisfaction with each aspect of the heat pump dryer.

	Very satisfied	Somewhat satisfied	Neither satisfied nor dissatisfied	Not very satisfied	Not at all satisfied	N/A or Don't know
Appearance						
Ease-of-use						
Noise level						
Dryness level						
Drying time						
No need for a dryer vent						
Hose for water drain on dryer						
Secondary lint filter						
Overall drying performance						

B7. How frequently do you clean the secondary filter on the dryer?

1. Before or after each load
2. About once a week
3. About once a month
4. I have not cleaned the secondary filter on the dryer.
5. I am not aware of a secondary filter on the dryer.
6. Other **[Record: _______________]**

B8. What do you like best about the heat pump dryer? **[Record: _______________]**

B9. What do you like least about the heat pump dryer? **[Record: _______________]**

B10. Please provide any additional comments in the space below: **[Record: _______________]**

C. Willingness to Pay and Likelihood of Recommending

C1. **Before** participating in this pilot, what is the most you would have paid for a new heat pump clothes dryer?

1. $1,500 to $1,999
2. $1,000 to $1,499
3. $500 to $999 to
4. Less than $499
5. I would not purchase a heat pump dryer.

-98. Don't know

C2. **After** participating in this pilot, what is the most you would have paid for a new heat pump clothes dryer?

1. $1,500 to $1,999
2. $1,000 to $1,499
3. $500 to $999 to
4. Less than $499
5. I would not purchase a heat pump dryer.

-98. Don't know

C3. How likely would you be to recommend a **heat pump dryer** to a friend?

1. Very likely
2. Somewhat likely
3. Neutral
4. Not very likely
5. Not at all likely

-98. Don't know

C4. Which of the following are most influential reasons to purchase a heat pump dryer? **[Multiple choices possible]**

1. To save money on energy bills
2. To save energy
3. To acquire the latest technology
4. To acquire eco-friendly technology
5. To replace an old clothes dryer and washer
6. To have a dryer that does not require venting
7. Other **[Record:________________]**

-98. Don't know

D. Additional Information

D1. How many people currently live in your household full time (at least 9 months of the year)?
[Specify:________________________]

D2. About how many laundry loads do you perform per week? **[Specify:________________________]**

End

Thank you for completing our survey. Your feedback will be used to help National Grid plan future program offerings.

III. Introduction

Keith Miller with National Grid (NGrid) requested engineering services from RISE Engineering. The intent of this study is to quantify the savings potential and market applicability of a new residential steam distribution system which operates under vacuum to deliver heat.

RISE Engineering conducted multiple site visits to perform a series of measurements in order to determine the overall system efficiency changes through different operating modes. These visits were performed at major system changes to download data from the monitors before each new test began.

IV. Executive Summary

Igor Zhadanovsky, PhD., the President of Applied Engineering Consulting, contacted Keith Miller of National Grid to request that his method to steam distribution be assessed for energy savings. Through this process, RISE Engineering was requested to perform measurement and verification of the energy savings potential of the vacuum distribution system approach. Based upon the collected data, the vacuum system retrofit produced favorable energy savings as a percentage of on-site fuel consumption. This technology could be installed at facilities which currently utilize single pipe steam to heat or those new construction facilities which are being designed with single pipe steam.

V. Facility Overview

The property that was utilized is a two story colonial that serves as both a day care and living quarters. Each floor has its own steam boiler and distribution system which are controlled by programmable thermostats. The first floor (noted as Unit #38), the day care, was not monitored in this study although it was stated that the thermostat was maintained at a constant setting. The top floor, Igor's home (Unit #36), was the focal point of the evaluation.

The residency is the 2nd floor of 1910 colonial, and is 1,150 square feet in floor area. Eight (8) radiators were utilized to heat the space. To ensure consistency between testing scenarios, two (2) of the cast iron radiators were disconnected from the system so that both the VSH and the single pipe steam system used the same number of radiators. The home's insulation level is low with most walls having no insulation. Fourteen (14) out of seventeen (17) windows are new, with the three (3) old windows being attached to a screened porch (each of which having storm windows). A forced air system in the attic space provides cooling only.

Radiator Location	Steam Delivery Order
Kitchen	1
Bedroom #1	2
Dining Room	3
Bedroom #2	4
Office	5
Living Room	6

A basic floor plan of Unit #36 is shown below. This lays out the various rooms, original and new radiators, and the space thermostat. The order in which the radiators receive steam is chronologically noted and shown in the table to the right.

VI. Vacuum Steam Heating

a. Technology

Residential homes constructed in the early 1900s with steam systems generally utilize one-pipe (SPS) or two-pipe steam distribution. In the scenario at Unit #36 (single pipe steam), gravity returns condensate back to the boiler through steam piping in a counter-flow manner[1]. The single pipe steam radiators are all high-mass cast iron units with air vents. These vents allow air within the system to purge during the "warm-up" cycle while preventing valuable steam from escaping. While this system is very easy to install, only one set of pipes, it generally lacks the maintenance necessary to keep it running properly.

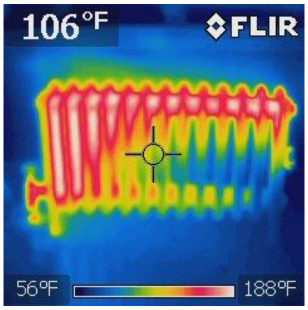

Figure 1: Single Pipe Steam Radiator (High mass cast iron)

Vacuum heating technology has been successfully utilized in both residential and commercial applications. Systems generally operate between 5 to 10 inches of mercury vacuum. The specific application being studied utilizes a deeper vacuum and modern plumbing / distribution replacement to further increase savings potential.

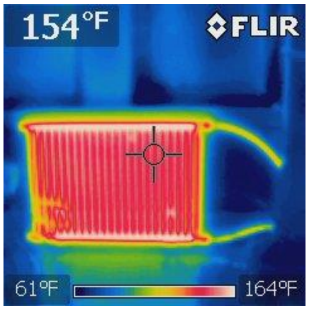

Figure 2: Vacuum Steam Heating system radiator (Low mass steam)

Modifying a standard single pipe steam system to a Vacuum Steam Heating system reduces operating temperatures while maintaining a high differential pressure across the system. In this specific scenario the single pipe steam system was abandoned in place. Tests were conducted in back-to-back weeks utilizing various scenarios to quantify the potential efficiency gain of switching to the VSH system. The VSH system utilized a supply and return hose to each radiator. The distribution system did not use a metal pipe but rather copper tubing and temperature-resistant clear plastic tubing. The VSH distribution system was attached to new low mass hydronic radiators. A vacuum pump maintained the vacuum in the system to between 20 and 24 inches of mercury vacuum.

Common practice within the industry generally calls for complete steam to hot water conversions. While this may be optimal for efficiency, costs to do so generally prohibit a customer from moving forward. The VHS may be a feasible alternative to obtain those savings.

[1] Two-pipe systems utilize a separate pipe to return condensate back to the boiler.

b. Analysis Methodology and Results

To quantify efficiency gains between the VSH system and the single pipe steam system a number of data monitors supplied both by RISE Engineering and Applied Engineering Consulting were utilized to track and trend the operational parameters of the various test scenarios. The monitors recorded data in increments of as little as 10 second intervals and up to 15 min intervals. Pulse meters were utilized to monitor the vacuum pump and the gas meter. A list of RISE Engineering's installed meters is as below.

Sensor #	Model	Use Description
1	Fyrite Tech Analyzer Model 60	Used to determine the combustion efficiency of the base case boiler
2	Flir Systems i7	Infrared camera utilized to document the heat output of the radiators
3	HOBO U12-011 Temp/RH	Used to monitor the basement temperature
4	HOBO UX100-011 Temp/RH	Used to monitor the temperature at the control thermostat
5	HOBO UA-002-64 Pendant Temperature/Light, 64K	Outdoor air and ambient solar conditions
6	HOBO UX120-017 4-Channel Pulse Input	Data recorded to measure time gaps in On/Off pulses from the CSV-A8
7	HOBO CSV-A8 AC Current Switch	The current switch which monitored run time on the vacuum pump

The meters that were deployed by Applied Engineering Consulting included the following.

Sensor #	Model	Use Description
1	Pulse Meter	Recorded Pulse output from Gas meter to record fuel consumption
2	Presure Sensor	Measure the Vacuum in the system
3 - 7	Temperature Sensors	Condensate return, Kitchen, Bedroom 1, Bedroom 2, Dining Room, Living Room, Office

The data from these meters was imported into a spreadsheet calculation to determine the savings for the following scenarios.

System Comparison
Old Boiler - Single Pipe Steam
Old Boiler - Vacuum System
New Boiler - Single Pipe Steam
New Boiler - Vacuum System
Old Boiler - Single Pipe Steam
New Boiler - Single Pipe Steam
Old Boiler - Vacuum System
New Boiler - Vacuum System
New Boiler - Vacuum System
New Boiler - Balanced Vacuum
Old Boiler - Single Pipe Steam
New Boiler - Balanced Vacuum

The first steps in determining the energy impact of the VSH system were to generate plot and trend lines from relevant data that would potentially impact the consumption of the facility. The two major independent variables for this project were the outdoor ambient conditions and the amount of potential solar heat gain. These two variables were identified as the independent variables because the thermostat was set to a specific load profile and was monitored to ensure that it held those conditions.

A plot of the outdoor air temperature vs. the fuel consumed by the boiler to heat the apartment is shown below.

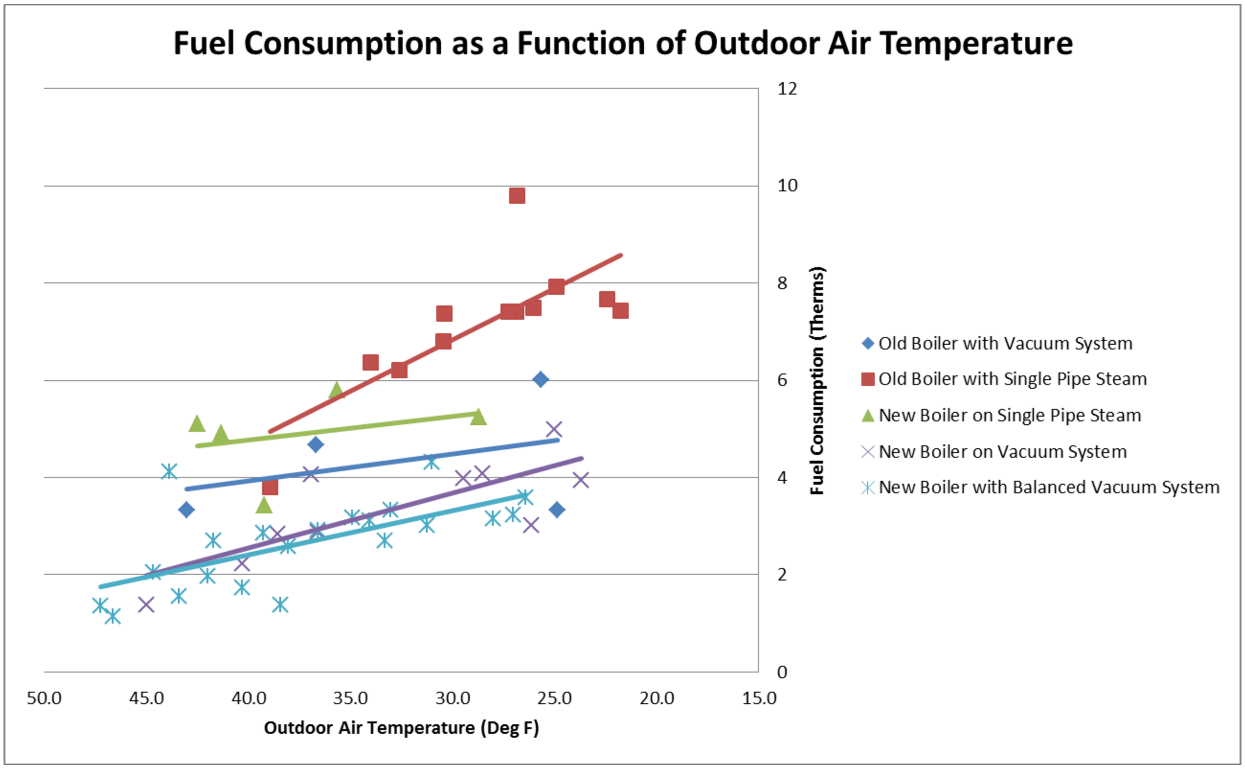

Figure 3: Fuel consumption as a function of outdoor air temperature per day

This graph (Figure 3) shows a direct relationship between the outdoor air temperature and fuel consumption of the facility. Note that the various tests took place across similar weather conditions despite taking multiple weeks to complete. Each data set represents its own test with the least efficient (Old Boiler with Single Pipe Steam (Red Squares)) being highest up the scale. Conversely, the most efficient test that was performed is lowest on the graph (New Boiler with the Balanced VSH System).

The second independent variable, the solar heat gain or in this case the lumens of light recorded by the light sensor, is plotted against the fuel consumption to determine the effect of solar heat gains on the property.

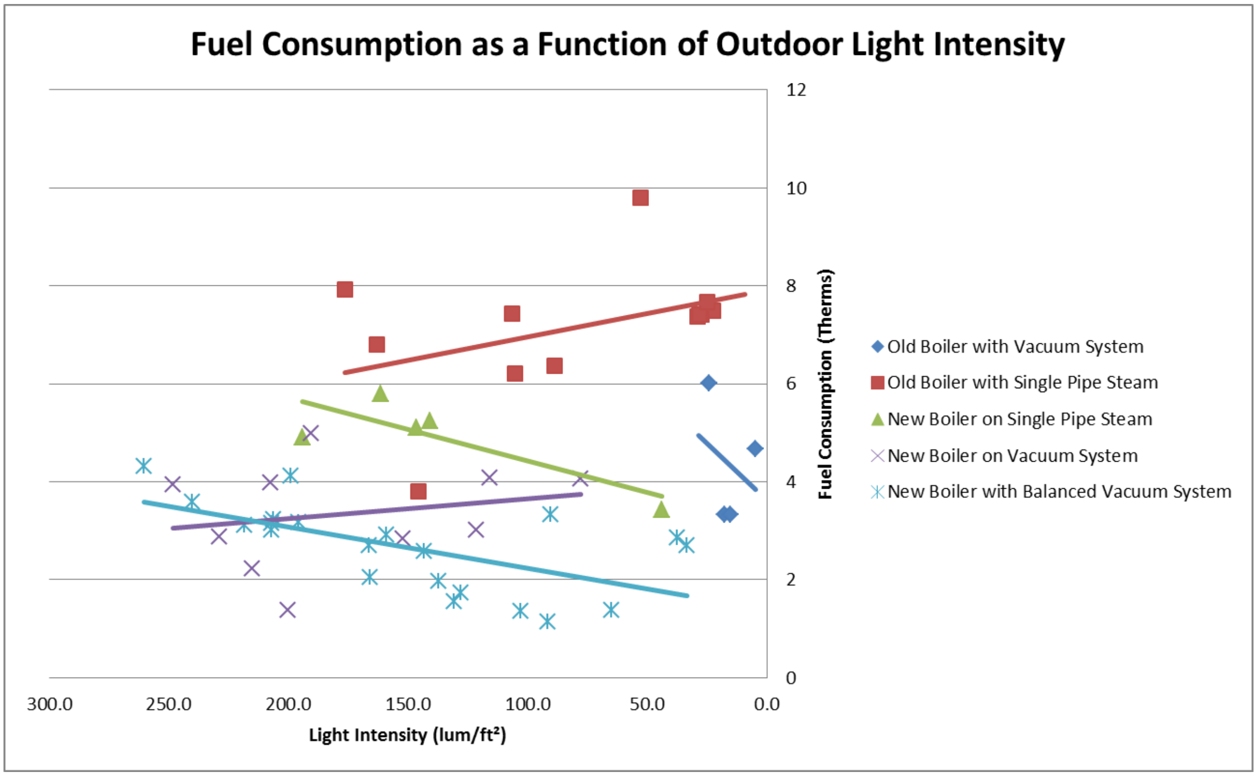

Figure 4: Fuel consumption as a function of outdoor light intensity per day

Figure 4 shows that the outdoor light intensity does not have the same linear effect on the fuel consumption as the outdoor air temperature (Figure 3) does. We can make this correlation because on days that have significantly different light intensities the fuel consumption can remain constant because the outdoor temperature was the same.

Since there is such a strong linear relationship between the fuel consumption and outdoor air temperature, a linear regression analysis was performed on the couplet of information to develop an equation for each test set. These equations were utilized to quantify average predicted daily fuel consumption values across a bin data set of Boston, MA compiled from the most recent TMY3 data[2].

Figure 5: Midpoints of 5 degree temperature bins to predict average daily fuel consumption

Figure 5 shows us the average predicted fuel consumption at the midpoints for 5 degree temperature bin data. The data above the midpoint temperature of 62.5°F is grayed out as the heating system should be operating above 65°F outdoor air temperature. The cells below negative 2.5°F are grayed out because there were no hours recorded in the TMY3 bin data for Boston, MA that met those conditions.

Once the daily average consumption values were determined for the midpoint conditions a generic heating profile for a building of 1,150 square feet was utilized to determine that there were approximately 4,271 heating hours over the course of a TMY3 year. Based on that information, annual fuel consumption for heating the facility was generated.

Yearly heating therm consumption based upon daily average temperature and heating consumption

Figure 6: TMY3 bin hours are used to predict yearly fuel consumption for heating

Figure 6 breaks down the predicted fuel consumption of each heating system based upon its midpoint temperature estimated and the hours in that temperature band. As the test data showed there is a significant improvement between the base case existing single pipe steam and very old steam boiler and the VSH system and a new higher efficiency steam boiler. Again cells above the 62.5°F midpoint and below the 2.5°F midpoint were not relevant to the study as there are either no heating hours in the temperature bands or the heating system should be off. There is one negative value in this chart; this value is carried over from the linear regression that was performed to develop the consumption equations. Since a boiler cannot generate natural gas it was not included in the calculation.

The savings for each test case is show below.

System Comparison	Predicted Consumption (Therms)	Percent Savings
Old Boiler - Single Pipe Steam	1,004	
Old Boiler - Vacuum System	741	26.2%
New Boiler - Single Pipe Steam	840	
New Boiler - Vacuum System	541	35.5%
Old Boiler - Single Pipe Steam	1,004	
New Boiler - Single Pipe Steam	840	16.4%
Old Boiler - Vacuum System	741	
New Boiler - Vacuum System	541	27.0%
New Boiler - Vacuum System	541	
New Boiler - Balanced Vacuum	500	7.7%
Old Boiler - Single Pipe Steam	1,004	
New Boiler - Balanced Vacuum	500	50.2%

Figure 7: Study Results showing percent savings between test cases

Figure 7 shows the percent savings based upon the analysis methodology described above. The savings range from 7.7% up to 50.2% depending on what type of a system change the facility undergoes. In many cases facilities will likely either utilize the "Old Boiler – Single Pipe Steam vs. Old Boiler – Vacuum System" comparison which in this specific test showed 26.2% savings.

In conjunction with the fuel savings associated with the VSH system installation there is a small electric penalty for the run hours of the vacuum pump. The pump was monitored for 29 days to record its change of state (pump on/pump off) to determine its total run time per day. Over the course of the 29 days it averaged 1:59.54 hours of run time. Extrapolating the run time out over the course of the 178 day heating season (as per the TMY3 midpoint heating hours) the vacuum pump will consume 163.58 kWh of electricity. The cost to run this pump is approximately $24.54 per year[3].

[3] $0.15 / kWh = "all-in" electric cost

VII. Explanation of Energy Savings

The predicted energy savings varies widely based on the system installed. As each scenario is independent from one another, a number of factors contribute to a reduction in the quantity of natural gas consumed by the boiler and measured at the meter. The following section of the study may be used as verification of energy savings and dissemination of such factors.

Savings were separated into the following categories for each of the scenarios reviewed

- Combustion Efficiency
- Boiler Standby Losses
- Off-cycle Losses
- Air removal

Other considerations in the categories above include:

- Piping Losses
- Cycling
- Condensate Return

A general summary / breakout of energy savings is shown below. While not exact, energy savings seen at the meter are related to those derived using monitored data points.

System Comparison	Derived from Fuel Metering		Quantified Using Data from Loggers				
	Predicted Consumption (Therms)	Percent Savings	Combustion Efficiency	Boiler Standby Losses	Off-cycle losses	Energy to Remove Air / Warm up pipes	Estimated Total Savings
Old Boiler - Single Pipe Steam	1,004.34	0%	0%	0%	0%	0%	0%
Old Boiler - Vacuum System	741.40	26%	2%	0%	14%	13%	29%
New Boiler - Single Pipe Steam	839.92	16%	16%	1%	-6%	3%	13%
New Boiler - Vacuum System	541.35	46%	16%	1%	20%	8%	45%
New Boiler - Balanced Vacuum System	499.74	50%	16%	1%	27%	6%	50%
Base	1,004.34	0%	0%	0%	0%	0%	0%

As the space being monitored is the second story of a residentially constructed building, any modifications to temperature set-points or occupancy conditions in the unit below could have a direct effect on the heat load of the evaluated unit. The fuel consumed by the boiler supplying heat to Unit #38 and other specific parameters were not monitored as part of this study. Historic fuel consumption for each of the units is shown below.

Normalized gas consumption associated with heating Unit #38 is depicted above. It should be noted that the site consumed approximately 11% more gas during 2013/2014 than in 2012/2013 when normalized for local weather conditions. This could be due to differences in temperature set-points at the thermostat or due to less heat being delivered indirectly from the steam system supplying Unit #36.

As part of this evaluation, the existing antiquated steam boiler was replaced with a new Peerless natural gas fired atmospheric cast iron sectional steam boiler. This four (4) section residential boiler features a spark ignition and a gross heating capacity of 147,000 BTU/hr. The original (approximately 100 years old) American Radiator Company boiler, as seen in the picture below on the left, had been retrofit with a Janitrol atmospheric natural gas conversion burner with a net input rating of 325,000 BTU/hr.

Series 63™													
Model Number	Input, MBH	Heating Capacity[3], MBH		Net Ratings[1]			Standing Pilot AFUE[3]		Spark Ignition AFUE[3]		Water Content		Approx. Shipping Weight, lb
		Water	Steam	Steam, sqft	Steam, MBH	Water, MBH	Water, %	Steam, %	Water, %	Steam, %	Water, gal	Steam, gal	
63-04	177	148	147	458	110	129	82.1	81	83.4	82.4	15.6	10.8	576

1 Net Ratings are based on DOE Heating Capacity less an allowance for normal piping and pickup as determined by the Testing and Rating Standard for Low Pressure Cast Iron Heating Boilers of the Hydronics Institute. Water ratings are based on a piping and pickup factor of 1.15. Steam ratings are based on a piping and pickup factor of 1.33. Consult PB Heat before selecting a boiler for gravity hot water installations or for installations having unusual piping and pickup requirements such as exposed piping, night set-back, etc. Ratings shown are for elevations up to 2,000 feet. For elevations above 2,000 feet, ratings should be reduced at the rate of 4% for each 1,000 feet above sea level.

2 Minimum Natural Gas Inlet Pressure exceptions: 63-04 STDG 5.3"; 63-06 STDG 5.5"; 63-06 SPRK 5.3".

3 Heating Capacity and Annual Fuel Utilization Efficiency (AFUE) ratings are based on U.S. Government tests. Before purchasing this appliance, read important information about its estimated annual energy consumption or energy efficiency rating that is available from your retailer.

a. Combustion Efficiency

Combustion Efficiency is a measure of how effectively the heat content of a fuel is transferred into usable heat. The stack temperature and flue gas oxygen (or carbon dioxide) concentrations are primary indicators of combustion efficiency.[4]

Installation of the new steam boiler is expected to have a large increase in the combustion efficiency of the overall system. The existing / original steam boiler was spot tested by RISE Engineering using a hand-held combustion analyzer displaying % oxygen, stack gas temperature and boiler efficiency. The analyzer displayed the following results while on single-pipe steam:

Combustion Efficiency Readings: SPS on 2/12/14			
Excess O2	14.5%	14.3%	14.4%
Stack Temperature (F)	450	495	504
Ambient Air Temperature (F)	41.7	43.3	[redacted]
Net Stack Temperature (F)	408.3	451.7	
Combustion Efficiency	64.0%	64.0%	63.6%

The stack temperature for all systems was measured using 10 second increment data provided by Igor. Data was provided for each monitored day. An average temperature was developed for each day during times when the boiler system was determined to be operating. Combustion air was supplied to the burner from the ambient basement air. Average daily basement temperatures are utilized as the combustion air temperature.

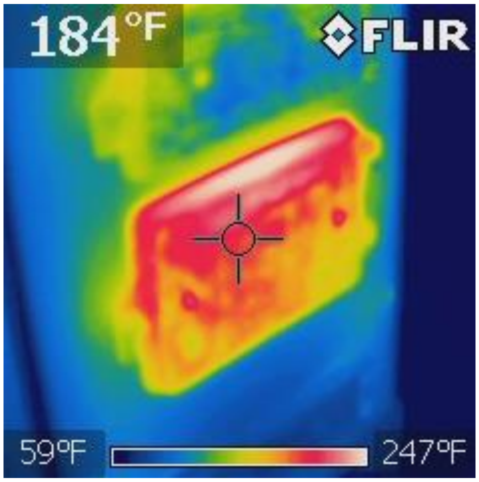
Excess %O2 in the stack was not measured on an incremental basis. The average excess %O2 for the existing boiler is approximately 14% based on spot measurements. The new boiler is predicted to be capable of firing at 10% excess O2 based on manufacturer's specifications. Excess O2 levels are kept the same between SPS and VSH when the using the same boiler as modifications were not made to the burner. Given this information and average flue gas and combustion air temperatures, the combustion efficiency for each of the heating scenarios is shown below. Available heat was calculated using the US Department of Energy's Process Heating Assessment and Survey Tool (PHAST) Version 3.0. There are slight combustion efficiency gains when switching between SPS and VSH (given the same boiler) due to a reduction in the overall net stack temperature.

Heating Scenario	Average Indoor Temperature (Deg F)	Average Stack Temperature (across all hours) - Deg. F	Average FGT when Blr On - Deg. F	Max. Stack Temperature	Average Basement Temperature	Excess O2:	Available Heat (% of HHV)	% Fuel Savings
Old Boiler Single Pipe Steam	65.96	197.83	477.10	515.93	63.24	14%	69.80%	0.0%
Old Boiler with Vac. System	65.78	167.64	451.19	505.89	62.97	14%	71.27%	2.1%
New Boiler Single Pipe Steam	66.51	200.39	326.71	361.24	60.38	10%	82.94%	15.8%
New Boiler Vac. System	66.11	144.40	316.86	360.09	59.04	10%	83.29%	16.2%
New Boiler Balanced Vac. System	66.25	129.39	320.76	362.23	59.86	10%	83.16%	16.1%

The % fuel savings all assume that the SPS with the original boiler is the "base" scenario.

[4] Advanced Manufacturing Office, Energy Efficiency and Renewable Energy, U.S. Department of Energy

b. Boiler Standby Losses



Boilers experience heat loss due to the boiler giving off heat by radiation and convection to the surroundings. This occurs because the temperate of the boiler jacket is greater than the air. The amount of jacket loss is determined largely by the surface area, surface temperature, and ambient temperature. [5]While the calculation to quantify the exact losses due to radiation and convection is complex, an acceptable approximation is considered to be 1.5% - 2% of the input rate.[6]

This percentage does not change with the load on the boiler so an oversized unit will have a greater reduction in performance efficiency.[7] With this in mind, it is apparent that the new boiler should have energy savings from a reduction in the input as well as it having a smaller surface area. It is also evident that the original boiler is currently oversized which would attribute more energy savings from reducing jacket losses to the new boiler. Additionally, the systems operating on a vacuum should also have energy savings because the temperature at which the water boils is reduced. This would reduce the surface temperature of the boiler, thus reducing jacket losses further.

As seen in the thermal image above, the original boiler's door is poorly insulated and transferring valuable energy to the ambient space. The average external temperature of the original steam boiler was measured at 113 °F versus 72 °F with the new boiler.

For the purpose of this analysis, 1.5% of the net input is assumed to be equivalent to the standby losses. No additional savings are attributed to scenarios in which the VSH is employed.

Boiler	Old	New
Input	325,000.00	177,000.00
Standby Loss	1.5%	1.5%
Standby Loss	4,875.00	2,655.00
% savings	0%	0.68%

The new boiler is estimated to save 0.68% of the base fuel consumption when compared to the original boiler.

c. Off-cycle Losses

Just as the various scenarios experienced a reduction in energy during operating (firing) conditions, the system also saves energy while the burner is not firing. Energy lost up the boiler flue during off-cycle conditions was quantified for each of the five (5) tested conditions. The draft was greatly affected between the SPS and VSH due to the large reduction in average stack temperature. A summary of savings is presented below.

Stack Draft Effect	Old Boiler - Single Pipe Steam	Old Boiler - Vacuum System	New Boiler - Single Pipe Steam	New Boiler - Vacuum System	New Boiler - Balanced Vacuum System
Volumetric Air Flow Requirements for Combustion - CFM	53.6	53.6	29.2	29.2	29.2
Stack Diameter (feet)	0.6	0.6	0.6	0.6	0.6
Stack Area (square feet)	0.3	0.3	0.3	0.3	0.3
Stack Height (ft)	30.0	30.0	30.0	30.0	30.0
Gravitation Acceleration (ft/s^2)	32.2	32.2	32.2	32.2	32.2
Discharge coefficient C	0.65	0.65	0.65	0.65	0.65
Average Stack Temperature (Degree F)	197.8	167.6	200.4	144.4	129.4
Average Stack Temperature (Degree R)	657.5	627.3	660.1	604.1	589.1
Average Outside Air Temperature During Run Hours (Degree F)	66.0	65.8	66.5	66.1	66.3
Average Outside Air Temperature During Run Hours (Degree R)	525.6	525.5	526.2	525.8	525.9
Average Combustion Air Temperature (Deg F)	63.2	63.0	60.4	59.0	59.9
Q (Stack Effect Draft Flow Rate) ft^3/s	3.4	3.1	3.4	2.7	2.5
Q (Stack Effect Draft Flow Rate) cfm	205.2	184.6	206.3	164.9	150.0
Off-cycle hours / year (Hrs On - FLRH)	2130.0	2210.9	1964.5	2133.2	2156.7
cubic feet / year of air required for combustion	6,844,698	7,104,681	3,438,073	3,733,293	3,774,437
cubic feet / year of combustion air due to stack draft effect	26,220,529	24,489,081	24,319,412	21,109,678	19,408,765
Btu / yr required for combustion air	16,582,153	13,386,402	8,664,721	5,736,206	4,723,892
Btu / yr required for combustion air due to stack draft effect	63,522,576	46,141,508	61,290,419	32,435,022	24,291,018
Losses per year due to stack effect (btu/yr)	46,940,422	32,755,106	52,625,698	26,698,817	19,567,126
Savings %	0.0%	14.1%	-5.7%	20.2%	27.3%

The pictures below show the original steam boiler flue on the left and newly installed steam boiler and stack on the right.

d. Air Removal

Each heating cycle has a "warm-up" time associated with it. As the distribution system was converted from single pipe steam to the vacuum system there is a significant difference in the duration of the preliminary cycle. In all cases, the radiators operating as an SPS system took much longer to receive steam and get up to temperature.

As vented air and water vapor will technically transfer to the space within the building's shell, only stack energy lost attributed to increased run time was determined to be "energy savings." A breakout of these savings may be seen in the following six (6) tables. Each of the radiators had their preliminary heating cycle characteristic measured for each of the five (5) testing scenarios.

Upon review, it is evident that radiators connected to the SPS system take much longer to get up to temperature. The table below shows the average time the boiler needed to fire before the radiators started to get warmer than the ambient conditions. It is believed that most of the savings related to the warm up time is directly related to the elimination of the air vents.

Average Heat-up Time (Hours)					
Radiator	Old Boiler - Single Pipe Steam	Old Boiler - Vacuum System	New Boiler - Single Pipe Steam	New Boiler - Vacuum System	New Boiler - Balanced Vacuum System
Living Room	0.62	0.15	0.46	0.13	0.21
Kitchen	0.35	0.14	0.24	0.12	0.19
Bedroom #1	0.41	0.16	0.31	0.13	0.21
Bedroom #2	0.48	0.17	0.33	0.13	0.20
Office	0.50	0.18	0.38	0.15	0.23
Dining Room	0.47	0.15	0.44	0.13	0.21

The following pages break out the energy savings associated with each radiator. Predicted % fuel savings are solely based on the fuel attributed to warming up that specific radiator.

The air vents in single pipe steam (SPS) play a vital role in the operation of the heating system. Each radiator as well as the end of the main supply line has an air vent that performs three functions every cycle. When a cycle begins and steam begins to enter the system, the air vent must open in order to allow the air to be pushed out of the radiator by the steam. Once steam has filled the radiator, the air vent must close to prevent steam loss. Once the heating cycle ends, the air vent must then be opened to allow air back into the system. This is important to break the vacuum caused by condensing steam. If the vacuum isn't broken when the steam enters the system during the next heating cycle, water hammer can occur and may cause damage to the system. The air vents also perform the important function of closing if the radiators flood.[8]

Air vents are most likely to waste energy if they are clogged. Clogging occurs through use over time. Since the system is open to air, rust and mineral deposits build up in the system. When the system is venting, small flakes and particles can build up in the holes of the vent.[9] Over time, these deposits can clog up the air vents, reducing the venting capacity. This affects the efficiency because the time it takes for the air to be removed from the system is proportional to the time heat is emitted by the radiators. Therefore, all of the energy used by the boiler during the time attributed to the inefficiency of the venting would be considered wasted energy.

VIII. Report Summary

The Vacuum Steam Heating system, as designed and implemented by Applied Engineering Consulting, appears to save a significant amount of natural gas with only a minor electric penalty. The savings range from as little as 7.7% savings up to 50.2% savings, depending on what the test scenario was. Based upon RISE Engineering's industry experience, a customer would most likely pursue the options which do not require steam boiler change out (retrofit). Using this scenario as a basis for savings a customer could expect, if upgrading from single pipe steam to the VSH system, between 20 to 28% fuel savings. The VSH system is theoretically infinitely scalable, with the only limiting factor being the size of the vacuum pump system required to hold the system at the required negative 24 inches of mercury.

Further testing, cost analysis, and code review should be performed to determine if the product is fully cost effective. In this test case, the customer did not use their existing high mass cast iron steam radiators for the vacuum system but rather low mass replacement units. While this is acceptable at the customer's residence, the capital cost to upgrade a facility with a completely new radiation system could be cost prohibitive. Beyond the potential cost issues, there was no testing performed to determine the efficiency gain by utilizing low mass radiators versus the high mass cast iron units.

There are alternatives to luxury steam radiators utilized in retrofit at a fraction of cost. Hot water panel radiators could potentially be utilized for vacuum heating after some modifications. Another valid option is cast aluminum steam radiators commonly used in Europe. Aluminum radiators' life span, warrantied to 10 years, can be exceeded significantly when operated under a vacuum.

If a customer decides to forgo replacement of their cast iron radiators their savings could be significantly different from the test data acquired here. Further, a building and plumbing code review would need to be performed to ensure that the methodologies utilized to operate the test system are code compliant.

If you have any questions with the material presented in this report please contact Jean-Paul Vandeputte at RISE Engineering by calling 800-843-3636 or by email at JPVandeputte@Thielsch.com.

Recommendations made in this report are based on engineering estimates and third party information. Costs and saving are not guaranteed. It is recommended that the customer obtain a proposal and firm price from a qualified contractor for recommended measures before making final decisions about a course of action. Any change in the measure, equipment size or efficiency may change or eliminate the estimated fuel savings.

IX. Appendices

a. Pulse Data to Therm Conversion

Applied Engineering Consulting installed a pulse recorder on the Elster gas meter. This pulse recorder would generate a pulse that was recorded into the data acquisition system. A pulse would be generated each time the magnetron in the pulse meter sensed that the gas meter had recorded 0.05 m^3 of natural gas had been consumed by the boiler. This was converted into therms to ensure that the pulse meter was recording data that would match what National Grid was billing the customer for gas consumed. The meter that National Grid was generating bills for served the entire apartment including the boiler and other gas equipment, while the secondary meter that was being monitored was an additional unit reading only consumption by the boiler. The National Grid bills can be seen below; in particular we are concerned about March 2014 (February 5th through March 7th).

Jun 2013	Jun 10,2013	35	25

March's bill was for 202 therms of natural gas. Since the customer typically consumes around 25 therms of natural gas during the summer months (a base line consumption where the boiler should not be running) the heating only consumption for the March bill should be around 175 therms of natural gas. The pulse output data, which does not include 8 days, is shown below.

	Number of Clicks from daily summary sheets	Therms Consumed based on .05m3 per pulse Therms = ((Pluse count)*0.05m^3)*0.36 Therm/m^3	m^3 consumption based upon pulse data

3/26/2014	185	3.33	9.25
3/27/2014	176	3.168	8.8
3/28/2014	76	1.368	3.8
3/29/2014	64	1.152	3.2
3/30/2014	150	2.7	7.5
3/31/2014	159	2.862	7.95
4/1/2014	229	4.122	11.45
4/2/2014	77	1.386	3.85

Less the 8 days that do not have data, the boiler consumed 134 therms of natural gas. When you utilize the average natural gas consumption per day to populate in the missing cells (Average = 5.83 Therms/Day) the total consumption by the boiler becomes 180 therms. Since 180 therms + 25 therms = 205 therms, RISE Engineering is led to believe that the pulse meter was recording data accurately, and that the correct conversion value from Pulse counts to actual consumption is $0.05m^3$ of natural gas.

b. Costing Information

The project costs are as show below. These costs were supplied by Applied Engineering Consulting.

Boiler		$3,000.00
installation		$1,850.00
	Subtotal	$4,850.00

Plumbing		
lines from basement to 2nd floor		$1,500.00
lines in basement		$800.00
	Subtotal	$2,300.00

Materials		
fittings		$800.00
tubing		$180.00
Insulation		$330.00
	Subtotal	$1,310.00

Radiators	$5,200.00
Controls	$474.00
Vacuum pump	$395.00

Total Project Cost	$14,529.00

The two major project types that could be seen for this type of installation is to either; convert an existing steam system to a VSH which would cost $9,679 (does not include cost of new boiler), or to convert an existing system to VSH and add a new boiler too $14,529. Utilizing the predicted savings from the report a simple pay back analysis was performed.

System Comparison	Predicted Consumption (Therms)	Cost of gas at $1.15/Therm	Savings ($)*	System Cost	Simple Payback (Years)
Old Boiler - Single Pipe Steam	1,004	$1,154.99	$189.08	$4,850.00	25.65
New Boiler - Single Pipe Steam	840	$965.91			
Old Boiler - Single Pipe Steam	1,004	$1,154.99	$277.84	$9,679.00	34.84
Old Boiler - Vacuum System	741	$852.61			
Old Boiler - Single Pipe Steam	1,004	$1,154.99	$507.90	$14,529.00	28.61
New Boiler - Vacuum System	541	$622.55			

*Penalty for increased electric consumption included

Based on the simple paybacks for this specific facility the projects would not pass a National Grid Benefit Cost Ratio (BCR) screening. A larger client could potentially generate the savings necessary to offset the project costs with their savings.

c. Daily outdoor average temperature

Hour of the Day	Average Temperature	Average Light Intensity (Lumens)	Fuel Consumption (Therms)

Cadmus thanks Keith Miller and Eliza Davis of National Grid and Peter Klint of Eversource Energy (formerly Northeast Utilities). We also thank the National Grid customers who volunteered to participate in this study. These participants volunteered their homes for our testing and provided thoughtful feedback that has been an integral part of this evaluation.

We also thank the contacts for each thermostat manufacturing company, Keyes North Atlantic, Inc., and Steve Carvelli for providing their industry knowledge and expertise to support this evaluation.

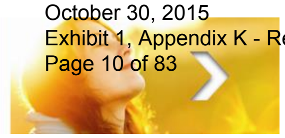
Important Considerations

The services and analysis provided in this report do not constitute or imply any endorsement by Cadmus for any product, process, manufacturer, or seller. Cadmus makes no warranty, express or implied, of merchantability or fitness for a particular purpose. Cadmus assumes no liability for any product and is not responsible for any decisions or use of any products in any way connected with this report.

The intention of this evaluation is to identify and examine potential thermostat issues that National Grid and Eversource Energy (the Companies) may consider when designing a large-scale program. When interpreting the results, we caution readers to keep in mind these important points:

- Findings are based on one thermostat installation in one home for each thermostat model;
- For the original seven thermostats, the space temperature data collection period took place over a two to three week period in February and March 2014, starting immediately after the thermostat installation. The data collection period for the three additional thermostats took place between November 2014 and March 2015;
- It is normal for the space temperature to vary up to three degrees above and below the thermostat setpoint (this is termed the temperature differential);
- A variety of factors impact how well a thermostat can regulate space temperature, including home insulation type, level of solar heat gain, and HVAC system type; and
- All ten thermostats have propriety algorithms that use feedback (which may include indoor/outdoor temperature, target setpoint, historical HVAC system run time) to adjust HVAC system run time; therefore, thermostat performance may vary over time and under different weather conditions.
- Throughout the report, the thermostat models are listed in the order the evaluation team tested them.



This page left blank.

CADMUS

Executive Summary

Utility rebate programs for programmable thermostats have been around for decades, but recent evaluations have shown low energy savings realization rates due to complex user interfaces and complicated settings options. In response, a new generation of user-friendly, Wi-Fi thermostats has entered the market to simplify programming and controlling a thermostat.[1] Many new thermostats also have energy-savings options that use algorithms to optimize the thermostat setpoints for both comfort and energy-efficiency.

National Grid and Eversource Energy (the Companies) are in the process of planning a large-scale Wi-Fi thermostat rebate program across their territories in Massachusetts and Rhode Island. The Companies solicited proposals from thermostat manufacturers interested in participating in the program and selected a short list of nine thermostat models for further research. Table 1 lists these thermostat models in the order they were tested.

Table 1. Selected Thermostat Models*

Make and Model	Abbreviation
Original Test Group	
Nest Learning Thermostat	Nest
Honeywell Wi-Fi Smart Thermostat RTH9580WF	HW
Ecobee Smart Si	ESS
Ecobee Smart	ES
EcoFactor	EF
Carrier ComfortChoice Touch	CCCT
Building 36 CT100	B36-CT
Additional Test Models	
Honeywell Lyric Thermostat	Lyric
Building 36 Intelligent Thermostat	B36-IT
Ecobee3	EC3

*Thermostat models are presented in the order they were tested. Cadmus investigated the seven thermostats in the original test group from February to April 2014, then completed tests for three additional thermostat models from November 2014 to March 2015.

In February 2014, the Companies engaged Cadmus to assess the selected thermostats in these areas:

- Ease of thermostat installation,

[1] In 2008, the EPA made it a requirement that customers "be able to change the settings on the programmable thermostat with little difficulty" for the programmable thermostat to be eligible for the ENERGY STAR® program.

- User experience and satisfaction, and
- Space temperature of participant homes.

Cadmus researched the features, functions, usability, and price of the ten selected thermostats and developed an assessment approach for each category. For each thermostat, we reviewed user manuals and other available manufacturer documentation and installed the thermostat in the home of a volunteer participant.

To assess the ease of installation, we developed an installer survey to document the installation process and findings for each thermostat. We installed and tested each of the ten thermostats in the homes of ten National Grid customers in Massachusetts. During the installation, we documented the process and any issues that occurred.

To assess the user experience and satisfaction, we distributed a customer survey at the conclusion of the 2-3 week study period.

To assess the accuracy of each thermostat in matching the space to the temperature setpoint, we installed temperature loggers next to the thermostat and compared our measured space temperature data to the programmed setpoint schedule over the duration of the study.

Summary of Findings

Table 2 summarizes the key findings for each thermostat. Rating are based on a review of product documentation and a single installation (performed by the Cadmus installer) for each thermostat model. The thermostat models are presented in the order they were tested.

CADMUS

Table 2. Summary of Thermostat Ratings (n=1 for each thermostat)*

Criteria	Nest	HW	ESS	ES	EF	CCCT	B36-CT	Lyric	B36-IT	EC3
Retail Price	$249	$289.95	$179.95	$276.38	N/A	N/A	$185	$199.99	$249	$249
Wholesale Price	N/A	N/A	N/A	N/A	~$125	~$136	$70-100	N/A	$70-100	N/A
Monthly Service Fee	N/A	N/A	N/A	N/A	$5-9	N/A	$1.50	N/A	$1.50	N/A
Ease of Installation										
Ease of Installation[A]	★★★	★★	★★★	★	★★★	★★	★★	★★★	★★	★
Total Time to Install[B]	43 min	90 min	40 min	103 min	40 min	160 min	70 min	28 min	30 min	111 min

User Experience										
Customer Usability Rating	Somewhat difficult	Easy	Easy	Easy	Difficult	Easy	Easy	Easy	Easy	Easy
Space Temperature (Based on 2-week data collection in February and March 2014)										
Space Temperature Range when User is Home/Awake	Normal: Space tends to be 0–2°F warmer than setpoint	Normal: Space tends to be 0–3°F warmer than setpoint	Cool: Space tends to be 0–4°F cooler than setpoint	Cool: Space tends to be 0–4°F cooler than setpoint	Cool: Space tends to be 0–4°F cooler than setpoint	Warm: Space tends to be 2–5°F warmer than setpoint	Normal: Space tends to be 0–3°F cooler than setpoint	Normal: Space tends to be within 0–1°F of setpoint	Normal: Space tends to be 0–2°F warmer than setpoint	Warm: Space tends to be 0–4°F warmer than setpoint

* The thermostat models are listed in the order they were tested.

[A] Ratings are based on a standard installation checklist developed by Cadmus. A three-star rating is the maximum rating.

[B] Total time to install includes time to install thermostat, program setpoints, and set up Wi-Fi connection. It does not include time to install new wiring, if applicable.

[C] Needed at interface, but not at thermostat. For additional detail, see Installation Assessment section.

[D] Recommended installer applies to thermostat installation, not wiring installation. If new wire must be installed, Cadmus recommends an HVAC technician or electrician perform the installation.

Easiest to Install

The Nest and Lyric models received the best ratings overall for ease of installation. These thermostats took less than 45 minutes install, received the maximum three-star rating from the installer for ease of installation, and do not require a 24 Volt (AC) common wire (C-wire).[2]

Although the Ecobee Smart Si and EcoFactor took only 40 minutes to install and received three-star ratings for ease of installation, these thermostats require a C-wire. This requirement limits the compatibility of these thermostats for many homes in New England, where Cadmus estimates less than one quarter of customer homes have a C-wire. In a large-scale program, customers without a C-wire may need to install new wiring to install thermostats that depend on a C-wire. For homes that do not have an existing C-wire or for which adding a C-wire is expensive, HVAC power extenders exist. The Ecobee3 is the only thermostat in the test group that comes with a power extender. Although the power extender makes the Ecobee3 compatible in most Massachusetts and Rhode Island homes, the installer gave it a one-star rating for ease of installation because the installation instructions for the power extender were not clear. For more information on wire extenders for other thermostat models, see Appendix A.

The Nest, Lyric, and Building 36 Intelligent thermostats are the most compatible with MA and RI homes because they do not require power from a C-wire. Instead, these thermostats use a standard two-wire setup, which is the minimum wiring requirement for any home thermostat. The Nest and Lyric draw power from the W-wire or Y-wire if no C-wire is available. In addition, the Lyric uses a AAA Lithium battery for initial start-up and to supplement the power stealing. Both Building 36 thermostats (CT100 and Intelligent) use four AA batteries. Although the Ecobee3's included power extender kit makes it compatible with many homes in Massachusetts and Rhode Island, it requires a minimum of three wires between the thermostat and HVAC unit.

The Building 36 models and EcoFactor require the installation of a Gateway for internet/cellular connectivity. Building 36 recommends a professional install their thermostats and Gateway.

Most User-Friendly

All thermostats except the Nest and EcoFactor received an overall rating of "easy" to use by the participant. Participants gave the Nest and EcoFactor overall ratings of "somewhat difficult" and "difficult" to use, respectively. The Nest was rated as "somewhat difficult" to use because the participant found it difficult to navigate the menu to program the setpoints. The installer noted that there was no copy/paste function—setpoints for each day had to be copied manually. Participants with

[2] Cadmus estimates that less than one quarter of homes in MA and RI have a C-wire. For more details on the C-wire, see the Installation Assessment section and Appendix A.

the Ecobee Smart and Building 36 CT100 also commented that programming their thermostat was "somewhat difficult" or "difficult" to do, but still gave overall ratings of "easy."

The EcoFactor was rated as "difficult" to use because the participant found it challenging to change the schedule and manage comfort level.

Eight of the nine participants who used the mobile application rated the application as "easy" to use and three of the six participants who used the web account found it "easy" to use.[3] The participant with the Ecobee Smart Si's rated the web account as "somewhat difficult" to use, reporting there were minor display quirks and some confusing wording that made it challenging to use. The participant with the Carrier ComfortChoice Touch thermostat rated the web account as "difficult" to use, citing that he or she had some difficulty setting up the account, possibly due to having a duplicate account.

Most Accurate Space Temperatures

Among the original seven thermostat models, our comparison of setpoints and measured space temperature show that the home with the Nest thermostat most closely matched the space temperature for the home/awake setpoint (which maintained temperature within two degrees of the scheduled setpoint when the participant was home/awake).[4] In the additional testing round, this result was surpassed by the home with the Lyric thermostat, which consistently maintained temperature within one degree of the scheduled setpoint when the participant was home/awake.

In five homes, the average difference between space temperature and setpoint exceeded three degrees. The Ecobee Smart Si, Ecobee Smart, and EcoFactor thermostats tended to keep the home temperature within four degrees below the setpoint. The Carrier ComfortChoice Touch kept the home temperature between two and five degrees above of the setpoint, while the Ecobee3 kept the home temperature within four degrees above the setpoint.

All ten of the thermostats use algorithms to regulate the temperature of the home. These proprietary algorithms vary among thermostat models. The algorithms may take into account current outdoor temperature, weather forecast, equipment type, temperature difference between current indoor temperature and setpoint, and equipment protection (to limit the number of times the compressor cycles on and off). Algorithms use these data to adjust the HVAC system "cut-in" time—the time at which the HVAC system begins to pre-heat or pre-cool the home. Because these algorithms use feedback to adjust HVAC system run time, thermostat performance may vary over time and under different weather conditions. In addition to using an algorithm, the Nest and Ecobee3 use an occupancy sensor to determine when users are away or sleeping and adjusts setbacks for these periods. The Nest's occupancy sensor is located at the thermostat, whereas the Ecobee3's occupancy sensor can be

[3] The participant with the Ecobee Smart Si thermostat did not use the mobile application enough to rate it.

[4] The home/awake setpoint is the temperature setting when the user is home and awake (as opposed to home and asleep, or away).

installed in any room. Ecobee3's occupancy sensor also measures indoor temperature. The thermostat uses the indoor temperature information to adjust the heating and cooling. Users can install remote sensors in multiple rooms.

Best for Data Collection

The Ecobee Smart Si, Ecobee Smart, and Ecobee3 thermostats have the most data available. These thermostats enable the user to view and download a 15-month history of HVAC system run time and indoor temperature data from a web account. The web account also shows hourly, daily, monthly, and weather-adjusted run time (hours/degree day).The user can also view monthly reports that show total system run time, average setpoint, energy saved, and comparisons to the state average.

The EcoFactor and Carrier ComfortChoice Touch thermostats also show a full history of system run time and indoor temperature. With the Carrier ComfortChoice Touch, users can also download the last 30 days of data. The Nest shows users the last ten days of run time history and when the user demonstrated energy efficient behavior.

CADMUS

Introduction

Cadmus conducted this study to support the design of residential energy-efficiency programs in Massachusetts. In this study, we assessed the installation process, user experience, and space temperature patterns for a total of nine Wi-Fi thermostats. We completed testing for seven thermostats (the original testing group) from February to April 2014 and then completed testing for three additional thermostats (the additional testing group) in November 2014 to March 2015.

Background

National Grid and Eversource Energy (the Companies) in the process of planning a large-scale Wi-Fi thermostat rebate program across its territory in Massachusetts and Rhode Island. The Company solicited proposals from thermostat manufacturers interested in participating in the program. After reviewing the manufacturer proposals, the Companies selected a short list of ten thermostat models for further research.

In February 2014, the company engaged Cadmus to assess the selected thermostats in these areas:

- Ease of thermostat installation,
- User experience and customer satisfaction, and
- Space temperature of participant homes.

The Companies plan to use the results of this assessment for the design of its thermostat program.

Thermostats

Table 3 shows pictures of the thermostat models the Companies selected for this study.

Table 3. Thermostats Included in Study*

Thermostats		
 Nest Learning Thermostat (Nest)	 Ecobee Smart Si (ESS)	 EcoFactor (EF)
 Honeywell Wi-Fi Thermostat RTH9580WF (HW)	 Ecobee Smart (ES)	 Carrier ComfortChoice Touch (CCCT)
 Building 36 CT100 (B36-CT)	 Honeywell Lyric Thermostat** (Lyric)	 Building 36 Intelligent Thermostat** (B36-IT)
 Ecobee3** (EC3)		

* The thermostat models are listed in the order they were tested.

** Indicates thermostats in the additional testing group.

Thermostat Review

Cadmus reviewed product documentation to assess the features of each thermostat. All thermostats are Wi-Fi connected and have a web account and mobile application to remotely monitor and control the thermostat except for the Lyric thermostat, which does not have a web account.

Methods

Cadmus created a features list and score card to assess and compare the characteristics and performance of each thermostat. Features included in our checklist include: thermostat characteristics, retail value, mobile application features, and web account features. To assess each thermostat, we collected information from the thermostat user manuals, the Cadmus thermostat installer, and study participants.

Pricing

To determine each thermostat's value, we referred to the manufacturers' websites and representatives. Readers should note that retail pricing is not indicative of what a utility might pay per unit when purchased in volume and the listed wholesale values may also vary depending on volume. Additional costs to consider when purchasing in bulk include annual fees and front loading of costs.

For the Nest, Ecobee3, and both Honeywell models, information was directly available on the manufacturers' websites.

For the Ecobee Smart Si and Ecobee Smart thermostats, the Ecobee website refers potential buyers to a list of preferred contractors for professional installation. We contacted three Massachusetts contractors and received quotes for installed costs from one; these quotes are listed in the footnotes of Table 4. We estimated the retail values for the two Ecobee models from Amazon.com.

The EcoFactor and Carrier ComfortChoice Touch are not available for retail sale, but are available wholesale to contractors. We spoke with representatives to get estimated wholesale costs, but readers should note that these quotes may vary depending on volume.

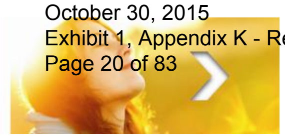
The Building 36 thermostats are available for both retail and wholesale; however, access to their cloud-based platform is only available wholesale to contractors. We listed retail and estimated wholesale values for these thermostats based on the estimated prices quoted by manufacturer representatives.

Web and Mobile Accounts

To assess the performance of web accounts and mobile applications, we obtained participants' usernames and passwords and browsed their accounts.

Results

The following tables compare each thermostat's features.



Thermostat

Table 4 shows the key characteristics of each thermostat.

Table 4. Key Thermostat Characteristics*

Criteria	Nest	HW	ESS	ES	EF	CCCT	B36-CT	Lyric	B36-IT	EC4
Color screen	X	X	X	X	-	X	-	X	-	-
Touchscreen	-	X	-	X	-	X	X	X	-	X
Programming Capabilities	7-day	7-day	7-day	7-day	5-2	7-day	7-day	7-day	7-day	7-day
Warranty (years)	2	1	3	3	1	1	1	2	1	3

* The thermostat models are listed in the order they were tested.

All of the thermostat models except for the EcoFactor and Building 36 Intelligent Thermostat have either color screens or touchscreen displays to make interacting with the thermostat user-friendly. The Honeywell, Ecobee Smart Si, EcoFactor, Carrier ComfortChoice Touch, and Building36 CT100 thermostats all have prominent buttons for adjusting the current setpoint. The Nest and Lyric have a spinning dial for adjusting the setpoint. The Ecobee Smart and Ecobee3 thermostats have a sliding button on the home touchscreen.

All thermostats, except for the EcoFactor, can program a different schedule for each day of the week. The EcoFactor has 5-2 programming capabilities, allowing for separate schedules on weekdays and weekends.

With a three-year warranty, the three Ecobee thermostat models offer the longest warranties among the thermostats tested in this evaluation. The remaining thermostats offer a one-year warranty, with the exception of Nest and Lyric, which offer two-year warranties.

Pricing

Thermostat values vary greatly depending on whether the manufacturer offers retail or wholesale values, the thermostat is self-installed or professionally installed, or if there is a monthly service fee or not (Table 5). Readers should note that retail pricing is not indicative of what a utility might pay per unit when purchased in volume and the listed wholesale values may also vary depending on volume. Additional costs to consider when purchasing in bulk include annual fees and front loading of costs.

Table 5. Thermostat Prices*[A]

Model	Value (April 2014)	Value (February 2015)	Source
Nest	$249 (retail)	$249 (retail)	Nest.com (Accessed 4/14/2014, 2/27/2015)
HW	$249 (retail)	$189.95 (retail)	Honeywell.com (Accessed 4/14/2014) Amazon.com (Accessed 2/27/15)
ESS	$270 (retail) $395 (when installed by Ecobee preferred contractor)	$179.95 (retail)	Amazon.com (Accessed 4/14/2014, 2/27/15)
ES	$454 (retail) $475 (when installed by Ecobee preferred contractor)	$276.38 (retail)	Amazon.com (Accessed 4/14/2014, 2/27/15)
EF	~$125 (wholesale) Monthly service: $5-9 (wholesale)	~$125 (wholesale) Monthly service: $5-9 (wholesale)	EcoFactor representative
CCCT	~$136 (wholesale)	~$136 (wholesale)	Carrier representative
B36-CT	$249 for first thermostat[B] (retail) $99 for each additional thermostat (retail) $70-100 (wholesale)	$185 for first thermostat[C] (retail) $90 for each additional thermostat (retail) $70-100 (wholesale) Monthly service: $1.50 (wholesale)	Building 36 representative
Lyric	n/a	$199.99 (retail)	Amazon.com (Accessed 2/13/15)
B36-IT	n/a	$249 for first thermostat[D] (retail) $99 for each additional thermostat (retail) $70-100 (wholesale) Monthly service: $1.50 (wholesale)	Building 36 representative
EC3	n/a	$249 (retail)	Ecobee.com (Accessed 3/24/15)

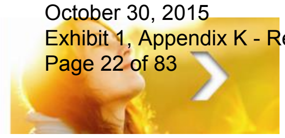
* The thermostat models are listed in the order they were tested.

[A] Retail pricing is not indicative of what a utility might pay per unit when purchased in volume. When purchased in volume, additional costs to consider include annual fees and front loading of costs.

[B] Breakdown of retail price for first Building 36 CT100 thermostat includes $99 for thermostat and $150 for Z-wave Gateway device for internet connectivity. Only one Gateway is needed for multiple Building 36 internet-connected devices.

[C] Breakdown of retail price for first Building 36 CT100 thermostat includes $90 for thermostat and $95 for Z-wave Gateway device for internet connectivity. Only one Gateway is needed for multiple Building 36 internet-connected devices.

[D] Breakdown of retail price for first Building 36 Intelligent Thermostat includes $99 for thermostat and $150 for cellular Gateway device. Only one Gateway is needed for multiple Building 36 devices.



Mobile Application

Table 6 (next page) lists the mobile application features for each thermostat.

Table 6. Thermostat Mobile App Features*

Mobile App Features	Nest	HW	ESS	ES	EF	CCCT	B36-CT	Lyric	B36-IT	EC3
Check Indoor Temperature	X	X	X	X	X	X	X	X	X	X
Check Outdoor Temperature	X	X	X	X	X	X	-	X	X	X
Adjust Setpoint	X	X	X	X	X	X	X	X	X	X
View Schedule	X	X	-	-	X	X	-	X	X	X
Program Schedule	X	X	-	-	X	X	-	X	-	X
Check Run time History	10 days	-	-	-	-	Full history	-	-	-	-
Check Indoor Temp History	-	-	-	-	-	Full history	-	-	-	-
Change Heat/Cool Mode	X	X	X	X	X	X	X	X	X	X
Change Fan Mode	X	X	X	X	X	X	-	-	-	X
Set To Away/Vacation Mode	X	-	X	X	X	X	-	X	-	X
View Weather Forecast	-	5 day	5 day	5 day	-	-	-	1 day	Current	5 day
Other Noteworthy Features: Nest: Can view when/why user demonstrated energy-efficient behavior B36-CT: Can view history of setting changes and alerts. Available home monitoring add-ons: plug load meters, light controls, lock controls. Lyric: Shortcuts for custom thermostat settings. Geofencing* tied to smart phone and app. Can define unique boundaries which trigger automatic changes in thermostat settings when smart phone enters in or out of the defined range. Auto setting option which accounts for temperature, humidity, and outdoor weather to determine most comfortable settings. Message notifications about unusual temperature swings, hardware issues, and other unexpected events. B36-IT: Can view a limited history (50 events) of setting changes and alerts. Available home monitoring add-ons: plug load meters, light controls, lock controls. EC3: Can set up reminders when HVAC, air handler filter, or UV lamp needs maintenance or to be replaced. Can create alerts when temperature and humidity is below or exceeds defined thresholds. Vacation mode where homeowner can set unique start and end date/time.										

* The thermostat models are listed in the order they were tested.

All ten thermostats feature mobile applications that enable users to check current indoor and outdoor temperatures, adjust setpoints, and change from heating to cooling mode. The Nest, Honeywell, EcoFactor, Carrier ComfortChoice Touch, Lyric, and Ecobee3 thermostats also let the user view and edit the setpoint schedule.

The Nest and Carrier ComfortChoice Touch mobile applications both provide features for checking performance history. The Nest shows users ten days of HVAC system run time history, when the user demonstrated energy efficient behavior and why. The Carrier ComfortChoice Touch gives users access to a full history of HVAC system run time and indoor temperature.

The Building 36 CT100 mobile application has the least number of features. The application only lets the user check indoor temperature, adjust the setpoint, and change from heating to cooling mode. The application does, however, have some unique add-ins for other home automation systems that can control lights and monitor appliance energy consumption, at an extra cost.

Web Account

Table 7 (next page) lists the web account features for each thermostat.

All thermostats except the Lyric come with a web account that enables the user to check current outdoor temperature and to check and adjust setpoints and schedules. Six of the nine thermostats that have a web account allow the user to view the HVAC system's run time history and/or indoor temperature history. For users who are especially interested in this kind of feedback on system performance, the Ecobee Smart Si, Ecobee Smart, Ecobee3, and Carrier ComfortChoice Touch thermostats enable users to download these data.

Other Noteworthy Features:

Nest: Can view when/why user demonstrated energy-efficient behavior

ESS: Shows hourly, daily, monthly run time AND weather-adjusted run time (hrs/degree day) View monthly reports with total system run time, average setpoint, energy saved, compare to state average.

ES: Shows hourly, daily, monthly run time AND weather-adjusted run time (hrs/degree day). View monthly reports with total system run time, average setpoint, energy saved, compare to state average

EF: Can set up estimated savings chart

CCCT: Geofencing through Energy Hub website.

B36-CT: Geofencing

Available home monitoring add-ons: plug load meters, light controls, lock controls.

B36-IT: Can view history of setting changes and alerts.

Available home monitoring add-ons: plug load meters, light controls, lock controls

Can program separate unique Heat and Cool schedules, and settings for extreme temperatures.

Can disable local thermostat controls.

Can receive alerts when target temperature has changed, when temps exceed thresholds, and when thermostat modes are changed

EC3: Can monitor and view history of heating and cooling schedule, sensor activity, temperature and humidity levels for both indoor and outdoor, and weather impacts.

Can set up reminders when HVAC, air handler filter, or UV lamp needs maintenance or to be replaced.

Can create alerts when temperature and humidity is below or exceeds defined thresholds

Quick Change feature allows user to immediately program home and away settings and override existing schedule.

Vacation mode where homeowner can set unique start and end date/time.

* The thermostat models are listed in the order they were tested.

Installation Assessment

Cadmus installed each thermostat in a participant household and completed an installer scorecard to document and assess the installation process for each thermostat.

Methods

Installer Score Card

Cadmus created the *Installer Score Card* to assess the requirements and ease of installation for each thermostat model and, at minimum, to address these elements:

- Ease of installation
- Ease of wiring
- Clarity of instructions provided
- Time frame needed for each installation including programming and Wi-Fi setup
- Skills required by the installer and if device can be installed by homeowner or requires HVAC technician and/or electrician
- Common issues or risks (if any) that may occur during installation

Installations

The Companies provided Cadmus with the names and contact information for eight participating homeowners. The ninth participant was a Cadmus employee. We reviewed the installation requirements with each participant to ensure all information was available to complete the thermostat installation and Wi-Fi setup.

A Cadmus electrician installed the seven thermostats in the original thermostat group between February 25 and March 11, 2014. The same Cadmus installer completed installations for the three additional thermostats between November 2014 and March 2015. During each installation, we connected the thermostats to the homeowners' Wi-Fi networks and rated the thermostat and installation process according to the Installer Score Card.

We replaced two of the original seven participants because their thermostat installations would have required extensive wiring that was out of the scope for this study.

Results

Table 8 presents the key thermostat installation findings from the Installer scorecard.

Table 8. Thermostat Installer Ratings*

* The thermostat models are listed in the order they were tested.

[A] Time to install does not include time it took to install a C-wire, if applicable.

[B] Detailed instructions were clear, but there was some key information on wiring was missing from Quick Start Guide.

[C] Not included.

[D] Recommended installer applied to thermostat installation, not wiring installation. If new wire must be installed, Cadmus recommends an electrician.

[E] Cadmus recommends an HVAC technician only if the Power Extender Kit needs to be installed.

[F] Minimum wiring requirement for connecting thermostat to heating system only.

[G] Wires needed from HVAC unit to interface, but not to thermostat.

[H] The Lyric thermostat took only 1 minute to program because it uses a default schedule and then adjusts the schedule using geofencing and user prompts.

[I] The Ecobee3 thermostat took only 1 minute to program because the thermostat allowed the user to apply a single setpoint schedule across all days of the week.

CADMUS

Thermostat Installation

The Nest and Lyric models received the best ratings overall for ease of installation. These thermostats took less than 45 minutes install, received the maximum three-star rating from the installer for ease of installation, and do not require a 24 Volt (AC) common wire (C-wire).[5]

The Nest, Lyric, Building 36 CT100 and Building 36 Intelligent thermostats are the most compatible with Massachusetts and Rhode Island homes because the thermostats do not require a C-wire for power. Instead, these thermostats use a standard two-wire setup, which is the minimum wiring requirement for any home thermostat. Although the Nest and Lyric can use a C-wire for power, it is not required. If no C-wire is present in a Nest installation, the Nest draws power from the W-wire or Y-wire through a method commonly called "power stealing." In this setup, the thermostat uses the circuits that turn on and off the HVAC system to charge an internal battery. The thermostat can charge its battery regardless of the HVAC system status (on or off), but the available power is limited when the HVAC system is running. If there is an extended home power outage and the battery level gets low, the Nest will turn off the Wi-Fi to conserve power.[6,7,8] The Lyric uses a similar "power stealing" method they term "Phantom Power" to store power and uses a AAA Lithium battery for initial start-up and to supplement Phantom Power. Both Building 36 thermostats (CT100 and Intelligent) use four AA batteries.

Cadmus estimates that less than one quarter of homes in New England have an existing C-wire. In a 2013 Cadmus pilot program evaluation for Liberty Utilities (LU) of New Hampshire, only seven of 29 pilot program participants (24%) had a C-wire.[9] During recruitment for the LU study, 45 customers provided information about their HVAC system type and thermostat wiring in a survey. Of the 45 survey respondents, eight (18%) had a C-wire. Of the respondents with heating and air conditioning, 25% had a C-wire. Of the respondents with heating only, 14% had a C-wire.

For homes that do not have an existing C-wire or for which adding a C-wire is expensive, HVAC wire extenders exist. The Ecobee3 is the only thermostat in the test group that comes with a power extender. Although the power extender makes the Ecobee3 compatible in most Massachusetts and Rhode Island homes, the installer gave it a one-star rating for ease of installation because the installation instructions for the power extender were not clear. In addition, although the Ecobee3's included power extender kit makes it compatible with many homes in Massachusetts and Rhode Island, it requires a minimum of

---

[5] Cadmus estimates that less than one quarter of homes in MA and RI have a C-wire. For more details on the C-wire, see the Installation Assessment section and Appendix A.

[9] The Cadmus Group, Inc. Wi-Fi Programmable Thermostat Pilot Program Evaluation. 2013.

three wires between the thermostat and HVAC unit. For more information on wire extenders for other thermostat models, see Appendix A.

Although the Ecobee Smart Si and EcoFactor took only 40 minutes to install and received three-star ratings for ease of installation, these thermostats require a C-wire.

The Building 36 models and EcoFactor require the installation of a Gateway for internet/cellular connectivity. Building 36 recommends a professional install their thermostats and Gateway.

The Ecobee Smart, Ecobee3, and Carrier ComfortChoice Touch were the most challenging to install. Both took over an hour to install, not including the installation of new wiring.

In total, six of the ten participants needed new thermostat wiring installed in their home to make it compatible with the new thermostat. Table 9 (next page) lists the reasons each participant's home required the installation of new wiring.

Table 9. Reasons for Installing New Wiring*

Thermostat	Time to Install New Wire	Reason for Installing New Wires
Ecobee Smart Si	1 hour 45 minutes[A]	Thermostat required C-wire. In addition, new transformer was installed because voltage from existing transforming was not high enough (19 V rather than 24 Volt (AC)).
Ecobee Smart	1 hour 15 minutes	New wiring had to be installed to run to from HVAC unit to interface.
EcoFactor	1 hour	Thermostat required a C-wire.
Carrier ComfortChoice Touch	20 minutes	New wiring had to be installed to run to from HVAC unit to interface. In addition, because of age of zone control box, had to run wire from zone control box to an isolation relay and HVAC unit in order to get power for C-wire.
Building 36 CT100	5 minutes	This thermostat only requires two wires. However, the existing wires were too short to connect to thermostat terminals so the wires were extended.[B]
Ecobee3	1 hour	Thermostat required a C-wire so had to use included Power Extender Kit. This took longer than expected because the instructions were confusing.

* The thermostat models are listed in the order they were tested.

[A] Took 45 minutes to figure out how to get a C-wire wire from the boiler.

[B] Building 36 is developing an updated thermostat model. Improvements include centrally located terminal placements to reduce the length of wire needed to make terminal connections and the addition of an optional back plate to cover any footprint from an old thermostat. The new model is scheduled to be released in July 2014.

All ten thermostats are not compatible with electric baseboard or electric wall heating because they are 110 or 120 Volt (AC) systems, which are considered high voltage (also called line voltage) for residential thermostat applications. The smart thermostat can be used with high voltage systems only if an electrician installs a relay. Smart thermostats are compatible with electric baseboard heating as part of heat pump systems because the relay is built into the heat pump. Nest recommends potential users check their thermostat wiring for wire nuts or wire thicker than 18 gauge to see if they have a high voltage system. Figure 1 shows high voltage thermostat wiring with wire nuts.

Figure 1. Line Voltage Residential Thermostat Wiring

Source: diyadvice.com

Nest estimates the thermostat is compatible with 95% of low voltage systems. Of low voltage systems, the Nest is not compatible with direct vent furnaces known as millivolt systems. Figure 2 and Figure 3 show examples of wall-mounted and floor direct vent furnaces.

Figure 2. Wall-mounted Direct Vent Furnace

Figure 3. Floor Direct Vent Furnace

Programming of Thermostat Setpoints and Schedule

All thermostats except the Honeywell Wi-Fi Smart Thermostat (RTH9580WF) took 15 minutes or less to program. Although the Honeywell Wi-Fi Smart Thermostat took longer to program, the installer gave it three stars for the clarity of instructions, ease of programming, and unique user survey format. The survey asks the user questions about daily behavior to set up the program, making it more intuitive than some of the other thermostats.

The Carrier ComfortChoice Touch was one of the quickest thermostats to program, but the installer gave it only a rating of one star because its web interface was not user-friendly.

At one minute, the Lyric and Ecobee3 were the fastest thermostats to program. For the Lyric, this is because the thermostat uses a default schedule, then adjusts the schedule based on geofencing and user prompts. One downside to setting up the Lyric is that the installer had to use the customer's tablet or smartphone—they could not use their own tablet or smartphone. The participant with the Ecobee3 reported the programming only took one minute because the thermostat allowed him/her to apply their settings for one day across all days of the week.

Wi-Fi Set Up

All ten thermostats except for the Carrier ComfortChoice Touch took 30 minutes or less to set up the Wi-Fi connection. All but the Carrier ComfortChoice Touch, Ecobee Smart, Ecobee3 and Building 36 models received three-star ratings for ease of setup. The Carrier ComfortChoice Touch received a low rating because an installation code and MAC address were required from the thermostat to complete setup and the instructions did not explain this clearly. The Ecobee Smart received a low rating because some of the icons and terminology in the setup process were vague. The Ecobee3 received a low rating because it required a registration code and the instructions did not clearly explain where to find it.

The EcoFactor and Building 36 models had unique internet connection setups because neither required a username or password. Both of these thermostats communicate wirelessly to an interface that plugs directly into the homeowner's router.

Building 36 offers two models of Gateways for wireless communication. One Gateway communicates with the thermostat using Z-wave, while the other uses cellular data. For a secure connection, Building 36 recommends the user keep the Z-wave Gateway within 50 ft of the thermostat and the cellular Gateway within 100 ft of the thermostat. To extend the range between the Gateway and thermostat, users can install repeaters. Each repeater will add another 50 fit (Z-wave) or 100 ft (celluar) to the range. If a C-wire is present, this will also act as a repeater and extend the range.

Key Findings by Thermostat

Table 10 lists the thermostat installer's observations from the installation process. To model a typical homeowner installation experience, the installer did not receive training on the installation protocols for

CADMUS

each specific device. In a utility program, a program installer would typically undergo training on how to install each thermostat.

Table 10. Key Findings by Thermostat – Installation and Wi-Fi Setup*

Thermostat	Installer Findings
Nest Learning Thermostat (Nest)	• The packaging included a back plate in case old thermostat was larger than Nest. • Programming setpoints was very easy but required a new setting for each day—did not have a copy/paste function. • The thermostat included a built-in level to support installation
Honeywell Wi-Fi Smart Thermostat RTH9580WF (HW)	• The quick setup guide does not note that C-wire and B-wire are the same; noted only in detailed instructions. The typical homeowner may not know these are the same. • There was not much space behind thermostat for wires; therefore, installer must push excess wire into wall before installing mounting plate.
Ecobee Smart Si (ESS)	• The instructions do not mention that thermostat requires C-wire was needed; the installer must check each wiring diagram. • Installer tried to program settings from computer but this was not possible (instructions did not make this clear). The website was a bit confusing—need to "Add a Thermostat." • If no C-wire and do not want to install new one, Ecobee sells Power Extender Kit.
Ecobee Smart (ES)	• The wiring diagram was difficult to interpret with old furnace. • This was more than just a thermostat installation, since interface needed to be installed. • At least three wires are needed from furnace to interface and four wires from interface to thermostat if system is heating only. This participant's setup required nine wires from furnace to interface because of the location of their C-wire terminal and because they had heating and cooling. • It was not obvious that ⃠ icon meant "skip." • The screen timeout was too fast. • The website cursor was difficult to see—color too similar to background. • For "home type," there was no option for "single family." Chose "detached." • The website asks to rate contractor, but does not give option if contractor is not on list. • The thermostat screen had three lines across bottom that did not go away after resetting. • User cannot create program while thermostat is on hold. • The scrolling is finicky. • The factory setting on thermostat was for heat pump, but instructions do not mention this. It was difficult to find the setting to change the system type.
EcoFactor (EF)	• There were no instructions were included with the thermostat.
Carrier ComfortChoice Touch (CCCT)	• Because there was no C-terminal at the heating system, we had to install an isolation relay. • The factory setting was for heating *and* cooling and instructions did not mention heat-only system. It took some time to understand heat-only setup. • We needed two wires to thermostat, access to zone control box, and 24 Volt (AC) isolation relay. The zone control box connects to basement unit and isolation relay. • User needs install code and MAC address from thermostat in order to set up web account.

Thermostat	Installer Findings
Building 36 CT100 (B36-CT)	• There is minimal space for wires behind thermostat. • The terminals on top of thermostat rather than in center. Current wiring was not long enough to reach so wires had to be extended. • There are hardly any instructions on how to program setpoints. Could not program from thermostat—had to use PC. • Building 36 recommends professional installation of thermostats • Building 36 recommends the thermostat be within 50 ft of the Gateway in order to maintain a wireless connection. If the thermostat is more than 50 ft away from the Gateway, they recommend using a repeater.
Honeywell Lyric (Lyric)	• Installer needed to use customer's tablet or smartphone to program. • There are no paper instructions. We had to download app to program setpoints. • Using the app allowed user to customize instructions for wiring setup. • There is a rubber gasket for wires to enter thermostat, which stops wall draft. • Thermostat has a built-in level.
Building 36 Intelligent (B36-IT)	• User has to program on tablet or PC. It was a little difficult on the tablet. • Thermostat has a built-in level. • Building 36 recommends professional installation of thermostats. • Building 36 recommends the thermostat be within 100 ft of the Gateway in order to maintain a wireless connection. If the thermostat is more than 100 ft away from the Gateway, they recommend using a repeater. If the thermostat uses a C-wire, then it acts as a repeater (if you have multiple zones/thermostats throughout the house).
Ecobee3	• The instructions for using the power extender kit were very confusing • When using the Power Extender Kit, a minimum of three wires is needed between the thermostat and HVAC unit.

* The thermostat models are listed in the order they were tested.

Key Installation Problems

Two of the original seven participants had to drop out of the study because their thermostat installations would have required an electrician rather than HVAC technician. The reasons Cadmus recommends an electrician are described below.

Ecobee Smart Si

This thermostat requires a C-wire, but the original participant's thermostat only had two wires. Installing new wire would involve running wire through another tenant's basement space and through a finished ceiling. Cadmus recommends an electrician perform this wiring installation.

EcoFactor

The original participant had an air handler in attic for cooling and a forced hot water boiler in the basement. The thermostat required the installation of a C-wire, but accessing a C-wire terminal from either the cooling or heating unit would have required an electrician. The thermostat was located on the first floor. Running the C-wire from the boiler in the basement to the first floor would require drilling into a wall and risking drilling into a floor. Running the C-wire from the attic to the first floor would require going through finished space. Cadmus recommends an electrician perform this wiring installation.

User Assessment

Cadmus developed and conducted a survey to assess participants' experiences and satisfaction with their installed thermostat.

Methods

Cadmus developed a web-based survey to address the following aspects of the user experience:

- How participants programmed their setpoints
- How frequently participants overrode their setpoints
- What the participant liked and disliked about the thermostat
- How the participant used the web account and mobile application
- If the participant believes they will save energy without compromising quality
- If the participant would purchase the thermostat
- If the participant had problems with the thermostat

Two-and-a-half weeks after each thermostat installation, Cadmus distributed the survey to study participants. A copy of the survey is available in Appendix B.

Results

All ten participants completed the web-based customer survey. To see responses on how participants programmed their setpoints, see the results of the Space Temperature Analysis section. Key survey responses that address the remaining items are shown in Table 11. Additional participant feedback is included in Table 12 through Table 18.

Participant Feedback

Participant responses to key open-ended survey questions are shown in the following tables. The thermostat models are listed in the order they were tested.

Table 12. What do you like best about the thermostat? Please describe.

Thermostat	Comments
Nest	Easy to use, good mobile app, learning feature, ability to set away mode from phone, cool design.
HW	I like the fact that it is Wi-Fi, which allows for mobile access. Having a vacation mode is another huge plus.
ESS	The screen was easy to read.
ES	The usability and easy setup. I also like the smart phone app.
EF	The simplicity and easiness of adjusting the temp online as well as being able to set an "away" temp was very useful and efficient.
CCCT	It set back when I left my house automatically.
B36	Ability to monitor and set remotely.
Lyric	Love the geofencing, since I have so many folks in and out of my house - me, husband, and nanny with kids. Also love programming with app instead of on wall.
B36-IT	Programmable, iPhone app.
EC3	Easy to use. I love the online capability.

Table 13. Is there anything you dislike about the thermostat? Please describe.

Thermostat	Comments
Nest	Price
HW	N/A
ESS	When I go away for a weekend, I need to go into several layers of the T-stat software to make changes. My old one had just a temp hold button. Not all vacations are for a long period of time.
ES	The screen is slightly lower quality with a grainy display.
EF	The thermostat did not work correctly as I previously stated. In addition to that, I also did not like that the actual device was not user-friendly. I was unable to adjust the settings using the device. I had to make all adjustments online, which is ok for me because I am constantly on my smart phone, but if someone is not typically online it would be very frustrating and inconvenient.
CCCT	N/A
B36	N/A
Lyric	One time internet went down in my house, so the thermostat disconnected and actually shut off the heat!!! That was very bad.
B36-IT	N/A
EC3	The registration process needs to be better described in directions.

CADMUS

Table 14. What features will you most likely continue to use and why?

Thermostat	Comments
Nest	Mobile app, see and control the temperature with the phone.
HW	Mobile app feature and vacation mode.
ESS	Usage and possible remote temp change when coming home from vacation.
ES	Mobile app, schedule and weather display.
EF	Due to complications, we replaced the new thermostat with old device. However, if I were to continue using one, I would definitely continue to use the mobile app to monitor, set and change the temperatures. I really liked that feature.
CCCT	The geofencing feature setback.
B36	Indoor temp.
Lyric	Geofencing and remote control app. I also liked that this thermostat seems to learn. Originally it went from 68 to 63 when I left home. After a few times when I manually set it at 58 when no one was home, it now automatically goes to 58 when no one is home.
B36-IT	Schedule -- easy to set through web interface.
EC3	All features.

Table 15. Which features … are most likely to help / reduce your energy consumption?

Thermostat	Comments
Nest	"Leaf" icon notifications on energy-efficient behavior, mobile app.
HW	The mobile app feature that will allow me to adjust the T-stat schedule if I am not home.
ESS	N/A (Participant did not use mobile app enough to provide feedback).
ES	Easy programming (result in using schedule more), ability to delay thermostat deadband (reducing short cycling).
EF	Being able to set "away" temp.
CCCT	Geofencing, remote access.
B36	Turning down temps in zones when unoccupied.
Lyric	Geofencing, ability to control easily from my phone and or automate.
B36-IT	Schedule -- but would save more I think in a cooling application than for the heating.
EC3	The ability to monitor remotely.

Table 16. Were there any features that might cause an increase in your energy / consumption?

Thermostat	Comments
Nest	No response.
HW	No response.
ESS	No response.
ES	No response.
EF	Yes, dropping the temp lower than scheduled causing me to increase the temp manually.
CCCT	No response.
B36	No response.
Lyric	No response.
B36-IT	No response.
EC3	No.

Table 17. Why do you think you will save energy with your new thermostat? If yes, how?

Thermostat	Comments
Nest	Yes, controlling the temperature when you are not home, and the away setting.
HW	Yes, because I will have the ability to adjust the temp when I know I won't be home at one of the setpoints.
ESS	Yes, newer devices should have more accurate temp settings and remote access.
ES	Yes, reduced system run time, easier to stick to schedule so less indulgence in temperature.
EF	I don't know.
CCCT	Yes, it will setback immediately when I am more than 4 miles from home.
B36	Yes, turning down zones remotely when people are not in the house.
Lyric	I don’t know.
B36-IT	I don’t know.
EC3	Yes, likely because I will be more engaged in monitoring temperature because I'll look at it more frequently; make changes.

CADMUS

Table 18. Are there any features your old thermostat had that you wish your new thermostat had?

Thermostat	Comments
Nest	No response.
HW	No response.
ESS	Easily accessible HOLD button. Also, scheduling took a little figuring out.
ES	No response.
EF	Mobile app to manually change temp and the ability to set an "away" temp
CCCT	No response.
B36	No response.
Lyric	No response.
B36-IT	No response.
EC3	No.

Problems with Thermostat

One participant reported problems with the thermostat. The participant with the EcoFactor thermostat made the following comment on the thermostat's ability to regulate the home temperature.

> *"Since the new thermostat was installed, the house was significantly colder throughout the day and night. The thermostat would read 68 – 70 ℉, but the data loggers and a personal thermometer would read 66 – 68 ℉. The differential was always two degrees colder. At night it would get worse. The temp was set at 67 ℉, but the new thermostat would at times read as low as 65 ℉.I was constantly manually changing the temp online to adjust for the coldness. I believe there had to have been a problem with the thermostat, but it was very frustrating."*

To try to resolve the issues, the participant increased the temperature setpoint but was concerned about how this would impact the energy bills.

The participant also reported that the thermostat was not very user-friendly, noting that he or she was unable to adjust the temperature settings using the device and had to make all adjustments with the mobile application and/or web account instead. The participant added personally liking using the mobile application to control the thermostat, but that this may not be convenient for all users.

In the end, the participant reinstalled the old thermostat and returned the EcoFactor.

Cadmus followed-up with EcoFactor about the disparity between the setpoint and the indoor air temperature. EcoFactor reported that the gateway and thermostat were not connected, so the thermostat was not operating on EcoFactor software, which is cloud-based, but rather the Computime thermostat default settings. They reported the thermostat must have been operating on the default schedule shown in Table 19 (next page).

Table 19. Computime Thermostat Default Settings

Schedule Period	Time	Start Heating At	Start Cooling At
Morning	6:00 am – 8:00 am	73	76
Day	8:00 am – 6:00 pm	71	78
Evening	6:00 pm – 10:00 pm	72	75
Night	10:00 pm – 6:00 am	72	76

Space Temperature Analysis

Cadmus collected thermostat setpoint and household temperature data to assess how closely the space temperature matched the thermostat setpoints. This comparison may demonstrate the performance of each thermostat in maintaining the thermostat setpoint temperature. However, when interpreting findings, readers should consider these important points:

- Findings are based on one thermostat installation in one home for each thermostat model;
- The space temperature data collection period took place immediately after the thermostat installation. This included a two to three week period in February and March 2014 for the original thermostat group and between November 2014 and January 2015 for the additional thermostat group;
- It is normal for the space temperature to vary up to three degrees above and below the thermostat setpoint (this is termed the temperature differential);
- There are a variety of factors that impact how well a thermostat can regulate space temperature, including home insulation type, level of solar heat gain, and HVAC system type; and
- All nine thermostats have propriety algorithms that use feedback (which may include indoor/outdoor temperature, target setpoint, historical HVAC system run time) to adjust HVAC system run time; therefore, thermostat performance may vary over time and under different weather conditions.

Methods

Cadmus used temperature data loggers to record space temperature for a minimum of two weeks after the thermostat installation. We analyzed the record of thermostat setpoints and schedules during the data collection period and assessed how well the measured household temperature matched the thermostat setpoint.

Data Collection

During the site visit, Cadmus installed a temperature data logger next to each thermostat. These high-accuracy data loggers recorded the space conditions at one-minute intervals throughout the data collection period (minimum of two weeks for each thermostat). Table 20 describes our data collection points for each participant household.

Table 20. Thermostat Assessment Data Collection Points

Parameter	Units	Equipment	Frequency	Duration
Temperature at thermostat	Deg. F/RH%	Onset U10	1-minute	2-3 weeks

Data Analysis

To assess how well the household temperature matched the thermostat setpoints, Cadmus compared the average hourly actual temperature (measured from the Onset U10 temperature loggers) to the setpoints the participant programmed during the installation for a 24-hour profile. One participant reported that she changed her setpoints during the data collection period. We contacted this participant to collect the new setpoint settings. We also quantified the average temperature difference between the actual temperature and setpoint.

Results

For each thermostat, we present a figure that demonstrates how closely the space temperature matched the thermostat setpoint. The figures compare the profiles of average hourly measured temperature to the thermostat setpoint for that hour. Each figure also shows the average temperature differences for each thermostat.

In each figure:

- Orange lines show scheduled setpoint temperatures;
- Blue lines shows average measured temperature; and
- The bar graphs show the average temperature difference between the setpoint and actual temperature.
    - Red bars indicate that the average measured space temperature was warmer than the setpoint temperature.
    - Blue bar graphs indicate that the average measured space temperature was cooler than the setpoint temperature.

Five participants programmed one setpoint schedule for all seven days of the week. The other participants scheduled either weekday/weekend (5-2) schedules or weekday/Saturday/Sunday (5-1-1) schedules. We assessed each setpoint schedule separately.

The thermostat models are presented in the order they were tested.

Nest

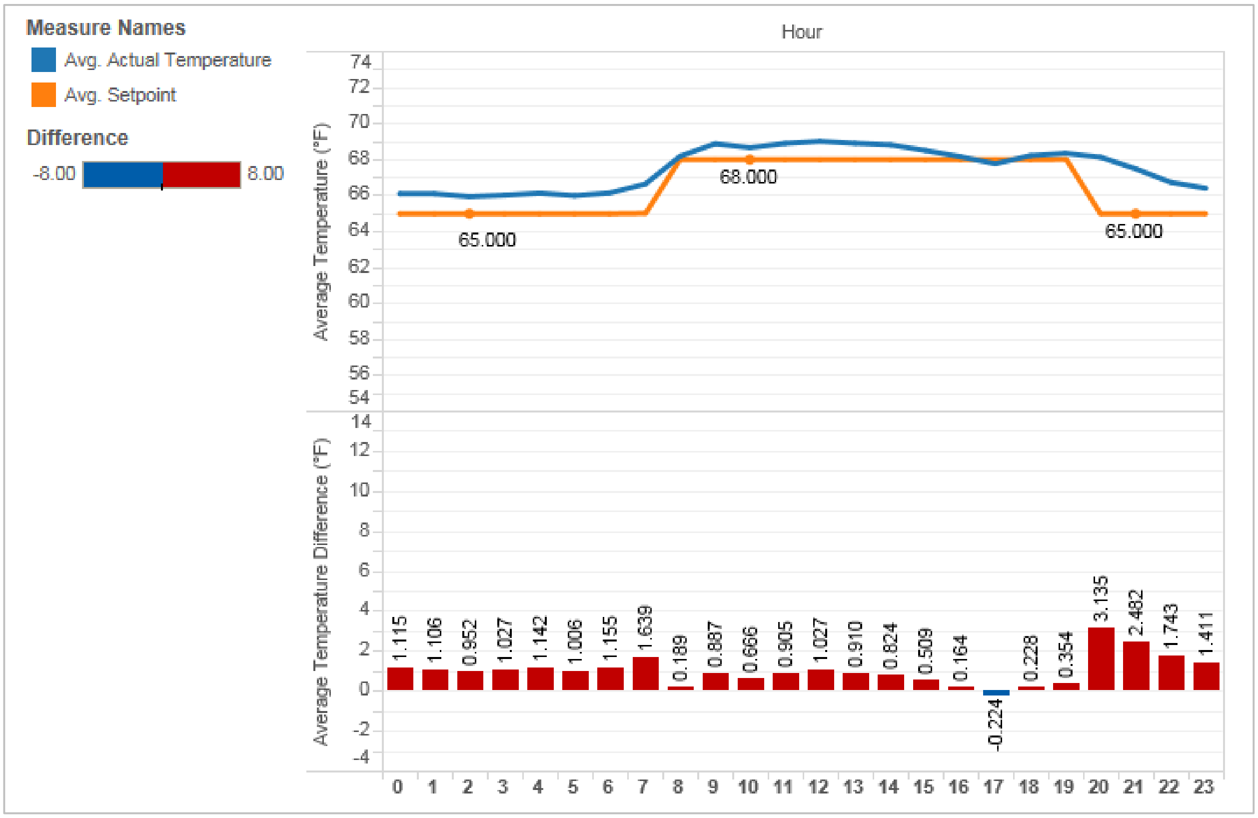
The Nest uses an algorithm to learn the user's preferred temperature and schedule and estimate the HVAC unit run time required to meet a particular setpoint and an occupancy sensor to learn when users are away or asleep. The Nest uses this data to learn when to start pre-heating or pre-cooling the home and to adjust setback periods.[10]

Although the Nest thermostat can program different schedules for each day of the week, the participant programmed the same setpoints for all seven days of the week. Figure 4 compares the thermostat

[10] Nest Labs. Nest Learning Thermostat Efficiency Stimulation: Update Using Data from First Three Months. April 2012.

setpoints (in orange) to the average measured space temperature (in blue), by hour. The bar graph shows the average difference between the setpoint and actual temperature, by hour.

Figure 4. Average Hourly Temperature – Nest – All Days



In the home with the Nest thermostat, the space temperature closely matched the scheduled setpoints of 65°F when home/asleep (20:00 to 8:00) and 68°when home/awake (8:00 to 20:00). During the home/awake period, the Nest kept the home within two degrees of the scheduled setpoint. During the home/asleep period, the average measured temperature was no more than four degrees warmer than the setpoint. The temperature difference is larger during the setback period because it takes time for the home to cool down to meet the 65°F setpoint.

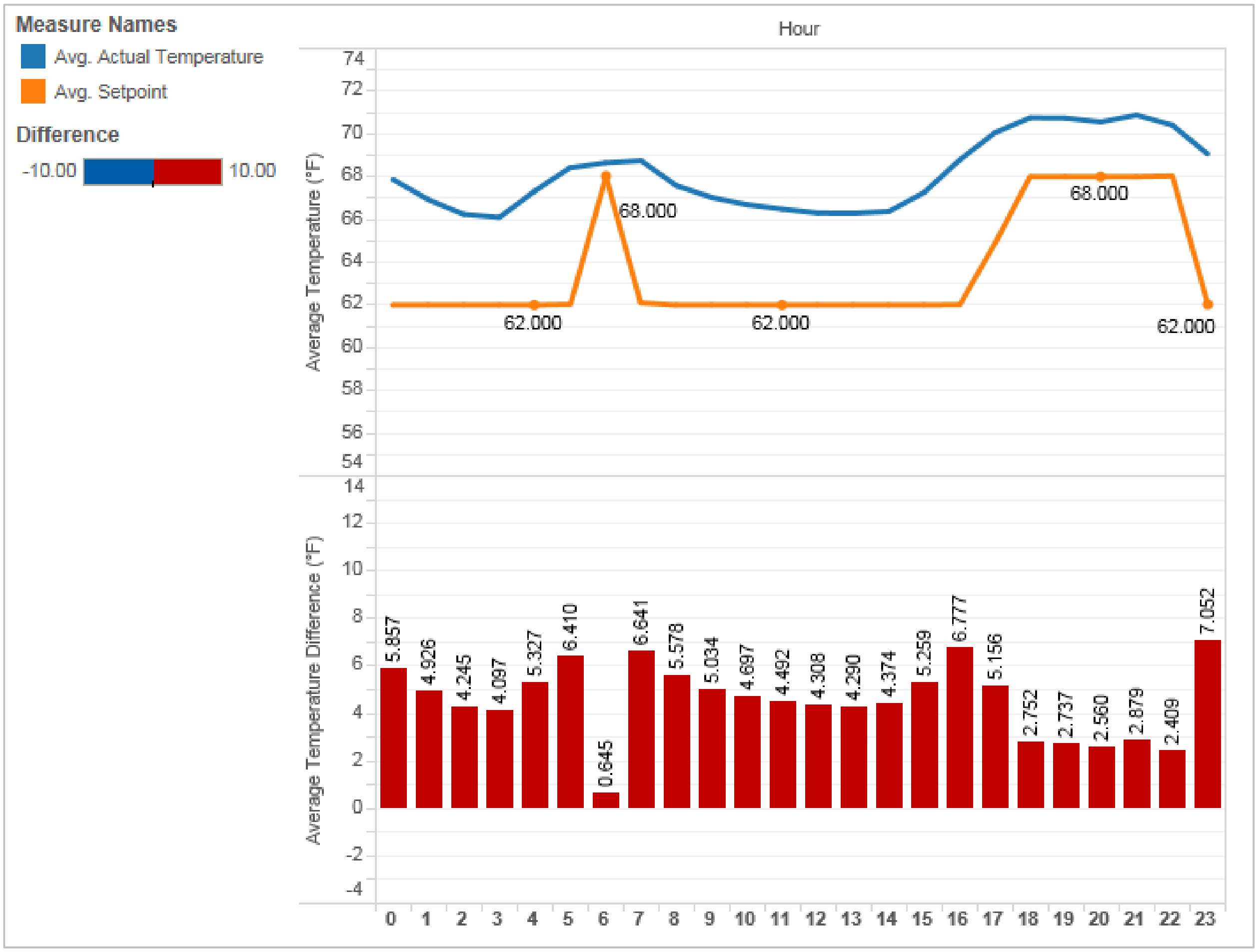
Honeywell Wi-Fi Smart Thermostat

This participant has Smart Response Technology enabled on their thermostat. Smart Response Technology uses an algorithm to learn heating and cooling cycle times and adjust the HVAC unit run time required to meet a particular setpoint. Over time, Smart Response Technology should improve how accurately the thermostat meets the setpoints.[11]

[11] http://yourhome.honeywell.com/home/Products/Thermostats/7-Day-Programmable/Wi-Fi+Smart+Thermostat.htm (Accessed 4/14/14)

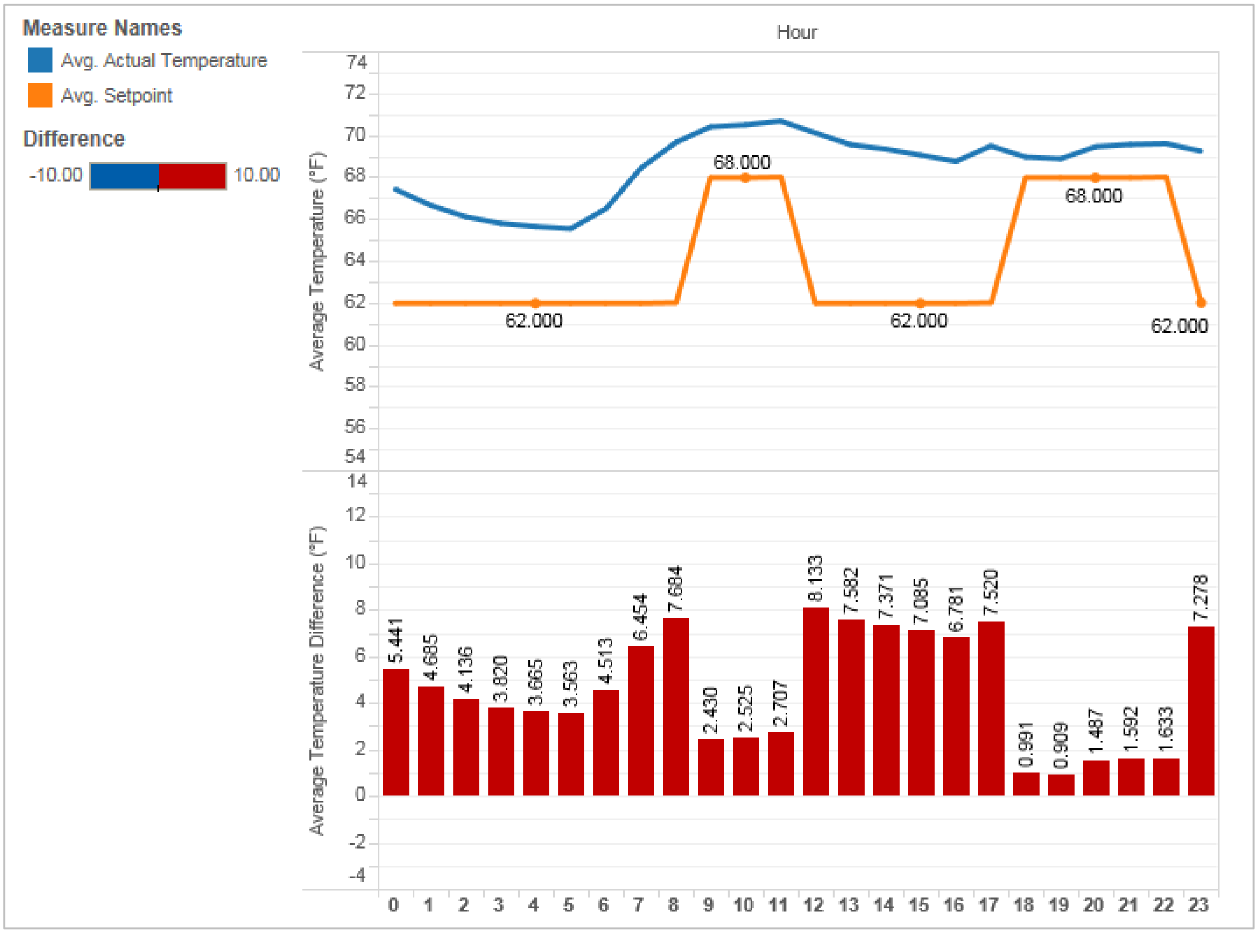
The participant who received the Honeywell thermostat programmed three setpoint schedules: one for weekdays, one for Saturdays, and one for Sundays. Figure 5, Figure 6, and Figure 7 show the space temperature analysis for each of these setpoint schedules.

Figure 5. Average Hourly Temperature – Honeywell – Weekdays



For weekdays, the participant programmed a setpoint of 62°F when away or home/asleep and 68°F when home/awake in the morning and evening. The Honeywell thermostat consistently kept the home temperature above both these setpoints. When home/awake, the average space temperature was 0–3° warmer than the setpoint. When away, the average space temperature was 4–7° warmer than the setpoint. This relatively large difference is because it takes hours for the space temperature to drop 8°F to reach the setback of 62° F. The space temperature drops approximately 2.5 degrees from 7:00 to 14:00, before the house begins to warm up again to meet the 68°F setpoint at 17:30.

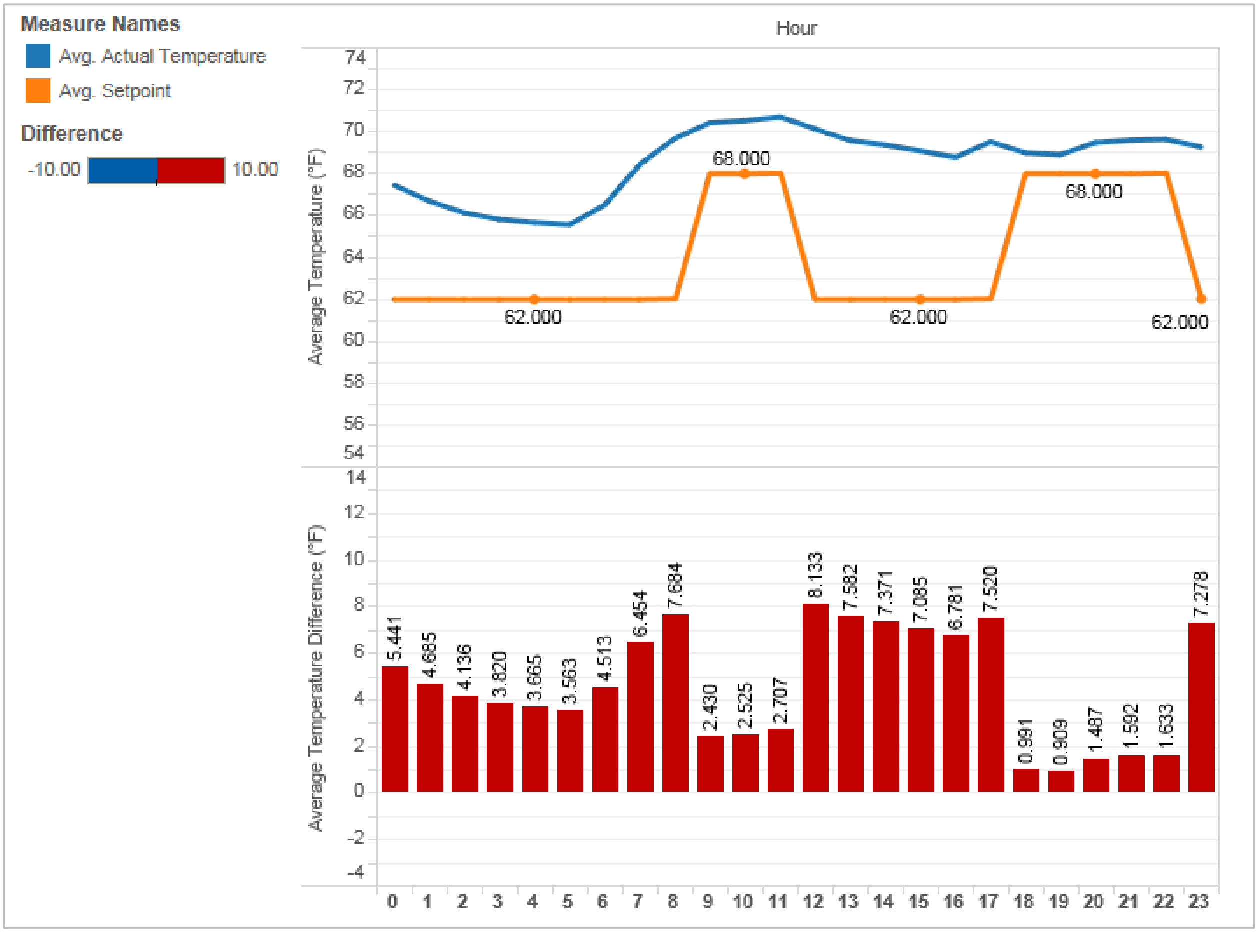
Figure 6. Average Hourly Temperature – Honeywell – Saturdays



For Saturdays, the participant programmed the same temperature setpoints as for weekdays but extended the morning's home/awake setpoint from one hour (6:00–7:00 on weekdays) to three hours (9:00–12:00 on Saturdays). The participant also shortened the evening home/awake setpoint from 5.5 hours (17:30–23:00 on weekdays) to 2.5 hours (20:30–23:00 on Saturdays).

Similar to weekdays, the thermostat consistently kept the space temperature within three degrees above the home/awake setpoint with larger temperature differences during the setback periods.

Figure 7. Average Hourly Temperature – Honeywell – Sundays



The Sunday setpoint schedule was similar to Saturday, except the afternoon away setpoint was shortened from 10.5 hours (12:00–20:30 on Saturdays) to six hours (12:00–18:00 on Sundays). Like on weekdays and Saturdays, the thermostat consistently kept the average space temperature within 3° F warmer than the setpoint with larger temperature differences during the setback periods.

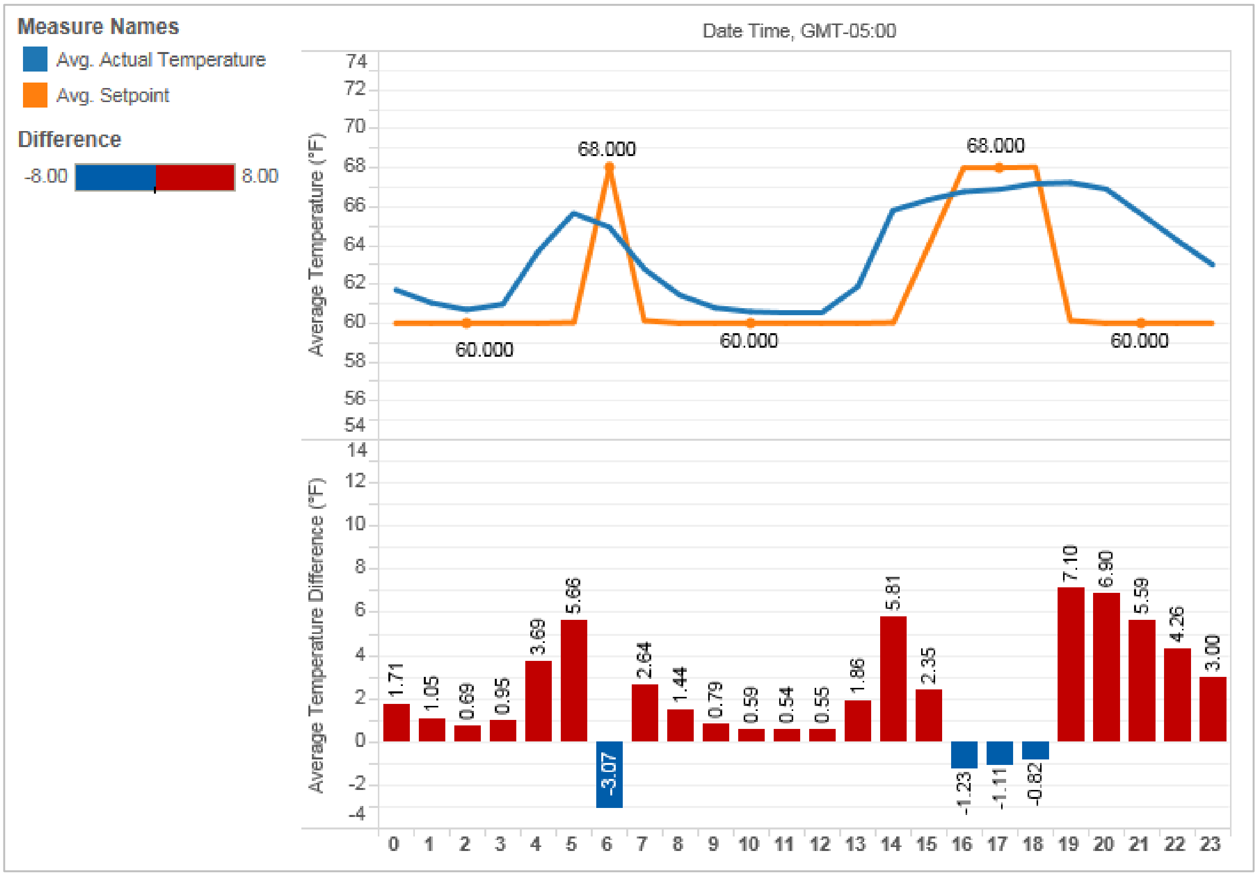
Ecobee Smart Si

The Ecobee Smart Si thermostat uses an algorithm and weather observations to adjust HVAC system run time.[12]

The participant with the Ecobee Smart Si thermostat programmed three setpoint schedules—one for weekdays, one for Saturdays, and one for Sundays. Figure 8, Figure 9, and Figure 10 show the space temperature analysis for these three schedules.

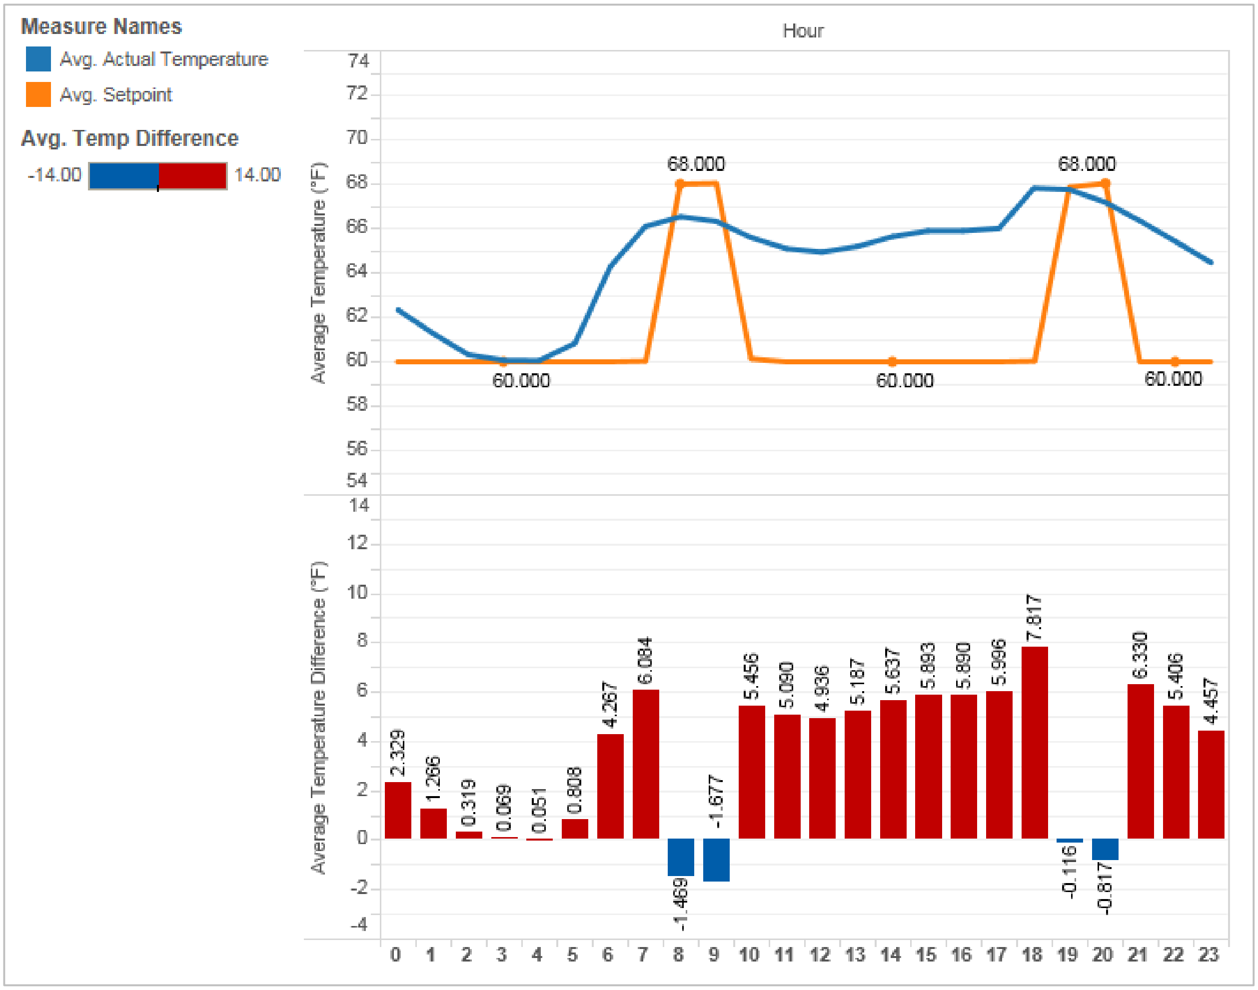
[12] http://www.ecobee.com/solutions/home/smart-si/ (Accessed 4/14/14)

Figure 8. Average Hourly Temperature – Ecobee Smart Si – Weekdays



On weekdays, the participant set the Ecobee Smart Si thermostat to 68°F when home/awake and 60°F when away or home/asleep. During the home/awake period, the average space temperature remained 1–3°F cooler than the 68°F setpoint. When in the away setback period, the average space temperature dropped until it was approximately 0.5 degrees above the setback temperature of 60°F before warming up again to meet the 68°F home/awake setpoint.

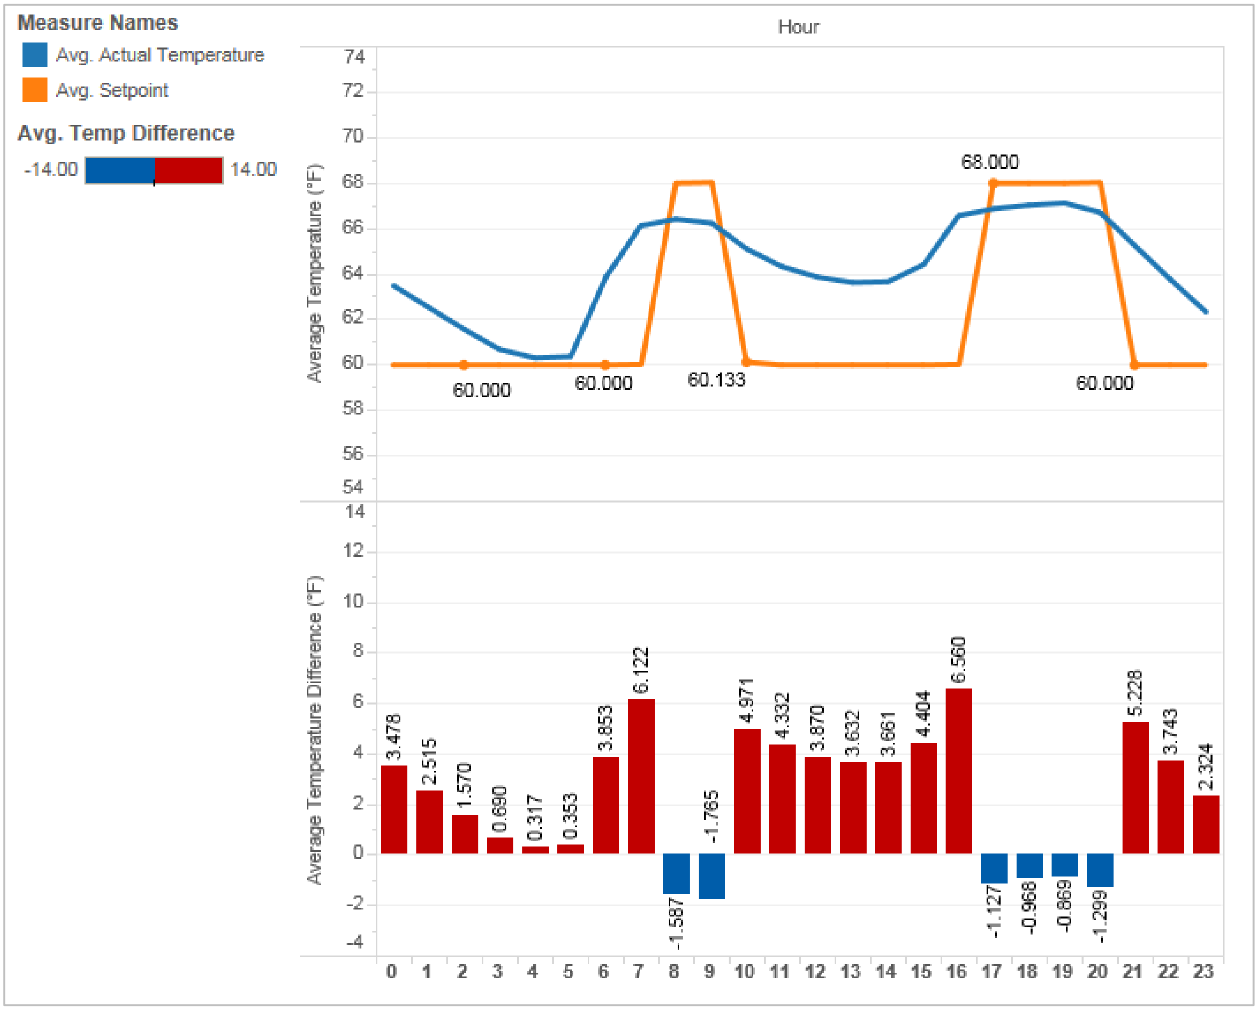
Figure 9. Average Hourly Temperature – Ecobee Smart Si – Saturdays



On Saturdays, the participant used the same setpoints, but shifted the home/awake setpoints from 6:00–7:00 and 15:30–19:00 to 8:00–10:00 and 19:00–21:00, respectively. For the home/awake setpoint periods, the average space temperature remained within two degrees cooler than the setpoint. During the home/asleep period, the average space temperature dropped to the setback temperature of 60°F, but during the day, the average space temperature did not typically drop to less than five degrees above the setback.

CADMUS

Figure 10. Average Hourly Temperature – Ecobee Smart Si – Sundays



On Sundays, the participant programmed similar setbacks as on Saturdays, but changed the away setback period from 10:00–19:00 to 10:00–17:00. During the home/awake period, the average space temperature was consistently 1–2 degrees cooler than the setpoint. During the home/asleep period, the average space temperature dropped to the setback temperature, but when away, it remained no less than four degrees above the setback temperature.

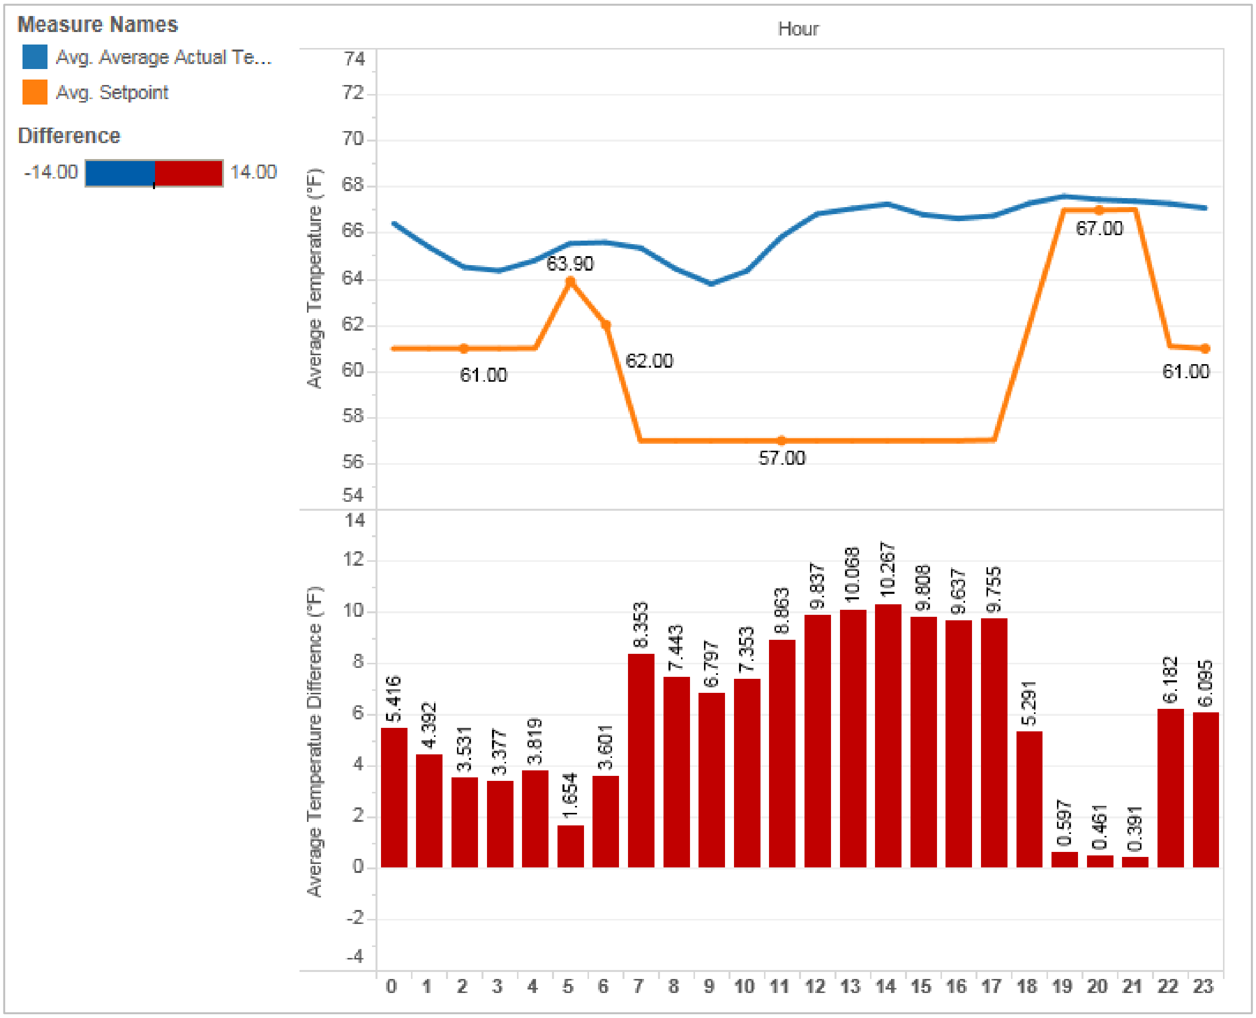
Ecobee Smart

The Ecobee Smart thermostat uses an algorithm and weather observations to adjust the HVAC unit run time to meet a particular setpoint.[13]

[13] http://www.ecobee.com/solutions/home/smart-si/ (Accessed 4/14/14)

The participant who received the Ecobee Smart thermostat programmed two schedules of setpoints—one for weekdays and one for weekends. Figure 11 and Figure 12 show the space temperature analyses for the Ecobee Smart thermostat.

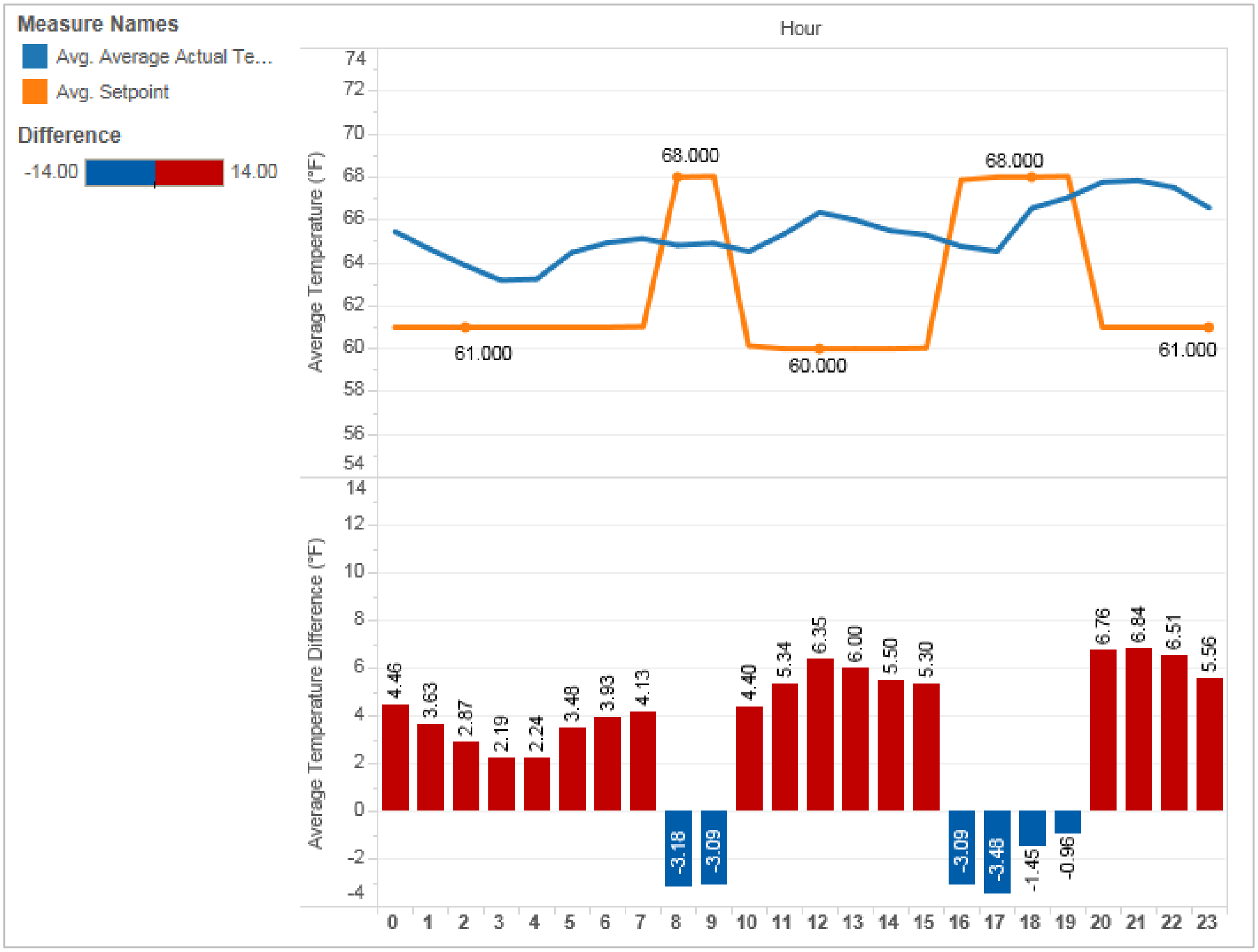
Figure 11. Average Hourly Temperature – Ecobee Smart – Weekdays



On weekdays, this participant scheduled a setpoint of 61°F when home/asleep and 57°F when away. During the home/awake period, the participant scheduled a setpoint of 67°F (5:30–6:30 and 18:30–22:00). Figure 11 shows the average hourly setpoint at 5:00 and 6:00 as 63.9°F and 62°F because the 67°F setpoint period overlaps the 5:00 and 6:00 hour.

The average space temperature when home/awake was consistently within two degrees warmer than the setpoint. When home/asleep, the average space temperature dropped to approximately three degrees above the setpoint before starting to increase in the 4:00 hour to meet the 6:30 setpoint of 67°F. When away, the average space temperature dropped to meet the 57°F setpoint, but remained about seven degrees warmer than this setpoint. By 14:00, the average space temperature increased to more than ten degrees warmer than the setpoint, which is over four hours earlier than needed to meet the 18:30 setpoint of 67°F.

Figure 12. Average Hourly Temperature – Ecobee Smart – Weekends



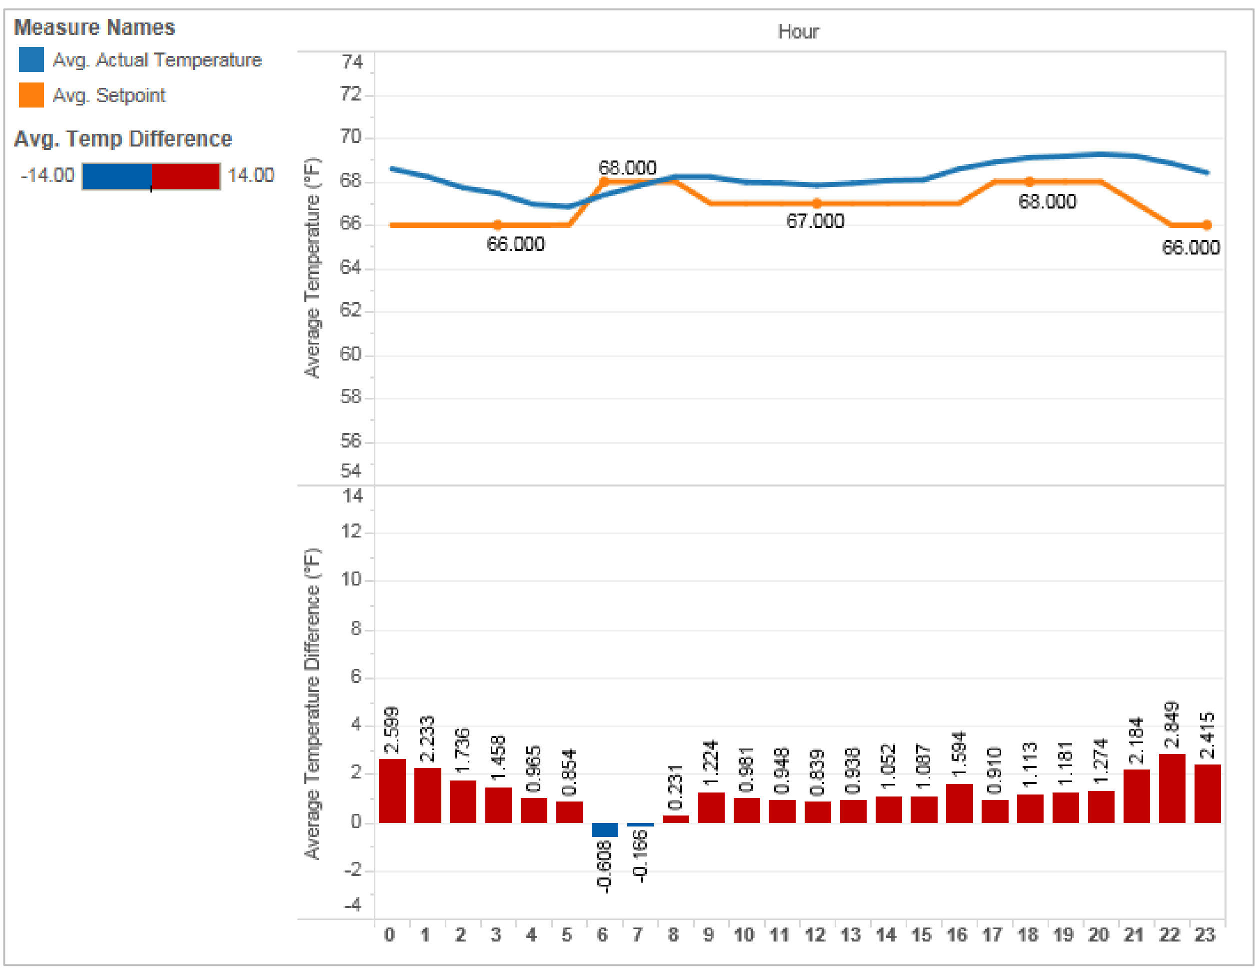
On weekends, the participant schedule changed their home/awake setpoint from 67°F to 68°F and shifted the time period from 6:60–8:30 and 18:30–22:00 to 8:00–10:00 and 16:00–22:00. They also changed their away setpoint to 60°F. Their home/asleep setpoint remained at 61°F. On weekends, the average space temperature was no more than four degrees cooler than the setpoint. During the away period, the average space temperature did not drop to the setpoint, but increased for several hours until it was no more than seven degrees warmer than the setpoint. During the home/asleep period, the average space temperature dropped until it was approximately two degrees above the 61°F setpoint, before increasing to meet the 68°F setpoint.

EcoFactor

The EcoFactor uses information including indoor/outdoor temperature, programmed setpoints, and HVAC system run time in an algorithm to determine how best to heat or cool a home while maintaining comfort.

The participant with the EcoFactor thermostat programmed a setpoint schedule for weekdays and weekends. One week into the study, the participant changed the schedule of setpoints for both weekdays and weekends. Figure 13 and Figure 15 show the space temperature analyses for the first week of the study (Phase 1). Figure 14 and Figure 16 show the space temperature analyses for the remainder of the study period (Phase 2).

Figure 13. Average Hourly Temperature – EcoFactor – Weekdays – Phase 1

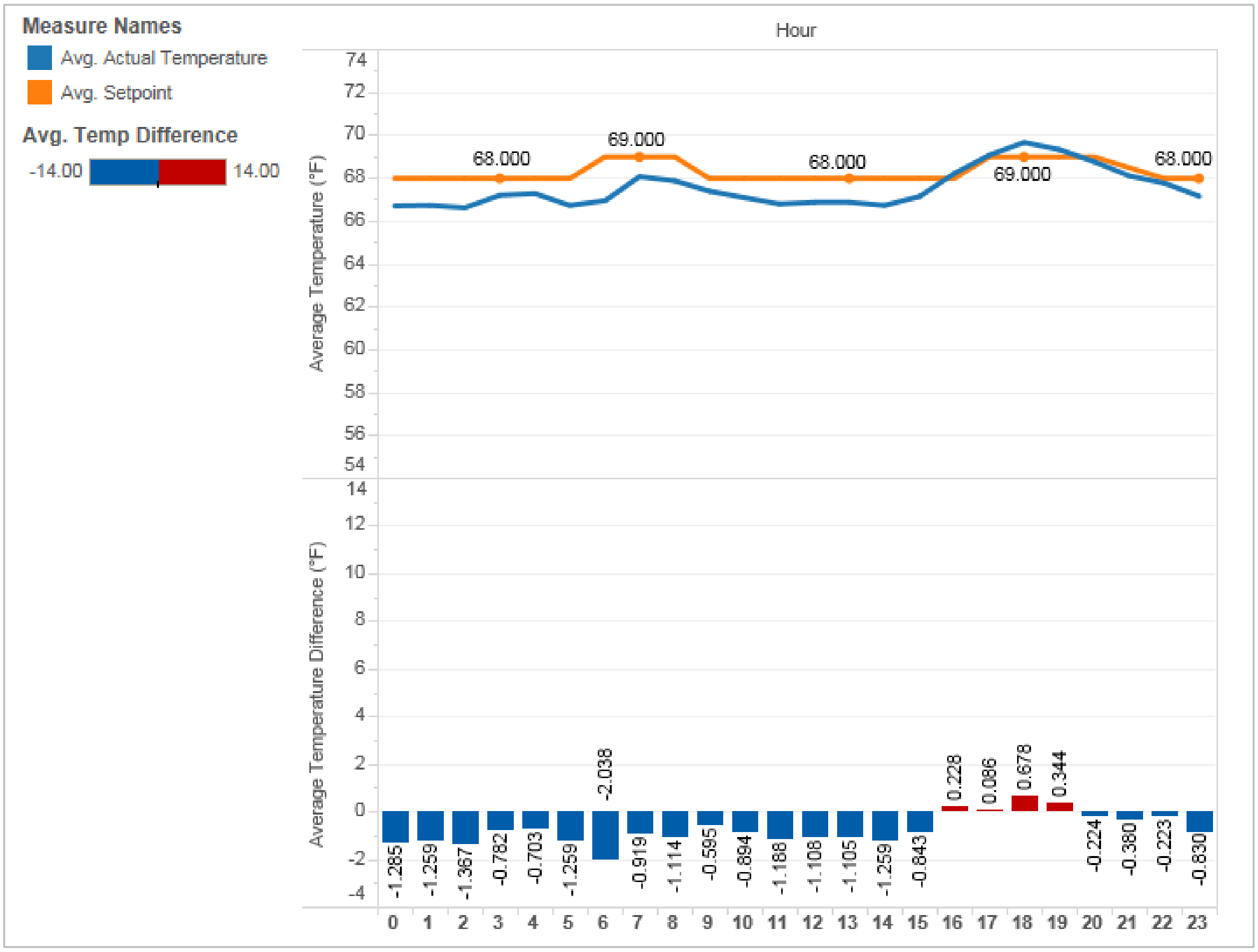


During the first week of the study, the participant scheduled the home/awake setpoint for 68°F, away setpoint for 67°F, and home/asleep setpoint for 66°F. During the morning home/awake setpoint period

CADMUS

(6:00–7:00), the average space temperature remained within one degree below the setpoint. During all other hours of the day, the average space temperature remained within two degrees above the setpoint, except when the home was cooling down during the setback period (home/asleep period).

Figure 14. Average Hourly Temperature – EcoFactor – Weekdays – Phase 2



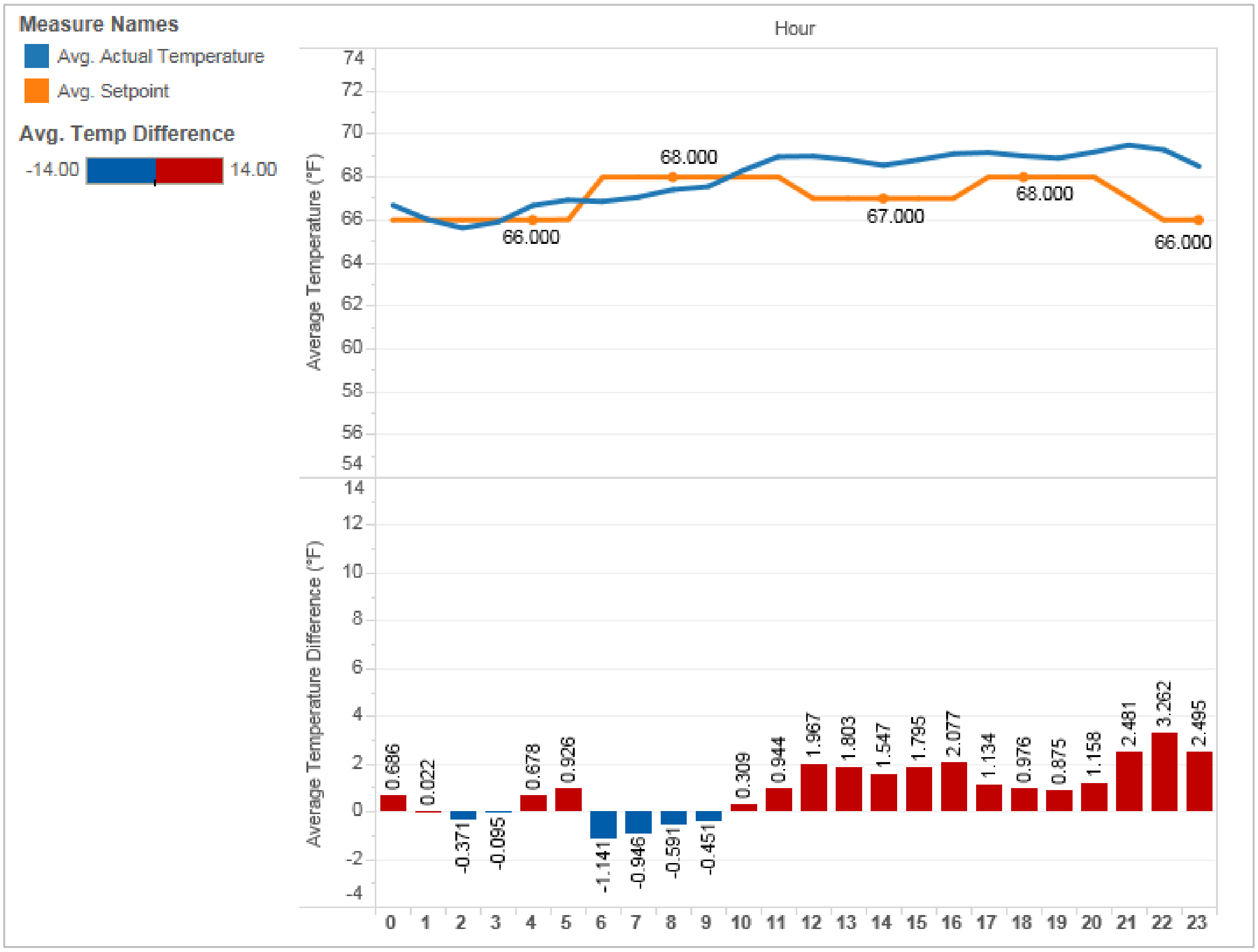
One week into the study, the participant with the EcoFactor thermostat changed the schedule of weekday setpoints in an effort to increase the thermal comfort of the home. The participant kept the same periods for home/awake, away, and home/asleep periods, but increased the setpoint temperatures. Table 21 shows the setpoint changes the participant made to the weekday schedule.

Table 21. Mid-study Weekday Setpoint Changes for EcoFactor

Time Frame	Old Setpoint(°F)	New Setpoint(°F)
6:00 AM – 9:00 AM	68	69
9:00 AM – 5:00 PM	67	68
5:00 PM – 9:30 PM	68	79
9:30 PM – 6:00 AM	66	68

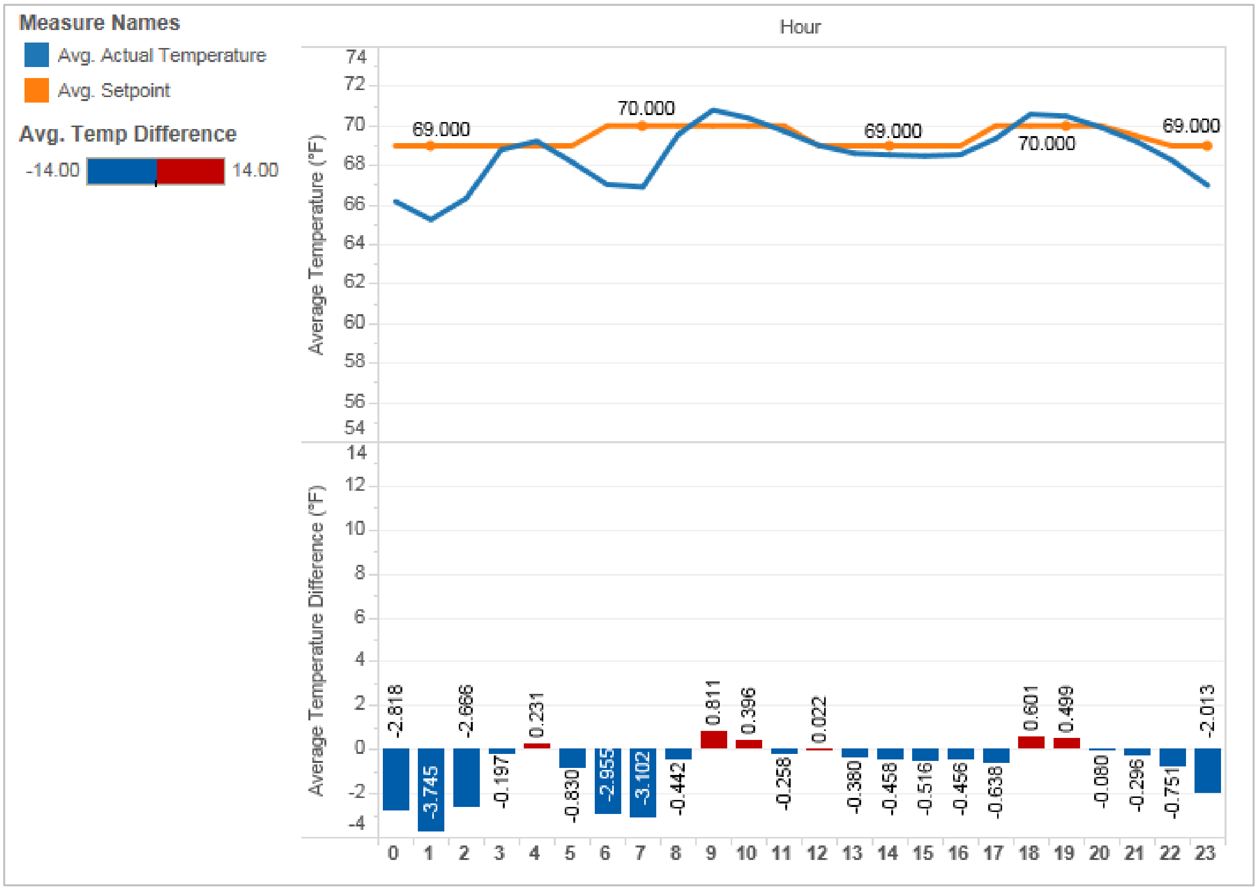
After the participant made the setpoint changes, the average space temperature tended to be within two degrees below the setpoint, whereas in phase 1, the average space temperature tended to be within two degrees above the setpoint.

Figure 15. Average Hourly Temperature – EcoFactor – Weekends – Phase 1



During the first week of the study, the weekend schedule the participant programmed for the EcoFactor thermostat was similar to the weekday schedule, but with an extended the morning home/awake setpoint period (6:00–12:00 rather than 6:00–9:00). During the morning home/awake period, the average space temperature remained approximately one degree cooler than the setpoint. During the evening home/awake period, the average space temperature remained approximately one degree warmer than the setpoint.

Figure 16. Average Hourly Temperature – EcoFactor – Weekends – Phase 2



One week into the study, the participant with the EcoFactor thermostat changed the schedule of weekend setpoints in an effort to increase the thermal comfort of the home. The participant kept the same periods for home/awake, away, and home/asleep periods, but increased the setpoint temperatures. Table 22 shows the setpoint changes the participant made to the weekday schedule.

Table 22. Mid-study Weekend Setpoint Changes for EcoFactor

Time Frame	Old Setpoint(°F)	New Setpoint(°F)
6:00 AM – 12:00 PM	68	70
12:00 PM – 5:00 PM	67	69
5:00 PM – 9:30 PM	68	70
9:30 PM – 6:00 AM	66	69

After the participant made the setpoint changes, the average space temperature tended to be within four degrees below the setpoint during the morning home/awake period, whereas in phase 1, the average space temperature tended to be within two degrees below the setpoint during this period.

During the home/asleep setback period, the difference between the space temperature and setpoint temperature increased to four degrees below the setpoint of 69°F.

Carrier ComfortChoice Touch

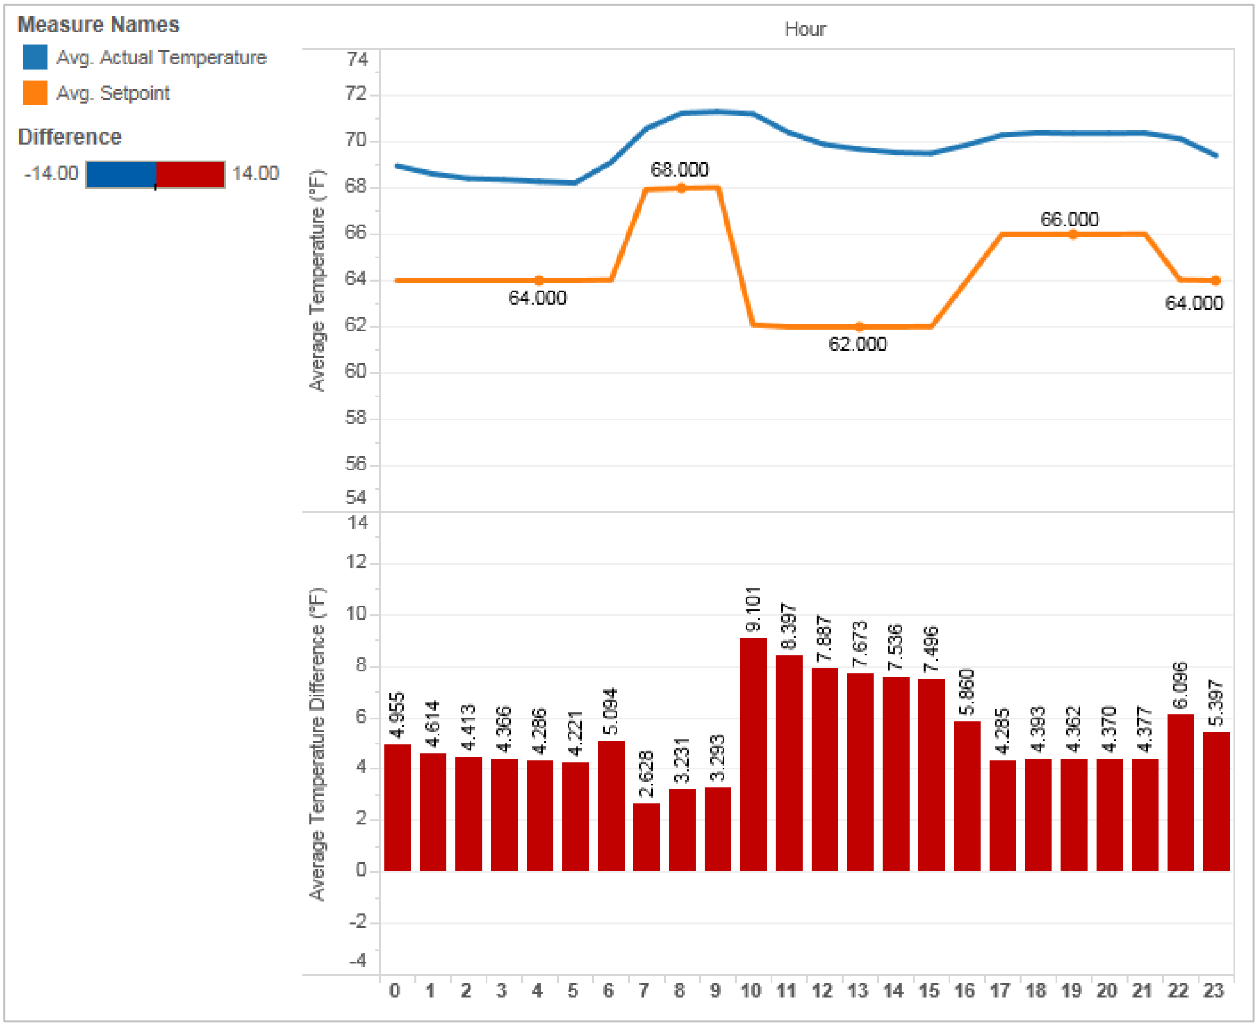
The Carrier ComfortChoice Touch thermostat uses an algorithm to adjust the HVAC run time. This algorithm takes into account the equipment type, temperature difference between indoor temperature and target setpoint, and equipment protection (to limit the number of times the compressor is cycled per hour and the time between cycling). It also has Smart Recovery, where the thermostat will gradually ramp up temperature to meet a target setpoint.[14]

The participant with the Carrier ComfortChoice Touch thermostat programmed a single setpoint schedule for all seven days of the week. Figure 17 shows the space temperature analysis for this thermostat.

[14] Carrier representative (4/29/14)

CADMUS

Figure 17. Average Hourly Temperature – Carrier ComfortChoice Touch – All Days



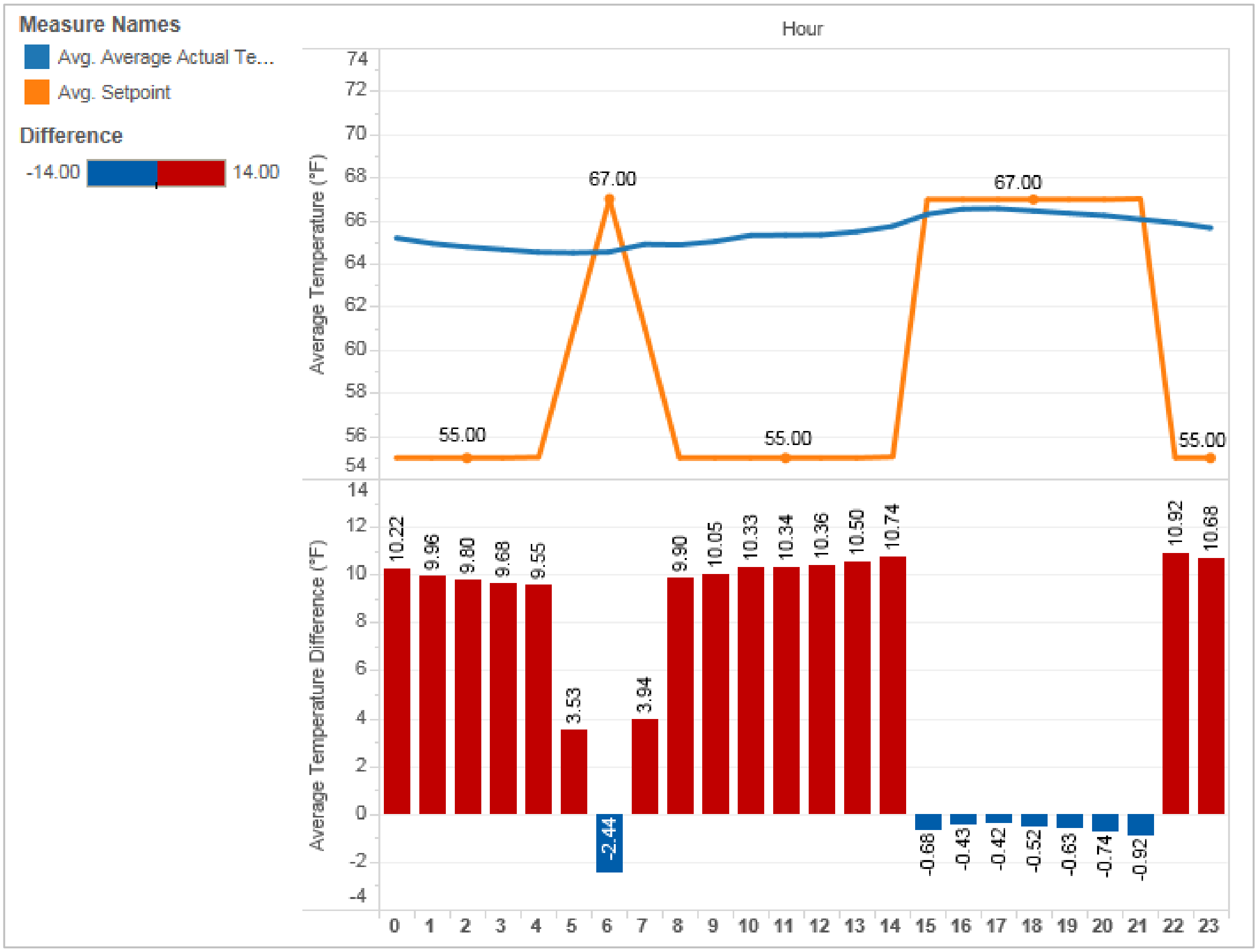
The participant programmed the Carrier ComfortChoice Touch setpoint to 68°F when home/awake in the mornings, 66°F when home/awake in the evening, 62°F when away during the day, and 64°F when asleep at night. When home/awake, the average space temperature was consistently 2–5 degrees above the setpoint. When away during the day, because it took time for the space temperature to drop, the average space temperature remained 5–9 degrees above the setpoint. Similarly, when the thermostat went into the sleep setback period, the average space temperature remained 4–6 degrees above the setback temperature.

Building 36 CT100

The Building 36 CT100 thermostat uses an algorithm to adjust HVAC run time based on factors including indoor/outdoor temperatures and weather data.[15]

The participant with the Building 36 CT100 thermostat programmed one schedule of setpoints for weekdays and one for weekends. Figure 18 and Figure 19 show the space temperature analysis for these two schedules.

Figure 18. Average Hourly Temperature – Building 36 CT100 – Weekdays



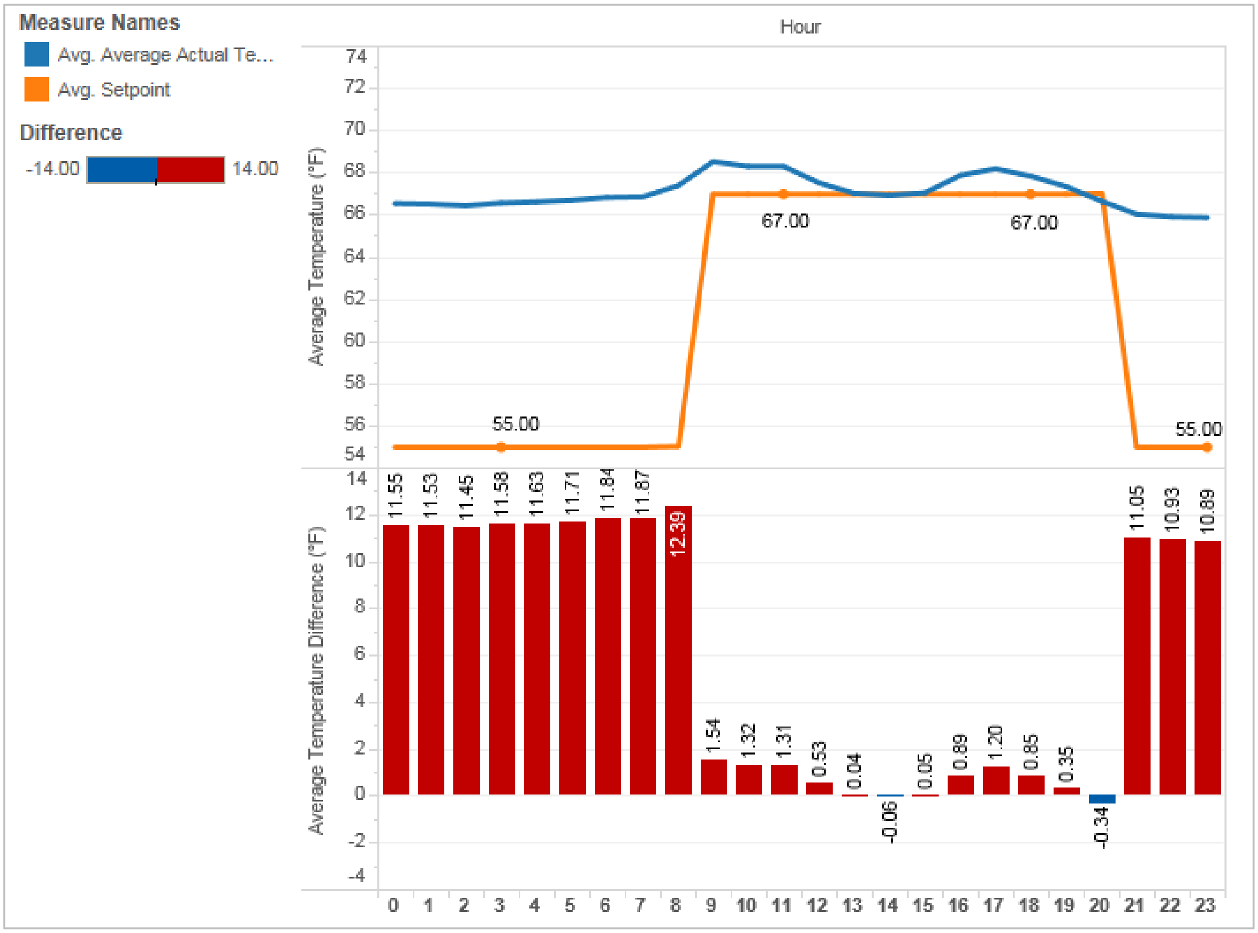
On weekdays, the participant scheduled a setpoint of 67°F when home/awake in the mornings and evenings, and 55°F when away or home/asleep. When home/awake in the evenings, the average space temperature was consistently less than one degree cooler than the setpoint. During the short morning home/awake period, the average space temperature was more than two degrees cooler than the setpoint. The difference between space temperature and setpoint is greater during this home/awake period because it is a shorter period, so the HVAC system has less time to reach and maintain a setpoint.

---

15 Building 36 representative (4/29/14)

When away and home/asleep, the average space temperature increased up to 11 degrees warmer than the setpoint. This is in part due to the fact the there is a 12 degree setback and it takes time for the home to cool down. Between the morning and evening home/awake periods when the user is away, the average space temperature does not drop enough to meet the 55°F setpoint.

Figure 19. Average Hourly Temperature – Building 36 CT100 – Weekends



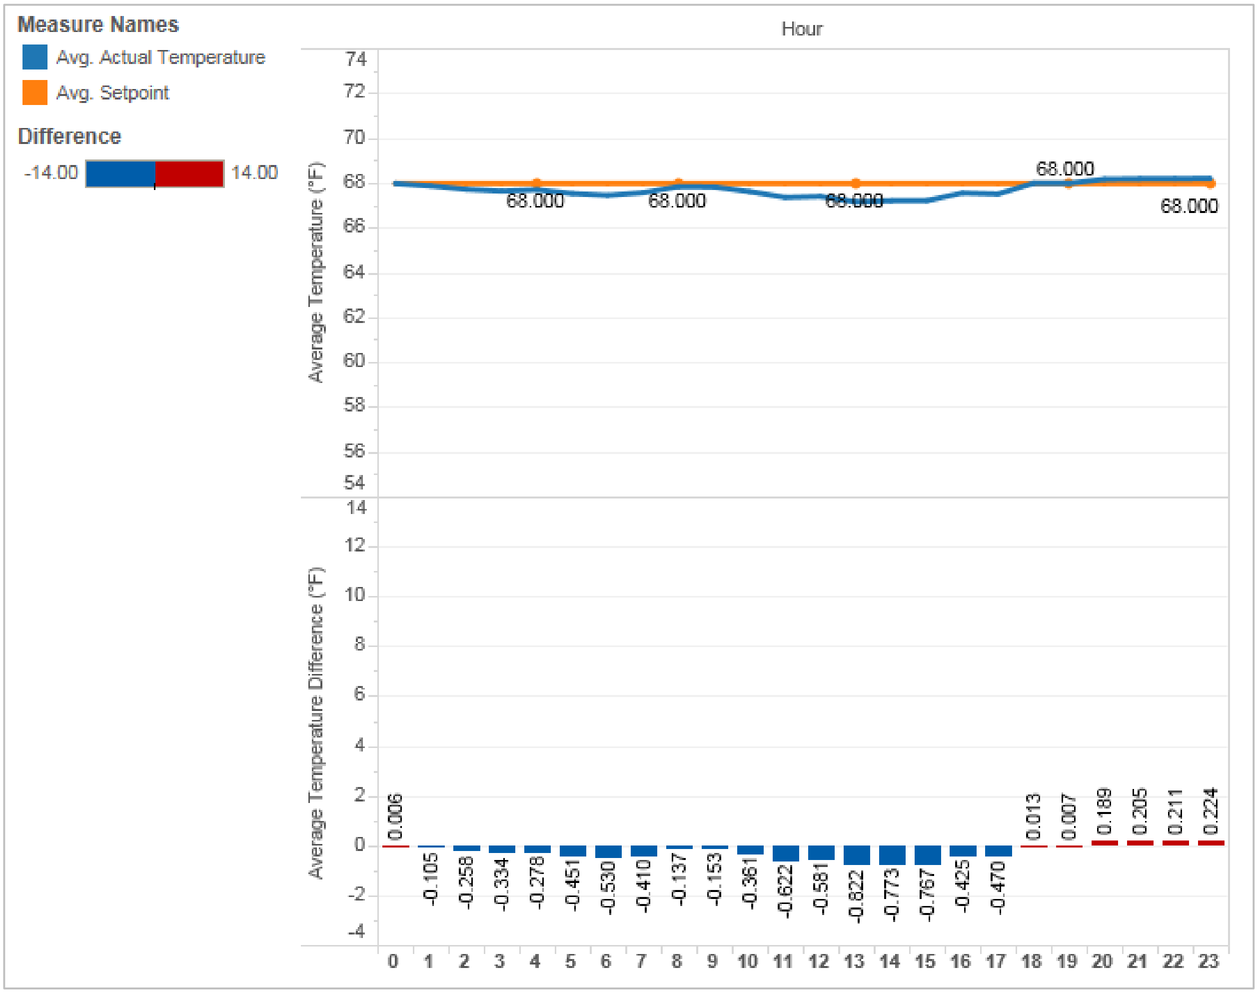
On weekends, the participant scheduled the same setpoints but changed the home/awake period to 9:00—21:00 and the home/asleep period to 21:00—9:00. During the home/awake period, the average space temperature remained no more than two degrees of the setpoint. During the home/asleep period, the average space temperature remained approximately 12 degrees warmer than the setback temperature of 55°F.

Honeywell Lyric

The Honeywell Lyric thermostat uses an algorithm to adjust settings based on factors including indoor/outdoor temperatures and weather data. The Lyric also has geofencing capabilities where the user can define unique boundaries which trigger automatic changes in thermostat settings when smart phone enters in or out of the defined range.

The participant with the Lyric thermostat set a single setpoint of 68 degrees. Figure 20 shows the space temperature analysis based on the user settings.

Figure 20. Average Hourly Temperature – Lyric – All Days



The participant scheduled a setpoint of 68 °F. The average space temperature was consistently within one degrees of the setpoint for all hours of the day.

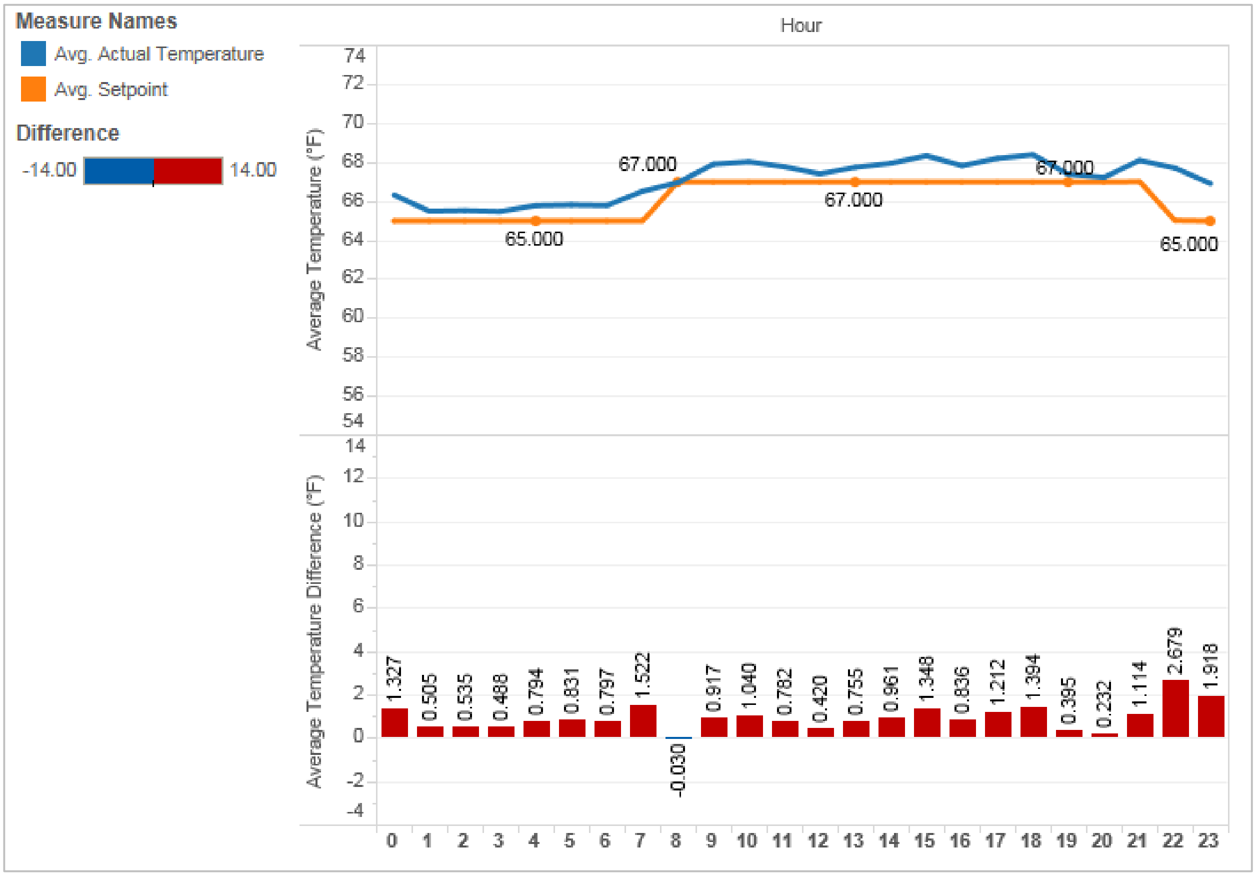
Building 36 Intelligent Thermostat

The Building 36 Intelligent Thermostat uses an algorithm to adjust HVAC run time based on factors including indoor/outdoor temperatures and weather data.

The participant with the Building 36 Intelligent Thermostat programmed a single setpoint schedule for all seven days of the week. Figure 21 shows the space temperature analysis for this thermostat.

CADMUS

Figure 21. Average Hourly Temperature – Building 36 Intelligent Thermostat – All Days



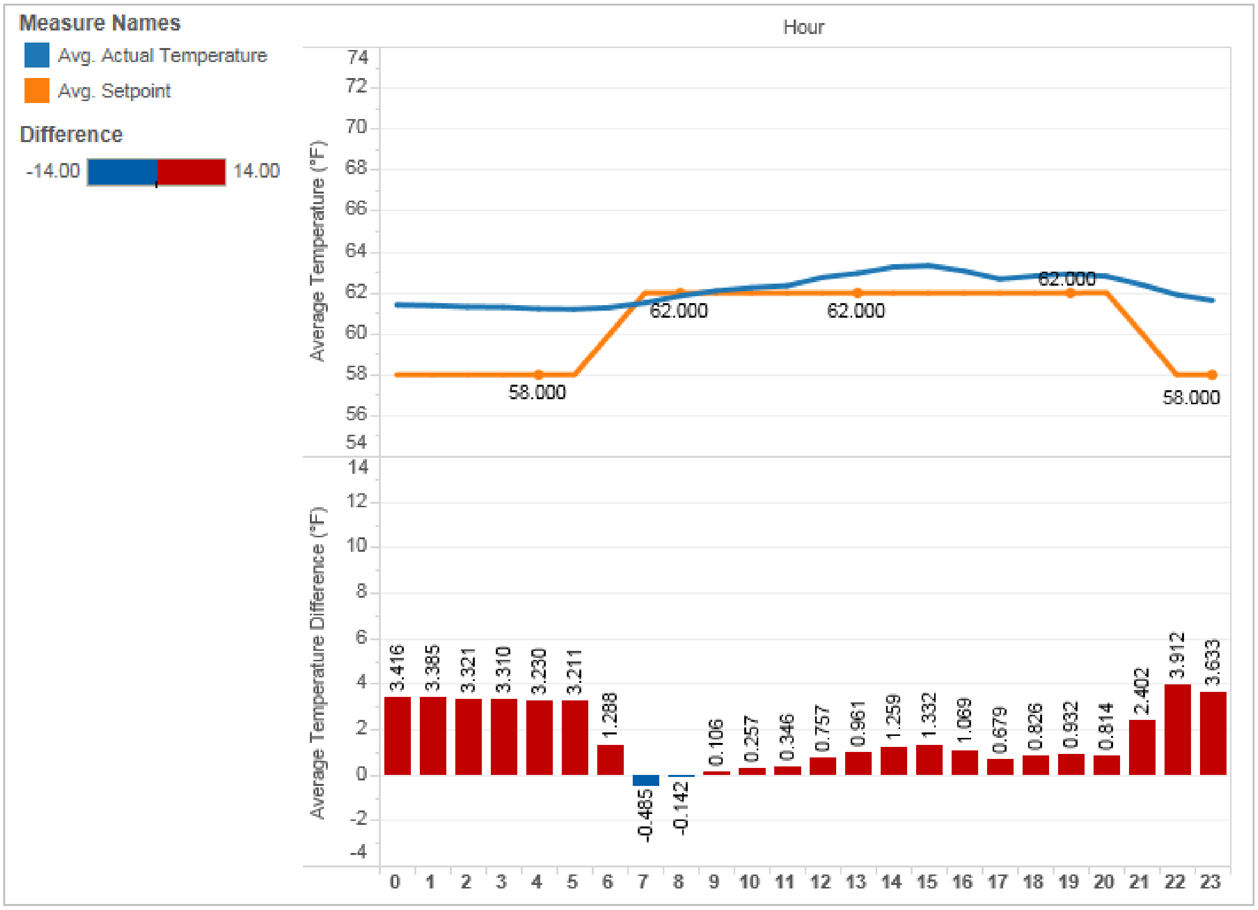
The participant programmed the Building 36 Intelligent Thermostat with a setpoint of 67 °F when home/awake during the day and 65 °F when asleep at night. During all hours of the day, the average space temperature was consistently within 2 degrees above the setpoint, except for 8:00 AM when the setpoint changed from 65 to 67 degrees.

Ecobee3

The Ecobee3 uses a remote occupancy and temperature sensor to adjust the heating and cooling based on the conditions in whatever space the user chooses to install it. It also uses an algorithm to adjust HVAC run time based on factors including indoor/outdoor temperatures and weather data and has geofencing capabilities.

The participant with the Ecobee3 programmed a single setpoint schedule for all seven days of the week. Figure 21 shows the space temperature analysis for this thermostat.

Figure 22. Average Hourly Temperature – Ecobee3 Thermostat – All Days



The participant programmed the Ecobee3 with a setpoint of 62 °F when home/awake during the day and 58 °F when asleep at night. During the daytime period, the average space temperature was consistently within 2 degrees above the setpoint. However, when the participant used a setback of four degrees at night, the average space temperature was up to four degrees warmer than the setpoint. This might be attributable to the quality of the home's insulation. If the home is well-insulated, it might not lose enough heat over the setback period to drop from 62 °F to 58 °F.

CADMUS

Conclusions and Recommendations

Cadmus gathered data to assess the ease of installation, user experience and satisfaction, and ability to maintain the setpoint temperature of nine thermostats selected by the Companies for this study. Despite the small sample size for this study, these data provide valuable information for the Companies. In addition, through our involvement with the study participants, we identified and examined potential issues for these thermostats as part of a large-scale utility program. The following sections describe the thermostats that performed the best and worst in the study.

Easiest to Install

The Nest and Lyric models received the best ratings overall for ease of installation. These thermostats took less than 45 minutes install, received the maximum three-star rating from the installer for ease of installation, and do not require a 24 Volt (AC) common wire (C-wire).[16]

Although the Ecobee Smart Si and EcoFactor took only 40 minutes to install and received three-star ratings for ease of installation, these thermostats require a C-wire. This requirement limits the compatibility of these thermostats for many homes in New England, where Cadmus estimates less than one quarter of customer homes have a C-wire. In a large-scale program, customers without a C-wire may need to install new wiring to install thermostats that depend on a C-wire. For homes that do not have an existing C-wire or for which adding a C-wire is expensive, HVAC power extenders exist. The Ecobee3 is the only thermostat in the test group that comes with a power extender. Although the power extender makes the Ecobee3 compatible in most Massachusetts and Rhode Island homes, the installer gave it a one-star rating for ease of installation because the installation instructions for the power extender were not clear. For more information on wire extenders for other thermostat models, see Appendix A.

The Nest, Lyric, and Building 36 Intelligent thermostats are the most compatible with MA and RI homes because they do not require power from a C-wire. Instead, these thermostats use a standard two-wire setup, which is the minimum wiring requirement for any home thermostat. The Nest and Lyric draw power from the W-wire or Y-wire if no C-wire is available. In addition, the Lyric uses a AAA Lithium battery for initial start-up and to supplement the power stealing. Both Building 36 thermostats (CT100 and Intelligent) use four AA batteries. Although the Ecobee3's included power extender kit makes it compatible with many homes in Massachusetts and Rhode Island, it requires a minimum of three wires between the thermostat and HVAC unit.

The Building 36 models and EcoFactor require the installation of a Gateway for internet/cellular connectivity. Building 36 recommends a professional install their thermostats and Gateway.

[16] Cadmus estimates that less than one quarter of homes in MA and RI have a C-wire. For more details on the C-wire, see the Installation Assessment section and Appendix A.

Most User-Friendly

All thermostats except the Nest and EcoFactor received an overall rating of "easy" to use by the participant. Participants gave the Nest and EcoFactor overall ratings of "somewhat difficult" and "difficult" to use, respectively. The Nest was rated as "somewhat difficult" to use because the participant found it difficult to navigate the menu to program the setpoints. The installer noted that there was no copy/paste function—setpoints for each day had to be copied manually. Participants with the Ecobee Smart and Building 36 CT100 also commented that programming their thermostat was "somewhat difficult" or "difficult" to do, but still gave overall ratings of "easy."

The EcoFactor was rated as "difficult" to use because the participant found it challenging to change the schedule and manage comfort level.

Eight of the nine participants who used the mobile application rated the application as "easy" to use and three of the six participants who used the web account found it "easy" to use.[17] The participant with the Ecobee Smart Si's rated the web account as "somewhat difficult" to use, reporting there were minor display quirks and some confusing wording that made it challenging to use. The participant with the Carrier ComfortChoice Touch thermostat rated the web account as "difficult" to use, citing that he or she had some difficulty setting up the account, possibly due to having a duplicate account.

Most Accurate Space Temperatures

Among the original seven thermostat models, our comparison of setpoints and measured space temperature show that the home with the Nest thermostat most closely matched the space temperature for the home/awake setpoint (which maintained temperature within two degrees of the scheduled setpoint when the participant was home/awake).[18] In the additional testing round, this result was surpassed by the home with the Lyric thermostat, which consistently maintained temperature within one degree of the scheduled setpoint when the participant was home/awake.

In five homes, the average difference between space temperature and setpoint exceeded three degrees. The Ecobee Smart Si, Ecobee Smart, and EcoFactor thermostats tended to keep the home temperature within four degrees below the setpoint. The Carrier ComfortChoice Touch kept the home temperature between two and five degrees above of the setpoint, while the Ecobee3 kept the home temperature within four degrees above the setpoint.

All ten of the thermostats use algorithms to regulate the temperature of the home. These proprietary algorithms vary among thermostat models. The algorithms may take into account current outdoor temperature, weather forecast, equipment type, temperature difference between current indoor temperature and setpoint, and equipment protection (to limit the number of times the compressor cycles on and off). Algorithms use these data to adjust the HVAC system "cut-in" time—the time at

[17] The participant with the Ecobee Smart Si thermostat did not use the mobile application enough to rate it.

[18] The home/awake setpoint is the temperature setting when the user is home and awake (as opposed to home and asleep, or away).

which the HVAC system begins to pre-heat or pre-cool the home. Because these algorithms use feedback to adjust HVAC system run time, thermostat performance may vary over time and under different weather conditions. In addition to using an algorithm, the Nest and Ecobee3 use an occupancy sensor to determine when users are away or sleeping and adjusts setbacks for these periods. The Nest's occupancy sensor is located at the thermostat, whereas the Ecobee3's occupancy sensor can be installed in any room. Ecobee3's occupancy sensor also measures indoor temperature. The thermostat uses the indoor temperature information to adjust the heating and cooling. Users can install remote sensors in multiple rooms.

Best for Data Collection

The Ecobee Smart Si, Ecobee Smart, and Ecobee3 thermostats have the most data available. These thermostats enable the user to view and download a 15-month history of HVAC system run time and indoor temperature data from a web account. The web account also shows hourly, daily, monthly, and weather-adjusted run time (hours/degree day).The user can also view monthly reports that show total system run time, average setpoint, energy saved, and comparisons to the state average.

The EcoFactor and Carrier ComfortChoice Touch thermostats also show a full history of system run time and indoor temperature. With the Carrier ComfortChoice Touch, users can also download the last 30 days of data. The Nest shows users the last ten days of run time history and when the user demonstrated energy efficient behavior.

Appendix A. The C-Wire Problem

This study confirmed that a major obstacle to installing Wi-Fi thermostats in many existing New England households is the absence of a 24 Volt (AC) common wire, or "C-wire." Five of the nine thermostats in this study require a C-wire,[19] but Cadmus estimates that less than one quarter of homes in Massachusetts and Rhode Island have a C-wire.. The most common heating systems operate with a simple two-wire thermostat. When there is a call for heat, the thermostat will connect the two wires together until the demand is satisfied.

What is the C-wire?

A C-wire is a 24 Volt (AC) common wire that brings power to a thermostat by connecting it to a 24 Volt power source at the transformer of an HVAC system. Most Wi-Fi connected thermostats require a C-wire to power the Wi-Fi connectivity. Five of the seven thermostats in this evaluation require a C-wire. The Nest does not because it can use the W-wire (heating) or Y-wire (cooling) to power itself by a method called "power stealing." In this setup, the thermostat uses the circuits that turn on and off the HVAC system to charge an internal battery. The thermostat can charge its battery regardless of the HVAC system status (on or off), but the available power is limited when the HVAC system is running. If there is an extended home power outage and the battery level gets low, the Nest will turn off the Wi-Fi to conserve power.[20,21]

Figure 23 shows a standard two-wire thermostat that does not require a C-wire. It requires only the standard R-wire (power) and W-wire (heating). When there is a call for heat, the R-wire and W-wire connect and the heating system turns on.

[19] The four thermostat models that do not require a C-wire are Nest, Lyric, Building36-CT, Building36-IT

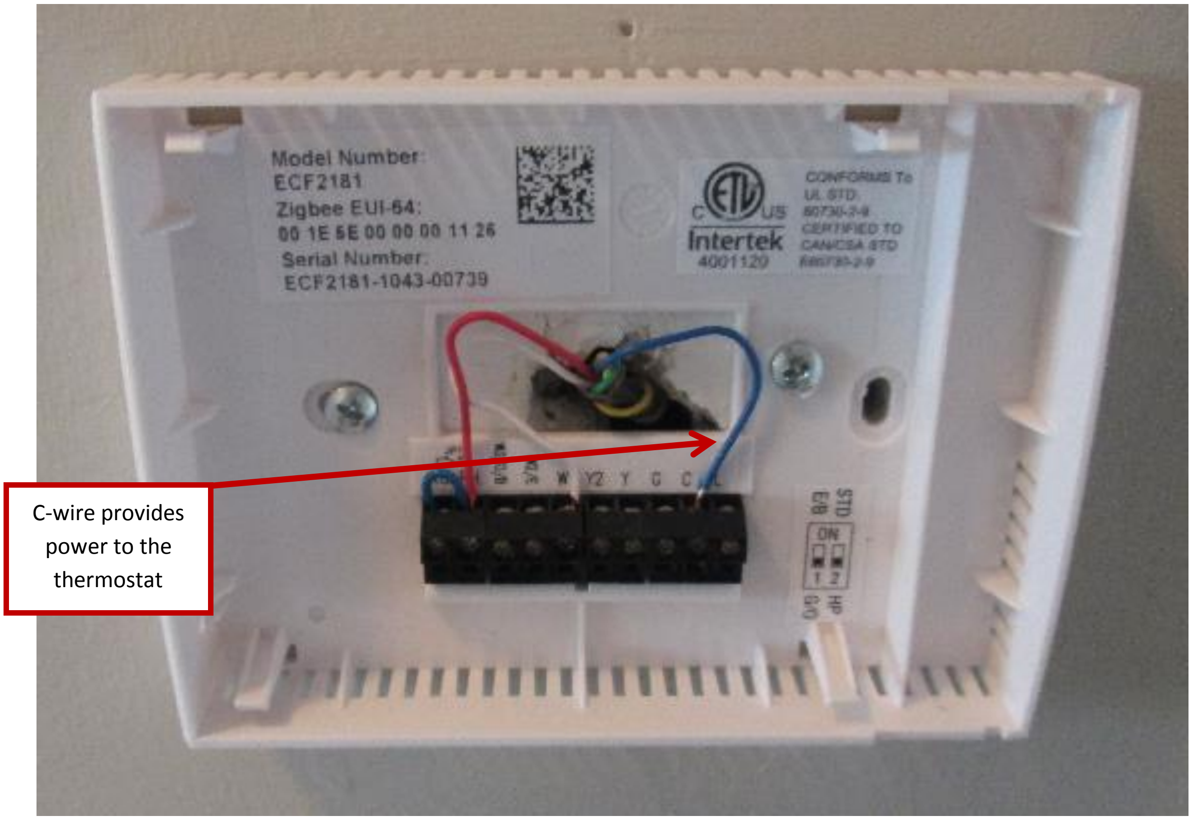
[21] http://www.ecobee.com/blog/the-problem-with-power-stealing/ (Accessed 5/14/14)

Figure 23. Standard Thermostat without C-wire

Figure 24 shows the EcoFactor thermostat, which requires a C-wire in addition to the R-wire and W-wire.

Figure 24. EcoFactor Thermostat with C-wire



How much of a problem is this?

Cadmus estimates that less than a quarter of households in Massachusetts and Rhode Island have a C-wire and that average installation costs could be $200-$300. In a 2013 Cadmus study of Wi-Fi thermostats in New Hampshire for Liberty Utilities (LU), seven of 29 participants (24%) had a C-wire in their homes.[22] During recruitment for the LU study, 45 customers responded to a survey about their HVAC system type and thermostat wiring. Of the 45 respondents, eight (18%) had a C-wire. Of the respondents with both heating and air conditioning, 25% had a C-wire. Of the respondents with heating only, 14% had a C-wire. For those participants who had a contractor install their thermostat wiring and thermostat, the average cost was $229.55 (n=11). The minimum cost was $80 and the maximum cost was $320. Costs varied depending on the distance the wire had to be run from the heating system to the thermostat.

Can we just add a C-wire to homes?

The cost and complexity of adding a C-wire to an existing home varies. For some homes, the installation is straightforward due to the proximity of the thermostat to the HVAC unit and an HVAC technician may be able to complete the installation. However, for the majority of homes, the C-wire should be added by

[22]The Cadmus Group, Inc. Wi-Fi Programmable Thermostat Pilot Program Evaluation. 2013.

a licensed electrician. The C-wire installation requires replacing the existing cable between the thermostat and HVAC unit. If the thermostat is not directly above or below an unfinished space, an electrician may need to drill many holes in finished surfaces to conceal the cable.

In this study, we only performed C-wire installations that an HVAC technician could perform. If a C-wire installation involves wiring through a finished space, Cadmus recommends an electrician perform the installation. For one 2-family site visit, the existing thermostat cable ran through a finished ceiling in the locked space of the other occupant. Coordination with the property owner, as well as many holes in the finished ceiling would have been necessary for this installation, which was aborted. Another installation that was aborted was a large single-family home where the thermostat was located between two finished levels. This installation would have required holes in a wall and ceiling of finished space.

Are there other options?

For homes that do not have an existing C-wire or for which adding a C-wire is expensive, HVAC wire extenders exist.

For homes with four wires at the existing thermostat—there is R (power), W (heating), G (fan), Y (cooling), but no C-wire (24 Volt AC)—Ecobee offers a Power Extender Kit for Ecobee Smart Si thermostat users. The kit is not compatible with the Ecobee Smart thermostat.

In addition, the Fast-Stat Common Maker (Figure 25) is a universally compatible device that provides a C-wire connection for thermostats using two or more wires. The Fast-Stat Common Maker uses a "sender" installed in the wall space behind the thermostat and a "receiver" installed at the HVAC unit to create a 24 Volt AC connection. The sender and receiver can be up to 2,500 feet apart.

Figure 25. Fast-Stat Common Maker – Sender

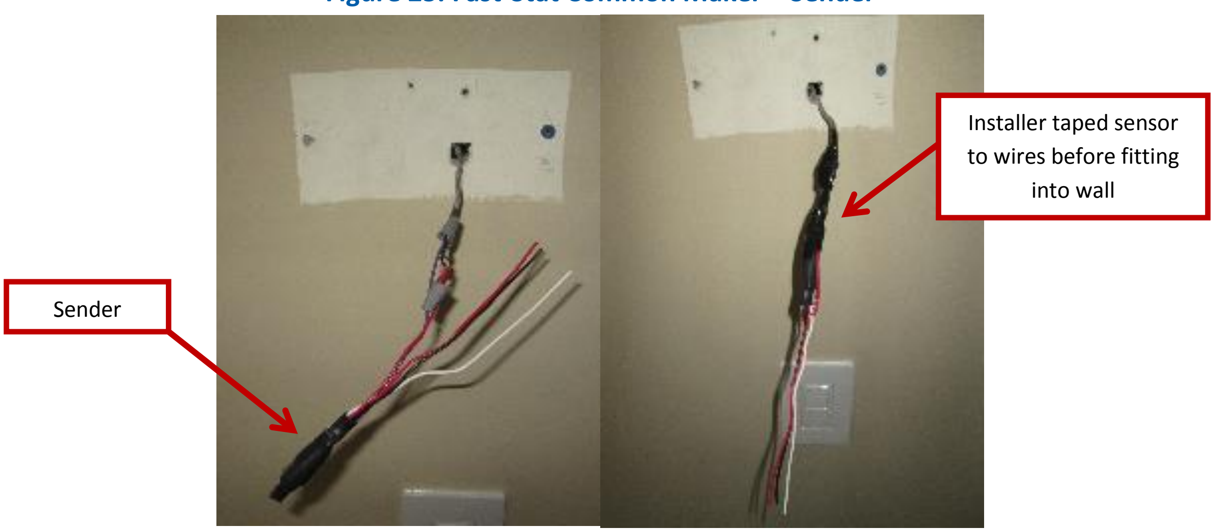


Figure 26. Fast-Stat Common Maker – Receiver

A Cadmus electrician installed the Fast-Stat Common Maker in a customer home with an Ecobee Smart Si thermostat. The Fast-Stat installation took 20 minutes—five minutes to install the sender and 15 minutes to install the receiver. The electrician found the installation to be straightforward, but it does require professional installation by an electrician or HVAC technician.

Cadmus contacted the Massachusetts Electrical Code Interpretation Committee to determine if the Fast-Stat is permitted for use in residential homes. We received written confirmation from the Chairman of the Electrical Code Interpretation Committee that products like Fast-Stat are permitted for use in residential homes as long as "the splice is accessible." If the splice is behind the thermostat in the wall (installer does not need to impact the wall plaster to get to it), then it is considered accessible. The written confirmation from the Massachusetts Electrical Code Interpretation Committee is attached in Appendix C.

CADMUS

How do the Wi-Fi thermostat powering options compare?

In this assessment, we encountered four methods of connecting power to the thermostat. Listed below are some of the advantages and disadvantage of each method.

Table 23. Comparison of Thermostat Power Methods

Wi-Fi Power Method	Description	Advantages	Disadvantages
Batteries + Gateway	Batteries power thermostat. Thermostat communicates over Z-Wave Network with Gateway. Gateway is connected to internet via Ethernet and powered by wall outlet. *(EF, B36-CT, B36-IT)*	• Only 2-wire system required • No professional installation required	• Batteries need to be replaced • Gateway requires access to wall outlet and Ethernet • Monthly service fee to use Gateway (estimated cost: $1.50-$8.99 per month)
C-wire	C-wire powers thermostat with 24 Volt (AC) power. This provides enough power for the thermostat to communicate over home Wi-Fi. *(HW, CCCT, ESS, ES)*	• Provides lifetime power	• Depending on home, new wiring may need to be installed • Estimated cost to install: $200-300
Power Stealing / Phantom Power	Thermostat uses the circuits that turn on and off the HVAC system to charge an internal battery. This provides enough power for the thermostat to communicate over home Wi-Fi. *(Nest, Lyric)*	• Only 2-wire system required • No professional installation required • Provides lifetime power	• Available power limited when HVAC system is running. If extended home power outage and the battery level gets low, the Nest will turn off the Wi-Fi to conserve power. Lyric requires AAA battery to supplement and for start-up.
Fast-Stat Common Maker	"Sender" installed in wall behind thermostat. "Receiver" installed at HVAC unit.	• Only 2-wire system required • Provides lifetime power	• Professional installation required • Additional expense ($29.95)*

*Fast-stat.net. Accessed 2/18/15.

Appendix B. Participant Survey

This document describes the participant survey for this Thermostat Assessment. Cadmus distributed this survey to all study participants using web-survey software Qualtrics®.

Research Questions for Participant Survey

Table 24 describes the research questions for this survey and indicates the related survey questions.

Table 24. Research Questions

Researchable Question	Survey Question
What thermostat setpoints and schedules did you use?	Installer score card
How frequently did you change or override the setpoint in home? How frequently did you change or override the setpoint remotely?	Q15 Remote control log
What did the participant like about the thermostat? What did you dislike about the thermostat?	Q26 Q27
Did customer use web site? How did they access it? Was it easy to use?	Remote control log, Q32 Q34 Q44-49
Did customer use mobile app? Was it easy to use?	Remote control log, Q32 Q44-49
What features were most appreciated?	Q36
What features are most likely to be used? What features are most likely to reduce or increase energy consumption?	Q32-36, Q44-49 Q56-60
Would the participant purchase the same thermostat model? If so, what price would they pay?	Q23-25 Q22
Does customer believe they will save energy without compromising quality with the device?	Q59, 60 (savings) Q36-37, Q38-Q43 (quality compared to old t-stat)
Has the customer had any problems with the thermostat since it was installed? What problem? How did you resolve it?	Q28-31

Outline of Participant Survey

This section outlines the progression of survey questions.

Survey Start

Thank you for participating in the Smart Thermostat study. Please complete this 15-minute survey about your experience and satisfaction with your new thermostat. Your responses provide valuable information for future energy-efficiency programs.

-----------------------------------NEW PAGE-----------------------------------

Baseline Thermostat

The questions in this section are designed to provide us with a baseline for how you used your *OLD* thermostat.

1) How did you use your old thermostat?
   - ☐ I programmed my thermostat.
   - ☐ I manually controlled my thermostat.
   - ☐ I used a single setpoint.
   - ☐ I never touched it.
   - ☐ Other
   - ☐ I don't know
2) [IF 1=OTHER] Please describe how you used your old thermostat.
3) How did you determine your temperature settings with your old thermostat? CHECK ALL THAT APPLY.
   - ☐ Based on comfort
   - ☐ Based on being energy efficient
   - ☐ Based on saving money
   - ☐ Based on habit
   - ☐ Other
   - ☐ N/A: I rarely changed the temperature on my thermostat.
4) [IF 3=OTHER] You indicated you determined your thermostat settings for a different reason. Please describe.
5) How comfortable was your home during winter with your old thermostat?
   - ☐ My home was usually comfortable.
   - ☐ My home was usually comfortable, with the exception of some rooms.
   - ☐ My home was usually comfortable, except on especially cold days.
   - ☐ My home was frequently uncomfortable.
6) How satisfied were you with your old thermostat?
   - ☐ Very satisfied: I would recommend my old thermostat.
   - ☐ Satisfied: It met my needs.
   - ☐ Somewhat satisfied: It met my needs, but I would change some things.
   - ☐ Unsatisfied: I wanted to replace my old thermostat.

7) Before participating in this study, how likely is it that you would have bought a smart thermostat on your own?
   - ☐ I was already planning to purchase a smart thermostat
   - ☐ Likely
   - ☐ Maybe
   - ☐ Not likely
   - ☐ I had never heard of a smart thermostat before.
8) Before participating in this study, what is the most you would have been willing to pay for a smart thermostat?
   - ☐ $0
   - ☐ $50
   - ☐ $100
   - ☐ $150
   - ☐ $200
   - ☐ $250
   - ☐ More than $250

---**NEW PAGE**---

New Thermostat

The questions in this section are designed to help understand how you used your *NEW* thermostat.

9) Our records indicate you received a [THERMOSTAT NAME] thermostat for this study. Please verify if this true.
   - ☐ Yes, this is the thermostat I received.
   - ☐ No, I received a different thermostat.
10) [IF 9=NO] What thermostat did you receive?
11) How have you used your new thermostat?
   - ☐ I programmed my thermostat.
   - ☐ I manually adjusted the thermostat temperature setting.
   - ☐ I used a single setpoint.
   - ☐ I have not touched it since it was installed.
   - ☐ Other
   - ☐ I don't know
12) [IF 11=OTHER] Please describe how you have used your new thermostat.
13) Do you control your new thermostat similarly to your old thermostat?
   - ☐ Yes
   - ☐ No
   - ☐ I don't know
14) [IF 13=NO] How is the way you control your new thermostat different?
15) How frequently you override your thermostat settings FROM HOME?
   - ☐ Several times per day

- ☐ Once per day
- ☐ Several times per week
- ☐ Rarely
- ☐ Never
- ☐ I don't know

16) Which of the following influence how you control your new thermostat? CHECK ALL THAT APPLY.
    - ☐ Based on comfort
    - ☐ Based on being energy efficient
    - ☐ Based on saving money
    - ☐ Based on habit
    - ☐ Other
    - ☐ N/A: I rarely change the temperature on my thermostat
17) [IF 16=OTHER] You indicated you determined your thermostat settings for a different reason. Please describe.
18) Has the comfort of your home changed since you installed your new thermostat?
    - ☐ Yes
    - ☐ No
    - ☐ I don't know
19) [IF 18=Yes] Please describe the change.
20) How satisfied are you with your new thermostat?
    - ☐ Very satisfied: I would recommend this thermostat
    - ☐ Satisfied: It meets my needs
    - ☐ Somewhat satisfied: It meets my needs, but I would change some things
    - ☐ Unsatisfied: I want to return the thermostat
21) Would you recommend your new thermostat to others?
    - ☐ I would definitely recommend this thermostat
    - ☐ Likely
    - ☐ Maybe
    - ☐ Not likely
    - ☐ I would definitely NOT recommend this thermostat
22) Now that you used your new thermostat, what is the most you would be willing to pay for it?
    - ☐ $0
    - ☐ $50
    - ☐ $100
    - ☐ $150
    - ☐ $200
    - ☐ $250
    - ☐ More than $250
23) The market cost of the [TSTAT MODEL] is [PRICE].If you were not allowed to keep your new thermostat, what would you do?
    - ☐ I would reinstall my old thermostat.

☐ I would purchase and install the same model of my new thermostat.
☐ I would purchase and install a different type of thermostat.
☐ Other.

Thermostat	List Price
Carrier	$249
HW RTH5980WF	$249
Ecobee Smart	$454
Nest	$249
Building 36	$249
Ecobee Smart Si	$270
EcoFactor	$150

24) [IF 23=OTHER] Please describe.
25) [IF 23=purchase different thermostat] What thermostat would you purchase?
26) What do you like best about the thermostat? Please describe.
27) Is there anything you dislike about the thermostat? Please describe.
28) Have you have any problems with your new thermostat?
   ☐ Yes
   ☐ No
29) [IF 28 = YES] What was the problem?
30) [IF 28=YES] Were you able to resolve it?
   ☐ Yes
   ☐ No
31) [IF 30 = YES] How did you resolve it?

Thermostat Features

32) Please indicate the features you have used with your thermostat, mobile app and web account. Check all that apply.

Feature	Thermostat	Mobile App	Online Web Account	N/A
Checked indoor temperature				
Checked outdoor temperature				
Adjusted setpoint				
Programmed schedule				
Changed schedule				
Checked system run time or temp history				
Other				

33) [IF Q32 = MOBILE APP and ONLINE WEB ACCOUNT = 0] If you did not use your web account or mobile app, please describe why.
34) [IF Q32 = MOBILE APP and ONLINE WEB ACCOUNT ≠ 0] How did you access the web account?
    - ☐ Computer
    - ☐ iPad
35) [IF Q32 = OTHER ≠ N/A] Please describe what other feature you used.

36) What features will you most likely continue to use and why?
37) Are there any features you dislike? Please describe.

Thermostat Comparison

The following questions will ask you to compare your NEW thermostat to your OLD thermostat.

38) Are there any features of your old thermostat that you wish your new thermostat had?
    - ☐ Yes
    - ☐ No
    - ☐ I don't know
39) [IF 38=YES] Please describe which features and why.
40) [IF Q32 = CHECKED SYSTEM RUN TIME OR TEMP HISTORY ≠ N/A] Has checking your system run time or temp history affected how you use your thermostat?
    - ☐ Yes
    - ☐ No
    - ☐ I don't know
41) [IF 40=YES] Please describe how.
42) Compared to your old thermostat, has your new thermostat been easier or more difficult to use?
    - ☐ New thermostat is easier to use
    - ☐ New thermostat is more difficult to use
    - ☐ They are the same
    - ☐ I don't know
43) [IF 42 = easier or more difficult]Please describe how.

Usability

The following questions explore your experience using your NEW thermostat.

44) Please rate the level of difficulty for each of the following installation/setup actions:

	Easy: It was mostly straightforward	Somewhat Difficult: It took some time to figure out	Difficult: I needed assistance	I don't know	N/A
Program schedule					

	Easy: It was mostly straightforward	Somewhat Difficult: It took some time to figure out	Difficult: I needed assistance	I don't know	N/A
Set up mobile application					
Set up web account					

45) Please use this space to include any comments or suggestions regarding your experience with the actions listed above.
46) Please rate the level of difficulty for each of the following actions:

	Easy: It was mostly straightforward	Somewhat Difficult: It took some time to figure out	Difficult: I needed assistance	I don't know	N/A
Navigate the thermostat menu					
View current thermostat settings					
View current indoor temperature					
View current temperature setting					
View system run time or temp history					
Change temperature setting					
Change schedule					
Manage comfort level					

47) Please use this space to include any comments or suggestions regarding your experience with the actions listed above.
48) Please rate the overall level of difficulty of using the following products/services:

	Easy: It was mostly straightforward	Somewhat Difficult: It took some time to figure out	Difficult: I needed assistance	I don't know	N/A
Thermostat					
Mobile application					
Web account					

49) Please use this space to include any comments or suggestions regarding your experience and satisfaction with the products/services listed above.

CADMUS

Customer Support

50) Have you contacted your thermostat manufacturer for customer support since the thermostat was installed?
    - ☐ Yes
    - ☐ No
    - ☐ I don't know
51) [IF 50=YES] Was it difficult to get connected to customer support?
    - ☐ Yes
    - ☐ No
52) [If 51=YES] Did you receive support from the manufacturer?
    - ☐ Yes
    - ☐ No
53) [If 52 = YES] What did you receive support for?
54) [If 52 = YES] Please rate the helpfulness of the support you received?
    - ☐ Very helpful
    - ☐ Somewhat helpful
    - ☐ Not too helpful
    - ☐ Not at all helpful
55) [If 54 = not too or not at all helpful] Please explain this rating.

Impact on Energy Usage

56) Which features of your new thermostat are most likely to help reduce your energy consumption?
57) Were there any features that might cause an increase in your energy consumption?
    - ☐ Yes
    - ☐ No
    - ☐ I don't know
58) [IF 57 = YES] List which features and describe why.
59) Do you think you will save energy with your new thermostat?
    - ☐ Yes
    - ☐ No
    - ☐ I don't know
60) [IF 59 = YES] Please describe why.

61) Please provide any additional comments you have about your new thermostat:

Appendix C. Electrical Code Interpretation

L. **PA-Specific Programming**

Introduction

In addition to the statewide plan, which is the core of the Compact's approved 2013-2015 Three-Year Plan, the Compact provides specific program enhancements in several plan areas. These program enhancements result from the Governing Board's policy direction to continue existing programs that are both successful and responsive to the Compact's unique customer population. The Compact has tailored the statewide program offerings, where necessary to better meet its customers' unique profiles and needs. The Compact's Governing Board has determined that these enhancements are necessary to continue to best serve the needs and meet the demands of the Compact's unique customer base.

In the following sections, the Compact explains by program the enhancements it proposes for the 2016-2018 Three-Year Plan term. In addition, the Compact provides a description of its enhancements to its 2016-2018 Energy Education offering, associated with the Residential Education offering. See the Statewide Plan for the full program descriptions associated with each program (See Section III of the Statewide Plan, annexed as Exhibit Compact-1 to the Compact's Petition).

Residential and Low-Income Program Descriptions

Residential Whole House

Program Goals	The Compact expects lifetime energy savings of 284,181 MWh.
Program Budget	$50,849,827
Compact Enhancements	<u>Home Energy Services Initiative</u> The Compact has identified cost-effective enhancements during the 2013-2015 term that assist customers with identified barriers such as split incentives and difficulty with co-payments. To address these issues, the Compact has offered 100% incentives, up to the program cap of $4,000, for qualified weatherization incentives (in a fuel blind manner) for year-round renters that are responsible for payment of the electric bill, those customers whose income is within 61-80% of state median income, and those that are operated by municipalities or other government entities. The Compact raised the cap for weatherization to $4,000 for all customers after it identified that average recommendations often surpassed the previous cap of $2,000. The change has allowed customers to make improvements within one year rather than over several years.

	Multi-Family Retrofit Initiative In addition to serving customers whose facilities are heated with electricity, the Compact is proposing to also serve customers with oil- and/or propane-heated facilities in order to provide enhanced benefits for increased participation at Multi-Family sites based upon the pending RCS updates by the Massachusetts Department of Energy Resources. Residential Behavior Feedback The Compact is offering its customers a unique initiative which is designed to promote energy savings through the use of automation tools that will give homeowners the ability to remotely control their homes' energy usage as well as potentially offer demand response incentives.

Residential Products

Program Goals	The Compact expects lifetime energy savings of 332,165 MWh.
Program Budget	$12,691,029
Compact Enhancements	Residential Lighting To continue educating customers in how to make smart, efficient lighting choices, the Compact will work with towns on the Cape and Vineyard in 2016 to offer a free LED bulb to town residents who attend the annual Town Meeting. In addition to the give-away, the Compact will provide residents with educational materials on how to make the best lighting purchase for their needs.

Commercial & Industrial ("C&I") Program Descriptions

C&I New Construction and Major Renovation

Program Goals	The Compact expects lifetime energy savings of 135,687 MWh.
Program Budget	$4,006,049
Compact Enhancements	The Compact continues to offer its municipal customers specialized incentives that cover 100% of incremental custom measure costs as part of this program. In 2016, the Compact proposes to enhance its new construction and major renovation program to include cost-effective thermal measures designed to save oil, propane and other unregulated fuels.

C&I Retrofit Program for Existing Buildings

Program Goals	The Compact expects lifetime energy savings of 793,980 MWh.
Program Budget	$40,053,121
Compact Enhancements	The Compact continues to offer its municipal customers specialized incentives that cover 100% of custom and direct install cost-effective measure costs as part of this program. The Compact also plans to continue two special incentive options first adopted in 2013 to assist small business customers further in overcoming barriers to participation: a 95% incentive option for qualifying small business tenants; and for other small businesses, the zero interest financing option. For 2016, the Compact is rolling out several additional enhancements to its C&I Retrofit Program, each designed to further reduce barriers to participation for key customer segments. First, the Compact proposes to enhance its commercial and industrial retrofit program to include all cost-effective thermal measures designed to save oil, propane and other unregulated fuels. Second, the Compact is launching a new effort for its small C&I customers. The new initiative will be modeled after the HES program and will include a BEA (Business Energy Audit) and a core offering of deemed savings measures, many of which can be installed in the first visit, some at 100% incentive coverage. For its small business direct install customers, the Compact continues to offer higher incentives for standard Direct Install measures (up to 100% rather than up to 70% as offered in the Statewide Plan). Third, the Compact plans to begin phasing in segment-focused delivery options. Fourth, the Compact will also offer 100% incentive for all cost-effective measures for up to 100 (first come, first serve) non-profit corporations on Cape Cod and Martha's Vineyard per year as follows: (a) Non-profit organizations must be a 501(c)(3); (b) Operating more than 5 years with an unrestricted annual operating revenue of less than $15M for non-profit serving low income customers and less than $2M for all other non-profit organizations.

Special Marketing and Education Activities

Energy Education

Program Goals	Recognizing that education is key to affecting change in our society, the Compact has made a strong commitment to education outreach and continues to be a nationally recognized leader in the design and implementation of energy education programs. The Compact strives to address the continuing need for greater consumer awareness and encourage the development of deeper and broader community knowledge and commitment of energy efficiency technology and practices. Using a model for science-based learning, the Compact's energy education program aligned with the Massachusetts State Frameworks for Science and Technology allowing teachers to introduce lessons discussing energy efficiency and conservation as well as emerging renewable energy technologies.
Program Budget	$375,000
Compact Enhancements	• Coordination between other PAs and education agencies on teacher training, In-service, workshops and graduate level courses for teachers • Co-ordination for "Kids Teaching Kids" program at the high school and middle school level • Support and coordination for school and community based Energy Clubs • In-class hands-on presentations on 1. Science of Energy and Energy Transformations 2. Energy Sources (renewable and non-renewable) 3. Electricity 4. Energy Efficiency and Conservation 5. Hydrogen Fuel Cells and Biofuels 6. Climate Change • Statewide Awards program in conjunction with other PAs, the Division of Energy Resources and the NEED Youth Awards Program • Support for school-based "Energy" summer camps • Support for school districts STEM improvements through energy education

	New Program Enhancements: • Classroom based energy efficiency education program designed to continue to the home in educational outreach to the school families. • This program will capture savings through measures taken by the students in their own homes through kits supplied to them by the Compact.

Cape Light Compact Demand Response Demonstration Offering

As described below, the Cape Light Compact ("Compact") is proposing a Demand Response Demonstration Offering ("DR Demonstration Offering") as part of its 2016-2018 Three-Year Energy Efficiency Plan.[1] Demand response ("DR"), however, is inextricably linked to grid modernization ("Grid Mod") and rate design. Currently, the Department of Public Utilities ("Department") has docketed each of the electric utilities' proposed Grid Mod plans for Department review and approval. The Compact's ability to implement a fully developed DR Demonstration Offering as part of its 2016-2018 Energy Efficiency Plan is dependent upon the outcomes of the Grid Mod dockets and the related implementation of Time Varying Rates ("TVR") in the Commonwealth.[2]

A. The Compact's Proposed Interim Demand Response Demonstration Offering

1. Offering Overview

The Compact proposes to roll out its DR Demonstration Offering to customers of Cape Cod and Martha's Vineyard in the second quarter of 2016. The goals of this DR Demonstration Offering are to reduce customer demand through curtailment events and to encourage load-shifting through technology and behavioral change.

- Building on the success of the behavioral initiatives pioneered early in the field, the Compact will begin to establish the platform for the "connected home" (and possibly "connected business") and will install The Energy Detective ("TED") devices on up to 200 residential and small commercial electric meters through the Compact's Home Energy Assessment ("HES") and Business Energy Assessment ("BEA") initiatives.
    - TED will allow electric customers to access their electric usage on a real time basis through a Cape Light Compact customized application on their mobile device or computer.
- Through a mobile application, the Compact plans to enable the "connected home," allowing customers to view real time energy use in their homes and businesses and to permit better management of their energy consumption and costs.
- The Compact intends to hold approximately 7-10 events each year over the 2016-2018 timeframe. During these events, customers will be asked to curtail electric usage for a specified number of hours during the event. Customers who successfully participate in the event will be provided an incentive payment.

---

[1] The Act Relative to Green Communities (2008) as amended by An Act Relative to Competitively Priced Electricity in the Commonwealth (2012) ("GCA") expressly directs the three-year plans for electric offering administrators "shall provide for the acquisition of all available energy efficiency and demand reduction resources." G.L. c. 25, § 21(b)(1).

[2] The Compact provided comments to the Department in D.P.U. 14-04 (Investigation into Time Varying Rates) and intends to participate in D.P.U. 15-122 (NSTAR Electric Company, d.b.a. Eversource Grid Mod Plan).

- If the customer is participating in the Compact's power supply program, the customer could be eligible for additional savings through a critical peak pricing option.
- Initially, participation in the Compact's DR Demonstration Offering will be targeted towards those customers with central air conditioning and electric heat. Participants will be offered Wi-Fi thermostats free of charge. The Compact will install Wi-Fi thermostats through its direct install core initiatives. Wi-Fi thermostats are available to all other customers with potential co-pays (as applicable).
- The Compact intends to incorporate connected appliances such as dishwashers, washing machines, refrigerators, freezers and smart window ACs. Potential rebates for smart appliances have not been determined at this time.
- The "connected home" is expected to grow in value by providing enhanced DR and energy efficiency benefits as other plug load uses, such as pool pumps/heaters, heat pump water heaters, electric vehicle charging stations become available.

2. *Customer Education, Outreach and Engagement*

The Compact will build on its existing community outreach efforts to offer the "connected home" DR Demonstration Offering. The Compact will promote the DR Demonstration Offering through its website, e-newsletter, and community civic/energy committee meetings.

3. *Budget Goals*

The attached Table 1 provides an estimate of the proposed budget for the DR Demonstration Offering as proposed.

B. The Next Generation of the Compact's DR Demonstration Offering

1. *The Importance of Full Implementation of DR*

The unique demographics of the Cape and Vineyard, the effects of generation retirement on SEMA capacity costs, the level of energy efficiency program participation, and growth of distributed energy resources present the case for a highly motivated market for DR. The Compact's DR Demonstration Offering will enable the Compact to further explore this market during the 2016-2018 Three-Year term.

Of particular importance is the ability of DR offerings to reduce demand during ISO-NE's annual system peak hour. Doing so allows participants, assuming ISO-NE settlement-quality data is available, to reduce their installed capacity tags. Given that FCM results show SEMA capacity prices for new resources reaching the administratively-set maximum for 2018-2019, reduced demand could help mitigate the multiple-cent price increase Cape and Vineyard ratepayers will face as a result of increasing capacity prices. Because capacity prices will begin increasing dramatically in 2017, a faster rollout is a priority. Reducing peak usage in the SEMA zone is the most effective method to prevent Cape and Vineyard electric customers from this impending rate increase.

2. Impediments to the Compact's Full Implementation of Demand Response

The Compact's unique status as the only municipal aggregator Program Administrator complicates its implementation of its ideal DR offering during the 2016-2018 Three-Year term. Ideally, the Compact would propose the installation of advanced metering instead of a TED but cannot do so until implementation of the local distribution company's Grid Mod plan. Advanced metering would provide seamless access to real-time energy usage, allowing customers to better understand and manage their consumption, would allow for two-way communications, and would provide the granular and accurate load data which would be required for the implementation of TVR as a method to reduce peak usage.

a. Implementation of TVR

The Compact is supportive of an opt-out TVR offering because experience has shown that while average participant response may be lower for opt-out offerings; higher participation outweighs this effect, resulting in more cost-effective DR offerings.[3] The Compact acknowledges that the Grid Mod plans filed by the distribution companies are inconsistent regarding implementation of TVR offerings. The Compact believes that there must be consistency between the offerings of distribution companies regarding the type of TVR (opt-out or opt-in) and customer TVR eligibility (basic service and competitive supply) so a full array of DR offerings may be available to the maximum number of customers and the full potential benefits of DR realized.

b. Energy Storage

The Compact maintains that a fully integrated DR offering should incorporate energy storage. The availability of TVR is necessary to capture full DR benefits from energy storage. Energy storage, both small and large scale, continues to decrease in price, making it an increasingly viable option for customers interested in DR options. Energy storage is presently being marketed by solar installation companies as a complement to photovoltaic ("PV") installations. Additionally, energy storage is a non-wires alternative ("NWA"), in certain circumstances, that presents a more cost-effective solution than traditional infrastructure upgrades as a means of meeting demand in congested areas. See National Grid DR Pilot Updates, by Tim Roughan, Washington, DC, May 28, 2015 (noting NWAs provide for the integration of customer-facing resources such as energy efficiency and distributed energy resources along with utility/grid-facing resources that together, in specific geographic areas, defer a planned transmission or distribution infrastructure investment). The Compact plans to advocate for policies that will

---

[3] Page vi, Department of Energy, "Interim Report on Customer Acceptance, Retention, and Response to Time-Based Rates from the Consumer Behavior Studies," June, 2015: http://energy.gov/sites/prod/files/2015/06/f24/ARRA-CBS_interim_offering_impact_report_June2015.pdf.

encourage the effective deployment of storage to defer infrastructure investments and allow storage owners to monetize these benefits.

c. Customer Data and AMI Electric Meters

As noted above, the installation of AMI electric meters is necessary to realize the full benefits of a DR offering. Moreover, participation in ISO New England's Demand Response Program is a priority as it will maximize the benefits of DR for electric ratepayers. ISO New England requires 5-minute interval data for participation in its DR program. This level of customer data is presently not available from the majority of existing electric meters on Cape Cod and Martha's Vineyard.[4] As such, in order to fully implement a DR offering to effectively reduce the peak on Cape Cod and Martha's Vineyard, upgrades to existing customer electric meters to AMI meters will be required. The Compact maintains that the cost for meter upgrades should be borne by the local distribution company on its regulated portion of the electric bill and not through the energy efficiency surcharge. The Compact strongly supports analysis that evaluates whether the cost of deploying AMI meters in the SEMA zone accompanied by full deployment of DR is less expensive for SEMA electric customers than the anticipated customer bill increases due to SEMA capacity prices, as noted above.

[4] While TED can provide real-time usage data for customers, it may not satisfy the data requirements for participating in ISO-NE energy and capacity markets. The Compact will work with ISO-NE to establish whether or not data from the installed TEDs can be used in these markets.

2016 Cape Light Compact Demand Response Budget

Sector	Program Planning and Administration	Marketing and Advertising	Participant Incentive	Sales, Technical Assistance & Training	Evaluation and Market Research	Total Program Costs
A - Residential	$ -	$ 4,500	$ 5,850	$ 156,957	$ -	$ 167,307

Eversource PA-Specific Materials

Demand Reductions

Eversource recognizes the importance and need to achieve demand reductions due to their numerous benefits such as the possibility to delay or defer transmission and distribution projects, mitigating spikes in electric prices, and lowering emissions. Eversource is committed to the research and customer engagement necessary to implement demand reductions properly. During the 2016-2018 Three Year Plan, Eversource will investigate these opportunities.

The Company has had tremendous success in its previous Three Year Plans by building a deliberate, systematic go-to-market strategy for its offerings that provide real value to its customers. Eversource will continue working to understand customers' needs and how best to serve them. It is important to note that not all customers consume electricity in the same manner and as such there is no "one size fits all" path to demand reductions. The Company will continue to take a customer first approach when exploring and subsequently introducing new technologies and offerings geared towards demand reduction. Eversource will kick off the 2016-2018 Plan with in-depth research to ensure demand reduction initiatives are aligned with customer and Company objectives.

This effort will be informed by activities already underway at Eversource. The Company is a regional participant in the additional Avoided Energy Supply Cost (AESC) study geared towards determining critical peak costs. This is a key first step in determining which demand reduction measures may be cost effective and appropriate for customers. Eversource has also teamed with the Fraunhofer Center for Sustainable Energy Systems and Navigant Consulting to better understand how customers' energy use coincides with peak demand at the system level and what technologies might alleviate that coincident demand.

Within its current portfolio of energy efficiency offerings, Eversource has identified several measures that are focused at reducing demand which it will emphasize during the 2016-2018 Three Year Plan. LED bulbs and lighting controls have the potential to significantly lower peak demand. Eversource will continue to push LED bulbs and lighting controls to its customers and work towards influencing the lighting market through its upstream programs. The Company intends to pursue a similar strategy with efficient HVAC equipment. Also within its existing portfolio, the Company plans to continue aggressively pursuing combined heat and power (CHP) opportunities, for both small and large units.

A new way the Company plans to help reduce demand is by offering a training program to building operators so that they use their existing equipment and systems as efficiently as possible. These trainings should help reduce demand by allowing existing systems to run more efficiently, encourage customers to add additional efficient equipment, and ensure the persistence of demand reductions by educating building operators on how to use their equipment properly over a long period of time.

Another new way the Company plans to promote demand reduction is by educating its customers about their peak demand consumption through its Customer Engagement Platform (CEP). The CEP will offer customers visualizations and high level analytics around their consumption patterns through its ability to pull in historical usage and interval data (where available). Demand reductions will be driven by the CEP's ability to offer custom behavioral and widget based solutions to reducing consumption.

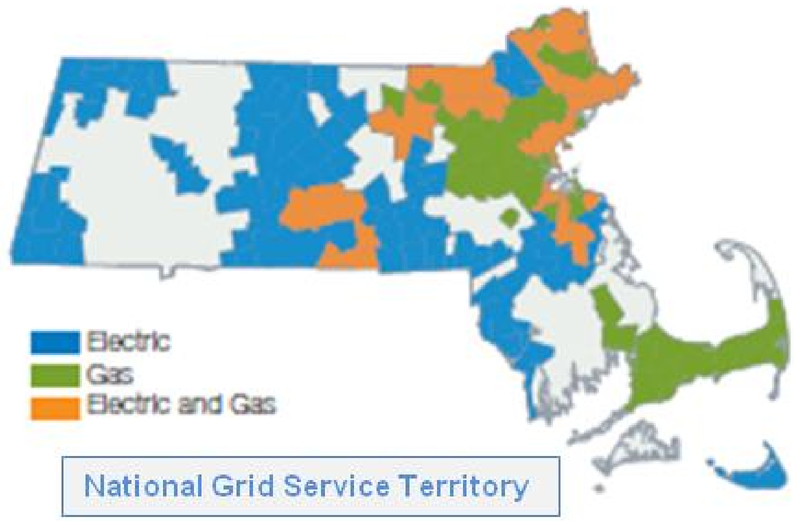
As always, Eversource is committed to exploring and advancing new technologies. Given the increased interest in demand reductions, the Company will be searching for promising technologies that can reduce demand in a cost effective manner and meet customers' needs. Eversource has a history of promoting new technologies where appropriate and intends to continue this strategy.

Lastly, it is important to note that energy efficiency is only one channel for reducing demand and the Company will leverage alternative channels to achieve its goal of lowering peak demand as well. To that end, Eversource has proposed spending over $100 million for advanced meters, over $7 million for storage technologies, and nearly $10 million for Volt VAR Optimization in its Grid Modernization plan. Opt-in time of use (TOU) rates have also been shown to reduce peak demand and are included in the Company's Grid Modernization plan. It is anticipated that energy efficiency will work in tandem with other grid modernization initiatives to maximize the impact the Company can have on reducing peak demand.

2016-2018 Energy Efficiency Plan:
National Grid Specific Elements

A. Overview

National Grid is committed to providing its customers with comprehensive energy efficiency solutions which drive economic and environmental benefits in support of the principles of the Green Communities Act, the Global Warming Solutions Act, and energy policy in the Commonwealth. The Company fully supports the efforts outlined in the 2016-2018 Massachusetts Statewide Three-Year Electric and Gas Energy Efficiency Plan and will supplement those efforts to take into account the unique communities it serves.



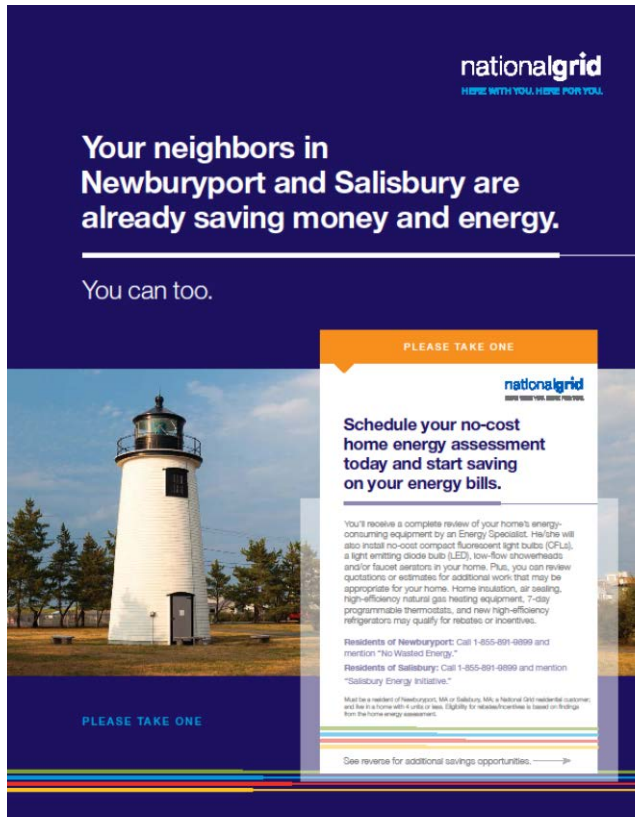
National Grid's service territory spans the full breadth of the state from Suffolk to Worcester to Berkshire counties. Thus, our 1.2 million electric customers in 172 communities and 850,000 gas customers in 116 communities represent a unique array of diverse demographic and economic circumstances. Our vision as a company is to create a more resilient, reliable, agile, efficient, and environmentally-sound energy network for all our customers, while connecting people, innovative technologies, and energy information. In light of this, National Grid has developed a variety of initiatives described below which collectively lay the groundwork to create this future.

B. Customer Partnerships

Communities Initiative: During 2013-2015, National Grid deployed a Communities Initiative in which the Company partnered directly with municipalities. National Grid began the program in 2013 with Medford, and expanded it in 2014 with Chelmsford, Malden, Newburyport, Salisbury, and Shirley. The Company plans to continue with this grant program in 2016-2018.

The Communities Initiative is designed specifically to accommodate the special circumstances of any community, regardless of demographic or socioeconomic characteristics. Each municipality is given participation and savings goals based upon past program performance levels in that specific town, creating a level playing field for achieving goals. Participating municipalities are provided with start-up funding and supported with training in education and outreach to their residents. Regular check-in calls allow municipalities to share their outreach tactics with each other and provide some sense of competition. Specific phone numbers and key words are set up for each municipality in order to track participation due to the program, and additional rewards are based on audits performed and additional measures completed, such as insulation and heating systems. The approach specifically rewards communities for increasing the volume of not just home energy assessments, but also measure installations, such as weatherization and heating systems.

For the 2013-2015 initiative, selection for the Communities Initiative was based on responses to an open request for information (RFI) to all of National Grid's dual-fuel communities. In 2016-2018, the Company anticipates coordinating efforts with other PAs so that initiatives like this can be expanded to communities where National Grid is either the electric provider or the gas provider, but not always both.



Geotargeting/Non-wires Alternatives: One consideration in choosing communities will be whether locations have projected high congestion and/or future planned infrastructure investments. The increase of energy efficiency in those areas due to the concentrated marketing tactics and/or enhanced incentives of the Communities Initiative may be able to alleviate the congestion.

The idea of geotargeting energy efficiency is not new to National Grid. In a 2011 study[1] on the Aquidneck Island area of Rhode Island, Opinion Dynamics Corporation found that National Grid efforts to target marketing to specific towns resulted in measurable increases to the energy efficiency participation in those areas above and beyond what would have otherwise been expected. In addition, a number of steps have been taken toward exploring non-wires alternatives (NWAs) in New England. National Grid defines NWAs as projects that combine multiple technologies, including energy efficiency, in a specific, geographical area with a goal of deferring a transmission or distribution investment. As part of its 2012 System Reliability Procurement Report[2], National Grid began implementing its first non-wires alternative (NWA) pilot in Little Compton and parts of Tiverton Rhode Island in an effort to reduce 1 MW of load (primarily through energy efficiency but also with some demand response efforts) during the area's peak times in order to defer a $2.9 million investment in an additional distribution feeder to serve the area. This pilot is now in the fourth year of its six-year

[1] *Evaluation of National Grid's Community Pilot Program - Energy Action: Aquidneck and Jamestown Final Report*. Prepared by Opinion Dynamics Corporation in October 2011.
[2] *2012 System Reliability Plan Report – Supplement*. Prepared by National Grid in February 2012.

planned lifetime, and the distribution investment, originally planned for 2014, has still not been constructed.

National Grid has also started to explore NWAs in Massachusetts on Nantucket. In 2015, implementation began on an initial plan, primarily composed of energy efficiency. In the long term, the goal of this project will be to defer 18 MW over 17 years to defer the construction of a third cable to serve the island's load by at least ten years. About 5-7 MW of this total reduction is projected to come from energy efficiency. The larger effort is projected to include renewables, energy storage, demand response and potentially time varying rates as potential sources of load reduction during peak hours.

In its 2016-2018 Plan, National Grid would like to expand on its experience with NWAs by employing targeted efforts to geographically concentrate some energy efficiency efforts in areas of greater need, i.e. areas that are projected to have higher load congestion over time or that are projected to need a distribution or transmission upgrade related to load growth. While no areas of need beyond Nantucket are projected for implementation in 2016-2018 at the time of this filing, screening for areas will take place on a rolling basis, and projects will be proposed as they are identified.

Nonprofit Referrals: While municipal partnerships are one way to diversify our marketing channels, nonprofit partnerships are another means to potentially reach more customers. In 2016-2018 National Grid intends to begin a Nonprofit Referral program, partnering with small, local nonprofits to reach their membership. This initiative will also reward nonprofits based on completed audits and installed measures.

D. Demand Response

National Grid proposes to offer broad demand response (DR) solutions to reduce customer demand through peak shaving solutions and load shifting opportunities. National Grid also plans to explore opportunities for gas DR. Demonstration projects will provide insights and help develop best practices and strategies to guide the deployment of solutions at scale. The Company, in consultation with the Council and other PAs, will develop a common framework for cost-effectiveness and proposed performance incentives for all demand response programs.

Commercial and Industrial Demand Response

Multi Year Strategy: Commercial and Industrial (C&I) demand response demonstration projects will be deployed to explore options for direct load control, as well as customer initiated interruptible load demand response in 2016 with further demonstration activities in 2017 and 2018, as appropriate. National Grid will analyze data collected from the demonstration projects to assess the market potential, test delivery strategies, identify market barriers, and develop the framework for cost-effectiveness for the screening of demand response (DR) programs. Findings from these demonstration projects and related evaluations, along with additional research and analysis, will inform and refine any future implementation of DR. National Grid plans to propose performance incentives for DR-related efforts after incremental DR-related benefits are better understood and determined through the demonstration projects.

Proposed Initiatives: For small commercial customers where interval meters do not currently exist, National Grid will focus on direct load control demand response. This initiative will explore opportunities to reduce peak load by providing incentives for the installation of technologies that automatically reduce energy usage during demand response events. Some of the potential technologies under consideration, where applicable, include Wi-Fi thermostats that control air conditioners, heat pumps, smart plugs, and smart water heaters. In addition, National Grid will research opportunities for other demand response-enabled technologies for small commercial customers, such as network lighting.

For large commercial and industrial customers with interval meters, National Grid will focus on interruptible load demand response. Here, customer meter data allows for measuring actual curtailment. Facility-specific assessments will be used to identify the most appropriate curtailment strategies for each customer, and could include HVAC system controls, network lighting controls, energy management systems (EMS), and other demand reducing opportunities specific to each customer facility. National Grid will coordinate energy efficiency assessments to include demand response opportunities where appropriate.

Technology Deployment: National Grid will provide incentives for demand response enabled technologies such as Wi-Fi thermostats, open automated demand response (ADR) enabled equipment, and network lighting controls through the ongoing energy efficiency programs to position the market for larger deployment of demand response in the future. Future investments in grid modernization, enabling widespread use of time varying rates and including a scalable demand response management system, could further enhance demand response capabilities. As new demand response-enabled technologies emerge, National Grid will continue to evaluate those technologies and, as appropriate, incorporate them into to its portfolio offerings.

Residential Demand Response

Multi-Year Strategy: Similar to the commercial and industrial demand response strategy, the residential demand response strategy will explore demonstration projects and seek to position the marketplace for broad deployment of demand response in the future. Lessons from planned demonstration projects in 2016 will be used to further develop and enhance residential demand response initiatives in 2017 and 2018.

Proposed Initiatives: For residential customers, National Grid intends to pursue full scale deployment of mature demand response-enabled technologies such as Wi-Fi thermostats, while also testing new technologies and progressively scaling those that prove successful. In 2016, National Grid plans to demonstrate the benefits of automated demand response with Wi-Fi thermostats. This technology allows the house to be pre-cooled prior to a demand response event and manages the indoor temperature during such an event, so that it is always within a given range to maximize customer comfort. This control strategy uses two-way communication through the in-home Wi-Fi network to maximize potential savings for customers with minimal impact on comfort. Also in 2016, National Grid plans to implement small-scale demand response with connected washers and dryers, and smart window air conditioning. In 2017 and 2018, National Grid plans to explore connected electric hot water heaters, heat pump water heaters, dishwashers, pool pumps and electric vehicle charging stations. Most of these technologies have both energy efficiency and demand response savings, and therefore the company intends to promote them though the existing energy efficiency programs.

Communication, Education and Engagement: National Grid strives to deliver customer solutions that optimize customer benefits. Therefore, significant efforts will be made to educate and engage customers with information through direct mail, email, and online portals. The company is currently exploring the best means to leverage existing customer communication channels such as our home energy reports and our in-person home energy assessments. Specific topics of focus may include the benefits of demand response, and the automatic smart control that allows National Grid to maximize in-home comfort and demand savings.

Budgets and Expected Results: National Grid is proposing budgets for demand response initiatives and has estimated the expected MW reduction associated with these efforts. The MW reduction targets are estimates based on the learnings from the Smart Energy Solutions pilot in Worcester and demand response programs from across the country. These MW reduction estimates will be refined and revised in the subsequent years based on findings from the demonstration projects.

The demand savings presented in the table below should not be considered formal goals. Rather, they are intended to provide a preliminary estimate of incremental demand savings from contemplated DR efforts. Goals for efforts that prove to be cost-effective will be set after the results of the proposed demonstration projects can be considered.

The demand response savings presented in the "Preliminary Estimate of Expected Demand Savings" table below reflect the average reduction in capacity per hour during a demand response event from residential and C&I demand response strategies that may be deployed in 2016 – 2018. These estimates are dependent on the expected time and length of a demand response event. The preliminary DR savings provided in the table are based on an average of 87 hours of residential demand response hours for each customer and 40 C&I demand response hours in a year for commercial customers. The assumed length of the demand response events will vary from 2-4 hours for residential customers.

Preliminary Estimate of Expected Demand Savings

NATIONAL GRID DR SAVINGS		
Year	**Program**	**Average hourly MW Reduction during an event**
2016	**Residential**	**2.6**
	Commercial	**0.3**
2017	**Residential**	**6.5**
	Commercial	**40.5**
2018	**Residential**	**11.0**
	Commercial	**41.0**

E. Electric Vehicle Charging Stations

National Grid believes that there is a unique opportunity to leverage the Company's energy efficiency related customer interactions to help the Commonwealth achieve its Clean Energy and Climate Plan transportation objectives. Promoting electrical vehicle (EV) charging stations along-side energy efficiency could increase customer interest and program participation while introducing a new tool to help manage energy loads over the long term. As part of its 2016-2018 Plan, the Company would like to explore the promotion of EV charging stations through the energy efficiency programs by examining potential funding mechanisms and quantifying the energy savings that could result from these efforts. Should this exploration show that the addition of EV charging stations can deliver program and customer benefits, National Grid would like to implement an integrated strategic promotion of this technology.

F. R&D and Technical Demonstration

National Grid is committed to evaluating new and innovative technologies to provide Massachusetts customers with enhanced savings and benefits. It is essential to develop and test next generation products to ensure they meet claimed economic benefits as well as the highest standards of reliability and safety

National Grid works with the Massachusetts Technical Assessment Committee (MTAC) in a collaborative manner that enables all stakeholders to consider the technologies demonstrated for future program design and implementation. The projects are both proactive and reactive in the marketplace as solutions develop.

The Company is planning the following residential demonstrations in 2016-2018: Smart Appliance Control and Multi-Channel Communication Platform for Connected Home; micro combined heat and power (MCHP); and other technologies as they emerge in the marketplace.

In addition, National Grid will be examining the following commercial demonstrations for 2016-2018: Performance Lighting Existing to Code -Tier Zero; Lighting Controls with Demand Response; Adaptive LED Troffer –Enhanced Controls Logic; Lighting Designer Incentive (LDI); Lighting Re-Specification Incentive; Building Tune Up (BTU_p); Lab Buildings Retrocommissioning (RCx) and/or Deep Dive; and Distributed Refrigeration.

G. Education

National Grid has been a long-term supporter of the National Energy Education Development (NEED) Project, bringing energy efficiency curricula and trainings to teachers in Massachusetts. In 2016-2018, the Company will supplement the NEED trainings with take-home energy-efficiency kits. Teachers who participate in the trainings will be able to request these kits, which contain instant-savings measures such as light bulbs, showerheads, and faucet aerators, as well as educational materials. After in-class lessons about energy-efficiency, students will bring the kits home and complete surveys regarding which measures their families install. In this way, the Company can capture additional savings and expand the reach of the education program beyond teachers and students, and to parents as well.

National Grid will continue offering a school lighting fundraiser in 2016-2018. In much the same style as other school fundraisers, in which students sell magazines, candy, or wrapping paper, students can sell light bulbs, smart power strips, and showerheads to family and friends, with all profits from the sale going to the school. This motivates students to not only learn about energy efficiency, but also to share what they have learned within their community.

It is the hope that the increased awareness and commitment represented by installing instant savings measures through the take home kits and lighting fundraiser will encourage families to pursue additional energy efficiency opportunities while fostering a culture of sustainability.

Berkshire Gas – Remaining Potential Study
Final Report

February 2nd, 2015

Table of Contents

Executive Summary - Purpose

This report presents Berkshire Gas-specific results from a comprehensive, six month assessment of remaining energy efficiency potential within Berkshire Gas, NEGC (now Liberty Utilities), Unitil Gas and Unitil Electric service territories

Executive Summary - Order

- In addition to assisting the small PAs in quantifying remaining potential within their service territories, this effort was conducted in accordance with the Massachusetts Department of Public Utilities' January 31, 2013 Order D.P.U. 12-100 through D.P.U. 12-111 (sections IV.B.2.a & 4.a – pages 18, 19 & 40) and subsequent DOER Consultant feedback
- Specifically, Section IV.B.2.a states:
  - "The Program Administrators with an aggregate three-year savings goal of greater than 20 percent below the statewide three-year aggregate goal will conduct a study, either jointly or individually, during the upcoming three-year term to document the penetration of energy efficiency within its service territory and the remaining cost-effective energy efficiency opportunities available.."

Executive Summary – Savings Goals

For the 2013-2015 Energy Efficiency Plan, Berkshire's three-year savings goals fell short of the statewide average:

Program Administrator	2013	2014	2015	Total 2013-2015
Berkshire Gas	0.70%	0.76%	0.81%	0.76%
Statewide	1.08%	1.17%	1.19%	1.14%
Variance from Statewide Aggregate				**33.3%**

Executive Summary – Key Tasks

Three major task areas were pursued:

1. Secondary data collection/data mining and data gap analysis, including review of ongoing work of the Evaluation Management Committee.
2. Primary data collection sample design, work plan development and implementation of telephone surveys (residential and small/medium C&I customers) and on site data collection (larger C&I customers).
3. Data analysis and reporting of likely achievable and high case remaining potential results.

Executive Summary – Scope/Timing

This was a fast tracked (approx. six month) effort coordinated across four Program Administrators (PAs) culminating in development of four separate, territory-specific reports – one for each PA (Berkshire Gas, Liberty Gas, Unitil Gas and Unitil Electric).

Executive Summary - Savings Potential Results

- The Likely Achievable savings potential across Berkshire's service territory is estimated to be 0.70% of 2016 annual sales (0.77% by 2018)
  - This is consistent with Berkshire's current three-year(2013-2015) territory-wide target of 0.76%
- The sectors with greatest potential for savings as a % of sector sales remain with Berkshire's residential and small/medium commercial customers (0.87% and .085% by 2018 respectively)
- Less potential remains within the large commercial sector (0.51% by 2018)

Summary Likely Achievable Scenario	2016	2017	2018
Residential			
Annual Therm Savings	272,624	280,745	287,083
Forecast Sales	31,195,551	32,108,411	32,839,013
Savings as % of sales	**0.87%**	**0.87%**	**0.87%**
PA Cost to Achieve	$ 3,434,278	$ 3,536,087	$ 3,605,746
Total Cost to Achieve	$ 5,507,737	$ 5,668,283	$ 5,792,784
Small and Med C&I			
Annual Therm Savings	138,418	169,043	194,922
Forecast Sales	22,434,695	23,022,680	23,018,703
Savings as % of sales	**0.62%**	**0.73%**	**0.85%**
PA Cost to Achieve	$ 424,287	$ 476,065	$ 515,842
Total Cost to Achieve	$ 788,834	$ 892,315	$ 972,856
Large C&I			
Annual Therm Savings	96,193	97,100	97,911
Forecast Sales	19,344,322	19,344,322	19,344,322
Savings as % of sales	**0.50%**	**0.50%**	**0.51%**
PA Cost to Achieve	$ 386,793	$ 388,640	$ 389,983
Total Cost to Achieve	$ 581,962	$ 585,539	$ 589,373
TOTAL			
Annual Therm Savings	507,235	546,889	579,916
Forecast Sales	72,974,568	74,475,413	75,202,039
Savings as % of sales	**0.70%**	**0.73%**	**0.77%**
PA Cost to Achieve	$ 4,245,359	$ 4,400,792	$ 4,511,571
Total Cost to Achieve	$ 6,878,534	$ 7,146,138	$ 7,355,013

Executive Summary - Top Savings Sources

Residential Sector	Total Savings 272,624	% of Savings
Improved Wall Insulation	92,809	34.0%
Behavior	21,529	7.9%
Air Sealing	19,055	7.0%
Boiler 95%	16,701	6.1%
Heating System Replacement	16,521	6.1%
Furnace w/ECM 97%	16,054	5.9%
Improved Attic/Roof Insulation	15,954	5.9%
Early Retirement (Steam) - Retire	9,926	3.6%
Early Retirement (FHW) - Retire	8,880	3.3%
Furnace w/ECM 95%	8,268	3.0%

Top 3 Residential Measures:

- Wall insulation
- Behavior
- Air sealing

Large Commercial	Total Savings 96,193	% of Savings
Custom - Large	38,057	39.6%
Condensing Boiler 500-999 mbh (.90 TE)	16,530	17.2%
Kitchen equipment	10,585	11.0%
Steam Traps	9,766	10.2%
Showerhead	7,904	8.2%
Faucet Aerator	4,435	4.6%
Boiler Reset Controls (retrofit only)	2,917	3.0%
Condensing Boiler 301-499 mbh (.90 TE)	2,399	2.5%
DHW systems	1,192	1.2%
Programmable Thermostat	633	0.7%

Small/Medium Commercial	Total Savings 138,418	% of Savings
Kitchen equipment	36,356	26.3%
Custom - Small & Medium	29,114	21.0%
Steam Traps	26,658	19.3%
Faucet Aerator	10,790	7.8%
Showerhead	8,331	6.0%
Condensing Boiler <= 300 mbh (.96 TE)	5,996	4.3%
Programmable Thermostat	4,903	3.5%
DHW systems	3,956	2.9%
Combo Condensing Boiler/DHW 90%	3,537	2.6%
Boiler Reset Controls (retrofit only)	2,917	2.1%

Top 3 Small/Medium Commercial Measures

- Kitchen equipment
- Custom measures
- Steam traps

Top 3 Large Commercial Measures:

- Custom measures
- Condensing boilers (500-999 mbh (.90 TE)
- Kitchen equipment

Executive Summary – Key Findings

Results from review of secondary and primary data sources suggest:

- A somewhat limited market exists for cost effective energy efficiency savings projects within Berkshire's large commercial sector over the next 3 to 5 years
  - A majority Berkshire's 103 largest customers have already participated, with few additional major projects on their near-term planning horizon
- Economic challenges within Berkshire's service territory are making it difficult for residential and business customers to prioritize and pursue energy efficiency projects
- The sectors with greatest potential for savings as a % of sector sales remain with Berkshire's residential and small/medium commercial customers
  - Although customers within these sectors are typically cash constrained, increased focus on Berkshire's residential, small & medium sized customers could yield additional savings

Service Territory Characterization

Residential – 890 average annual therms/customer (36,008 customers)

- 965 average annual therms/customer (32,639 heat customers)
- 170 average annual therms/customer (3,369 non-heat customers)
- 5,928 (16.5%) of Berkshire's residential customers have been program participants within the past 3 years (including repeat participants and low income customers)

METHODOLOGY

There were three major tasks completed as a part of this effort:

1. Secondary Data Collection/Data Mining
2. Primary Data Collection
3. Data Analysis and Reporting

Methodology – Secondary Data

Task 1 – Secondary Data Collection Activities:

- Reviewed existing evaluation reports including ongoing evaluation planning and implementation activities assessments
  - Participated as Berkshire's representative in relevant Evaluation Management Committee meetings including: Residential, C&I and Cross-Cutting working groups
- Reviewed utility specific data
  - Customer data and program data provided by Berkshire

METHODOLOGY – SECONDARY DATA

Findings:

- Very little territory-specific data available from statewide evaluation efforts
- Utility specific data from Berkshire was used in Task 3 – Data Analysis

Methodology – Primary Data

Task 2 – Primary Data Collection Activities:

- Used to fill gaps identified through Task 1 effort
- Used to develop savings estimates for Task 3 data analysis and reporting
  - Telephone Surveys
  - On-Site Surveys

Methodology – Sample Design

- Residential – A sample size of 41 was targeted to obtain a confidence and precision of 80/10 at the Residential sector level.
- Commercial and Industrial – A sample size of 41- split between small and medium commercial phone surveys and larger commercial/industrial site visits - was targeted to obtain a confidence and precision of 80/10 at the C&I sector level.
- Territory Level – Overall, a goal of 82 surveys was targeted to achieve statistical significance of at least 90/10 across the Berkshire service territory.

Methodology – Sample Selection

- Residential – A random sample of 41households was ultimately selected for phone surveys by study team member RKM Research & Communications.
  - The sample was drawn from a randomized list of Residential Customers (Rates R1, R2, R3 & R4) provided by Berkshire Gas.
- Small Commercial – A random sample of 44 customers was ultimately selected for phone surveys by study team member RKM Research & Communications.
  - The sample was drawn from a randomized list of Small Commercial Customers (Rates: G41, G42, G51 & G52) provided by Berkshire Gas.
- Large Commercial & Industrial – A randomly selected sample of 17 customers were ultimately recruited for on-site data collection by GDS field staff.
  - The sample was drawn from a randomized list of Berkshire's total pool of Large Commercial & Industrial Customers (Rates: G43 & G53).
  - A randomized list of customers was provided and called through, in order, to avoid sample bias and procure a representative mix of participating and non-participating customers.
  - Soft leads were recruited with the help of utility representatives. GDS then contacted the customer and set-up a time to complete the site visit. Some coordination with DNV-GL was also required to avoid duplication of effort with their simultaneous site data collection efforts for another ongoing evaluation project and to minimize customer confusion.

METHODOLOGY – FINAL SAMPLE SIZES

Final Sample Sizes				
	Residential Customer Population	# Phone Surveys Targeted	# Phone Surveys Completed	Achieved Confidence/Precision
Residential Telephone Surveys	33,076	41	41	80/10
C&I Customer Surveys*	5,153	21 (phone) / 20 (site)	44 (phone)/ 17 (site)	80/8.2
Territory Level	38,229	62 (phone) / 20 (site)	85 (phone) / 17 (site)	90/8.1

* Includes a mix of on -site data collection and telephone surveys

During fielding of the small commercial telephone surveys, the target sample size was increased to from 21 to 41 to collect more data on smaller to medium sized commercial customers.

METHODOLOGY – PHONE SURVEYS

Residential Response Rates:

- The overall response rate of the Residential phone surveys was ***13.8%.***
- A total of 607 customers were dialed, and 41 surveys were completed.
- Only 2 calls experienced a language barrier ***(0.33%)***

Call Code	Disposition	Total	%TOTAL DIALINGS

	RESPONSE RATE(%)		***14.7***

Methodology – Data Analysis

Task 3 – Data Analysis Activities:

- Reviewed raw survey data
- Determined end-use saturation and efficiency penetrations by customer sector
- Developed remaining energy efficiency potential savings estimates

Methodology – Survey Data Review

- Raw telephone survey and on-site data collection results were reviewed, analyzed and summarized
- Sector specific presentations were developed to document detailed results and identify key findings from each research area including:
  - Demographics/firmography
  - Individual energy end-use findings
  - Past purchases and practices
  - Attitudes
  - Program awareness, participation and satisfaction
- Survey and site-visit data was then used to develop estimates of Potential Savings

Methodology – Savings Estimates

A combination of data sources were used to develop factors for calculating remaining potential energy savings:

- Survey and site visit results
- Customer counts
- Existing efficiency program measures
- Existing program data on energy savings
- Massachusetts 2013 Report Technical Reference Manual
- Current utility Net-To-Gross (NTG) ratios
- Benefit/Cost modeling (Total Resource Cost Test – TRC)

Methodology – Savings Estimates

Equation of Potential Energy Savings

Participation × Savings (therms) × NTG Ratio

Methodology – Participation Est.

Participation

GDS used a number of factors to arrive at an annual estimate of measure participation

- Estimate of base homes
  - Customers with gas heating and percent of customers with the baseline measure (i.e. boiler, furnace)
- Applicability factor
  - Split between competing measures (i.e. 90% AFUE boiler, 95% AFUE boiler)
  - Accounts for consumer choice
  - Used past program installations to estimate future installation ratios
  - Benefit/Cost modeling was conducted using the TRC test to assess cost-effectiveness of individual measures. However, measures with B/C ratios less than 1.0 were not dropped from the analysis because cost-effectiveness is not assessed at the measure level in MA, but at the program level . B/C ratios were used, where appropriate, to prioritize installations among competing measures → greater factor weight applied to measures with a higher B/C ratio.
- Burnout rate of measure (1/measure life)
  - What percentage of the market is expected to need replacing
- Convertibility factor
  - What percent might not be physically convertible to new technology or other limitation (i.e. wall insulation improvements would not be available for brick, stone or asbestos siding exteriors)

METHODOLOGY – PARTICIPATION EST.

Participation

GDS used a number of factors to arrive at an annual estimate of measure participation

- Energy Efficiency Saturation
  - Percentage of market that is selecting efficient equipment
  - Based on survey data
- Willingness to Participate
  - Included only in the "likely achievable potential scenario"
  - Not included in the "high-case" scenario (i.e., before consideration of territory-specific realities, customer behaviors and measure installation barriers)
  - Reflects survey response assessed percentage of customers likely to move forward with a project

Methodology – Measure Savings

Savings (therms)

GDS used a number of sources to estimate measure specific savings

- 2013 Report Massachusetts Technical Reference Manual
  - Included deemed savings values for many measures
- Utility Specific Program Data
  - Used for New Construction Program
- REM Rate Energy Modeling
  - Calibrated to utility climate and average annual heating usage

Methodology – NTG Ratios

NTG Ratios

GDS used current NTG ratios to adjust savings estimates

- NTG Ratios
  - Utility specific or statewide where applicable
  - Included or adjusted for free-ridership and spillover rates in some cases, but not all
  - Typically developed through rigorous evaluation efforts

METHODOLOGY - SCENARIOS

When estimating remaining potential, two modeling scenarios were run:

1. Likely achievable potential scenario – This scenario represents the study team's best estimate of the remaining potential within Berkshire's service territory and applies a "customer willingness" factor derived from telephone survey and site visit responses, along with sector-level budget constraints where applicable.
2. High-case scenario – This scenario represents the study team's estimated upper bound of the remaining potential without consideration of territory-specific realities, including customer behaviors and budget constraints.

High-Case Scenario - Savings Potential Results

- The total High-Case savings potential across Berkshire's service territory is estimated to be 1.17% of 2016 annual sales (1.34% by 2018).
  - The PA cost to achieve this potential is substantial at nearly $7.5M in 2016 ($8.1M in 2018) vs $5.3M current budget.
- Greatest potential, as % of sector sales, is in the residential customer sector (1.60% of 2016 sales, 1.62% by 2018).
- Very little change in potential exists within the large commercial sector when compared to the Likely Achievable Potential scenario (0.50% to 0.51% in both cases).

Summary - High-Case	2016	2017	2018
Residential			
Annual Therm Savings	499,646	516,883	533,104

Total Cost to Achieve	$12,122,280	$12,672,471	$13,163,788

Territory-Specific Insights - Residential

- Program awareness, participation & satisfaction
  - Although a large majority of respondents stated awareness of Berkshire's programs, a much smaller percentage reported participating – leaving a solid pool of potential new participating customers
- Demographics
  - Berkshire's residential telephone survey respondents included a large proportion of older (55+), educated and English-speaking residents
- Home characteristics
  - A majority of Berkshires' residential customer respondents live in older, single family homes that they own – excellent targets for potential building envelope improvements
- ENERGY STAR® awareness
  - While the majority of respondents are familiar with ENERGY STAR®, there is potential opportunity in reaching out to the 17% who are still unfamiliar
- Past purchase practices
  - A majority of respondents appear to have energy efficiency features on their radar screens
- Attitudes
  - Although cost is a major reason cited for not pursuing energy efficiency opportunities, a large majority of respondents express interest in purchasing energy efficient equipment for a multitude of reasons

Territory-Specific Insights - Residential

- Building envelope
  - There remains some likely achievable potential for building envelope improvements within Berkshire's residential customer sector.
- Space heating
  - Potential for heating system replacements exists in homes with older systems, where owners may be looking for replacements within the next five years. Savings associated with controllable thermostats may be limited.
- Water heating
  - Potential for water heater replacements exists in homes with older units, where owners may be looking for replacements within the next five years. Additional opportunities may exist for water saving devices.
- Clothes washing
  - Potential for energy efficient clothes washer and dryers exists in homes with older units, where owners may be looking for replacements within the next five years.
- Dishwashing
  - Potential for energy efficient dishwashers exists in homes with older units, where owners may be looking for replacements within the next five years.
- Hot tubs and heated pools
  - Based on survey responses, there does not appear to be much of a market for efficiency improvements within the pool and hot tub end-use.

Territory-Specific Insights – Small/Medium Commercial

- Program awareness, participation & satisfaction
  - A majority (52%) of Berkshire small business customers are non-participants and nearly all of those who have participated(48%) would be interested in doing so again.
- Firmographics
  - Berkshire's small commercial business base appears stable, with potential opportunities for energy efficiency investments in both leased and owned buildings. Small business owners would be best target for decisions.
- Building size, age & use
  - The make-up of Berkshire's small commercial building stock (relatively old, large square footage, small number of employees, sufficient hours of operation, somewhat efficiency conscious), suggests potential opportunities for targeted efficiency improvements.
- Past purchase practices
  - 27% of small commercial customer respondents stated they had purchased energy efficient products in the past, and 67% of those customers said they had plans to do so again over the next 12 months – suggesting additional potential for efficiency projects within Berkshire's small commercial customer sector.
- Attitudes
  - Rebates remain a major motivator for customer action in the small business sector.

TERRITORY-SPECIFIC INSIGHTS – SMALL/MEDIUM COMMERCIAL

- Building envelope
  - Good opportunities exist for building envelope improvements within Berkshire's small commercial business sector.
- Space heating
  - Based on survey responses, there does not appear to be much potential for replacement heating systems, heating system tune-ups or programmable thermostats within Berkshire's small commercial business sector.
- Water heating
  - Based on survey responses, only a small potential for water heater replacements currently appears to exist within Berkshire's small commercial business sector, but a majority (61%) of Berkshire's small business customer respondents are not taking advantage of other water saving measures (i.e., faucet aerators).
- Commercial kitchen and laundry
  - A small, but high energy use market exists within Berkshire's small business sector for commercial kitchen and laundry customers.
- On-site generation
  - 9% of Berkshire's small commercial customer respondents reported having onsite generation (emergency backup generators). There could be an opportunity to explore this market.

Territory-Specific Insights – Large Commercial

- Program awareness, participation and satisfaction
  - A majority (73%) of large business customer respondents are aware of and have participated in Berkshire's energy efficiency programs and are interested in doing so again.
- Past purchase practices
  - 47% of respondents have completed renovation projects in the past 5 years
  - 18% are planning a renovation in the next 12 months.
  - A small market for efficiency projects (18% of respondents) may exist within Berkshire's large commercial customer sector over the next 12 months.
- Attitudes
  - Lower bills and receipt of rebates remain major motivators for customer action in the large business sector.
  - These attitudes are also impacted by the number of businesses that have moved, sold, gone out of business or otherwise have cut back due to recession.

Territory-Specific Insights – Large Commercial

- HVAC
  - Energy savings potential remains for replacement of inefficient unit heaters.
- Water heating
  - Potential appears to exist for efficient water heating equipment, with greater opportunities for pre-rinse spray valves.
- Cooking and laundry equipment
  - Potential appears to exist for efficient C&I cooking and laundry equipment.
- Process equipment
  - There could be some opportunities for process efficiency improvements – but given the small number of large customers, limited availability of new projects on the planning horizon and unique characteristics of individual business processes, such determinations are best assessed on a custom/case-by-case basis.
- On-site generation
  - There appears to be an opportunity to explore the potential to include renewably-fueled process–related heating and power generation systems and efficient back-up generation systems.

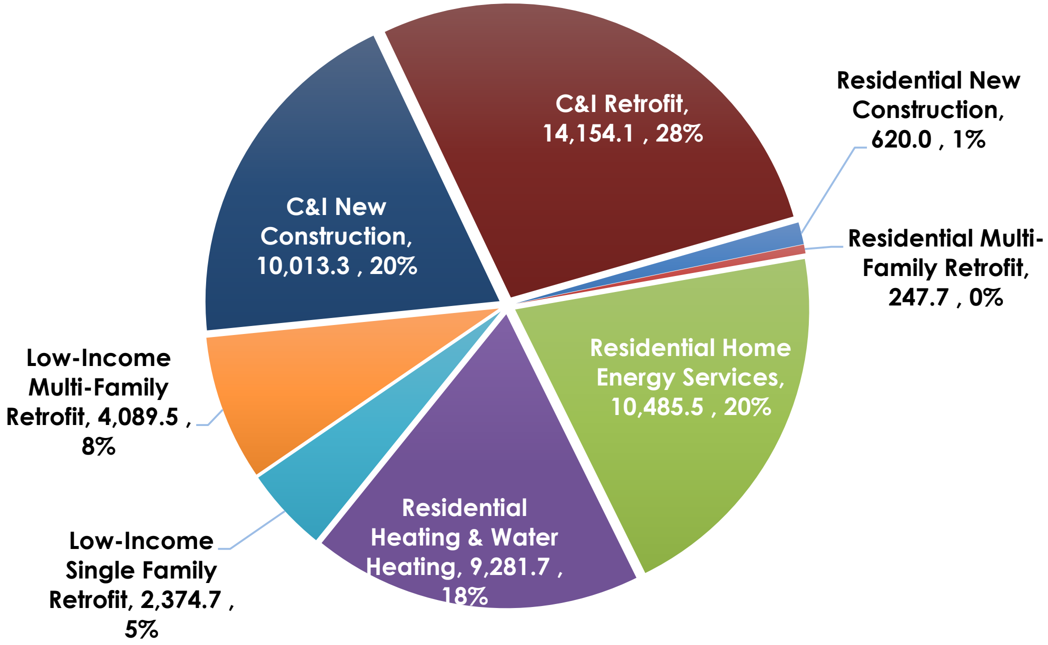
* Several MF LI buildings are under commercial rate. Each unit is counted as one participant.

[1] For 2011, sales from 2011-2012 split year used; for 2012, sales from 2012-2013 split year used; for 2013 sales from 2013-2014 split year used.

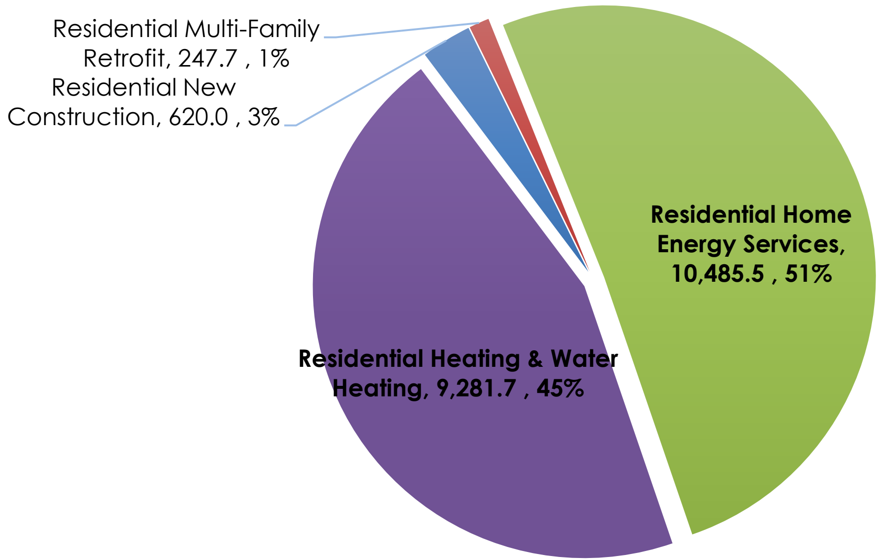
2013 EE Savings Characterization

2013 Evaluated Energy Savings by Initiative, MMBtu



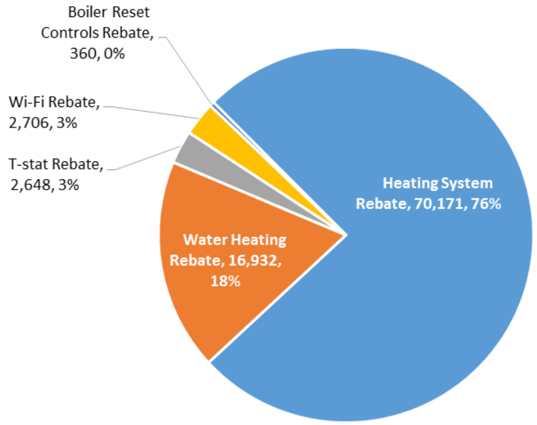
2013 EE Savings - Residential

2013 Evaluated Energy Savings Residential Initiatives, MMBtu



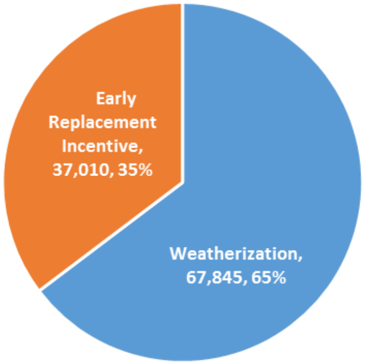
2013 EE Savings-Residential

- Residential Heating & Water Heating (HEHE)
  - 76% of savings from heating systems
    - 67% or 47,049 therms from Boilers
    - 33% or 23,112 therms from Furnaces
  - 18% from water heating
  - 3% Wi-Fi T-Stat
  - 3% Programmable T-Stat
  - <1% Boiler Reset Controls



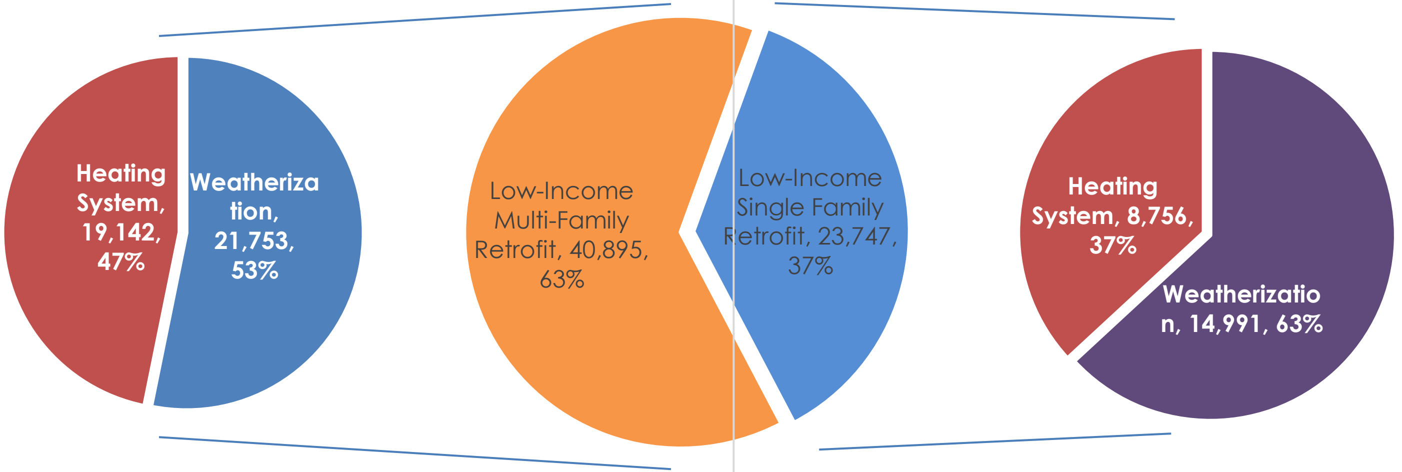
2013 EE Savings-Residential

- Home Energy Services
  - 65% of savings comes from weatherization
    - 67,845 therms from weatherization
  - 35% from Early Boiler Replaceme
    - 37,010 therms
  - <1% Boiler Reset Controls
  - *Total Audits 1,141*
    - *Early Boiler Replacements 99 (8.75%*
    - *Weatherization 310 (27%)*



2013 EE Savings – Low Income

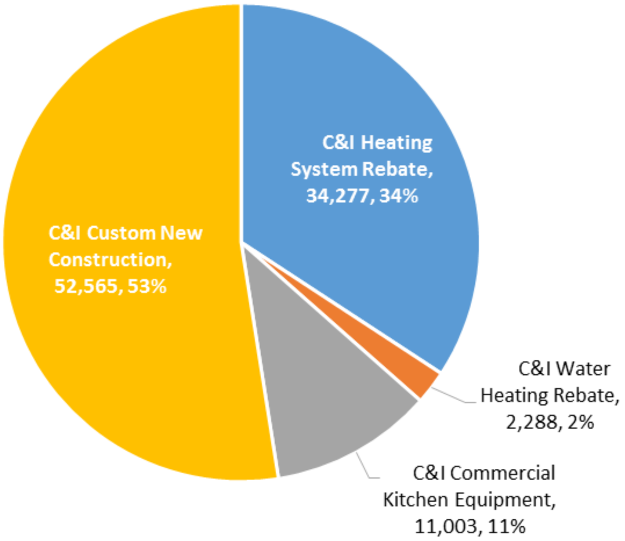
Low Income Programs



Overall the LI Program exceeded Savings goals, by nearly 52%. The Multifamily Retrofit program exceeded its goal by over 150%, while the Single Family program was lightly under its target (met 90.3% of goal).

2013 EE Savings – C&I NC

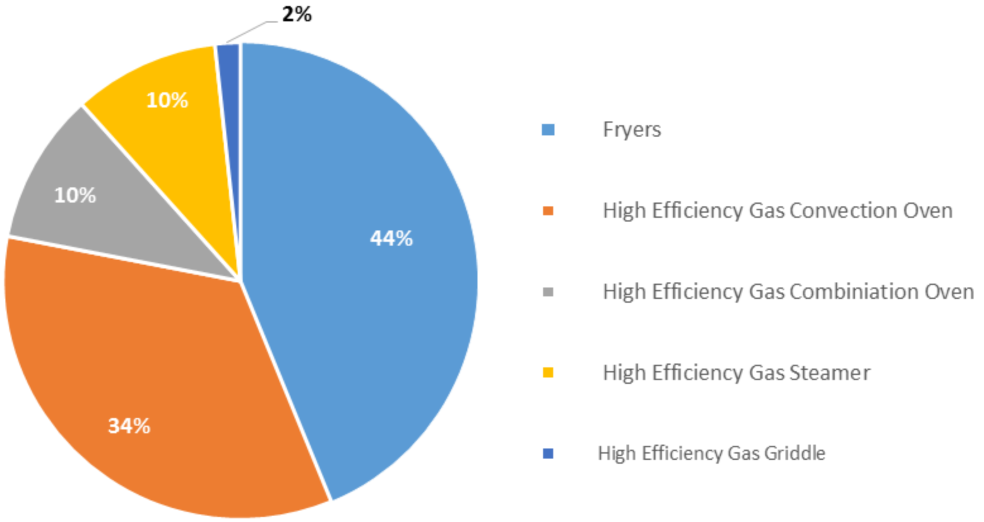
- Of the Total Savings from the C&I New Construction sector, over half was from custom installations. The rest is broken out as follows:
  - Heating Systems 34%
  - Commercial Kitchen 11%
  - Water Heating 2%



2013 EE Savings – C&I NC

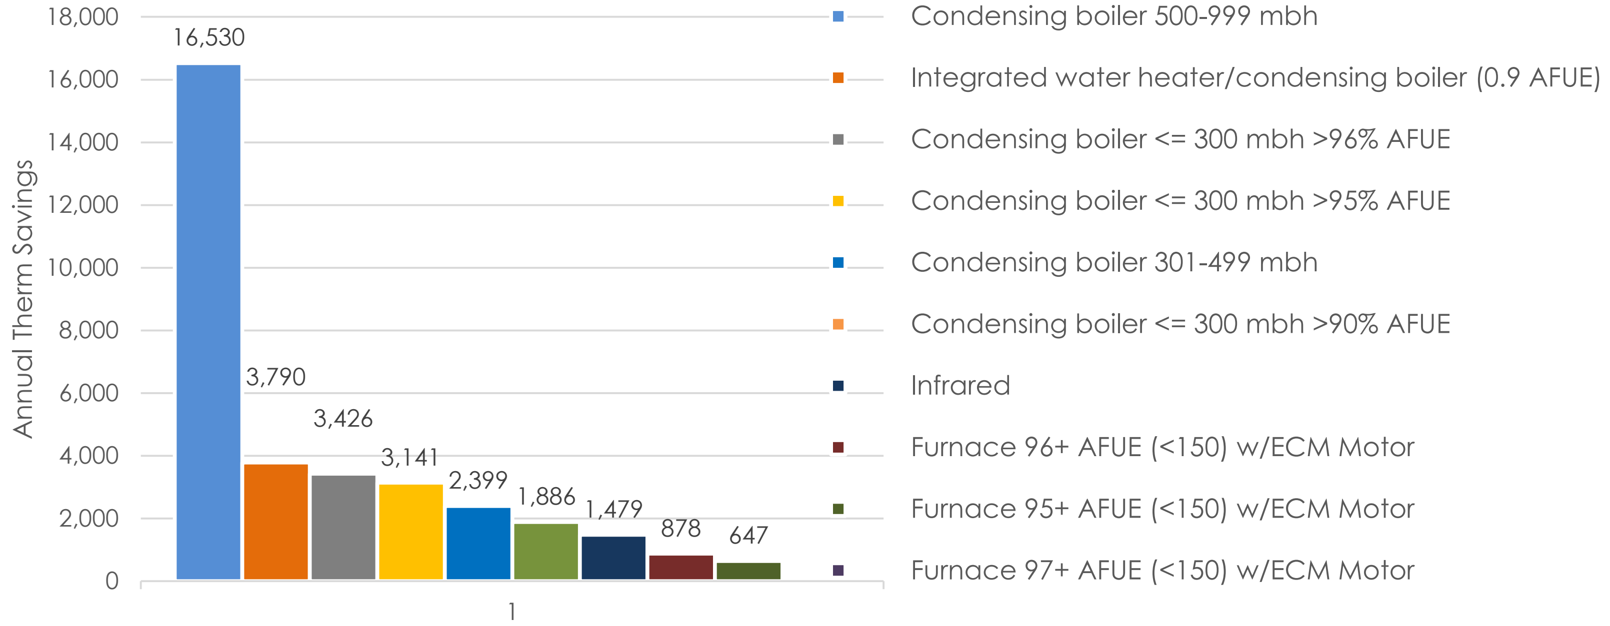
- Types of Commercial Kitchen Equipment

(percentage of total savings from kitchen equipment)



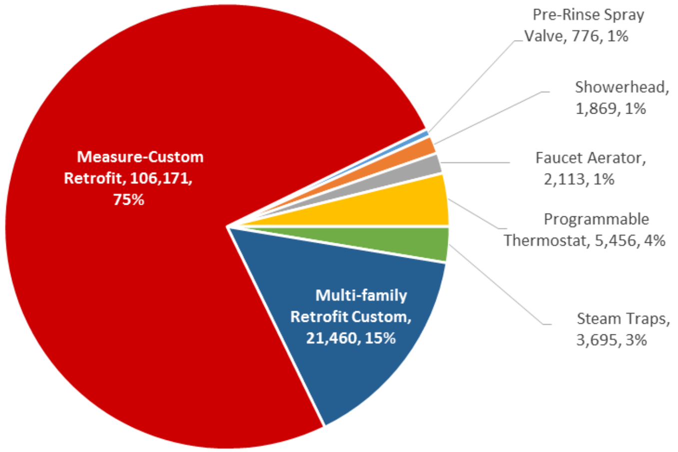
2013 EE Savings – C&I NC

- Types of Space Heating Equipment



2013 EE Savings – C&I Retrofit

- Of the Total Savings from the C&I New Construction sector, about three quarters was from custom installation.



Custom retrofit measures included steam traps, Boilers, Dryers, EMS, Kitchen Hood Controls and an Industrial Dryer. The Industrial Dryer comprised more than half of the custom measure savings.

Liberty Utilities – Remaining Potential Study Final Report

February 2nd, 2015

Table of Contents

Executive Summary - Purpose

This report presents Liberty Utilities-specific results from a comprehensive, six month assessment of remaining energy efficiency potential within Liberty Utilities (formerly NEGC), Berkshire Gas, Unitil Gas and Unitil Electric service territories.

Executive Summary - Order

- In addition to assisting the small PAs in quantifying remaining potential within their service territories, this effort was conducted in accordance with the Massachusetts Department of Public Utilities' January 31, 2013 Order D.P.U. 12-100 through D.P.U. 12-111 (sections IV.B.2.a & 4.a – pages 18, 19 & 40) and subsequent DOER Consultant feedback.
- Specifically, Section IV.B.2.a states:
  - "The Program Administrators with an aggregate three-year savings goal of greater than 20 percent below the statewide three-year aggregate goal will conduct a study, either jointly or individually, during the upcoming three-year term to document the penetration of energy efficiency within its service territory and the remaining cost-effective energy efficiency opportunities available.."

Executive Summary – Savings Goals

For the 2013-2015 Energy Efficiency Plan, Liberty's three-year savings goals fell short of the statewide average:

Program Administrator	2013	2014	2015	Total 2013-2015
Liberty Utilities	0.83%	0.84%	0.85%	0.84%
Statewide	1.08%	1.17%	1.19%	1.14%
Variance from Statewide Aggregate				**26.3%**

Executive Summary – Key Tasks

Three major task areas were pursued:

1. Secondary data collection/data mining and data gap analysis, including review of ongoing work of the Evaluation Management Committee.
2. Primary data collection sample design, work plan development and implementation of telephone surveys (residential and small/medium C&I customers) and on site data collection (larger C&I customers).
3. Data analysis and reporting of likely achievable and high case remaining potential results.

Executive Summary – Scope/Timing

This was a fast tracked (approx. six month) effort coordinated across four Program Administrators (PAs) culminating in development of four separate, territory-specific reports – one for each PA (Berkshire Gas, Liberty Gas, Unitil Gas and Unitil Electric).

Executive Summary - Savings Potential Results

- The Likely Achievable potential across Liberty's service territory is estimated to be 0.49% of 2016 annual sales (0.48% by 2018)
  - This is much lower than Liberty's current three-year(2013-2015) territory-wide target of 0.84%
- The sector with greatest potential for savings as a % of sector sales remains with Liberty's small commercial customers (0.51% of 2016 sales, 0.60% by 2018)
- Slightly less potential remains within Liberty's residential and largest commercial customer sectors (0.48% & 0.50% respectively by 2018)

Summary Likely Achievable Scenario	2016	2017	2018
Residential			
Annual Therm Savings	185,340	185,629	187,331

Forecast Sales	64,338,330	65,127,870	65,375,910
Savings as % of sales	**0.49%**	**0.49%**	**0.50%**
PA Cost to Achieve	$ 2,845,665	$ 2,855,177	$ 2,886,657
Total Cost to Achieve	$ 4,587,179	$ 4,614,415	$ 4,678,536

Executive Summary - Top Savings Sources

Residential Sector	Total Savings 185,340	% of Savings
Improved Wall Insulation	45,231	24.4%
Improved Attic/Roof Insulation	23,306	12.6%
Heating System Replacement	11,940	6.4%
Showerhead	10,044	5.4%
RNC New Homes (Heating)	8,800	4.7%
Combo Condensing Boiler/DHW 90%	8,354	4.5%
Boiler Reset Control	5,490	3.0%
Boiler 95%	5,443	2.9%
Early Retirement (FHW) - Retire	4,884	2.6%
DHW - Indirect	3,917	2.1%

Top 3 Residential Measures:

- Wall insulation
- Attic Insulation
- Heating system replacement

Small/Medium Commercial	Total Savings 75,978	% of Savings
Custom - Small & Medium	39,568	52.1%
Kitchen equipment	9,398	12.4%
Condensing Boiler 500-999 mbh (.90 TE)	4,989	6.6%
Showerhead	4,352	5.7%
Steam Traps	3,984	5.2%
Faucet Aerator	2,213	2.9%
Programmable Thermostat	2,029	2.7%
Condensing Boiler 301-499 mbh (.90 TE)	1,810	2.4%
DHW systems	1,722	2.3%
Boiler Reset Controls (retrofit only)	1,101	1.4%

Large Commercial	Total Savings 51,009	% of Savings
Steam Traps	20,316	39.8%
Showerhead	5,964	11.7%
Condensing Boiler 500-999 mbh (.90 TE)	4,989	9.8%
Faucet Aerator	4,190	8.2%
Custom - Large	3,768	7.4%
Programmable Thermostat	2,268	4.4%
Kitchen equipment	2,080	4.1%
Condensing Boiler 301-499 mbh (.90 TE)	1,810	3.5%
Boiler Reset Controls (retrofit only)	1,651	3.2%
Condensing Unit Heater <= 300 mbh	951	1.9%

Top 3 Small/Medium Commercial Measures

- Custom measures
- Kitchen equipment
- Condensing boilers 500-999 mbh (0.90 TE)

Top 3 Large Commercial Measures:

- Steam traps
- Low-flow showerheads
- Condensing boilers 500-999 mbh (0.90 TE)

Executive Summary – Key Findings

Results from review of secondary and primary data sources suggest:

- A somewhat limited potential exists for cost effective energy efficiency savings projects within Liberty's small/medium and large commercial sector over the next 3 to 5 years.
  - A majority Liberty's 19 largest customers have already participated, with few additional major projects on their near-term planning horizons.
- Economic challenges within Liberty's service territory are making it difficult for residential and business customers to prioritize and pursue energy efficiency projects.
- The sector with greatest potential for savings as a % of sector sales remains with Liberty's small commercial customers
  - Although customers within this sector are typically cash constrained, increased focus on Liberty's small commercial customer base could yield additional savings.

Service Territory Characterization

Residential – 768 average annual therms/customer (50,056 customers)

- 805 average annual therms/customer (47,131 heat customers)
- 160 average annual therms/customer (2,925 non-heat customers)
- 3,300 (7%) of Liberty's residential customers have been program participants within the past 3 years (including multiple measures at a single participant location, repeat participants and low income customers)

METHODOLOGY

There were three major tasks completed as a part of this effort:

1. Secondary Data Collection/Data Mining
2. Primary Data Collection
3. Data Analysis and Reporting

Methodology – Secondary Data

Task 1 – Secondary Data Collection Activities:

- Reviewed existing evaluation reports including ongoing evaluation planning and implementation activities assessments.
  - Participated as Liberty's representative in relevant Evaluation Management Committee meetings including: Residential, C&I and Cross-Cutting working groups.
- Reviewed utility specific data
  - Customer data and program data provided by Liberty.

Methodology – Secondary Data

Findings:

- Very little territory-specific data available from statewide evaluation efforts.
- Utility specific data from Liberty was used in Task 3 – Data Analysis.

Methodology – Primary Data

Task 2 – Primary Data Collection Activities:

- Used to fill gaps identified through Task 1 effort
- Used to develop savings estimates for Task 3 data analysis and reporting
  - Telephone Surveys
  - On-Site Surveys

Methodology – Sample Design

- Residential – A sample size of 41 was targeted to obtain a confidence and precision of 80/10 at the Residential sector level.
- Commercial and Industrial – A sample size of 41- split between small and medium commercial phone surveys and larger commercial/industrial site visits - was targeted to obtain a confidence and precision of 80/10 at the C&I sector level.
- Territory Level – Overall, a goal of 82 surveys was targeted to achieve statistical significance of at least 90/10 across the Liberty's service territory.

Methodology – Sample Selection

- Residential – A random sample of 41households was ultimately selected for phone surveys by study team member RKM Research & Communications,
  - The sample was drawn from a randomized list of Residential Customers (Rates R1, R2, R3 & R4) provided by Liberty Utilities.
- Small Commercial – A random sample of 42 customers was ultimately selected for phone surveys by study team member RKM Research & Communications.
  - The sample was drawn from a randomized list of Small Commercial Customers (Rates: G41, G42, G51 & G52) provided by Liberty Utilities.
- Large Commercial & Industrial – A randomly selected sample of 16 customers were ultimately recruited for on-site data collection by GDS field staff.
  - The sample was drawn from a randomized list of Liberty's pool of Medium and Large Commercial & Industrial Customers (Rates: G43 & G53 and several G42 & G52).
  - A randomized list of customers was provided and called through, in order, to avoid sample bias and procure a representative mix of participating and non-participating customers.
  - Soft leads were recruited with the help of utility representatives. GDS then contacted the customer and set-up a time to complete the site visit. Some coordination with DNV-GL was also required to avoid duplication of effort with their simultaneous site data collection efforts for another ongoing evaluation project and to minimize customer confusion.

Methodology – Final Sample Sizes

Final Sample Sizes				
	Residential Customer Population	# Phone Surveys Targeted	# Phone Surveys Completed	Achieved Confidence/Precision
Residential Telephone Surveys	45,402	41	41	80/10
C&I Customer Surveys*	3,319	21 (phone) / 20 (site)	42 (phone)/ 16 (site)	80/8.3
Territory Level	48,721	62 (phone) / 20 (site)	83 (phone) / 16 (site)	90/8.3

* Includes a mix of on -site data collection and telephone surveys

During fielding of the small commercial telephone surveys, the target sample size was increased to from 21 to 41 to collect more data on smaller to medium sized commercial customers.

METHODOLOGY – PHONE SURVEYS

Residential Response Rates:

- The overall response rate of the Residential phone surveys was ***8.7%.***
- A total of 1,253 customers were dialed, and 41 surveys were completed.
- 23 calls experienced a language barrier ***(1.84%)***

Call Code	Disposition	Total	%TOTAL DIALINGS

	RESPONSE RATE(%)	***8.8***	

Methodology – Data Analysis

Task 3 – Data Analysis Activities:

- Reviewed raw survey data
- Determined end-use saturation and efficiency penetrations by customer sector
- Developed remaining energy efficiency potential savings estimates

Methodology – Survey Data Review

- Raw telephone survey and on-site data collection results were reviewed, analyzed and summarized
- Sector specific presentations were developed to document detailed results and identify key findings from each research area including:
  - Demographics/firmography
  - Individual energy end-use findings
  - Past purchases and practices
  - Attitudes
  - Program awareness, participation and satisfaction
- Survey and site-visit data was then used to develop estimates of Potential Savings

METHODOLOGY – SAVINGS ESTIMATES

A combination of data sources were used to develop factors for calculating remaining potential energy savings:

- Survey and site visit results
- Customer counts
- Existing efficiency program measures
- Existing program data on energy savings
- Massachusetts 2013 Report Technical Reference Manual
- Current utility Net-To-Gross (NTG) ratios
- Benefit/Cost modeling (Total Resource Cost Test – TRC)

Methodology – Savings Estimates

Equation of Potential Energy Savings

Participation × Savings (therms) × NTG Ratio

Methodology – Participation Est.

Participation

GDS used a number of factors to arrive at an annual estimate of measure participation

- Estimate of base homes
  - Customers with gas heating and percent of customers with the baseline measure (i.e. boiler, furnace)
- Applicability factor
  - Split between competing measures (i.e. 90% AFUE boiler, 95% AFUE boiler)
  - Accounts for consumer choice
  - Used past program installations to estimate future installation ratios
  - Benefit/Cost modeling was conducted using the TRC test to assess cost-effectiveness of individual measures. However, measures with B/C ratios less than 1.0 were not dropped from the analysis because cost-effectiveness is not assessed at the measure level in MA, but at the program level . B/C ratios were used, where appropriate, to prioritize installations among competing measures → greater factor weight applied to measures with a higher B/C ratio.
- Burnout rate of measure (1/measure life)
  - What percentage of the market is expected to need replacing
- Convertibility factor
  - What percent might not be physically convertible to new technology or other limitation (i.e. wall insulation improvements would not be available for brick, stone or asbestos siding exteriors)

Methodology – Participation Est.

Participation

GDS used a number of factors to arrive at an annual estimate of measure participation

- Energy Efficiency Saturation
  - Percentage of market that is selecting efficient equipment
  - Based on survey data
- Willingness to Participate
  - Included only in the "likely achievable potential scenario"
  - Not included in the "high-case" scenario (i.e., before consideration of territory-specific realities, customer behaviors and measure installation barriers)
  - Reflects survey response assessed percentage of customers likely to move forward with a project

Methodology – Measure Savings

Savings (therms)

GDS used a number of sources to estimate measure specific savings

- 2013 Report Massachusetts Technical Reference Manual
  - Included deemed savings values for many measures
- Utility Specific Program Data
  - Used for New Construction Program
- REM Rate Energy Modeling
  - Calibrated to utility climate and average annual heating usage

Methodology – NTG Ratios

NTG Ratios

GDS used current NTG ratios to adjust savings estimates

- NTG Ratios
  - Utility specific or statewide where applicable
  - Included or adjusted for free-ridership and spillover rates in some cases, but not all
  - Typically developed through rigorous evaluation efforts

METHODOLOGY - SCENARIOS

When estimating remaining potential, two modeling scenarios were run:

1. Likely achievable potential scenario – This scenario represents the study team's best estimate of the remaining potential within Liberty's service territory and applies a "customer willingness" factor derived from telephone survey and site visit responses, along with sector-level budget constraints where applicable.
2. High-case scenario – This scenario represents the study team's estimated upper bound of the remaining potential without consideration of territory-specific realities, including customer behaviors and budget constraints.

High-Case Scenario - Savings Potential Results

- The total High-Case savings potential across Liberty's service territory is estimated to be 1.23% of 2016 annual sales (1.28 by 2018).
  - The PA cost to achieve this potential is substantial at over $8.7M in 2016 ($8.9M in 2018) vs $3.3M current budget.
- Greatest potential, as % of sector sales, is in the residential customer sector (1.66% of 2018 sales).
- Limited potential exists within the small/medium and large commercial sectors(0.83% & 0.60% respectively in 2018).

Summary - High-Case	2016	2017	2018

Territory-Specific Insights - Residential

- Program awareness, participation & satisfaction
  - More than half of Liberty's residential respondents were not aware of Liberty's energy efficiency programs or products – participation appears hampered by other cash priorities or the transient nature of their accommodations
- Demographics
  - Liberty's residential telephone survey respondents include a majority of younger (18-54) , and low-income residents .
- Home characteristics
  - A large majority of Liberty's residential building stock is old (35+ years) – typically good candidates for building envelope improvements. However, nearly half of Liberty's residential customers live in apartments and/or rent their homes – making it difficult to encourage such improvements.
- ENERGY STAR® awareness
  - There is potential opportunity for reaching out to a large proportion of Liberty's residential population who, 44% based on respondent data, are not very or at all familiar with ENERGY STAR®.
- Past purchase practices
  - A majority of residential respondents appear to have energy efficiency features on their radar screens – but less than a quarter have acted on that vision in Liberty's territory.
- Attitudes
  - Although cost is a major reason cited for not pursuing energy efficiency opportunities, approximately 2/3rd of respondents express interest in purchasing energy efficient equipment for a multitude of reasons.

Territory-Specific Insights - Residential

- Building envelope
  - There remains some likely achievable potential for building envelope improvements within Liberty's residential customer sector.
- Space heating
  - Potential for heating system replacements exists in homes with older systems, where owners may be looking for replacements within the next five years. This may require targeted outreach to apartment building owners/property managers. Savings associated with controllable thermostats may be an opportunity for tenants that pay for their own fuel.
- Water heating
  - Potential for water heater replacements exists in homes with older units, where owners may be looking for replacements within the next five years. This may require targeted outreach to apartment building owners/property managers. Additional opportunities may exist for water saving devices.
- Clothes washing
  - Approximately 1/3rd of Liberty's residential customer respondents do not own a clothes washer /dryer. Potential for energy efficient clothes washer and dryers exists in homes with older units, where owners may be looking for replacements within the next five years.
- Dishwashing
  - Just over 1/3rd of Liberty's residential customer respondents reported owning a dishwasher. Potential for energy efficient dishwashers exists in homes with older units, where owners may be looking for replacements within the next five years.
- Hot tubs and heated pools
  - Based on survey responses, there does not appear to be much potential for efficiency improvements within the pool and hot tub end-use.

Territory-Specific Insights – Small/Medium Commercial

- Program awareness, participation & satisfaction
  - A majority (52%) of Liberty's small business customers are non-participants and all of those who have participated(48%) would be interested in doing so again.
- Firmographics
  - Liberty's small commercial business base appears stable, with potential opportunities for energy efficiency investments in both leased and owned buildings. Small business owners would be best target for decisions.
- Building size, age & use
  - The make-up of Liberty's small commercial building stock (relatively old, large square footage, small number of employees, sufficient hours of operation, somewhat efficiency conscious), suggests potential opportunities for targeted efficiency improvements.
- Past purchase practices
  - Based on survey responses, there does not appear to be much opportunity for efficiency projects within Liberty's small commercial customer sector over the next 12 months.
- Attitudes
  - Rebates remain a major motivator for customer action in the small business sector.

Territory-Specific Insights – Small/Medium Commercial

- Building envelope
  - Good opportunities exist for building envelope improvements within Liberty's small commercial business sector.
- Space heating
  - Potential for replacement heating systems, heating system tune-ups and programmable thermostats exists within Liberty's small commercial business sector.
- Water heating
  - Based on survey responses, only a small potential for water heater replacements currently appears to exist within Liberty's small commercial business sector, but a majority (57%) of Liberty's small business customer respondents are not taking advantage of other water saving measures (i.e., faucet aerators).
- Commercial kitchen and laundry
  - A small, but high energy use market exists within Liberty's small business sector for commercial kitchen and laundry customers.
- On-site generation
  - 12% of Liberty's small commercial customer respondents reported having onsite generation (3 emergency back-up generators, 1 onsite electric generator, 1 unsure source) . There could be an opportunity to explore this market.

Territory-Specific Insights – Large Commercial

- Program awareness, participation and satisfaction
  - A majority (94%) of large business customer respondents are aware of and have participated (84%) in Liberty's energy efficiency programs and are interested in doing so again.
- Past purchase practices
  - Over 50% of respondents have completed renovation projects in the past 5 years.
    - Over 17% of these included lighting renovations.
  - 18% of respondents are planning a renovation in the next 12 months.
    - 12% indicate potential projects, but are unsure.
  - A small market for efficiency projects (18% of respondents) may exist within Liberty's large commercial customer sector over the next 12 months.
- Attitudes
  - Lower bills and receipt of rebates remain major motivators for customer action in the large business sector.
  - These attitudes are also impacted by the number of businesses that have moved, sold, gone out of business or otherwise have cut back due to recession.

Territory-Specific Insights – Large Commercial

- HVAC
  - Energy savings potential remains for replacement of inefficient steam boilers.
- Water heating
  - Potential appears to exist for efficient water heating equipment, with greater opportunities for pre-rinse spray valves.
- Cooking and laundry equipment
  - Potential appears to exist for efficient C&I cooking and laundry equipment, although certain sites could be targeted for collecting additional information related to natural gas ranges.
- Process equipment
  - Process heating equipment is a significant end use for natural gas in the Liberty territory. There could be opportunities for process efficiency improvements – but given the small number of large customers, limited availability of new projects on the planning horizon and unique characteristics of individual business processes, such determinations are best assessed on a custom/case-by-case basis.
- On-site generation
  - There appears to be an opportunity to explore the potential to include renewably-fueled process–related heating and power generation systems and efficient back-up generation systems.

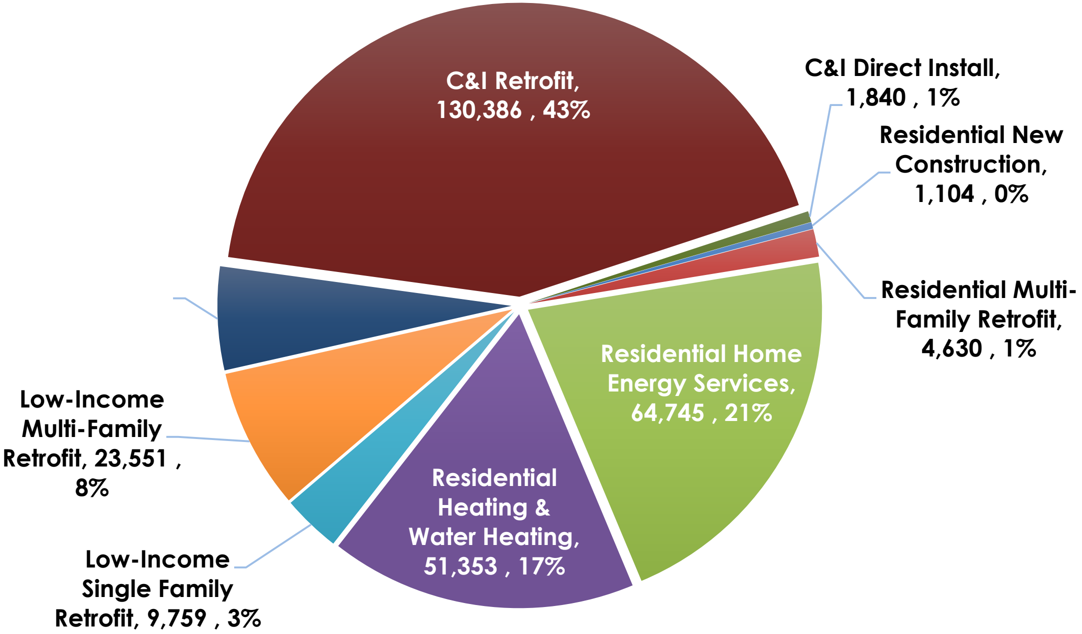
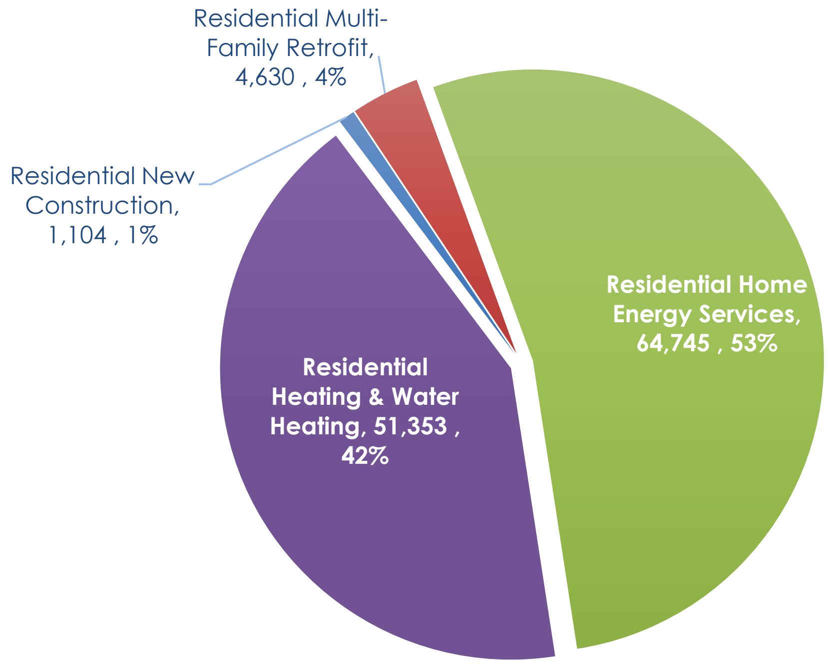
2013 EE Savings Characterization

2013 Evaluated Energy Savings by Initiative, therms



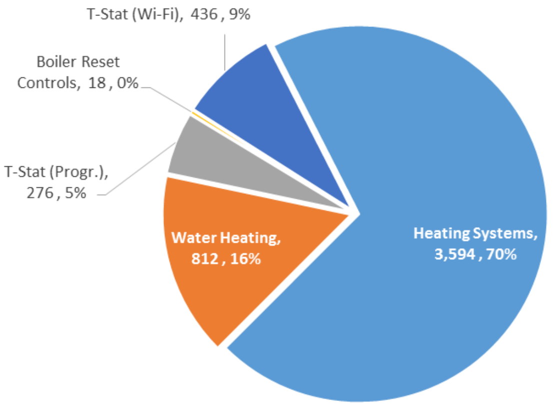
2013 EE Savings - Residential

2013 Evaluated Energy Savings Residential Initiatives, MMBtu



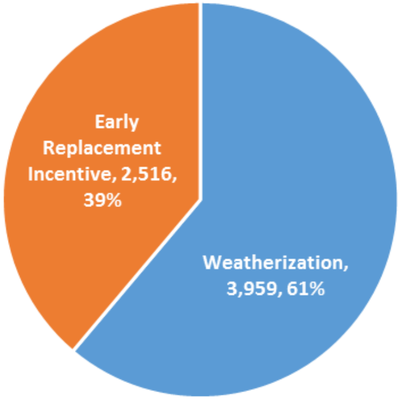
2013 EE Savings-Residential

- Residential Heating & Water Heating (HEHE)
  - 70% of savings from heating systems
    - 71% or 2,552 MMBtu from Boilers
    - 29% or 1,043 MMBtu from Furnaces
  - 16% from water heating
  - 9% Wi-Fi T-Stat
  - 5% Programmable T-Stat
  - <1% Boiler Reset Controls



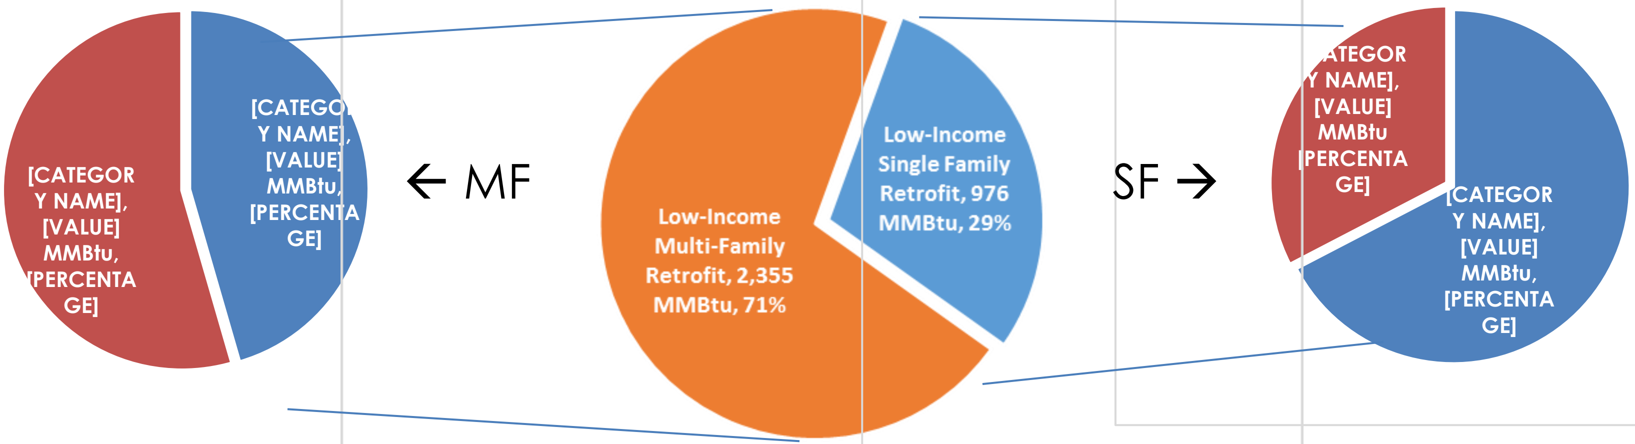
2013 EE Savings-Residential

- Home Energy Services
  - 61% of savings comes from weatherization
    - 3,959 MMBtu from weatherization
  - 39% from Early Boiler Replacement
    - 2,516 MMBtu
  - Weatherization Measures:
    - Attic, Wall, Crawl Space Insulation
    - Faucet Aerators, Showerheads
    - Thermostats



2013 EE Savings – Low Income

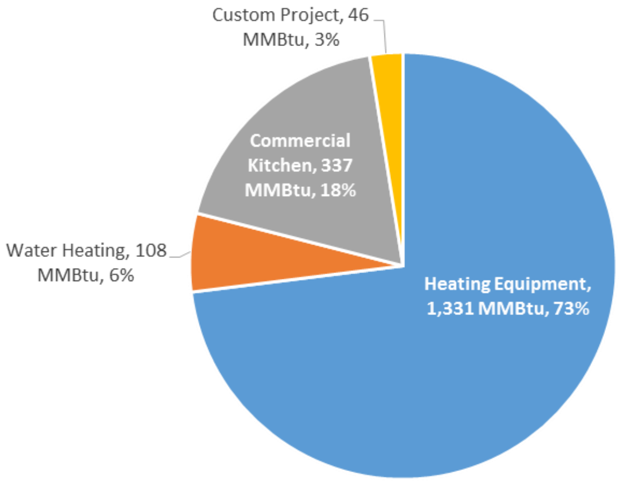
Low Income Programs



Overall the LI Program exceeded Savings goals, by nearly 52%. The Multifamily Retrofit program exceeded its goal by over 150%, while the Single Family program was lightly under its target (met 90.3% of goal).

2013 EE Savings – C&I NC

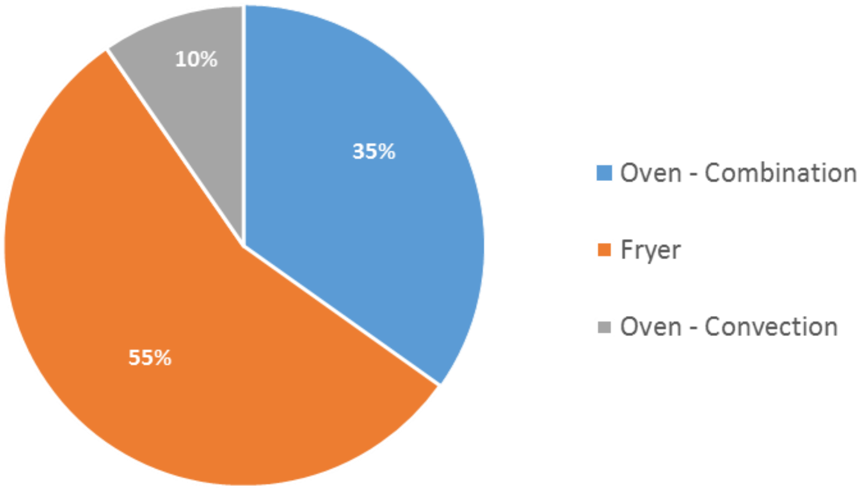
- Of the Total Savings from the C&I New Construction sector, nearly three quarters was from heating equipment. The rest is broken out as follows:
  - Commercial Kitchen 18%
  - Water Heating 6%
  - Custom Projects 3%



2013 EE Savings – C&I NC

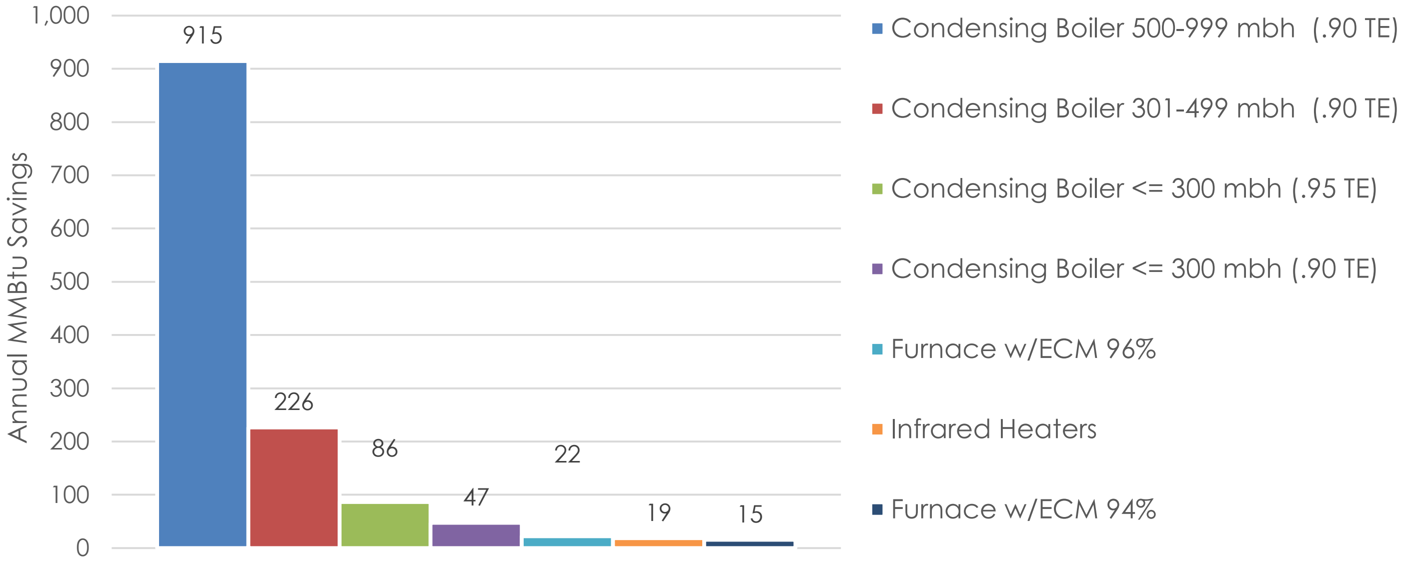
- Types of Commercial Kitchen Equipment

(percentage of total savings from kitchen equipment)



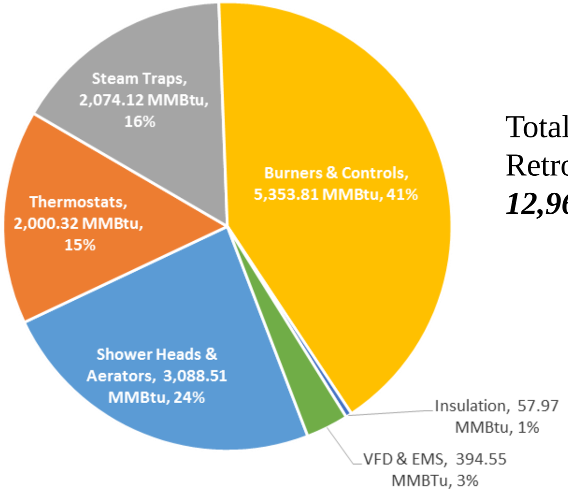
2013 EE Savings – C&I NC

- Types of Space Heating Equipment



2013 EE Savings – C&I Retrofit

- C&I Retrofit and C&I Direct Installation accounted for 13,223 MMBtu in annual savings. 98% came from the C&I Retrofit Program (13,039). Custom retrofit measures accounted for almost all of the C&I Retrofit savings.



Total Custom Retrofit C&I Savings
12,969 MMBtu

Custom retrofit measures included burners & controls, steam traps, faucet and shower aerators, thermostats, insulation and VFDs.

UNITIL GAS – REMAINING POTENTIAL STUDY
FINAL REPORT

February 2nd, 2015

Table of Contents

Executive Summary - Purpose

This report presents Unitil Gas-specific results from a comprehensive, six month assessment of remaining energy efficiency potential within Unitil Gas, Unitil Electric, Berkshire Gas and Liberty Utilities (formerly NEGC)service territories.

EXECUTIVE SUMMARY - ORDER

- In addition to assisting the small PAs in quantifying remaining potential within their service territories, this effort was conducted in accordance with the Massachusetts Department of Public Utilities' January 31, 2013 Order D.P.U. 12-100 through D.P.U. 12-111 (sections IV.B.2.a & 4.a – pages 18, 19 & 40) and subsequent DOER Consultant feedback.
- Specifically, Section IV.B.2.a states:
  - "The Program Administrators with an aggregate three-year savings goal of greater than 20 percent below the statewide three-year aggregate goal will conduct a study, either jointly or individually, during the upcoming three-year term to document the penetration of energy efficiency within its service territory and the remaining cost-effective energy efficiency opportunities available.."

EXECUTIVE SUMMARY – SAVINGS GOALS

For the 2013-2015 Energy Efficiency Plan, Unitil Gas's three-year savings goals fell short of the statewide average:

Program Administrator	2013	2014	2015	Total 2013-2015
Unitil Gas	0.70%	0.77%	0.85%	0.77%
Statewide	1.08%	1.17%	1.19%	1.14%
Variance from Statewide Aggregate				**32.5%**

Executive Summary – Key Tasks

Three major task areas were pursued:

1. Secondary data collection/data mining and data gap analysis, including review of ongoing work of the Evaluation Management Committee.
2. Primary data collection sample design, work plan development and implementation of telephone surveys (residential and small/medium C&I customers) and on site data collection (larger C&I customers).
3. Data analysis and reporting of likely achievable and high case remaining potential results.

Executive Summary – Scope/Timing

This was a fast tracked (approx. six month) effort coordinated across four Program Administrators (PAs) culminating in development of four separate, territory-specific reports – one for each PA (Berkshire Gas, Liberty Gas, Unitil Gas and Unitil Electric).

Executive Summary - Savings Potential Results

- The Likely Achievable savings potential across Unitil Gas's service territory is estimated to be 0.68% of 2016 annual sales (0.69% by 2018).
  - This is lower than Unitil Gas's current three-year(2013-2015) territory-wide target of 0.77%.
- The sector with greatest potential for savings as a % of sector sales remains with Unitil Gas's large commercial customers (0.81% of 2016 and 2018 sales).
- Less potential remains within Unitil Gas's residential and small/ medium commercial customer sectors (0.59% and 0.66% respectively by 2018).

Summary Likely Achievable Scenario	2016	2017	2018
Residential

Executive Summary - Top Savings Sources

Top 3 Residential Measures:

- Wall insulation
- Boilers 95%
- Air sealing

Residential Sector	Total Savings 63,900	% of Savings
Improved Wall Insulation	16,361	25.6%
Boiler 95%	7,794	12.2%
Air Sealing	5,774	9.0%
RNC New Homes (Heating)	5,688	8.9%
Improved Attic/Roof Insulation	4,513	7.1%
Heating System Replacement - ER FHW Custom	3,996	6.3%
Heating System Replacement	2,985	4.7%
Furnace w/ECM 95%	2,544	4.0%
Combo Condensing Boiler/DHW 90%	2,056	3.2%
Faucet Aerator	1,851	2.9%

Executive Summary - Top Savings Sources

Top 3 Small/Medium Commercial Measures:

- Condensing boilers 1701+ mbh (0.90 TE)
- Kitchen equipment
- Programmable thermostats

	Total Savings	
Small/Medium Commercial	**19,246**	**% of Savings**
Condensing Boiler 1701+ mbh (.90 TE)	5,225	27.1%
Kitchen Equipment	4,438	23.1%
Programmable Thermostat	1,749	9.1%
Custom - Small & Medium	1,507	7.8%
Condensing Boiler 1000-1700 mbh (.90 TE)	1,493	7.8%
Faucet Aerator	991	5.1%
Showerhead	984	5.1%
Condensing Boiler 500-999 mbh (.90 TE)	812	4.2%
Condensing Boiler <= 300 mbh (.96 TE)	631	3.3%
Boiler Reset Controls (retrofit only)	537	2.8%

Executive Summary - Top Savings Sources

Top 3 Large Commercial Measures:

- Custom measures
- Condensing boilers 1701+ mbh (0.90 TE)
- Low-flow showerheads

Large Commercial	Total Savings 81,956	% of Savings
Custom - Large	65,947	80.5%
Condensing Boiler 1701+ mbh (.90 TE)	5,225	6.4%
Showerhead	2,913	3.6%
Faucet Aerator	2,072	2.5%
Programmable Thermostat	1,749	2.1%
Condensing Boiler 1000-1700 mbh (.90 TE)	1,493	1.8%
Condensing Boiler 500-999 mbh (.90 TE)	812	1.0%
Condensing Boiler <= 300 mbh (.96 TE)	631	0.8%
Boiler Reset Controls (retrofit only)	269	0.3%
Oven - Convection	232	0.3%

Executive Summary – Key Findings

Results from review of secondary and primary data sources suggest:

- A somewhat limited potential exists for cost effective energy efficiency savings projects within Unitil Gas's residential and business sectors over the next 3 to 5 years.
  - A majority Unitil Gas's 25 largest customers have already participated, with few additional major projects on their near-term planning horizons.
- Economic challenges within Unitil's service territory are making it difficult for residential and small business customers to prioritize and pursue energy efficiency projects.
  - Although customers within these sectors are typically cash constrained, increased focus on Unitil's residential and small business customer base could yield additional savings.

SERVICE TERRITORY CHARACTERIZATION

Residential – 751 average annual therms/customer (14,226 customers)

- 855 average annual therms/customer (11,697 heat customers)
- 267 average annual therms/customer (2,530 non-heat customers)
- 1,284 (9%) of Unitil Gas's residential customers have been program participants within the past 3 years (including multiple measures at a single participant location, repeat participants and low income customers)

SERVICE TERRITORY CHARACTERIZATION

Commercial – 8,411 average annual therms/customer (1,697 customers)

- 2,071 average annual therms/customer (1,441 small customers – rate codes: G41/G51)
- 21,650 average annual therms/customer (232 medium customers – rate codes: G42/G53)
- 227,052 average annual therms/customer (24 large customers – rate codes: G43/G53)
- 203 (12%) of Unitil Gas's commercial customers have been program participants within the past 3 years (including repeat participants and a majority of Unitil Gas's largest customers)

* Forecast sales data was revised subsequent to initial draft

Source: FGE G 2009-2020 Cust & Sales 8-11-14.xlsx

METHODOLOGY

There were three major tasks completed as a part of this effort:

1. Secondary Data Collection/Data Mining.
2. Primary Data Collection.
3. Data Analysis and Reporting.

Methodology – Secondary Data

Task 1 – Secondary Data Collection Activities:

- Reviewed existing evaluation reports including ongoing evaluation planning and implementation activities assessments.
  - Participated as Unitil's representative in relevant Evaluation Management Committee meetings and working groups, when requested.
- Reviewed utility specific data
  - Customer data and program data provided by Unitil.

Methodology – Secondary Data

Findings:

- Very little territory-specific data available from statewide evaluation efforts.
- Utility specific data from Unitil was used in Task 3 – Data Analysis.

METHODOLOGY – PRIMARY DATA

Task 2 – Primary Data Collection Activities:

- Telephone surveys.
- On-site data collection.
- Used to fill gaps identified through Task 1 effort.
- Used to develop savings estimates for Task 3 data analysis and reporting.

METHODOLOGY – SAMPLE DESIGN

- Residential – A sample size of 41 was targeted to obtain a confidence and precision of 80/10 at the Residential sector level. 41 completes were targeted for Unitil’s Gas territory and an additional 41 for Unitil’s Electric territory.
- Commercial and Industrial – A sample size of 41, split between small and medium commercial phone surveys and large industrial site visits was targeted to obtain a confidence and precision of 80/10 at the C&I sector level.
  - 41 completes were targeted for Unitil’s Gas territory and an additional 41 for Unitil’s Electric territory.
- Territory Level – Overall a goal of 164 surveys was targeted to achieve a statistical significance of 90/9 across the two Unitil service territories (electric and gas – 82 surveys in each).

METHODOLOGY – SAMPLE SELECTION

- Residential – A random sample of 45 (gas) and 74 (electric) households was ultimately selected for phone surveys by study team member RKM Research & Communications.
  - The sample was drawn from a randomized list of Residential Customers (Rates R1, R2, R3 & R4) provided by Unitil.
- Small Commercial – A random sample of 52 (gas) and 65 (electric) customers was ultimately selected for phone surveys by RKM Research & Communications.
  - The sample was drawn from a randomized list of Small Commercial Customers (Rates: G41, G42, G51 & G52) provided by Unitil.
- Large Commercial & Industrial – A randomly selected sample of 17 (gas and electric) customers were ultimately recruited for on-site data collection by GDS staff.
  - The sample was drawn from a randomized list of Unitil's pool of Medium and Large Commercial & Industrial Customers (Rates: G43 & G53 and several G42 & G52). Medium customers included in the on-site sample frame were removed from the telephone survey sample frame.
  - A randomized list of customers was provided and called through, in order, to avoid sample bias and to procure a representative mix of participating and non-participating customers.
  - Soft leads were recruited with the help of utility representatives. GDS then contacted the customer and set-up a time to complete the site visit. Some coordination with DNV-GL was also required to avoid duplication of effort with their simultaneous site data collection efforts for another ongoing evaluation project and to minimize customer confusion.

Methodology – Final Sample Sizes

Final Sample Sizes				
	Customer Population	# Phone Surveys Targeted	# Phone Surveys Completed	Achieved Confidence/Precision
Residential Telephone Surveys (Gas)	14,007	41	45	80/9.5
Residential Telephone Surveys (Electric)	24,903	41	74	80/7.4
Residential Telephone Surveys (Total)	na	82	119	na
C&I Customer Surveys (Gas)*	1,664	21 (phone) / 20 (site)	52 (phone) / 17 (site)	80/7.6
C&I Customer Surveys (Electric)*	3,708	21 (phone) / 20 (site)	65 (phone) / 17 (site)	80/7.0
C&I Customer Surveys (Total)*	na	42 (phone) / 40	117 (phone) / 34 (site)	na
Territory Level (Gas)	15,671	61 (phone) / 20 (site)	97 (phone) / 17 (site)	90/7.7
Territory Level (Electric)	28,611	61 (phone) / 20 (site)	139 (phone) / 17 (site)	90/6.6

* Includes a mix of on -site data collection and telephone surveys

Please note that overlap exists in the phone and onsite surveys. For example if one customer was a Unitil Gas and Electric customer their phone survey was counted as one complete for gas and one complete for electric.

During fielding of small commercial telephone surveys, the target sample size was increased from 21 to 41 to collect more data on smaller to medium-sized commercial customers.

METHODOLOGY – PHONE SURVEYS

Residential Response Rates:

- The overall response rate of the Residential phone surveys was ***17.9%.***
- A total of 1,980 customers were dialed, and 119 surveys were completed.
- 27 calls experienced a language barrier ***(1.36%).***

Call Code	Disposition	Total	%TOTAL DIALINGS
1	Complete	119	6.01%
2	No Answer	81	4.09%

	TOTAL DIALINGS	**1814**	**100%**
	RESPONSE RATE(%)	**11.7**	

METHODOLOGY – DATA ANALYSIS

Task 3 – Data Analysis Activities:

- Reviewed raw survey data.
- Determined end-use saturation and efficiency penetrations by customer sector.
- Developed remaining energy efficiency potential savings estimates.

Methodology – Survey Data Review

- Raw telephone survey and on-site data collection results were reviewed, analyzed and summarized.
- Sector specific presentations were developed to document detailed results and identify key findings from each research area including:
  - Demographics/firmography
  - Individual energy end-use findings
  - Past purchases and practices
  - Attitudes
  - Program awareness, participation and satisfaction
- Survey and site-visit data was then used to develop estimates of Potential Savings.

METHODOLOGY – SAVINGS ESTIMATES

A combination of data sources were used to develop factors for calculating remaining potential energy savings:

- Survey and site visit results
- Customer counts
- Existing efficiency program measures
- Existing program data on energy savings
- Massachusetts 2013 Report Technical Reference Manual
- Current utility Net-To-Gross (NTG) ratios
- Benefit/Cost modeling (Total Resource Cost Test – TRC)

Methodology – Savings Estimates

Equation of Potential Energy Savings

Participation × Savings (therms) × NTG Ratio

METHODOLOGY – PARTICIPATION EST.

Participation

GDS used a number of factors to arrive at an annual estimate of measure participation

- Estimate of base homes
  - Customers with gas heating and percent of customers with the baseline measure (i.e. boiler, furnace)
- Applicability factor
  - Split between competing measures (i.e. 90% AFUE boiler, 95% AFUE boiler)
  - Accounts for consumer choice
  - Used past program installations to estimate future installation ratios
  - Benefit/Cost modeling was conducted using the TRC test to assess cost-effectiveness of individual measures. However, measures with B/C ratios less than 1.0 were not dropped from the analysis because cost-effectiveness is not assessed at the measure level in MA, but at the program level . B/C ratios were used, where appropriate, to prioritize installations among competing measures → greater factor weight applied to measures with a higher B/C ratio.
- Burnout rate of measure (1/measure life)
  - What percentage of the market is expected to need replacing
- Convertibility factor
  - What percent might not be physically convertible to new technology or other limitation (i.e. wall insulation improvements would not be available for brick, stone or asbestos siding exteriors)

Methodology – Participation Est.

Participation

GDS used a number of factors to arrive at an annual estimate of measure participation

- Energy Efficiency Saturation
  - Percentage of market that is selecting efficient equipment
  - Based on survey data
- Willingness to Participate
  - Included only in the "likely achievable potential scenario"
  - Not included in the "high-case" scenario (i.e., before consideration of territory-specific realities, customer behaviors and measure installation barriers)
  - Reflects survey response assessed percentage of customers likely to move forward with a project

Methodology – Measure Savings

Savings (therms)

GDS used a number of sources to estimate measure specific savings

- 2013 Report Massachusetts Technical Reference Manual
  - Included deemed savings values for many measures
- Utility Specific Program Data
  - Used for New Construction Program
- REM Rate Energy Modeling
  - Calibrated to utility climate and average annual heating usage

METHODOLOGY – NTG RATIOS

NTG Ratios

GDS used current NTG ratios to adjust savings estimates

- NTG Ratios
  - Utility specific or statewide where applicable
  - Included or adjusted for free-ridership and spillover rates in some cases, but not all
  - Typically developed through rigorous evaluation efforts

Methodology - Scenarios

When estimating remaining potential, two modeling scenarios were run:

1. Likely achievable potential scenario – This scenario represents the study team's best estimate of the remaining potential within Unitil Gas's service territory and applies a "customer willingness" factor derived from telephone survey and site visit responses, along with sector-level budget constraints where applicable.
2. High-case scenario – This scenario represents the study team's estimated upper bound of the remaining potential without consideration of territory-specific realities, including customer behaviors and budget constraints.

HIGH-CASE SCENARIO - SAVINGS POTENTIAL RESULTS

- The total High-Case savings potential across Unitil Gas's service territory is estimated to be 1.07% of 2016 annual sales (1.15% by 2018).
  - The PA cost to achieve this potential is nearly $2.3M in 2016 ($2.4M in 2018) vs $1.9M current budget.
- Greatest potential savings, as % of sector sales, is in the residential and small/medium commercial customer sectors (1.18% and 1.42% of 2018 sales).
- Less potential exists within the large commercial sector(0.99% in 2016 and 1.04% by 2018).

Summary - High-Case	2016	2017	2018
Residential			
Annual Therm Savings	122,004	124,797	127,764

* Forecast sales data was revised subsequent to initial draft

Territory-Specific Insights - Residential

- Program awareness, participation & satisfaction
  - Approximately a third (38%) of Unitil Gas's residential customer respondents stated they were not aware of Unitil's energy efficiency programs and products, and around half of those that are aware have never participated – leaving a solid pool of potential new participating customers.
- Home characteristics
  - A majority of Unitil Gas's residential customer respondents live in older, single family homes that they own – excellent targets for potential building envelope improvements.
- ENERGY STAR® awareness
  - While the majority of respondents are familiar with ENERGY STAR®, there is potential opportunity in reaching out to the 20% who are still completely unfamiliar.
- Past purchase practices
  - A majority of residential respondents appear to have energy efficiency features on their radar screens.
- Attitudes
  - Although cost is a major reason cited for not pursuing energy efficiency opportunities, over 2/3rd of respondents express interest in purchasing energy efficient equipment for a multitude of reasons.

TERRITORY-SPECIFIC INSIGHTS - RESIDENTIAL

- Building envelope
  - There remains some likely achievable potential for building envelope improvements within Unitil's residential customer sector.
- Space heating
  - Potential for heating system replacements exists in homes with older systems, where owners may be looking for replacements within the next five years. Additional savings associated with controllable thermostats may also exist.
- Water heating
  - Potential for water heater replacements exists in homes with older units, where owners may be looking for replacements within the next five years. Additional opportunities may exist for water saving devices.
- Clothes washing
  - Potential for energy efficient clothes washer and dryers exists in homes with older units, where owners may be looking for replacements within the next five years.
- Dishwashing
  - Potential for energy efficient dishwashers exists in homes with older units, where owners may be looking for replacements within the next five years.
- Hot tubs and heated pools
  - Based on survey responses, there does not appear to be much potential for efficiency improvements within the pool and hot tub end-use.

Territory-Specific Insights – Small/Medium Commercial

- Program awareness, participation & satisfaction
  - A majority of Unitil Gas's small business customers are non-participants and nearly all of those who have participated would be interested in doing so again.
- Firmographics
  - Unitil Gas's small commercial business base appears solid, with potential opportunities for energy efficiency investments in both leased and owned buildings. Small business owners would be best target for decisions.
- Building size, age & use
  - The make-up of Unitil Gas's small commercial building stock (relatively old, large square footage, small number of employees, sufficient hours of operation, somewhat efficiency conscious), suggests potential opportunities for targeted efficiency improvements.
- Past purchase practices
  - 10% of small commercial customer respondents stated they had purchased energy efficient products in the past, and 60% of those customers said they had plans to do so again over the next 12 months – suggesting additional potential for efficiency projects within Unitil Gas's small commercial customer sector.
- Attitudes
  - Rebates remain a major motivator for customer action in the small business sector.

Territory-Specific Insights – Small/Medium Commercial

- Building envelope
  - Good opportunities exist for building envelope improvements within Unitil Gas's small commercial business sector.
- Space heating
  - Potential for replacement heating systems, heating system tune-ups and programmable thermostats exists within Unitil Gas's small commercial business sector.
- Water heating
  - Based on survey responses, only a small potential for water heater replacements currently appears to exist within Unitil Gas's small commercial business sector, but a majority (70%) of Unitil's small business customer respondents are not taking advantage of other water saving measures (i.e., faucet aerators)
- Commercial kitchen and laundry
  - A small, but high energy use market exists within Unitil Gas's small business sector for commercial kitchen and laundry customers.
- On-site generation
  - 16% of Unitil Gas's small commercial customer respondents reported having onsite generation (6 emergency back-up generators and 1 onsite electric generator) . There could be an opportunity to explore this market.

Territory-Specific Insights – Large Commercial

- Program awareness, participation and satisfaction
  - A majority of Unitil Gas's large business customer respondents are aware of (75%) and have participated in (81%) Unitil's energy efficiency programs and are interested in doing so again.
- Past purchase practices
  - 42% of respondents are planning a renovation in the next 12 months.
  - A market for efficiency projects may exist within Unitil's large commercial customer sector if coupled with these respondents' planned renovation activities.
- Attitudes
  - Lower bills and receipt of rebates remain major motivators for customer action in Unitil Gas's large business sector.
  - These attitudes are also impacted by the number of businesses that have moved, sold, gone out of business or otherwise have cut back due to recession.

Territory-Specific Insights – Large Commercial

- Building Envelope
  - Opportunities likely exist for building envelope improvements within Unitil Gas's largest business customer sector.
- HVAC
  - Energy savings potential remains for replacement of some aging hot water boilers. Opportunities may also exist for greater use of EMS and boiler reset controls.
- Water heating
  - Potential appears to exist for efficient water heating equipment, with greater opportunities for pre-rinse spray valves, low flow showerheads and faucet aerators.
- Process equipment
  - Process heating equipment is a significant end use for natural gas in the Unitil territory. There could be opportunities for additional process efficiency improvements – but given the small number of large customers, limited availability of new projects on the planning horizon and unique characteristics of individual business processes, such determinations are best assessed on a custom/case-by-case basis.
- Cooking and laundry equipment
  - Based on conditions observed during large C&I customer site visits, potential appears to exist for efficient cooking and laundry equipment.
- On-site generation
  - There appears to be some potential to explore this market given that on-site natural gas-powered generation equipment was not identified during the site visits.

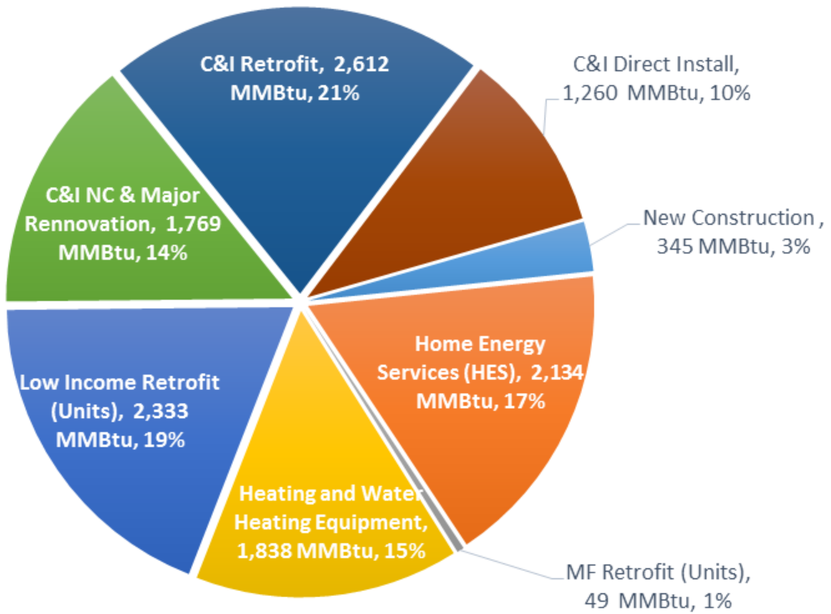
2013 Savings Characterization – Gas

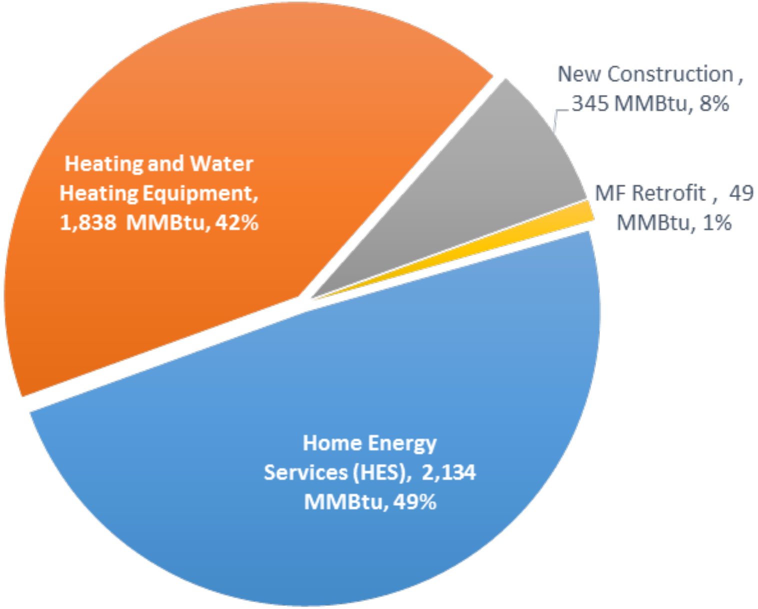
2013 ***Evaluated*** Energy Savings by Initiative, MMBtu



2013 EE Savings – Res. Gas

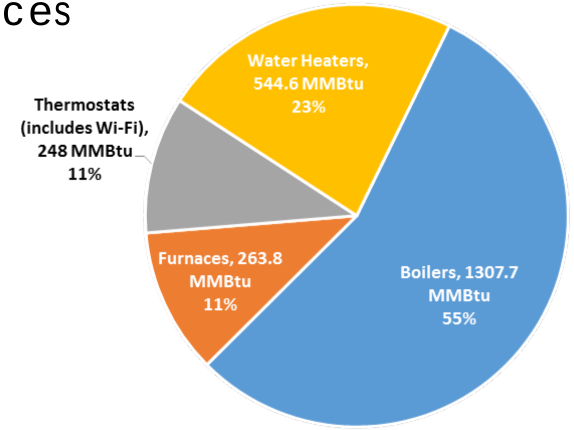
2013 *Evaluated* Energy Savings Residential Initiatives, MMBtu

*Please note that savings reported in the remaining slides is derived from program tacking data which is reported as ***Gross*** MMBtu savings and will not match to this figure or the figure on the previous slide as these are reported as ***Evaluated*** savings.



2013 EE Savings-Residential

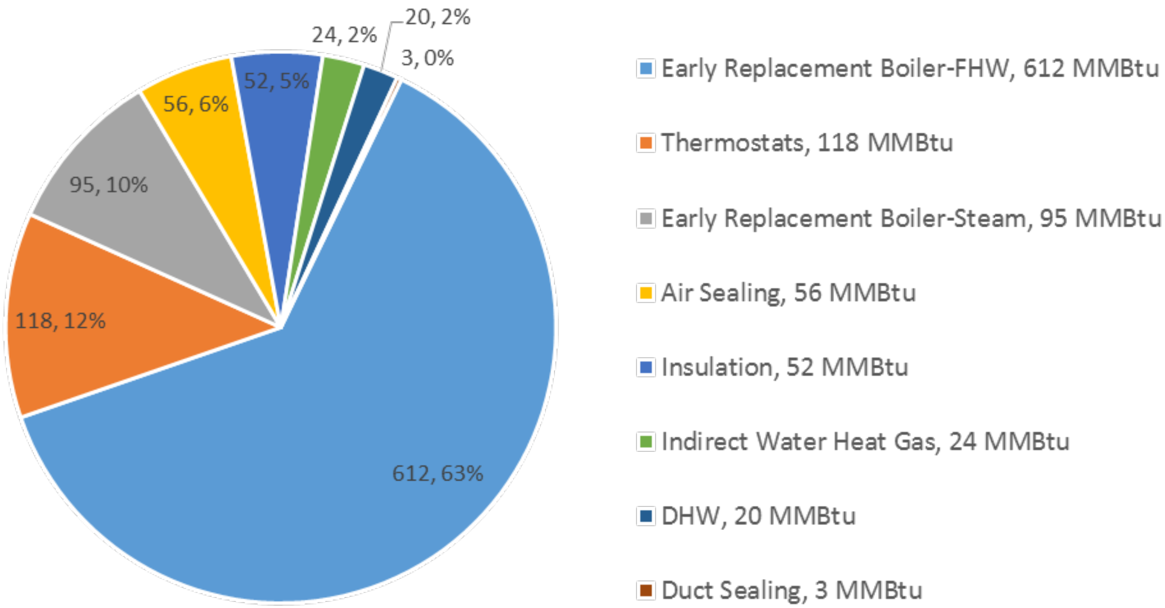
- Residential Heating & Water Heating (HEHE)
  - 66% of savings from heating systems
    - 55% or 1,307 MMBtu from Boilers
    - 11% or 263 MMBtu from Furnaces
  - 23% from water heating
  - 11%Wi-Fi T-Stat & programmable T-Stat



*Please note that savings reported is derived from program tacking data which is reported as ***Gross*** MMBtu savings and will not match figure on previous slide of ***Evaluated*** savings.

2013 EE Savings-Residential

2013 ***Gross*** Energy Savings Single Family Retrofit (1-4 Units)



2013 EE Savings-Residential

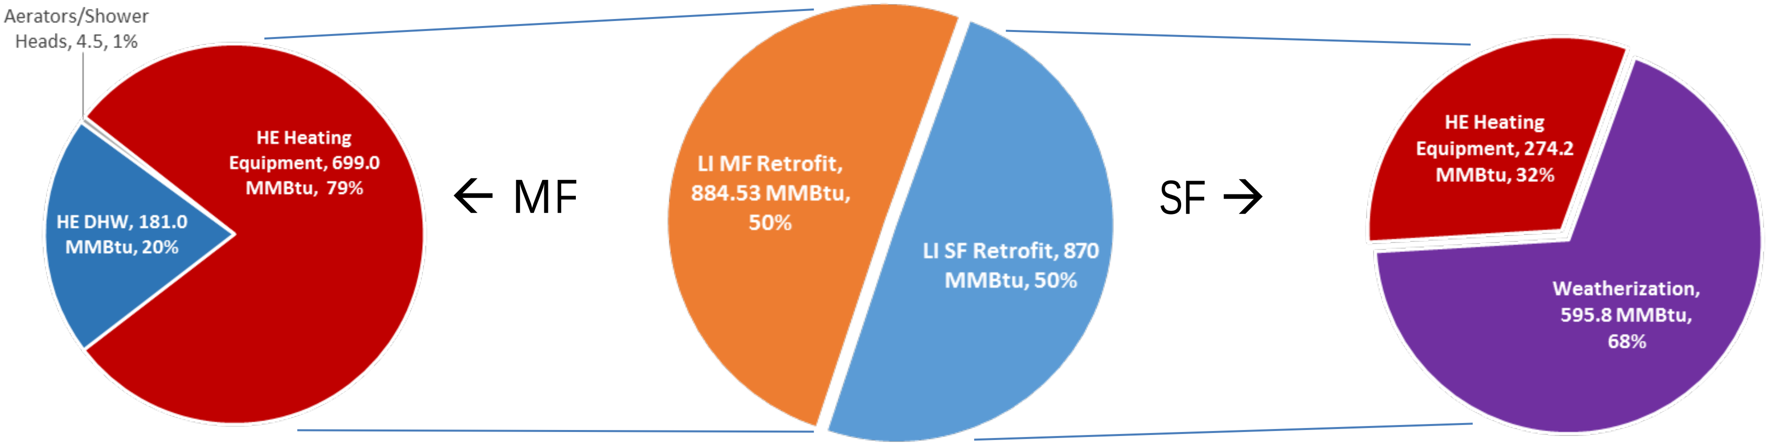
- Single Family Retrofit (1-4 Units)
  - 73% of savings comes from early boiler replacement
    - 63% (612 MMBtu) from FHW boiler
    - 10% (95 MMBtu) from steam boiler
  - 12% from thermostats
    - 118 MMBtu
  - 11% from air sealing, insulation and duct sealing
    - 111 MMBtu
  - 4% from DHW
    - 24 MMBtu from indirect water heating
    - 20 MMBTU from DHW

2013 EE Savings - Residential

- New Construction
  - Shell heating measures accounted for 98.7% of savings (341 MMBtu).
  - Water heating accounted for the balance of savings (4.3 MMBtu)

2013 EE Savings – Low Income

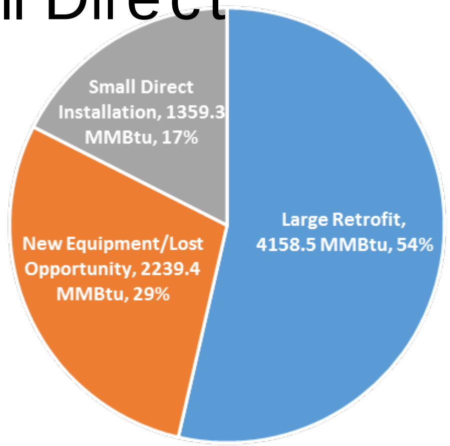
Low Income Programs



Savings for the Low Income program was split between the SF and MF Programs. In the SF program 68% of savings came from Wx measures and 32% from heating equipment. In the MF program, 79% of savings came from heating equipment and 21% from DHW equipment and low flow shower heads and aerators.

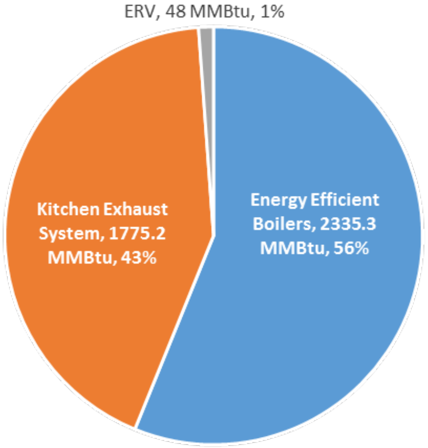
2013 EE Savings – C&I Sector

- Of the Total Savings from the C&I sector, over half (54%) came from the Large Retrofit Program, 29% came from the New Equipment Program, and the remaining 17% came from the Small Direct Installation Program.
  - Large Retrofit – 4,159 MMBtu
  - New Equipment – 2,239 MMBtu
  - Direct Installation – 1,359 MMBtu



2013 EE Savings – C&I Large Retrofit

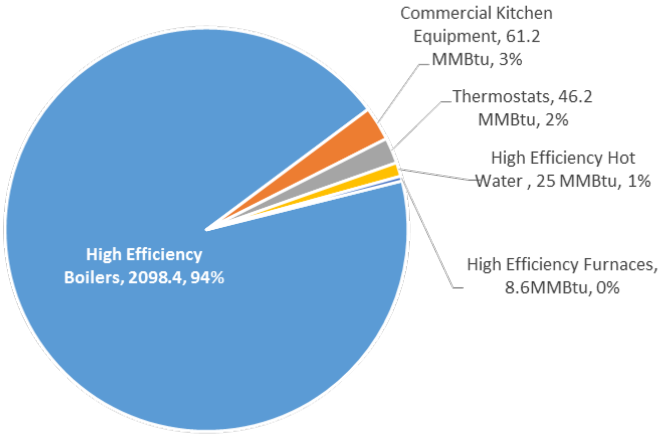
- All of the C&I Large Retrofit measures were classified as custom projects. These custom projects included Energy Efficient Boilers (2,335 MMBtu), Kitchen Exhaust Systems (1,775 MMBtu), and ERVs (48 MMBtu).



Custom retrofit measures included energy efficient boilers, a kitchen exhaust system, and ERVs.

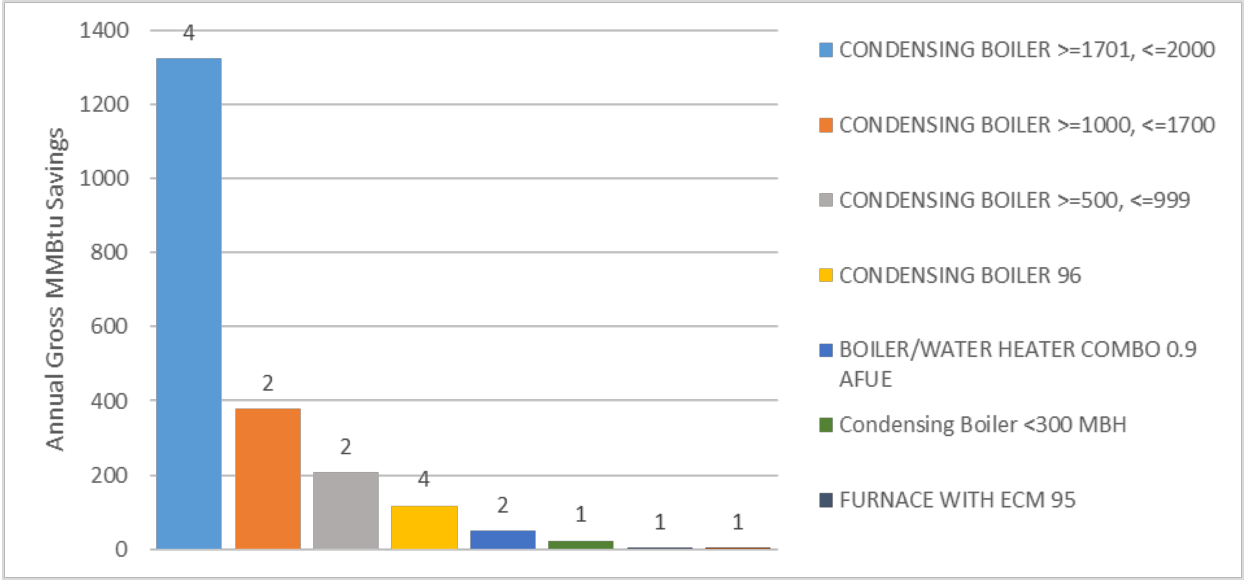
2013 EE Savings – C&I New Equip.

- Of the Total Savings from the C&I New Equipment program, ninety-four percent was from high efficiency boilers. The remaining 6% of savings came from:
  - Commercial Kitchen 3%
  - Thermostats 2%
  - High Efficiency Hot Water 1%
  - High Efficiency Furnaces >1%



2013 EE Savings – C&I New Equip.

- Types of Space Heating Equipment and quantities rebated



2013 EE Savings – C&I Direct Install

- The C&I Direct Installation Program savings is split between weatherization measure savings and thermostat measure savings. One weatherization project was completed though the program and accounts or 69% of program savings for 2013.

The weatherization measure completed was for an energy shade screen for a farm greenhouse.

UNITIL ELECTRIC – REMAINING POTENTIAL STUDY
FINAL REPORT

February 24th, 2015

TABLE OF CONTENTS

Executive Summary - Purpose

This report presents Unitil Electric-specific results from a comprehensive, six month assessment of remaining energy efficiency potential within Unitil Electric, Unitil Gas, Berkshire Gas and Liberty Utilities (formerly NEGC)service territories.

Executive Summary - Order

- In addition to assisting the small PAs in quantifying remaining potential within their service territories, this effort was conducted in accordance with the Massachusetts Department of Public Utilities' January 31, 2013 Order D.P.U. 12-100 through D.P.U. 12-111 (sections IV.B.2.a & 4.a – pages 18, 19 & 40) and subsequent DOER Consultant feedback.
- Specifically, Section IV.B.2.a states:
  - "The Program Administrators with an aggregate three-year savings goal of greater than 20 percent below the statewide three-year aggregate goal will conduct a study, either jointly or individually, during the upcoming three-year term to document the penetration of energy efficiency within its service territory and the remaining cost-effective energy efficiency opportunities available.."

EXECUTIVE SUMMARY – SAVINGS GOALS

For the 2013-2015 Energy Efficiency Plan, Unitil Electric's three-year savings goals fell short of the statewide average:

Program Administrator	2013	2014	2015	Total 2013-2015
Unitil Electric	1.91%	1.95%	1.96%	1.94%
Statewide	2.50%	2.55%	2.60%	2.55%
Variance from Statewide Aggregate				**23.9%**

Executive Summary – Key Tasks

Three major task areas were pursued:

1. Secondary data collection/data mining and data gap analysis, including review of ongoing work of the Evaluation Management Committee.
2. Primary data collection sample design, work plan development and implementation of telephone surveys (residential and small/medium C&I customers) and on site data collection (larger C&I customers).
3. Data analysis and reporting of likely achievable and high case remaining potential results.

Executive Summary – Scope/Timing

This was a fast tracked (approx. six month) effort coordinated across four Program Administrators (PAs) culminating in development of four separate, territory-specific reports – one for each PA (Unitil Electric, Unitil Gas, Berkshire Gas and Liberty).

Executive Summary - Savings Potential Results

- The Likely Achievable savings potential across Unitil Electric's service territory is estimated to be 1.65% of 2016 annual sales (1.70% by 2018).
  - This is slightly lower than Unitil Electric's current three-year(2013-2015) territory-wide target of 1.94%.
- The sector with greatest potential for savings as a % of sector sales remains with Unitil Electric's commercial/industrial customers (2.02% of 2016 sales & 2.08% by 2018).
- Less potential remains within Unitil Electric's residential customer sector (1.11% 2016 & 1.16% 2018).

Likely Achievable	2016	2017	2018
Residential			
Annual kWh Savings	2,002,433	2,052,648	2,107,381
Forecast Sales	180,229,213	181,144,875	182,429,709
Savings as % of sales	**1.11%**	**1.13%**	**1.16%**
PA Cost to Achieve	$ 2,116,832	$ 2,137,887	$ 2,186,225
Total Cost to Achieve	$ 2,848,283	$ 2,884,654	$ 2,951,069
Commercial/Industrial			
Annual kWh Savings	5,255,694	5,393,637	5,422,060
Forecast Sales	259,855,732	260,332,321	261,118,104
Savings as % of sales	**2.02%**	**2.07%**	**2.08%**
PA Cost to Achieve	$ 2,245,192	$ 2,296,216	$ 2,306,657
Total Cost to Achieve	$ 4,306,875	$ 4,426,191	$ 4,442,523
TOTAL			
Annual kWh Savings	7,258,127	7,446,285	7,529,441
Forecast Sales	440,084,945	441,477,197	443,547,813
Savings as % of sales	**1.65%**	**1.69%**	**1.70%**
PA Cost to Achieve	$ 4,362,024	$ 4,434,103	$ 4,492,883
Total Cost to Achieve	$ 7,155,158	$ 7,310,844	$ 7,393,592

Executive Summary - Top Savings Sources

Residential Sector	Total Savings 2,002,433	% of Savings
Lighting (CFLs, LEDs, T8s, Torchiers, Indoor/Outdoor)	1,471,780	73.5%
Building envelope & duct sealing (elec/non-electric)	129,554	6.5%
ENERGY STAR TVs & Smart Power Strips	94,152	4.7%
Refrigerator & Freezer replacement & rebates	61,497	3.1%
HP Water Heaters (50 & 80 gallon)	55,922	2.8%
New Construction (heating, cooling & lighting)	53,075	2.7%
CoolSmart Ductless MS HP (SEER 16/18 & QIV)	42,077	2.1%
Refrigerator & Freezer recycle	34,269	1.7%
CoolSmart AC SEER 16 & Room/Window ACs	28,901	1.4%
DHW ISMs (electric/non-electric, indirect/on demand)	7,836	0.4%

Lighting measure mix based on Unitil 2013 actual program data and likely overstates potential savings from CFLs, while understating LED savings potential.

Executive Summary - Top Savings Sources

	Total Savings	
Small/Medium Commercial	**1,274,206**	**% of Savings**
Custom Lighting measure	841,730	66.1%
Custom HVAC	271,900	21.3%
Custom Compressed Air measure	63,162	5.0%
Custom Motors and Drives	52,694	4.1%
Custom Process measure	32,918	2.6%
Lighting - LED Lamps (upstream)	6,732	0.5%
Lighting - T8 U-Bends (upstream)	3,009	0.2%
Lighting - LED MR-16, PAR 20, 30, 38 (upstream)	1,618	0.1%
Lighting - T5 (upstream)	330	0.0%
Lighting - T8 25W (upstream)	111	0.0%

Executive Summary - Top Savings Sources

	Total Savings	
Top 100 Largest Commercial Customers	**3,981,488**	**% of Savings**
Custom Lighting measure	1,364,997	34.3%
Custom Motors and Drives	733,905	18.4%
Lighting - LED Lamps (upstream)	625,076	15.7%
Custom HVAC	544,930	13.7%
Lighting - LED MR-16, PAR 20, 30, 38 (upstream)	299,474	7.5%
Custom Compressed Air measure	234,376	5.9%
Custom Process measure	119,066	3.0%
Lighting - T8 U-Bends (upstream)	58,181	1.5%
Lighting - T5 (upstream)	1,259	0.0%
Lighting - T8 25W (upstream)	223	0.0%

Executive Summary – Key Findings

Results from review of secondary and primary data sources have confirmed:

- A somewhat limited potential exists for cost effective energy efficiency savings projects within Unitil Electric's residential and business sectors over the next 3 to 5 years.
  - A majority Unitil Electric's 25 largest customers have already participated, with few additional major projects on their near-term planning horizons.
- Economic challenges within Unitil's service territory are making it difficult for residential and small business customers to prioritize and pursue energy efficiency projects.
  - Although customers within these sectors are typically cash constrained, increased focus on Unitil's residential and small business customer base could yield additional savings.

SERVICE TERRITORY CHARACTERIZATION

Residential – 7,150 kWh/customer annual average (25,363 customers)

- 2,172 (9%) of Unitil Electric's residential customers have been program participants within the past 3 years (including multiple measures at a single participant location, repeat participants and low income customers, but excluding lighting and appliance participants).

METHODOLOGY

There were three major tasks completed as a part of this effort:

1. Secondary Data Collection/Data Mining.
2. Primary Data Collection.
3. Data Analysis and Reporting.

METHODOLOGY – SECONDARY DATA

Task 1 – Secondary Data Collection Activities:

- Reviewed existing evaluation reports including ongoing evaluation planning and implementation activities assessments.
  - Participated as Unitil's representative in relevant Evaluation Management Committee meetings and working groups, when requested.
- Reviewed utility specific data
  - Customer data and program data provided by Unitil.

METHODOLOGY – SECONDARY DATA

Findings:

- Very little territory-specific data available from statewide evaluation efforts.
- Utility specific data from Unitil was used in Task 3 – Data Analysis.

Methodology – Primary Data

Task 2 – Primary Data Collection Activities:

- Telephone surveys.
- On-site data collection.
- Used to fill gaps identified through Task 1 effort.
- Used to develop savings estimates for Task 3 data analysis and reporting.

METHODOLOGY – SAMPLE DESIGN

- Residential – A sample size of 41 was targeted to obtain a confidence and precision of 80/10 at the Residential sector level. 41 completes were targeted for Unitil's Electric territory and an additional 41 for Unitil's Gas territory.
- Commercial and Industrial – A sample size of 41, split between small and medium commercial phone surveys and larger customer site visits was targeted to obtain a confidence and precision of 80/10 at the C&I sector level.
  - 41 completes were targeted for Unitil's Electric territory and an additional 41 for Unitil's Gas territory.
- Territory Level – Overall a goal of 164 surveys was targeted to achieve a statistical significance of 90/9 across the two Unitil service territories (electric and gas – 82 surveys in each).

Methodology – Sample Selection

- Residential – A random sample of 74 (electric) and 45 (gas) households was ultimately selected for phone surveys by study team member RKM Research & Communications.
  - The sample was drawn from a randomized list of Residential Customers (Rates R1, R2, R3 & R4) provided by Unitil.
- Small and Medium Commercial – A random sample of 65 (electric) and 52 (gas) customers was ultimately selected for phone surveys by RKM Research & Communications.
  - The sample was drawn from a randomized list of Small and Medium Commercial Customers (Rates G41, G42, G51 & G52) provided by Unitil.
- Larger Commercial & Industrial – A randomly selected sample of 17 (electric and gas) customers were ultimately recruited for on-site data collection by GDS staff.
  - The sample was drawn from a randomized list of Unitil's Medium and Large Commercial & Industrial Customers (Rates G43 & G53 and several G42 & 52) to achieve a total sample frame representing Unitil's largest 100 electric customers. Medium customers included in the on-site sample frame were removed from the telephone survey sample frame.
  - A randomized list of customers was provided and called through, in order, to avoid sample bias and to procure a representative mix of participating and non-participating customers.
  - Soft leads were recruited with the help of utility representatives. GDS then contacted the customer and set-up a time to complete the site visit. Some coordination with DNV-GL was also required to avoid duplication of effort with their simultaneous site data collection efforts for another ongoing evaluation project and to minimize customer confusion.

METHODOLOGY – FINAL SAMPLE SIZES

Final Sample Sizes				
	Customer Population	# Phone Surveys Targeted	# Phone Surveys Completed	Achieved Confidence/Precision
Residential Telephone Surveys (Gas)	14,007	41	45	80/9.5
Residential Telephone Surveys (Electric)	24,903	41	74	80/7.4
Residential Telephone Surveys (Total)	na	82	119	na
C&I Customer Surveys (Gas)*	1,664	21 (phone) / 20 (site)	52 (phone) / 17 (site)	80/7.6
C&I Customer Surveys (Electric)*	3,708	21 (phone) / 20 (site)	65 (phone) / 17 (site)	80/7.0
C&I Customer Surveys (Total)*	na	42 (phone) / 40	117 (phone) / 34 (site)	na
Territory Level (Gas)	15,671	61 (phone) / 20 (site)	97 (phone) / 17 (site)	90/7.7
Territory Level (Electric)	28,611	61 (phone) / 20 (site)	139 (phone) / 17 (site)	90/6.6

* Includes a mix of on -site data collection and telephone surveys

Please note that overlap exists in the phone and onsite surveys. For example if one customer was a Unitil Gas and Electric customer their phone survey was counted as one complete for gas and one complete for electric.

During fielding of small commercial telephone surveys, the target sample size was increased from 21 to 41 to collect more data on smaller to medium-sized commercial customers.

METHODOLOGY – PHONE SURVEYS

Residential Response Rates:

- The overall response rate of the Residential phone surveys was ***17.9%.***
- A total of 1,980 customers were dialed, and 119 surveys were completed.
- 27 calls experienced a language barrier ***(1.36%).***

Call Code	Disposition	Total	%TOTAL DIALINGS

METHODOLOGY – DATA ANALYSIS

Task 3 – Data Analysis Activities:

- Reviewed raw survey data.
- Determined end-use saturation and efficiency penetrations by customer sector.
- Developed remaining energy efficiency potential savings estimates.

Methodology – Survey Data Review

- Raw telephone survey and on-site data collection results were reviewed, analyzed and summarized.
- Sector specific presentations were developed to document detailed results and identify key findings from each research area including:
  - Demographics/firmography
  - Individual energy end-use findings
  - Past purchases and practices
  - Attitudes
  - Program awareness, participation and satisfaction
- Surveys and site-visit data were then used to develop territory-specific inputs necessary for estimating Potential Savings.

METHODOLOGY – SAVINGS ESTIMATES

A combination of data sources were used to develop factors for calculating remaining potential energy savings:

- Survey and site visit results
- Customer counts
- Existing efficiency program measures
- Existing program data on energy savings
- Massachusetts 2013 Report Technical Reference Manual
- Current utility Net-To-Gross (NTG) ratios
- Benefit/Cost modeling (Total Resource Cost Test – TRC)

METHODOLOGY – SAVINGS ESTIMATES

Equation of Potential Energy Savings

Participation × Savings (therms) × NTG Ratio

METHODOLOGY – PARTICIPATION EST.

Participation

GDS used a number of factors to arrive at an annual estimate of measure participation

- Estimate of base homes
  - Electric customers and percent of customers with the baseline measure
- Applicability factor
  - Split between competing measures
  - Accounts for consumer choice
  - Used past program installations to estimate future installation ratios
  - Benefit/Cost modeling was conducted using the TRC test to assess cost-effectiveness of individual measures. However, measures with B/C ratios less than 1.0 were not dropped from the analysis because cost-effectiveness is not assessed at the measure level in MA, but at the program level . B/C ratios were used, where appropriate, to prioritize installations among competing measures → greater factor weight applied to measures with a higher B/C ratio.
- Burnout rate of measure (1/measure life)
  - What percentage of the market is expected to need replacing
- Convertibility factor
  - What percent might not be physically convertible to new technology or other limitation (i.e. wall insulation improvements would not be available for brick, stone or asbestos siding exteriors)

METHODOLOGY – PARTICIPATION EST.

Participation

GDS used a number of factors to arrive at an annual estimate of measure participation

- Energy Efficiency Penetration
  - Percentage of market that is selecting efficient equipment
  - Based on survey data
- Willingness to Participate
  - Included only in the "likely achievable potential scenario"
  - Not included in the "high-case" scenario (i.e., before consideration of territory-specific realities, customer behaviors and measure installation barriers)
  - Reflects survey response assessed percentage of customers likely to move forward with a project

Methodology – Measure Savings

Savings (kWh)

GDS used a number of sources to estimate measure specific savings

- 2013 Report Massachusetts Technical Reference Manual
  - Included deemed savings values for many measures
- Utility Specific Program Data
  - Used for New Construction Program
- REM Rate Energy Modeling
  - Calibrated to utility climate and average annual heating usage (where applicable)

METHODOLOGY – NTG RATIOS

NTG Ratios

GDS used current NTG ratios to adjust savings estimates

- NTG Ratios
  - Utility specific or statewide where applicable
  - Included or adjusted for free-ridership and spillover rates in some cases, but not all
  - Typically developed through rigorous evaluation efforts

Methodology - Scenarios

When estimating remaining potential, two modeling scenarios were run:

1. Likely achievable potential scenario – This scenario represents the study team's best estimate of the remaining potential within Unitil Electric's service territory and applies a "customer willingness" factor derived from telephone survey and site visit responses, along with sector-level budget constraints where applicable.
2. High-case scenario – This scenario represents the study team's estimated upper bound of the remaining potential without consideration of territory-specific realities, including customer behaviors and budget constraints.

High-Case Scenario - Savings Potential Results

- The total High-Case savings potential across Unitil Electric's service territory is estimated to be 2.36% of 2016 annual sales (2.56% by 2018).
  - The PA cost to achieve this potential is over $7.8M in 2016 ($8.2M in 2018), compared with Unitil Electric's current budget of $5.3M in 2015.
- Greatest potential savings, as % of sector sales, is in the commercial/ industrial customer sector (2.76% of 2016 & 2.99% of 2018 sales).
- Less potential exists within the residential sector(1.79% in 2016 and 1.94% by 2018).

Summary - High-Case	2016	2017	2018
Residential			
Annual kWh Savings	3,222,071	3,378,379	3,537,300
Forecast Sales	180,229,213	181,144,875	182,429,709
Savings as % of sales	**1.79%**	**1.87%**	**1.94%**
PA Cost to Achieve	$ 4,781,330	$ 4,855,528	$ 4,993,830
Total Cost to Achieve	$ 6,279,046	$ 6,415,635	$ 6,613,722
Commercial/Industrial			
Annual kWh Savings	7,179,409	7,491,441	7,805,437
Forecast Sales	259,855,732	260,332,321	261,118,104
Savings as % of sales	**2.76%**	**2.88%**	**2.99%**
PA Cost to Achieve	$ 3,026,556	$ 3,135,801	$ 3,240,548
Total Cost to Achieve	$ 6,104,256	$ 6,357,353	$ 6,607,036
TOTAL			
Annual kWh Savings	10,401,480	10,869,820	11,342,736
Forecast Sales	440,084,945	441,477,197	443,547,813
Savings as % of sales	**2.36%**	**2.46%**	**2.56%**
PA Cost to Achieve	$ 7,807,886	$ 7,991,329	$ 8,234,379
Total Cost to Achieve	$ 12,383,302	$ 12,772,989	$ 13,220,758

Territory-Specific Insights - Residential

- Program awareness, participation & satisfaction
  - Over 40% of Unitil's residential customer respondents stated they were not aware of Unitil's energy efficiency programs and products, and nearly half (47%) of those that are aware have never participated – leaving a solid pool of potential new participating customers.
- Home characteristics
  - A majority of Unitil's residential customer respondents live in older, single family homes that they own – excellent targets for potential building envelope improvements.
- ENERGY STAR® awareness
  - While the majority of respondents are familiar with ENERGY STAR®, there is potential opportunity in reaching out to the 14% who are still completely unfamiliar.
- Past purchase practices
  - A majority of residential respondents appear to have energy efficiency features on their radar screens.
- Attitudes
  - Although cost is a major reason cited for not pursuing energy efficiency opportunities, a large majority of respondents express interest in purchasing energy efficient equipment for a multitude of reasons.

Territory-Specific Insights - Residential

- Lighting
  - Potential exists for electric energy savings from interior and exterior CFLs & LED lighting measures.
- Building envelope
  - Potential exists for electric and non-electric energy savings from building envelope improvements within Utility's residential electric customer sector.
- Televisions & Computers
  - Potential exists for ENERGY STAR televisions and smart power strips for use with televisions and computer equipment.
- Refrigerators & Freezers
  - Potential exists for replacement of older primary refrigerators and for removal /recycling of primary standalone freezers and second refrigerators.
- Space heating and cooling
  - Given the nearly 50% of respondents that heat their homes primarily with oil and a small additional percentage (11%) of respondents heating their homes primarily with electricity (10% use electricity as a secondary heating source), there could be potential for fuel switching opportunities – i.e., ductless mini-split systems.
  - Potential may also exist within Unitil's service territory for central air conditioner system tune-ups and room/wall ACs.
- Water heating
  - Potential for energy efficient electric water heaters may exist within Unitil's residential sector specifically for customers that have older systems.
- Clothes washing
  - Potential may exist for energy efficient clothes washer and dryers in homes with older units, where owners may be looking for replacements within the next five years.
- Dishwashing, dehumidifiers & air purifiers
  - Potential may exist for energy efficient dishwashers exists in homes with older units, where owners may be looking for replacements within the next five years.
  - Based on survey responses, there does not appear to be much potential for efficiency improvements within the dehumidifiers & air purifiers end-use.
- Hot tubs & heated pools
  - Based on survey responses, there does not appear to be much potential for efficiency improvements within the pool & hot tub end-use.

Territory-Specific Insights – Small/Medium Commercial

- Program awareness, participation & satisfaction
  - A majority of Unitil Electric's small business customers are non-participants and nearly all of those who have participated would be interested in doing so again.
- Firmographics
  - Unitil Electric's small commercial business base appears solid with potential opportunities for energy efficiency investments in both leased and owned buildings. Small business owners would be best target for decisions.
- Building size, age & use
  - The make-up of Unitil Electric's small commercial building stock (relatively old, large square footage, small number of employees, sufficient hours of operation), suggests a potential opportunities for targeted efficiency improvements.
- Past purchase practices
  - 10% of small commercial respondents stated they had purchased energy efficient products in the past, and 60% of those customers said they had plans to do so again over the next 12 months – suggesting additional potential for energy efficiency projects within Unitil Electric's small commercial customer sector.
- Attitudes
  - Rebates remain a major motivator for customer action in the small business sector.

Territory-Specific Insights – Small/Medium Commercial

- Lighting
  - Substantial potential continues to exist for lighting improvements within Unitil Electric's small commercial business sector
- Space heating, cooling, mechanical ventilation
  - Based on survey responses, there appears to be some potential for replacement heating systems (fuel switching), heating system tune-ups and programmable thermostats within Unitil Electric's small commercial business sector.
  - Similarly, there appears to be potential for replacement cooling systems and system tune-ups within Unitil Electric's small commercial business sector.
- Specialty equipment (including motors, computers/servers , process, laundry, kitchens & pools)
  - Potential exists within Unitil Electric's small business sector for process and other specialty equipment efficiency improvements.
  - In addition, potential exists for replacement mechanical ventilation, commercial kitchen ventilation and energy management systems.
- Building envelope
  - Based on survey responses, there appears to be some potential for building envelope improvements within Unitil Electric's small commercial business sector.
- Refrigeration
  - Based on survey responses, there appears to be some potential for refrigeration and freezer improvements within Unitil Electric's small commercial business sector.
- Water heating
  - Only a small potential exists within Unitil's small commercial business sector for water heating efficiency improvments. But a majority (79%) of Unitil's small business customer respondents are not taking advantage of other water saving measures.
- On-site generation
  - 15% of Unitil Gas's small commercial customer respondents reported having onsite generation (7 emergency back-up generators , 1 onsite electric generator, 1 co-generator & 1 other system). There could be an opportunity to explore this market.

Territory-Specific Insights – Large Commercial

- Program awareness, participation & satisfaction
  - A majority (88%) of Unitil Electric's large business customer respondents are aware of and have participated (93%) in Unitil's energy efficiency programs and are interested in doing so again.
- Past purchase practices
  - 39% of respondents are planning a remodel in the next 12 months.
  - Potential for efficiency projects may exist within Unitil's top 100 largest commercial customers if coupled with these respondents' planned remodeling activities.
- Attitudes
  - Lower bills and receipt of rebates remain major motivators for customer action with Unitil Electric's largest top 100 customers.
  - These attitudes are also impacted by the number of businesses that have moved, sold, gone out of business or otherwise have cut back due to recession.

Territory-Specific Insights – Large Commercial

- Building Envelope
  - Opportunities likely exist for building envelope improvements within Unitil Electric's 100 largest customer's buildings.
- Lighting
  - Some of the greatest opportunities for lighting improvement could include replacement of HPS and Metal Halide bulbs, as well as utilization of additional lighting controls.
- Compressed Air & Motors
  - Due to the large number of sites with compressed air systems, implementation of Leak Reduction Maintenance Programs represent a potential opportunity in the Unitil Electric territory.
  - Additional pump maintenance may represent an opportunity for improvement among Unitil Electric's largest customers.
- HVAC
  - Potential remains for replacement of some aging oil-fired steam boilers. Potential may also exist for greater use of boiler controls.
  - Based on site visit findings, a limited potential appears to exist for facility cooling equipment. Maintenance and tune-up services may also represent an opportunity for some businesses.
- Water heating
  - Based on site visit findings, a limited potential appears to exist for oil and electric water heating equipment, with greater opportunities for pre-rinse spray valves, low flow showerheads and faucet aerators.
- Commercial equipment (including kitchens, refrigeration, laundry & electronics)
  - Potential appears to exist for further evaluation of commercial range hoods.
  - Potential also appears to exist for replacement of incandescent bulbs in walk-in/prep areas, as well as scheduling of additional maintenance activities.
- On-site generation
  - There appears to be some potential to explore this market given the lack of on-site generation equipment identified during the site visits.

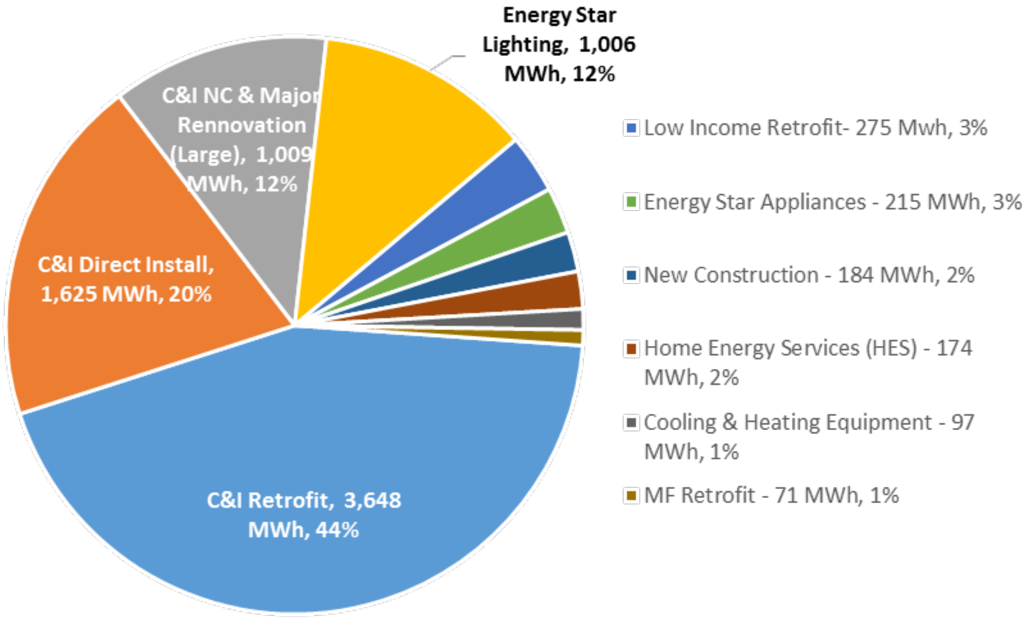
2013 Savings Characterization - Elec.

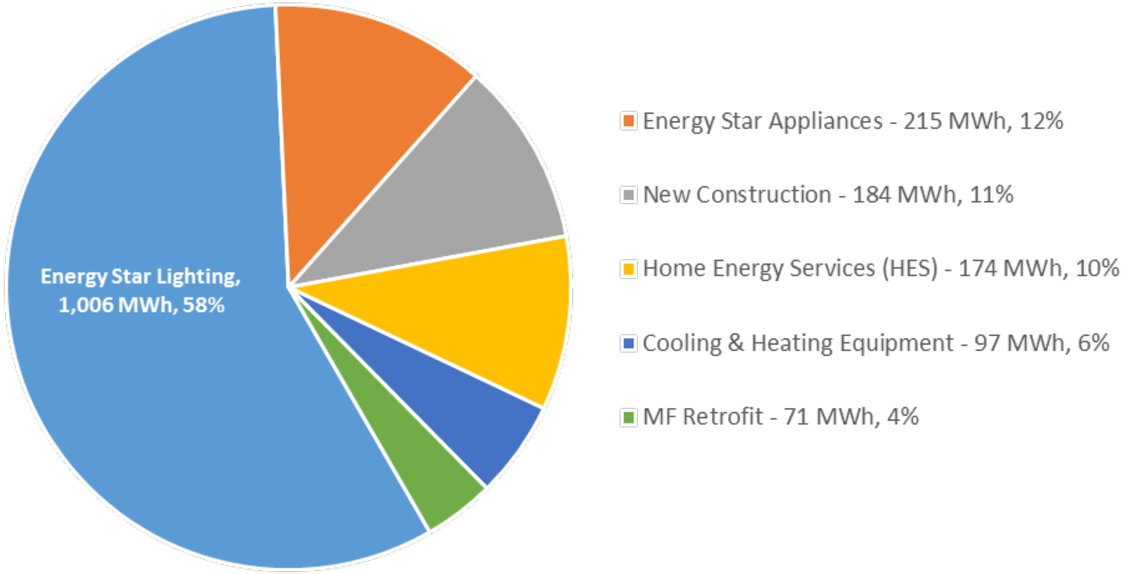
2013 ***Evaluated*** Energy Savings by Initiative, MWh



2013 EE Savings – Residential

2013 *Evaluated* Energy Savings Residential Initiatives, MWh

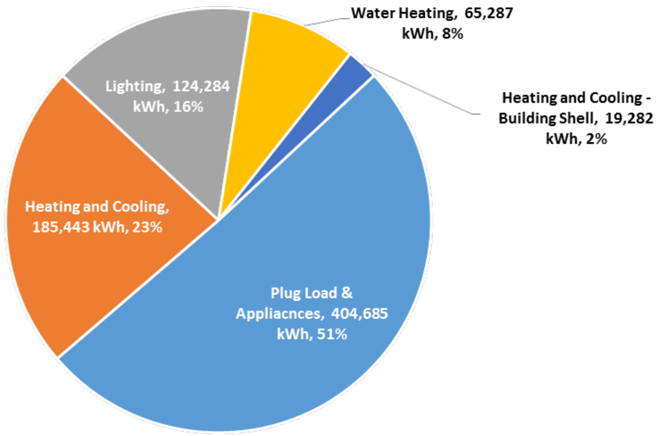
*Please note that savings reported in the remaining slides is derived from program tacking data which is reported as ***Gross*** MWh savings and will not match to this figure or the figure on the previous slide as these are reported as ***Evaluated*** savings.



2013 EE Savings – Residential

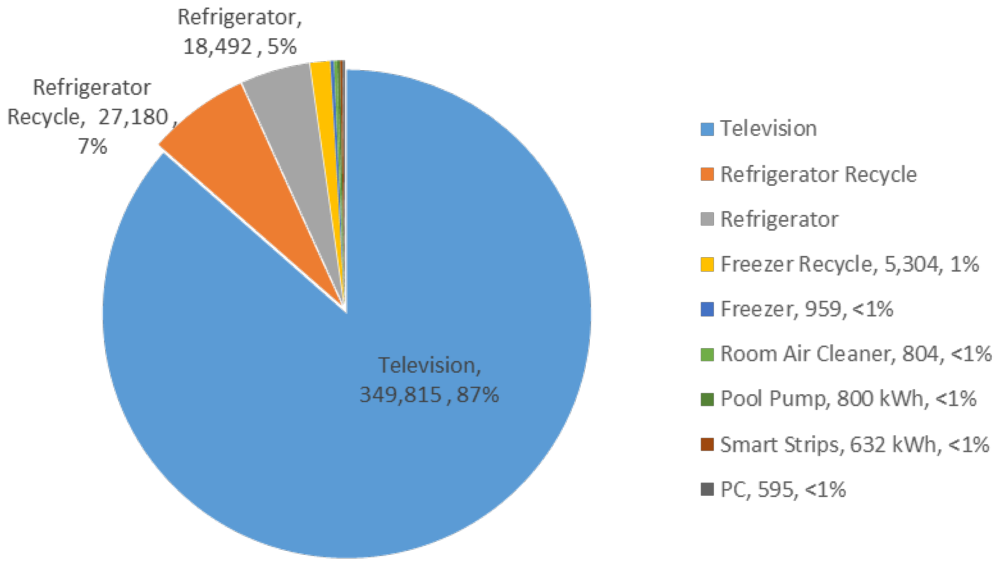
2013 ***Gross*** Energy Savings by End Use, kWh

- Over 50% of Savings is from Plug Load & Appliances
  - About 88% of Appliance Savings if from Televisions
  - Low NTG Factors diminish Gross savings
- Heating and Cooling 23%
- Lighting 16%
  - Lighting savings dominate ***Evaluated*** savings, less predominant in ***Gross*** figures.
- Water Heating 8%
- Building Shell 2%



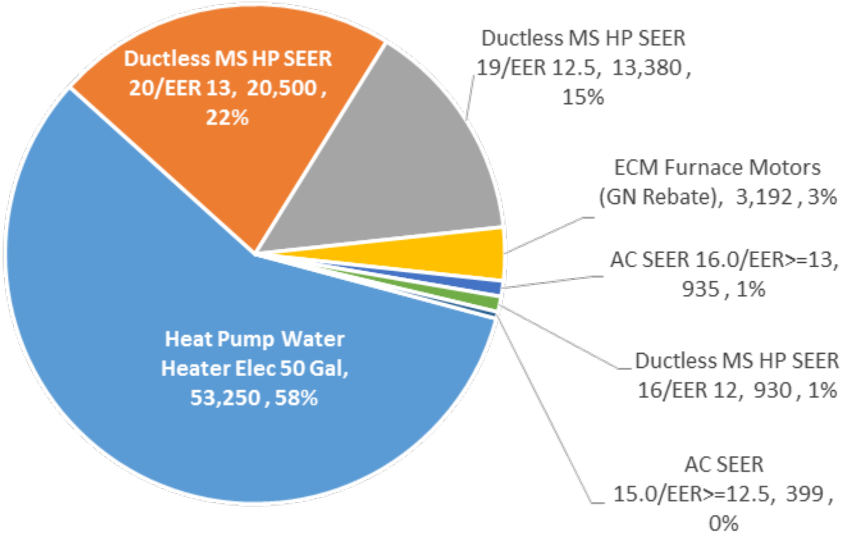
2013 EE Savings-Residential

2013 ***Gross*** Energy Savings Energy Star Appliances, kWh



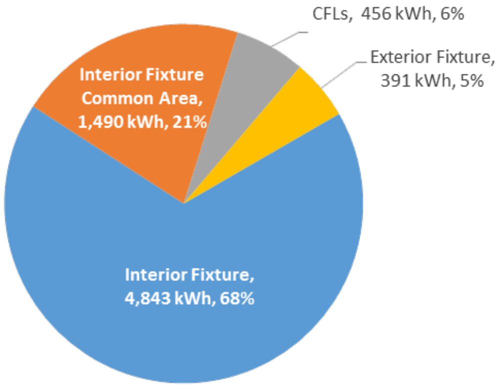
2013 EE Savings-Residential

2013 ***Gross*** Energy Savings Heating & Cooling Equipment, kWh



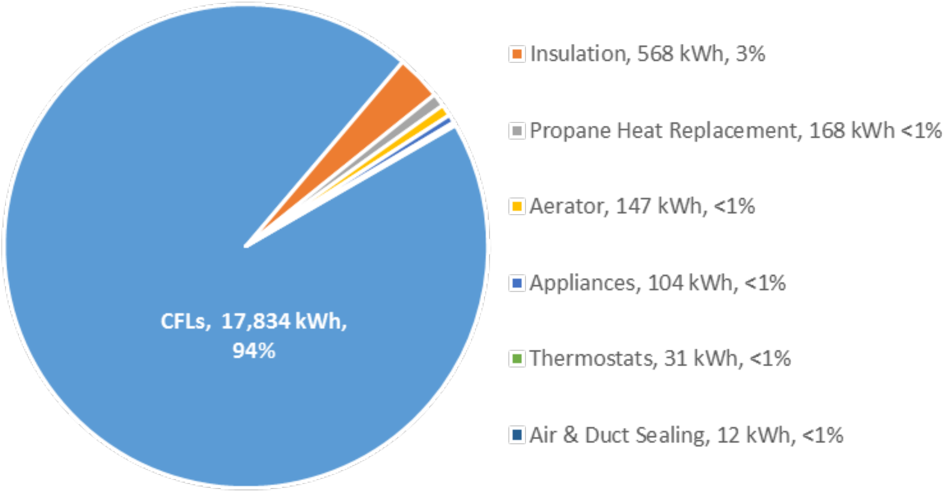
2013 EE Savings-Residential

- Multi-Family Retrofit (5+ Units)
  - 100% of savings comes from lighting
    - 68% (4,843 kWh) interior, in-unit, lighting fixtures
    - 21% (1490 kWh) from common area lighting fixtures
    - 6% (456 kWh) from CFLs
    - 5% (391 kWh) from exterior lighting fixtures



2013 EE Savings - Residential

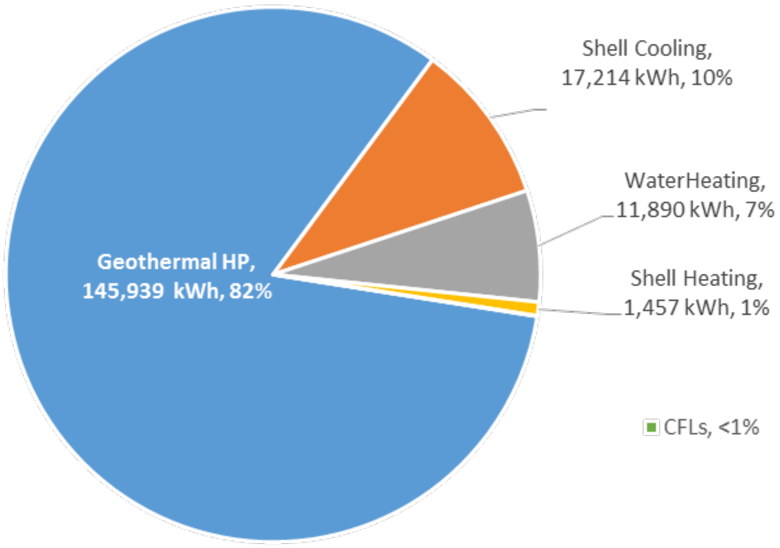
2013 ***Gross*** Energy Savings Home Energy Services (HES), kWh



2013 EE Savings - Residential

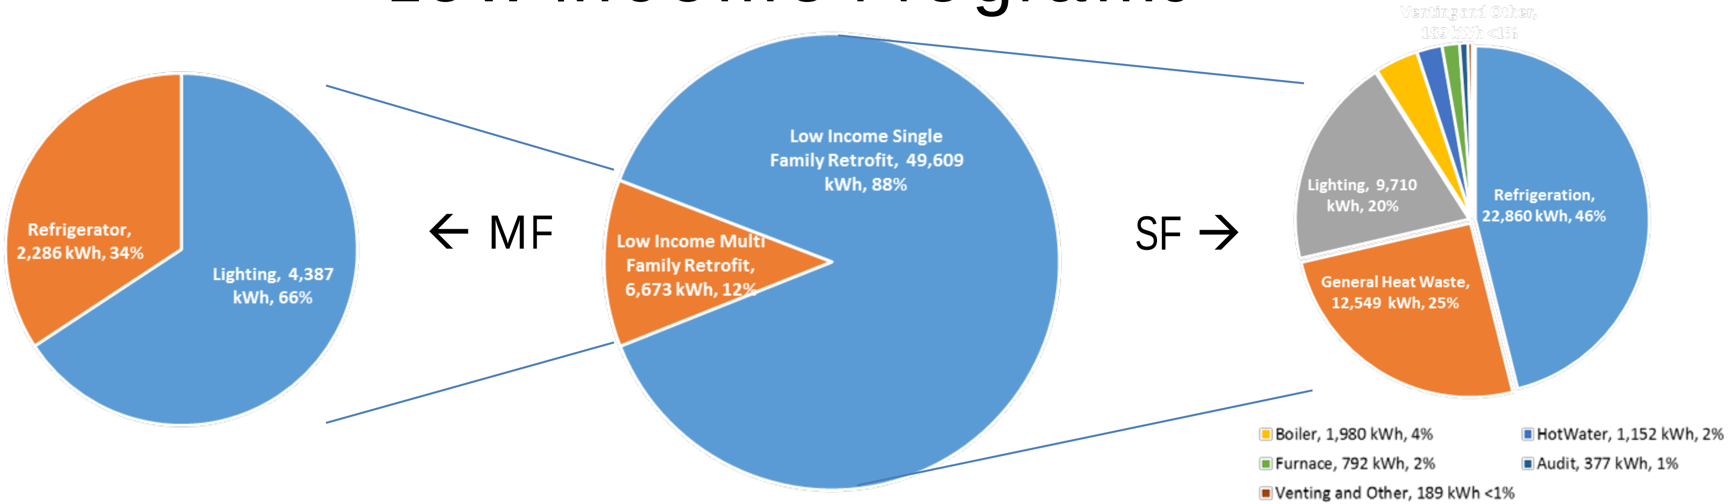
2013 *Gross* Energy Savings ENERGY STAR Homes, kWh

Geothermal Heat Pump installations at multiple program participant homes dominated this program's savings in 2013.



2013 EE Savings – Low Income

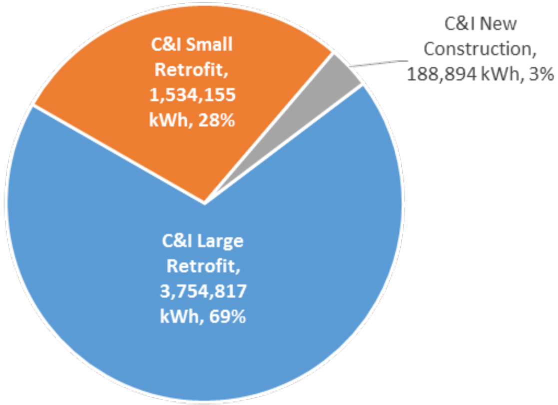
Low Income Programs



Savings for the Low Income program was split between the SF and MF Programs. In the SF program 46% of savings came from refrigerators and 25% from Weatherization (General Heat Waste). Lighting made up 20% of savings and boilers, furnaces, and vending machines also contributed to savings. In the MF program, 66% of savings came from lighting and 34% from refrigerators.

2013 EE Savings – C&I Sector

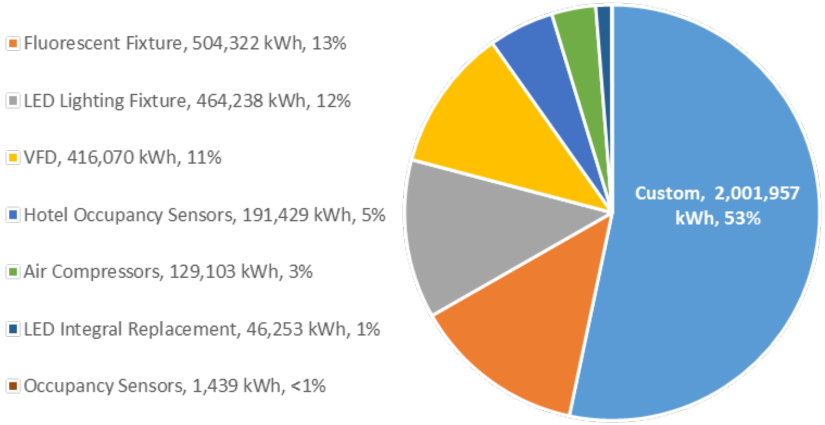
- Of the Total Savings from the C&I sector, 69% came from the Large Retrofit Program, 28% came from the Small Retrofit Program, and the remaining 3% came from the New Construction Program.
  - Large Retrofit – 3,754,817 MWh
  - Small Retrofit – 1,534,155 MWh
  - New Construction – 188,894 MWh



2013 EE Savings – C&I Large Retrofit

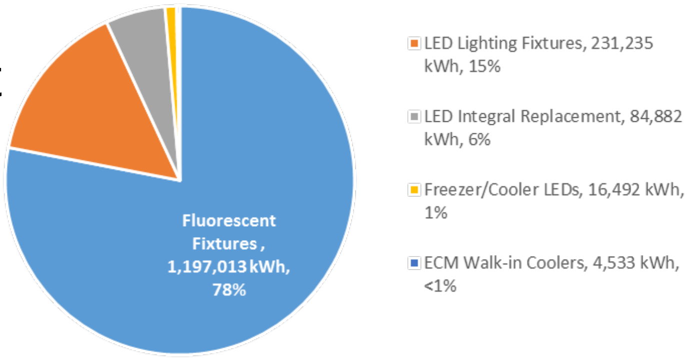
- Over half of the saving of the C&I Large Retrofit program were from custom projects. These custom projects included a compressor retrofit, rooftop replacement and EMS, and VFD and controls for an exhaust fan system.

Other measures included lighting (Fluorescent & LED), VFDs, Air Compressors, and Occupancy sensors (Hotel and Standard).



2013 EE Savings – C&I Small Retrofit

- Of the Total Savings from the C&I Small Retrofit Program, over three-quarters of the savings was from fluorescent light fixtures (over 1 million kWh) the remaining savings came from:
  - LED Lighting/Integral Replacement
  - Freezer/Cooler LEDs
  - ECMs for Walk In Coolers



2013 EE Savings – C&I New Equip.

- Of the Total Savings from the C&I New Equipment program, ninety-four percent was from two custom injection molding projects (177,168 kWh). Other savings came from Lighting and Air Compressors:
  - Lighting, 9,830 kWh 5%
    - All lighting from the Upstream Program
  - Compressors, 1,896 kWh 1%
    - Refrigerated Air Dryer

Executive Summary

This report summarizes the methodology and results of the 2014 Cape Light Compact Penetration, Potential, and Program Opportunity Study, conducted by Opinion Dynamics Corporation and Dunsky Energy Consulting. The goal of this research was to determine the remaining achievable potential from electric measures among residential, low income, and commercial and industrial customers for the six-year period 2016-2021 and to inform CLC's program planning efforts. The outputs of this study satisfy the requirements of the Massachusetts Department of Public Utilities ("DPU") Order dated January 31, 2013 (D.P.U. 12-107) to document the penetration of energy efficiency within the Compact's service territory and develop estimates of remaining savings potential.[1]

The results presented in this report are based on extensive primary and secondary data collection. The primary data collection activities for the residential and low income sectors included a mail survey with 2,785 customers, in-home visits at 169 homes, and a telephone survey with 144 customers. The primary data collection activities for the commercial & industrial sector included a telephone survey with 448 customers and on-site visits at 150 facilities. We also conducted in-depth interviews with a small number of local contractors to inform assumptions for the potential model.

We estimate CLC's total achievable energy efficiency potential for the six-year period 2016-2021 to be 246 annual GWh[2] and 62 MW.[3] Achievable potential represents 51% of economic potential and 36% of technical potential. On average over the six-year period, achievable energy savings represent 1.98% of CLC forecasted annual sales.[4] These electric savings would be expected to cost CLC $220 million (incentive and non-incentive program costs;[5] in 2016 dollars), an average of $37 million per year or $0.895 per annual kWh.[6] It should be noted that per kWh projected costs are relatively high for CLC as compared to the statewide average due to a number of territory-specific reasons, including the small base of large C&I customers and the seasonal nature of many homes and businesses. The total cost (including the participants' net cost) amounts to $246 million for the six-year period. All of the 2016-2021 proposed investments are currently cost-effective, with an expected Total Resource Cost (TRC) ratio of 3.6 and a Program Administrator Cost (PAC) ratio of 2.8.

---

[1] MA DPU Order dated January 31, 2013 (D.P.U. 12-107) included the following requirement: "The Program Administrators with an aggregate three-year savings goal of greater than 20 percent below the statewide three-year aggregate goal will conduct a study, either jointly or individually, during the upcoming three-year term to document the penetration of energy efficiency within its service territory and the remaining cost-effective energy efficiency opportunities available."

[2] The gigawatt-hour, or GWh, is a measure of energy, and is equal to 1,000 megawatt-hours (MWh).

[3] These findings reflect the best information and assumptions available as of April 2015. Cape Light Compact and the Opinion Dynamics/Dunsky team plan to refresh these results, prior to the September Three Year Plan draft filing, to incorporate any newly available evaluation findings, as well as updates to non-incentive program costs.

[4] Note that annual sales are forecasted by Eversource.

[5] Non-incentive program costs, dated March 31, 2015, are estimates based on the average actual Cape Light Compact non-incentive costs for plan years 2013 and 2014, and projected non-incentive costs for plan year 2015.

[6] This compares to a projected average cost of $0.794/kWh during the 2013-2015 Three Year Plan Cycle.

Table ES-1 summarizes these results for the six-year period 2016-2021, as well as for each of the next two three-year planning periods.

Table ES-1. Key Potential Results – All Sectors, by Period

	2016-2021		2016-2018		2019-2021	
Potential (Total)	GWh	MW	GWh	MW	GWh	MW

Total Resource Cost Test	3.6		3.6		3.6	
Program Administrator Cost Test	2.8		2.8		2.9	

Table ES-2 and Table ES-3 detail annual achievable potentials as a percentage of sales, by year and sector, for the first three-year period and the second three-year period, respectively.

Table ES-2. Achievable Potential as a Percentage of Forecasted Energy Sales – 2016 to 2018

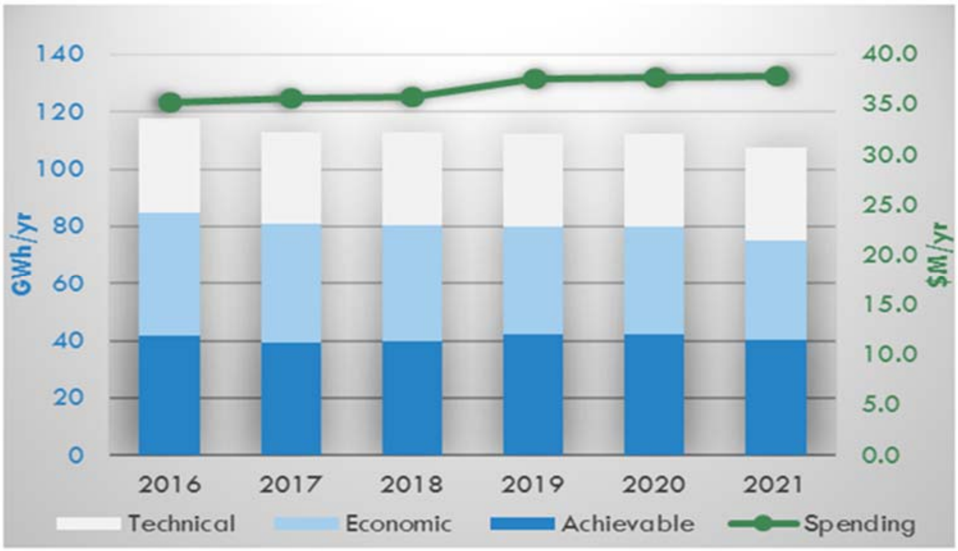
	2016	2017	2018	2016-2018
Residential	2.06%	1.80%	1.79%	1.88%
Low Income	2.39%	2.05%	2.04%	2.16%
Commercial	1.94%	2.00%	2.04%	1.99%
All Sectors	**2.02%**	**1.89%**	**1.90%**	**1.94%**

Table ES-3. Achievable Potential as a Percentage of Forecasted Energy Sales – 2019 to 2021

	2019	2020	2021	2019-2021
Residential	2.00%	2.01%	1.87%	1.96%
Low Income	2.18%	2.19%	2.12%	2.16%
Commercial	2.07%	2.11%	2.07%	2.09%
All Sectors	**2.03%**	**2.06%**	**1.96%**	**2.02%**

Figure ES-1 presents annual savings (GWh) for the three types of potential – technical, economic, and achievable – as well as annual spending required to meet the achievable potential. The increase in spending during the second three-year period (2019–2021) is due to higher LED uptake, which results from an assumption of lower market barriers.[7] While savings from LEDs are higher for that period, they are counterbalanced by somewhat lower savings for other measures.

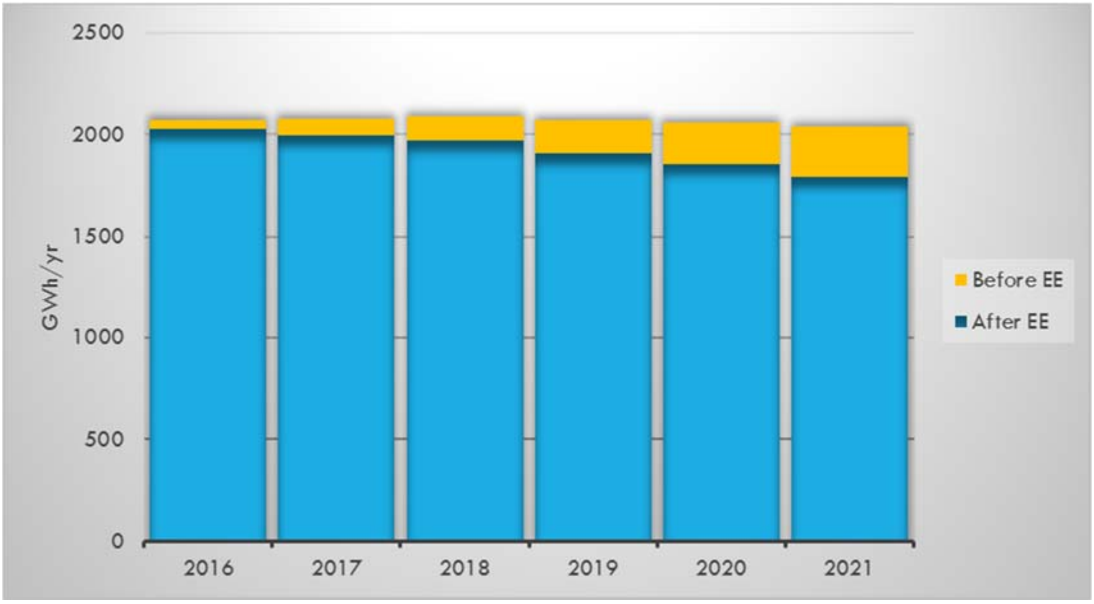
Figure ES-1. Annual Savings and Spending



Energy sales, provided to CLC by Eversource, are forecasted to decline slightly, before energy efficiency (EE) efforts, over the six-year period, with total sales of 2,041 GWh in 2021 compared to 2,071 in 2016. With EE efforts at the level of the achievable potential, energy sales would decline faster, with 2021 sales amounting to 1,795 GWh, a drop of 12% from 2016 sales (Figure ES-2).

[7] The assumptions for measure uptake are based on the best information available at this time and could change in the future.

Figure ES-2. Impact of Achievable Potential on Annual Sales



Achievable potential estimated in this study (120.8 GWh total for the three plan years 2016-2018) is lower than the 2016-2018 savings goal in CLC's Three-Year Plan[8] (156.3 GWh total for the three plan years 2016 - 2018). When comparing CLC's published goal to results from the potential model, it is important to remember that the potential study is not meant to be a direct forecast of claimable savings, because some of the assumptions and inputs used to estimate potential are different from those used for setting goals and claiming savings. In particular, a key objective of this potential study was to reflect the unique circumstances of CLC's service territory and customer base, including the effects on achievable savings of having a large share of seasonal customers. To this end, we collected a wealth of primary data which is reflected in the potential study results. In contrast, the Massachusetts goal setting and savings claiming process requires consistency with Technical Resource Manual (TRM) assumptions.

A key programmatic area where different potential model and TRM assumptions lead to a difference in savings is C&I upstream lighting: The Three-Year Plan estimates savings of 40.9 GWh from C&I upstream lighting whereas the potential model only estimates 8.7 GWh. The main drivers of this difference are assumptions about (1) the mix of baseline (replaced) bulbs (i.e., incandescent vs CFL units); (2) the size (wattage) of the baseline (replaced) bulbs; and (3) hours of use. Aligning potential model assumptions with TRM assumptions for these (and a few other) parameters would increase the achievable potential of the C&I upstream lighting offering to 35.1 GWh and total CLC achievable potential to 147.3 GWh. This change of assumptions would yield an annual achievable potential as a percentage of sales of 2.36% overall in 2016-2018, as compared to 1.94% in the base case (as shown in Table ES-1 above).[9]

[8] References to the Three Year Plan in this document denote the April 30, 2015 draft of this document.

[9] It should be noted, however, that even with these adjustments to C&I upstream lighting, Plan goals are not perfectly comparable to the achievable potential estimated in this study. The potential model also uses CLC-specific assumptions in the other sectors (residential and low income), which we did not vary for this analysis.

1. Introduction

Cape Light Compact contracted with the Opinion Dynamics team to complete a Penetration, Potential, and Program Opportunities Study of its residential, low income, and commercial & industrial sectors. The goal of this research was to determine the remaining achievable potential from electric measures for the six-year period 2016 – 2021 and to inform program planning efforts. The outputs of this study satisfy the requirements of the Massachusetts Department of Public Utilities ("DPU") Order dated January 31, 2013 (D.P.U. 12-107) to document the penetration of energy efficiency within the Compact's service territory and develop estimates of remaining savings potential.[10]

This document, Volume 1, presents the methodology for this study as well as penetration and saturation results and electric potential estimates. Volume 1 is organized as follows:

- **Section 2: Methodology.** This section presents information about our approaches to primary data collection and potential modeling. It includes details about our survey sampling and weighting methodology, and defines key terms and concepts used throughout this report.
- **Section 3: Summary of Key Penetration and Saturation Results.** This section presents the penetration and saturation data collected in the mail and telephone surveys and adjusted, where necessary, by site visit results.
- **Section 4: Overall Potential Results.** This section shows potential results for CLC's service territory, including estimates of technical, economic, and achievable potential for 2016 – 2018, 2019 – 2021 as well as for the six-year period 2016 – 2021. Results are presented by sector, segment, and end-use. This section also includes a comparison of potential model results to CLC three-year Plan.
- **Section 5: Residential Potential Results.** This section shows potential results for the residential sector.
- **Section 6: Low Income Potential Results.** This section shows potential results for the low income sector.
- **Section 7: Commercial & Industrial Potential Results.** This section shows potential results for the commercial and industrial sector.

In addition to this report, separate volumes present additional technical details of the potential modeling, the primary data collection instruments, as well as detailed results from the residential/low income mail survey (adjusted by site visit information) and from the C&I Telephone Survey (also adjusted by site visit information).

However, the different assumptions for C&I upstream lighting can explain a significant portion of the difference between Plan goals and our estimated achievable potential.

[10] MA DPU Order dated January 31, 2013 (D.P.U. 12-107) included the following requirement: "The Program Administrators with an aggregate three-year savings goal of greater than 20 percent below the statewide three-year aggregate goal will conduct a study, either jointly or individually, during the upcoming three-year term to document the penetration of energy efficiency within its service territory and the remaining cost-effective energy efficiency opportunities available."

2. Methodology

Key activities in support of the Potential and Program Opportunities Study included extensive primary data collection as well as potential modeling. The following sections present details about each of these activities.

2.1 Primary Data Collection – Residential & Low Income Sectors

The primary data collection activities for the residential and low income sectors included a mail survey with 2,785 customers, in-home visits at 169 homes, and a telephone survey with 144 customers. This section describes the sampling and weighting methodologies associated with these three activities.

2.1.1 Residential/LI Mail Survey

The 2014 Residential Energy Use Survey consisted of a mail/internet survey of CLC residential and low income customers. The mail survey was designed to collect comprehensive penetration and saturation data on energy-using equipment as well as information about the customers and their homes.

The survey was sent to 12,000 homes in June 2014. To enhance recognition and response rates, all written communications with customers were conducted on specially-designed stationery, displaying the CLC logo. The cover letter included a reference to a website and a personal identification number (PIN), and offered customers the option to complete the survey on-line instead of by mail. The cover letter also announced a drawing of ten $100 gift cards as well as a grand prize of $1,000 in new energy efficient appliances among respondents who returned the completed survey by the specified deadline.

About two and four weeks later, respectively, two reminder mailings – one postcard and one mailing containing another copy of the survey booklet – were sent to customers who had not yet returned a completed survey.

Sample Design

As of February 2014, there were 165,203 residential and 8,530 low income accounts in CLC's service territory.[11] After consultation with CLC, we moved a total of 2,692 accounts classified as residential and low income (including Condo Associations, Realities, Trusts, and Housing Authorities) into the commercial sample frame. We also moved 2,567 accounts classified as "commercial residential" from the commercial sample frame into the residential sample frame, typically because they were single family homes on a commercial rate because of their ownership status as a rental or new construction property in the name of a commercial entity. In either instance, we reclassified these accounts to better capture their energy usage with our primary data collection instruments for their respective sector. Table 2-1 summarizes these account relocations.

[11] It should be noted that the number of CLC customers fluctuates throughout the year.

Table 2-1. Mail Survey Sample Frame Account Relocations

	Residential	Low Income	Total
Number of Accounts in Customer Files	165,203	8,530	173,733
Accounts Moved to Commercial	- 2,688	- 4	- 2,692
Accounts Added from Commercial Residential	+ 2,567	+ 0	+ 2,567
Final Number of Accounts	165,082	8,526	173,608

We then aggregated accounts with the same name and service address to the premise level, resulting in 160,444 residential and 8,507 low income premises. Of these, we dropped records that had no valid usage data (i.e., usage for all 12 months was missing or zero). We also dropped records that had less than 2 kWh average daily usage and an on-Cape mailing address (indicating homes that are likely vacant, rather than seasonal).

The final sample frame for the mail survey consisted of 156,747 residential and 8,338 low income premises (see Table 2-2).

Table 2-2. Mail Survey Sample Frame Premise Drops

	Residential	Low Income	Total
Initial Number of Premises	160,444	8,507	168,951
Dropped Because of Missing or Zero Usage	1,987	136	2,123
Dropped Because of Low Usage (Average Daily Usage < 2 kWh and On-Cape Mailing Address)	1,710	33	1,743
Final Number of Premises (Sample Frame)	156,747	8,338	165,085

The residential premises in the sample frame were classified into non-seasonal and seasonal, based on their 2013 electricity usage pattern. We considered premises seasonal if their usage in June through September exceeded their usage during the rest of the year.

The target number of completed surveys was 1,750. To achieve this number we sent out 12,000 survey booklets, assuming a response rate of approximately 15%. The sampling approach was a random sample within each of the three analysis segments (residential non-seasonal, residential seasonal, and low income).

The following table presents, for the three segments, the number of premises in the population as well as the sample for the outgoing surveys and the expected number of completed surveys.

Table 2-3. Mail Survey Sample Frame and Targets

Sector/Segment	Population	Sample	Expected Completes
Residential Non-Seasonal	107,077	3,500	500
Residential Seasonal	49,670	3,500	500
Low Income	8,338	5,000	750
Total	165,085	12,000	1,750

Summary of Survey Statistics

Overall, we received 2,815 responses to the survey, 2,541 by mail and 274 via the Internet. Of these, 29 responses were duplicates and one was completed by a business. Removing these ineligible responses resulted in a total of 2,785 usable responses. Overall, 1% of mailed surveys were undeliverable. The resulting response rate, calculated as the number of completed surveys divided by the number of deliverable surveys, was 24%. The percentage of undeliverables and the response rates were almost identical for the three segments.

Given this higher than expected response rate, we greatly exceeded the target number of completes in all three segments. Table 2-4 summarizes these survey statistics.

Table 2-4. Summary of Mail/Internet Survey Responses

	TOTAL	Residential Non-Seasonal[a]	Residential Seasonal[a]	Low Income
Total Mailed	12,000	3,500	3,500	5,000
Completed Survey – Mail	2,514	721	699	1,094
Completed Survey – Internet	271	103	86	82
Completed Survey – Total	2,785	824	785	1,176
Undeliverable – Number	154	33	50	71
Undeliverable – Percent	1%	1%	1%	1%
Response Rate	24%	24%	23%	24%

[a] Note that we reclassified the segments for a few respondents, based on their occupancy patters reported in the mail survey.

Weighting

To ensure that mail survey results are representative of CLC's populations of residential and low income customers, respectively, we developed and applied weights. We developed these weights in a two-step process, as described below.

Sample Weights

We first developed sample weights for the residential sector to correct for the fact that we over-sampled seasonal homes and under-sampled non-seasonal homes.[12] For each segment, we estimated the weight by dividing the segment's share of the overall residential population by its share of responses. For example, the seasonal segment represents 32.1% of the residential population but 49.3% of the residential mail survey responses. The weight for this segment is calculated as 32.1% divided by 49.3%, or approximately 0.65. This means that the survey responses of seasonal customers are weighted down, i.e., each response only counts about two-thirds, compared to a weight of 1. Conversely, the weight for non-seasonal customers is 1.34, meaning that each response from a non-seasonal customer is weighted up.

[12] For analysis purposes, both residential segments had the same target number of completes even though the non-seasonal segment is much larger than the seasonal segment.

Table 2-5. Mail Survey Residential Sample Weights

Segment	Population[a]		Responses		Sample Weight
	Count	%	Count	%	
Residential Non-Seasonal	106,399	67.9%	816	50.7%	1.3385
Residential Seasonal	50,348	32.1%	793	49.3%	0.6517
Total Residential	156,747	100%	1,609	100%	

[a] Population counts for the two segments are based on 2013 usage, but were adjusted to reflect occupancy patters reported in the mail survey.

We did not develop sample weights for the low income sector since we did not stratify that sample. Rather, the low income sample was drawn as a simple random sample from the population of low income customers.

Post-Stratification Weights

Post-stratification can be used as a basis for adjusting samples that are not representative of the population for important variables. In other words, it is used when (1) survey respondents are not representative of the population from which they were selected, i.e., some subgroups of interest are over-represented and some are under-represented; and (2) over-represented subgroups are different from under-represented subgroups on important variables. In order to conduct post-stratification, information is required on both the percentage of the population and the percentage of the respondents that fall into the subgroups of interest (or strata). It is important that the strata available for the population are the same as the strata available for survey respondents.

We determined the need for post-stratification by comparing survey responses with known statistics about the population. We compared the survey data across core demographic and household characteristics with 2007-2011 American Community Survey data for CLC's service territory. This comparison found that homes with older heads-of-household are over-represented in our survey responses relative to the population.[13] Since customers of different ages likely vary in their ownership and use of certain electricity-using equipment, we developed an age-based post-stratification weight. This weight is calculated the same way as the sample weight, by dividing the stratum's share of the population by the stratum's share of the sample. It should be noted that to determine the stratum's share of the sample, we first apply the sample weights.

Since the distribution of the age of the head-of-household is different for residential and low income populations, we created separate weights for each. The residential post-stratification weights are shown in Table 2-6; the low income post-stratification weights are shown in Table 2-7.

[13] We also compared the housing type (i.e., single-family attached, single-family detached, apartment/condominium, and mobile home) of respondents to the population in CLC's service territory. Since the distribution of housing types among respondents was almost identical to that in the population, we did not develop post-stratification weights for this statistic.

Table 2-6. Mail Survey Residential Post-Stratification Weights

Age	Population		Responses		Weight
	Count	%	Count	%	
Under 44 years	20,843	22.3%	108	6.9%	3.2448
45 to 64 years	39,866	42.6%	566	36.0%	1.1822
65 years and over	32,950	35.2%	899	57.1%	0.6157
Missing Response			36		1.0000
TOTAL	93,659		1,609		

Table 2-7. Mail Survey Low Income Post-Stratification Weights

Age	Population		Responses		Weight
	Count	%	Count	%	
Under 44 years	2,866	33.0%	161	14.1%	2.3451
45 to 64 years	3,262	37.6%	454	39.7%	0.9465
65 years and over	2,556	29.4%	529	46.2%	0.6365
Missing Response			32		1.0000
TOTAL	8,684		1,176		

Rebalancing Weights

When we applied post-stratification weights for residential customers, the distribution of the sample between seasonal and non-seasonal homes slightly changed from its original proportions. To preserve the proper proportion of the two segments, we developed rebalancing weights. These weights are 1.052 for seasonal homes and 0.977 for non-seasonal homes.

Note that this step was not necessary for the low income sector since it consists of a single segment.

Final Mail Survey Weights

The final weight for each mail survey respondent is the product of the respondent's sample weight, their post-stratification weight (based on their reported age of head-of-household), and their rebalancing weight.[14] These final weights have to be applied whenever mail survey responses are aggregated across multiple respondents. The exception is mail survey variables that have been adjusted with site visit data. For those variables, variable-specific adjustment factors are applied to the final weights (see discussion in the next section).

Adjustment of Mail Survey Data

We used some of the information from the in-home visits, discussed in more detail below, to adjust certain mail survey responses. In general, we considered for adjustment items that are technical in nature and often difficult for customers to report correctly, e.g., questions about

[14] Note that for all low income customers, the sample weight is equal to 1.0 since we did not stratify the sample and the rebalancing weight is equal to 1.0 since the sector consists of a single segment. As a result, the final weight for low income customers is equal to their post-stratification weight.

equipment age or ENERGY STAR rating or questions about the customer's type of windows. We did not consider for adjustment items that cannot be observed during in-home visits (such as questions about home occupancy). We also did not adjust questions with very low incidence in the in-home sample.

We first conducted a Pearson's chi-squared test for questions considered for adjustment. For each question tested, we compared the on-site observations and the mail survey responses for the same set of households (i.e., the comparison only included mail survey responses for homes that received an on-site visit). Only if the test showed that mail survey responses are significantly different from on-site observations, did we include the question for adjustment.

Table 2-8 below presents the survey questions we adjusted, by report section. The number in parentheses indicates the question number in the mail survey (see Appendix 2 for the final mail survey instrument).

Table 2-8. Mail Survey Questions Adjusted with Site Visit Data

B. Central Air Conditioning/Cooling o ENERGY STAR rating of CAC (B4) **C. Window Air Conditioning** o ENERGY STAR rating of window unit (C4a) **D. Insulation and Ventilation** o Inches of attic insulation (D2) o Exterior walls are insulated (D3) o Basement walls are insulated (D4) o Basement ceiling insulated (D5) o Type of windows (D6) **F. Water Heating** o Presence of low-flow showerheads (F5) o Presence of faucet aerators (F6)	**G. Appliances** o ENERGY STAR rating of clothes washer (G2) o ENERGY STAR rating of refrigerators (G8c) o ENERGY STAR rating of dishwasher (G15) **H. Entertainment and Technology** o Count of various TV types (H2a, H2b, H2c, H2f, H2h, H2k) **J. Lighting** o Number of bulbs inside the home (J1) o Percentage of indoor bulbs that are CFLs (J2) o Percentage of indoor bulbs that are LEDs (J3) o Number of bulbs outside the home (J4) o Percentage of outdoor bulbs that are CFLs (J5) o Percentage of outdoor bulbs that are LEDs (J6)

Adjustment Methodology

We used a ratio adjustment approach to adjust the mail survey responses for the questions listed above. The values to be adjusted can be either a mean or a proportion. The ratio adjustment method first develops an adjustment factor, based on the unweighted value of the 169 in-home visits and the unweighted value of the survey responses for the same 169 households:

$$Adjustment\ Factor = \frac{Y_{\text{In-Home Visits}}}{Y_{\text{Survey Responses}}}$$

Where:

$Y_{\text{In-Home Visits}}$	=	unweighted mean or proportion from the 169 in-home visits
$Y_{\text{Survey Responses}}$	=	unweighted mean or proportion from the survey responses for the 169 households with in-home visits

The adjustment factor is then multiplied by the weighted number of survey responses for all households (by sector), to develop an adjusted distribution of responses across response categories. This new distribution is then used to calculate new means or proportions for the adjusted question.

Consider the following example:

If a home reported having a clothes washer, we collected information on whether or not the washer is ENERGY STAR rated (at the time of purchase). The in-home visits found that 56.4% of clothes washers are ENERGY STAR rated. By contrast, the mail survey responses provided by the same 169 households reported that 83.8% are ENERGY STAR rated.[15] Using these values, we developed an adjustment factor for each response category of this question, as follows:

Clothes washer is ENERGY STAR rated: $Adjustment\ \ Factor = \frac{56.4\%}{83.8\%} = 0.673$

Clothes washer is not ENERGY STAR rated: $Adjustment\ \ Factor = \frac{43.6\%}{16.2\%} = 2.691$

We then apply these adjustment factors to weighted mail survey results by response category. Of all residential mail survey respondents with a clothes washer, 916 reported that their washer is ENERGY STAR rated and 212 reported that it is not (valid n=1,128). Multiplying these responses by the adjustment factor yields:

Clothes washer is ENERGY STAR rated: *Adjusted "n" = 916 * 0.673 = 617*

Clothes washer is not ENERGY STAR rated: *Adjusted "n" = 212 * 2.691 = 571*

When adjusting proportions, an additional step is necessary. Because each response category is adjusted separately, the total number of responses no longer sums to the correct valid "n". In the example above, the correct "n" is 1,128 but the adjusted "n"s sum to 1,188 (617+571). To correct for this, we developed an additional balancing factor, which is the ratio of the correct "n" and the adjusted "n". This ratio is multiplied by the adjustment factor for each response category to derive the final adjustment factors for the question.

The final adjustment factor is then multiplied by the post-stratification weight, by response category, to develop adjusted weights. These adjusted weights are specific to each adjusted question. They are used when developing the results used in this analysis.

[15] Percentages are based on unweighted responses.

Precision of Results

Overall, the estimated precision of mail survey results is approximately 2.4% for residential customers and 2.6% for low income customers (at a 95% confidence level). This estimate is based on a two-tailed test, corrected for a finite population, uses an assumed coefficient of variation of 0.5, and includes the total number of responses received (i.e., 1,609 for residential customers and 1,176 for low income customers).

For equipment with low incidence in the population (e.g., central air conditioning), the precision value is higher (i.e., results are less precise) for follow-up questions about equipment characteristics. Similarly, the precision level is higher for questions with many incomplete or invalid responses. For example, a typical rate of incomplete or invalid responses to the mail survey is about 5%. This translates into slightly less precise results, with precision levels of 2.5% for residential customers and 2.7% for low income customers (at a 95% confidence level and holding all other assumptions constant). However, in both examples here, the precision is very good.

2.1.2 Residential/LI In-Home Visits

We conducted a total of 169 in-home visits with Cape Light Compact residential and low income customers. The in-home visits were designed to collect data to verify mail survey responses and to collect additional, more technical data (such as equipment capacity or efficiency ratings) that we did not include in the mail survey as customers generally find it difficult to report.

The site visits took place between August and September 2014 and typically took 60 to 90 minutes per survey. To compensate customers for their efforts, we offered an incentive of $75 for site visits.

Sample Design

The target number of in-home visits was 175. This included 50 residential non-seasonal, 50 residential seasonal, and 75 low income visits. The sampling approach was a random sample within each of these three segments.

The in-home visits were designed as a nested sample, i.e., we drew the sample of homes from the population of mail survey respondents. Therefore, we have a completed mail survey for every in-home visit we conducted.

Overall, we conducted 169 in-home visits. We conducted 61 visits with residential non-seasonal customers, 36 with residential seasonal customers, and 72 with low income customers. The final distribution of site visits by segment was different from the quota since we reassigned the segment for some residential customers based on their self-reported occupancy patterns.

Table 2-9. In-home Visit Quotas by Segment

Segment	Quota	Completed Visits
Residential Non-Seasonal	50	61
Residential Seasonal	50	36
Low Income	75	72
Total	175	169

Weighting

To ensure that in-home results are representative of CLC's population of residential and low income customers, we developed and applied weights. We used the same two-step weighting process that was used for the mail survey.

Sample Weights

We first developed sample weights for the residential sector to correct for the fact that we oversampled seasonal households and under-sampled non-seasonal households. For each segment, we estimated the weight by dividing the segment's share of the overall residential population by its share of responses.[16]

Table 2-10. Site Visit Residential Sample Weights

Segment	Population		Responses		Sample Weight
	Count	%	Count	%	
Residential Non-Seasonal	106,399	67.9%	61	62.9%	1.0794
Residential Seasonal	50,348	32.1%	36	37.1%	0.8655
Total Residential	156,747	100%	97	100%	

We did not develop sample weights for the low income sector since we did not stratify that sample.

Post-Stratification Weights

As with the mail survey, we compared demographics of in-home visit participants with those of the population and found that homes with older heads-of-household are over-represented in our visits. To correct for this, we developed an age-based post-stratification weight. This weight is calculated the same way as the sample weight, by dividing the stratum's share of the population by the stratum's share of the sample. It should be noted that to determine the stratum's share of the sample, we first apply the sample weights.

Since the distribution of the age of the head-of-household is different for residential and low income populations, we created separate weights for each. The residential post-stratification weights are shown in Table 2-11; the low income post-stratification weights are shown in Table 2-12.

[16] As with the mail survey, residential segments had the same target number of completes for analysis purposes even though the non-seasonal segment is much larger than the seasonal segment.

Table 2-11. Site Visit Residential Post-Stratification Weights

Age	Population		Responses		Weight
	Count	%	Count	%	
Under 44 years	20,843	22.3%	7	7.2%	3.0874
45 to 64 years	39,866	42.6%	26	27.5%	1.5487
65 years and over	32,950	35.2%	63	65.3%	0.5387
Missing Response			1		1.0000
TOTAL	93,659		97		

Table 2-12. Site Visit Low Income Post-Stratification Weights

Age	Population		Responses		Weight
	Count	%	Count	%	
Under 44 years	2,866	33.0%	8	11.4%	2.8878
45 to 64 years	3,262	37.6%	29	41.4%	0.9067
65 years and over	2,556	29.4%	33	47.1%	0.6243
Missing Response			2		
TOTAL	8,684		72		

Rebalancing Weights

When we applied post-stratification weights for residential customers, the distribution of the sample between seasonal and non-seasonal homes slightly changed from its original proportions. To preserve the proper proportion of the two segments, we developed rebalancing weights. These weights are 1.058 for seasonal homes and 0.896 for non-seasonal homes.

Note that this step was not necessary for the low income sector since it consists of a single segment.

Final In-Home Visit Weights

The final weight for each in-home visit participant is the product of the participant's sample weight, their post-stratification weight (based on their reported age of head-of-household), and their rebalancing weight.[17] These final weights have to be applied whenever in-home data are aggregated across multiple participants.

2.1.3 Residential/LI Barriers Telephone Survey

The residential/low income telephone survey was aimed at persons in the household who make decisions about purchasing new energy-using equipment for the home. It collected information on barriers to energy efficiency and participation in CLC programs, the role of incentives in adopting energy efficient technologies, as well as program awareness and past program participation. Questions about barriers and incentives were asked separately for

[17] Note that for all low income customers, the sample weight is equal to 1.0 since we did not stratify the sample and the rebalancing weight is equal to 1.0 since the sector consists of a single segment. As a result, the final weight for low income customers is equal to their post-stratification weight.

three major end-use categories: heating and cooling systems, major appliances, and lighting. Survey responses were a key input into the adoption curves developed for the potential model.

The survey was fielded between October 10th and November 10th, 2014 and resulted in 144 completed interviews. On average, the survey took just under 15 minutes to complete. Our response rate was 5.5% with a cooperation rate of 18.0%.

The telephone survey instrument is included in Appendix 2.

Sample Design

Our sampling unit was the residential or low income household. Similar to the mail survey, the population included 107,077 residential non-seasonal households; 49,670 residential seasonal households; and 8,338 low income households. We removed customers who had already received the mail survey and drew a random sample of 2,000 households for each segment. We further removed customers with duplicate or invalid phone numbers. The resulting sample frame included 1,961 residential non-seasonal households; 1,924 residential seasonal households; and 1,965 low income households.

Summary of Telephone Survey Statistics

Table 2-13 presents the final dispositions for the telephone survey. The response rate[18] was 5.5% and the cooperation rate 18.0%, computed using the equations following the table.

[18] Using AAPOR Rate3 (RR3).

$$\text{Cooperation Rate} = \frac{I}{(I+R)}$$

2.2 Primary Data Collection – Commercial & Industrial Sector

The primary data collection activities for this effort included a telephone survey with 448 C&I customers and on-site audits at 150 businesses. This subsection describes the sampling and weighting, data collection, and adjustment methodologies associated with these activities.

The telephone survey primarily gathered high level penetration information on electricity-using equipment and information on barriers to energy efficiency and participation in CLC programs. We conducted site visits with a subset of customers who completed the telephone survey. The site visits collected more detailed information about electricity-using equipment, including penetration, saturation, efficiency, and end-use specific information such as wattage, cooling capacity, and horsepower. We used the combined data from these two sources to characterize penetration and saturation of energy efficiency equipment in the C&I sector and estimate potential.

The primary objective of the sample design was to have a large enough pool of completed phone interviews to recruit site visit participants and to have a distribution of business segments and sizes to enable us to aggregate findings to the sector level. Because the site visit recruits came from the respondents who completed the telephone survey, the basic sample development steps outlined for the telephone survey also form the foundation of the site visit sample.

2.2.1 Telephone Survey

The telephone survey collected high level penetration information on electricity-using equipment and building characteristics, as well as information about customers' decision-making and barriers to purchasing energy-using equipment, and firmographic information, including hours of operation. End-uses for equipment penetration included lighting, cooling, electric space heating, refrigeration, motors, office equipment, water heating, compressed air, cooking, and other energy-using equipment. To maintain a reasonable length and to reduce the likelihood of collecting inaccurate information, the survey only asked high level penetration questions that respondents could be expected to be able to answer over the phone.

The survey was aimed at building owners, business managers, and facility managers with knowledge of energy-using equipment at the premise. We also used the telephone survey to recruit a subset of survey respondents for on-site audits. We implemented the survey through our call center between August 25 and November 3, 2014, and completed 448 interviews.[19] On average, the survey took 15 minutes and 10 seconds to complete. Our response rate was 7%. The telephone survey instrument is presented in Appendix 2.

[19] Nine of the 448 interviews with CLC's top 20 highest usage customers, were completed by more trained Opinion Dynamics analysts in an effort that was managed separately outside of our call center.

Table 2-14. Types of Information Collected in Commercial Telephone Surveys

Business and Occupancy	Penetration of major end-uses	Energy Decision-Making and Barriers
▪ Business segment verification ▪ Own/rent space ▪ Seasonal occupancy ▪ Building structure type ▪ Square footage ▪ Number of employees	▪ Lighting ▪ Cooling ▪ Ventilation ▪ Refrigeration ▪ Electric space heating ▪ Electric water heating ▪ Motors, fans and pumps ▪ Compressed air ▪ Office equipment ▪ Electric food service equipment	▪ Decision-making structure ▪ Equipment investment criteria ▪ Benefits of energy efficiency ▪ Barriers to energy efficiency ▪ Role of incentives on energy efficiency

Sample Design

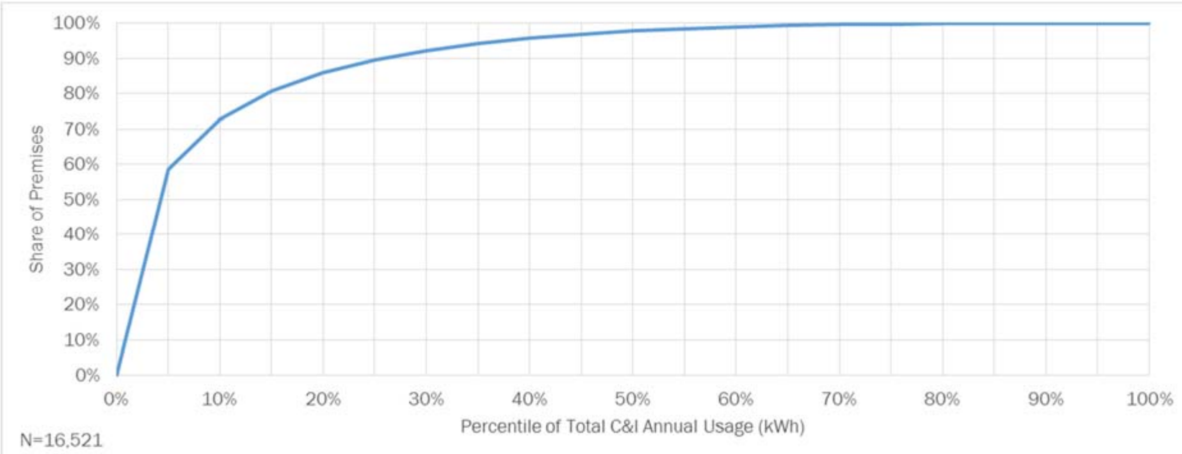
Our sampling unit was the business premise. We developed the population of premises in CLC's territory using two steps. First, we identified accounts with the same name and address and consolidated them. Next, we identified accounts with similar names and addresses, using fuzzy text match, and reviewed these names manually to identify which accounts should be combined to the business premise level. Using an extract of customer data provided by CLC in March 2014, we identified 25,111 customer accounts in CLC's territory, which we consolidated to 18,635 premises. A portion of these premises (2,114, or 11%) were out of scope for this study (e.g., communication towers and street lighting) or had only zero or missing usage data. These records were excluded from the sample frame, resulting in a final frame of 16,521 C&I premises.

Businesses on Cape Cod and Martha's Vineyard are predominantly low users of electricity. As illustrated in Figure 2-1, 9,701 (59%) of 16,521 premises[20] in the sample frame have annual usage that falls within the bottom 5% of total usage.[21]

[20] These premises were not cross-checked with CLC premises as defined by Eversource. As mentioned, low users are defined as low users of electricity and do not reflect fuel use (oil, propane, natural gas).

[21] The threshold for bottom 5% of usage is 11,730 kWh per year.

Figure 2-1. Breakout of C&I Premises by Percentile of Total Annual Usage



To optimize our primary research budget, we used different research approaches for the top 95% of C&I usage and the bottom 5%. We targeted customers in the top 95% usage category with both the telephone survey and site visits while customers in the lowest usage category only completed the telephone survey. The sampling approaches for both groups are described below.[22]

Top 95% Usage Group

The primary objective of the sample design was to have a large enough pool of completed phone interviews to recruit site visit participants and to have a distribution of business segments and sizes to enable us to report findings at the segment level. As such, we developed the target number of site visits needed to meet our research objectives and then determined the number of completed phone interviews required to recruit and complete the site visits based on an average target conversion rate of approximately 33%. We thus targeted 455 completed phone interviews from the Top 95% Usage Group to meet our target of 148 site visits.

Our sample design employed a stratified random sampling approach, with strata based on customers' annual electricity usage. For the stratification, we used the Dalenius-Hodges method to determine strata boundaries and the Neyman allocation to determine the optimal allocation of the available projects to the strata. Table 2-15 shows the number of premises in the sample frame by stratum and the targeted number of phone interviews and site visits.

---

[22] While we did not specifically sample for Martha's Vineyard businesses, we attempted to survey a representative proportion. Martha's Vineyard customers make up 7% of the total sample and 10% of completed interviews.

Table 2-15. Sample Frame and Expected Completes by Usage Category of Top 95% Usage Group

Stratum	Usage Range	Number of Premises in Sample Frame	Targeted Number of Phone Interviews	Targeted Number of Site Visits
3	≥ 1000 MWh/year	84	34	16
2	125-1000 MWh/year	936	121	41
1	<125 MWh/year and still in top 95% of usage	5,800	300	91
Total		6,820	455	148

After defining the sample frame and strata, we assigned a phone number to each premise.[23] We identified 5,573 premises in the top 95% group with unique phone numbers. These premises represent our CATI sample.[24]

Bottom 5% Usage Group

We targeted 70 completed interviews from the Bottom 5% Usage Group.[25] We drew a stratified random sample of 2,200 from the Bottom 5% Usage Group, ensuring that the proportion of business segments was representative of the population of businesses on Cape Cod and Martha's Vineyard.

C&I Segment Classification

We established 10 business segments based on discussions with CLC and our review of the customer data. CLC provided segment classifications for all CLC C&I premises.[26] Although we did not use these segments to develop the sample for the Top 95% Usage Group, we sought to complete surveys with a representative share of businesses in each business segment (to ensure that the overall results matched the mix of business segments on Cape Cod and Martha's Vineyard). We therefore set quotas for each business segment in each usage stratum. However, given the low number of premises in some of the segments, we were unable to meet the quotas for all segments. In order to maximize the total number of responses, we conducted a census attempt of all businesses in the Top 95% Usage Group. We then weighted the results of the completed surveys and site visits back to the population (as described below).

Table 2-16 shows the segment groupings, based on CLC's assignments and the customer usage data.

[23] We assigned phone numbers based on account information, program implementer contact data, and results from a matching service used to identify phone numbers for premises with non-unique or missing phone numbers.

[24] After assigning the best phone number to each premise, we also removed four premises from the sample because they participated in Project 21.

[25] The sample frame from which we drew the sample was developed using the same sample cleaning and phone number assignment processes as the top 95% group.

[26] We verified these segment assignments as part of our phone survey.

Table 2-16. C&I Segment Definitions

Study Segment	SIC Category Code	SIC Segment	Number of Premises		
			Top 95%	Bottom 5%	Total
Small Retail	C3	Retail - Small	915	1,135	2,050
	C14	Health Club/Spa	113	175	288
	C94	Gallery/Museum	52	130	182
Office	C71	Office - Large	10	0	10
	C7	Office - Small	758	1,383	2,141
	C100	Charitable/Non-Profit	70	74	144
Restaurant	C31	Restaurant - Full Service	441	159	600
	C1	Restaurant - Fast Food	324	107	431
Government or Education	G4	Government	494	611	1,105
	C98	Schools K-12	81	20	101
	C101	Laboratory/Research Facility	38	14	52
	C18	Library	23	5	28
	C25	Community College/University	2	0	2
Lodging/ Hospitality	C15	Lodging - Hotel/Motel	258	66	324
	C11	Lodging - B&B/Inn/Rooming House	175	126	301
Multifamily or Rental Housing[A]	C96	Multifamily Commercial	562	2,337	2,899
Health Services	C6	Healthcare - Clinic	347	320	667
	C27	Healthcare - Hospital/Nursing Home	51	9	60
Grocery, Convenience or Large Retail	C2	Grocery - Small/ Convenience/Liquor	197	62	259
	C28	Grocery - Supermarket	35	9	44
	C32	Retail - Large	53	4	57
	C91	Big Box	5	1	6
	C99	Warehouse - Refrigerated	8	9	17
Automotive, Warehouse/ Distribution or Industrial	C9	Automotive	253	255	508
	C92	Water and Waste Water Treatment	112	34	146
	C93	Industrial - Light	279	507	786
	C95	Industrial - Heavy	3	3	6
	C30	Transportation	49	110	159
	C26	Warehouse	232	752	984
Other Commercial	C104	Mixed Use Commercial	322	573	895
	C22	Recreational - Other	242	240	482
	C23	Religious/Houses of Worship	132	146	278
	C8	Other	69	152	221
	C29	Agriculture	44	93	137
	C10	Assembly Hall	44	53	97
	C17	Laundry/dry cleaning	23	13	36
	C97	Recreational - Ice Arena	3	1	4
	M2	Unknown	1	13	14
TOTAL			6,820	9,701	16,521

[A]To leverage the C&I sector's telephone survey contact strategy, 1,476 centrally managed residential rental premises were included in the multifamily/rental housing segment.

Summary of Telephone Survey Statistics

Opinion Dynamics fielded the telephone survey between August 25 and November 3, 2014.[27] Table 2-17 presents the final dispositions for the CATI telephone survey, including both the Top 95% and Bottom 5% Usage Groups. The response rate[28] was 7.0% and the cooperation rate was 12.3%, computed using the same equations described for the residential/LI barriers telephone survey in Section 2.1.3. Please note that this includes only full completes for the CATI telephone survey. An additional two respondents completed nearly all of the phone survey, for a total of 439 usable responses. Opinion Dynamics analysts also completed 9 interviews of CLC's top 20 accounts, an effort that was managed separately, resulting in the total number of completes of 448 we present elsewhere in this report.

Table 2-17. C&I Customer Survey Disposition

Disposition	Number
Completed Interviews (I)	437*
Eligible Non-Interviews	5,224
Refusals (R)	*2,945*
Mid-interview terminate (R)	*161*
Respondent never available (NC)	*1,469*
Answering machine confirming contact (NC)	*636*
Language problem (NC)	*13*
Not Eligible (e)	1,520
Fax/data line	*122*
Duplicate number	*46*
Non-Working	*766*
Wrong Number	*366*
Business, government office, other organization	*199*
No eligible respondent	*18*
Quota filled	*3*
Unknown Eligibility Non-Interview (U)	537
Not dialed/worked	*2*
No answer	*495*
Busy	*21*
Call Blocking	*19*
Total Contacts in Sample	7,748
Response Rate	7.0%
Cooperation Rate	12.3%

*Includes only full completes for the CATI C&I telephone survey. Does not include an additional 2 respondents who completed nearly all of the survey or the 9 interviews of CLC's top 20 accounts completed by Opinion Dynamics analysts.

[27] In addition, Opinion Dynamics analysts completed two of nine interviews with top 20 accounts in January 2015.

[28] Using AAPOR Rate3 (RR3).

2.2.2 Telephone Survey Data Weighting and Adjustments

The telephone survey data presented in this report were weighted to be representative of the population and adjusted using the data collected during the site visits. We also adjusted several key survey questions using other sources when respondents could not accurately provide answers. We describe the weighting and data adjustments in the sections below.

Telephone Survey Weighting

We developed and applied weights to ensure that the telephone survey results are representative of the population of premises in CLC's commercial and industrial sector. The penetration and saturation findings presented in this report are weighted to account for the following factors:

1) Differences in the distribution of customer counts by usage group within our sample compared with the population (i.e., customer base), since we oversampled premises with high usage to collect information on electricity-using equipment typically only found in large facilities. For example, chillers are typically only found in large facilities and to collect enough information on this type of equipment, we needed to oversample large facilities (i.e., those with usage over 1,000 MWh/year).
2) Differences in the distribution of customer counts by segment, to account for variations in survey response rates by segment.

We developed the weights using a multiple step process. First, we created a segment weight by dividing the segment's share of the overall commercial population by its share of respondents. For example, the small retail segment represents 18% of survey responses but only 15% of the C&I population. We therefore weighted down the survey responses from this segment so that, when aggregated to the total, the responses are representative of the overall population. The segment weight for small retail is 15% divided by 18%, or 0.8436. Next, we calculated a usage weight by dividing the usage category's share of the overall population by its share of respondents. For example, the Less than 125 MWh/Year stratum accounts for 70% of survey completes but only 35% of the all premises in that stratum, resulting in a weight of 0.5009. The initial sample weight is the product of the segment weight and the usage weight. In this example, the initial sample weight for small retail respondents in the Less than 125 MWh/Year stratum is 0.4226 (0.8436 multiplied by 0.5009).

We then evaluated the initial sample weights for undesirable unequal weighting effects and determined that one weight (7.04 for lodging/hospitality in the Bottom 5% stratum) was higher than desirable.[29] To correct this, we reweighted the data, trimming the weighting factor at 4.70 and equally redistributing the differential across the other categories.[30] The weights applied to the C&I telephone survey results presented in this report are shown in the Final Sample Weight column in Table 2-18.

---

[29] A weighting scheme with a high standard deviation of weights relative to the mean weight can yield undesirable results by allowing some customer responses too much influence on the direction of results of their segment.

[30] We trimmed the weight for this segment to three standard deviations from the mean, which is the cutoff recommended by Levy and Lemeshow. (Paul S. Levy and Stanley Lemeshow. Sampling of Populations. 2008. p. 513.)

Table 2-18. C&I Telephone Survey Sample Weights

Usage Stratum	Segment	Premise Count	Responses	Initial Sample Weight	Final Sample Weight
Bottom 5%	Small Retail	1,440	13	3.1704	3.2415
Bottom 5%	Office	1,457	16	3.5981	3.6788
Bottom 5%	Restaurant	266	3	2.2840	2.3353
Bottom 5%	Government or Education	650	1	3.2814	3.3550
Bottom 5%	Lodging/Hospitality	2,529	4	7.0415	4.7051
Bottom 5%	Health Services	329	3	3.5279	3.6070
Bottom 5%	Grocery, Convenience or Large Retail	85	0	--	--
Bottom 5%	Automotive, Warehouse/ Distribution or Industrial	1,661	20	3.3825	3.4584
Bottom 5%	Other Commercial	1,284	10	4.4105	4.5094
<125 MWh/Year	Small Retail	996	66	0.4226	0.4320
<125 MWh/Year	Office	791	48	0.4796	0.4903
<125 MWh/Year	Restaurant	601	33	0.3044	0.3113
<125 MWh/Year	Government or Education	444	24	0.4374	0.4472
<125 MWh/Year	Lodging/Hospitality	843	36	0.9385	0.9596
<125 MWh/Year	Health Services	334	12	0.4702	0.4808
<125 MWh/Year	Grocery, Convenience or Large Retail	171	9	0.3251	0.3324
<125 MWh/Year	Automotive, Warehouse/ Distribution or Industrial	844	51	0.4508	0.4609
<125 MWh/Year	Other Commercial	776	35	0.5879	0.6010
125 - 1000 MWh/Year	Small Retail	84	2	0.4283	0.4379
125 - 1000 MWh/Year	Office	45	1	0.4860	0.4969
125 - 1000 MWh/Year	Restaurant	163	10	0.3085	0.3154
125 - 1000 MWh/Year	Government or Education	163	9	0.4432	0.4532
125 - 1000 MWh/Year	Lodging/Hospitality	141	9	0.9512	0.9725
125 - 1000 MWh/Year	Health Services	54	2	0.4765	0.4872
125 - 1000 MWh/Year	Grocery, Convenience or Large Retail	98	5	0.3295	0.3369
125 - 1000 MWh/Year	Automotive, Warehouse/ Distribution or Industrial	84	7	0.4569	0.4672
125 - 1000 MWh/Year	Other Commercial	104	5	0.5958	0.6091
>1000 MWh/Year	Small Retail	0	0	--	--
>1000 MWh/Year	Office	2	0	--	--
>1000 MWh/Year	Restaurant	1	0	--	--
>1000 MWh/Year	Government or Education	31	6	0.1421	0.1453

Usage Stratum	Segment	Premise Count	Responses	Initial Sample Weight	Final Sample Weight
>1000 MWh/Year	Lodging/Hospitality	11	2	0.3049	0.3117
>1000 MWh/Year	Health Services	10	4	0.1527	0.1562
>1000 MWh/Year	Grocery, Convenience or Large Retail	29	2	0.1056	0.1080
>1000 MWh/Year	Automotive, Warehouse/ Distribution or Industrial	0	0	--	--
>1000 MWh/Year	Other Commercial	0	0	--	--
Total		16,521	448		

Adjustment of Telephone Survey Data

We used information from the site visits to adjust for self-report error in certain phone survey responses. In general, we considered for adjustment any items that customers would be likely to misreport (e.g., penetration of relatively minor equipment and systems), as well as specific equipment types within an overall category (e.g., types of air conditioning systems when a customer had already reported they had air conditioning).

We first conducted a Pearson's chi-squared test for questions considered for adjustment. Only if the test showed that phone survey responses are significantly different from on-site observations, did we include the question for adjustment. We did not adjust questions with low incidence in the site visit sample.

Below are the phone survey questions we adjusted.

- Central Air Conditioning/Cooling
  - Presence of packaged air conditioners (M8)
  - Presence of split air conditioning systems (M8)
  - Presence of heat pumps[31] (M8)
- Water Heating
  - Presence of water heating equipment (M17)
- Refrigeration
  - Presence of ice machines (M27)
- Compressed Air
  - Presence of compressed air equipment (M30)
- Energy Management Systems
  - Presence of EMS (M34)

[31] This study categorizes split air conditioning systems and heat pumps separately. While a heat pump can also be a split system – i.e., have a separate evaporator unit and condenser and compressor unit – a split air conditioning system only provides cooling and cannot provide heating like a heat pump.

Adjustment Methodology

We used the ratio adjustment method to adjust the phone survey responses for the items listed above.[32] This method first develops an adjustment factor, based on the unweighted values of the completed phone survey responses for those sites that later received an on-site visit and the value from the unweighted site visit measurements analogous to the phone survey question being adjusted. The adjustment factor is then multiplied by the value from the survey responses for all sites. The values to be adjusted can be either a mean or a proportion. In the case of this study, we adjusted only penetration, or "presence of" information.

The equation below shows this two-step ratio adjustment method.

$$\text{Adjustment Factor} = \frac{Y_{\text{Site Visits}}}{Y_{\text{Survey Responses}}}$$

Where:

$Y_{\text{Site Visits}}$	=	unweighted proportion from the 150 site visits
$Y_{\text{Survey Responses}}$	=	unweighted proportion from the survey responses for the 150 premises with site visits

The adjustment factor is then multiplied by the weighted number of survey responses for all premises to develop an adjusted distribution of responses across response categories. This new distribution is then used to calculate new proportions for the adjusted question.

Consider the following example:

The on-site visits found that 26% of premises (unweighted) have ice machines. By contrast, the unweighted phone survey responses provided by the same 150 premises reported that 40% have ice machines. Using these values, we first developed the adjustment factor for ice machines, as follows:

Have ice machine: $Adjustment \quad Factor = \frac{26.0\%}{40.3\%} = 0.645$

Do not have ice machine: $Adjustment \quad Factor = \frac{74.0\%}{59.7\%} = 1.239$

We then apply these adjustment factors to unweighted phone survey results by response category. Of all phone survey respondents, 120 reported that that they have an ice machine and 324 reported that they do not (valid n=444). Multiplying these responses by the adjustment factor yields:

Have ice machine: *Adjusted Value = 120 * 0.645 = 77*

[32] Judith T. Lessler and William D. Kalsbeek. Nonsampling Error in Surveys. 1992. p. 269.

Do not have ice machine: *Adjusted Value = 324*1.239 = 401*

When adjusting proportions, an additional adjustment step is necessary. When the data is categorical (including yes/no or present/not present), each category is adjusted separately. As a result, as is the case in the example above, the total number of responses no longer sums to the correct valid "n". To correct for this, we also adjust the base of our results to match the original "n".

Finally, we apply sample weights to these results to produce the final results presented in Volume 3 of this report.

2.2.3 Site Visits

The 150 on-site audits were designed to collect data to verify the telephone survey responses and to collect more detailed and technical data that customers are generally unable to report on during a telephone survey. We also collected energy use and behavioral information from these facilities. The objective of this data collection was primarily to gather information about the saturation and penetration of different types of equipment.

Our team of qualified technicians conducted the site audits between September and November 2014. They entered facility data using tablet computers and a comprehensive Excel-based data collection instrument. The data collection instrument covered the topics listed in Table 2-19.

Table 2-19.Types of Information Collected in C&I Site Visits

Business and Occupancy	Penetration and Saturation of Major End-Uses	Equipment Characteristics	Operations/Behaviors
▪ Seasonal occupancy ▪ Building age ▪ Square footage (facility and occupied) ▪ Conditioned space	▪ Lighting ▪ Cooling ▪ Ventilation ▪ Refrigeration ▪ Electric space heating ▪ Water heating (and fuel type) ▪ Motors, fans and pumps ▪ Compressed air ▪ Office equipment ▪ Electric food service equipment ▪ Wastewater treatment equipment	▪ Equipment type ▪ Nameplate information (make, model, age, size/capacity) ▪ Lighting wattage ▪ Efficiency rating (e.g., EER/SEER, AFUE, insulation levels) ▪ ENERGY STAR status ▪ Efficient and inefficient components (e.g., VFDs, demand-controlled ventilation, tank insulation)	▪ Monthly, weekly, and daily operation ▪ Lighting hours-of-use ▪ Equipment hours-of-use ▪ Control strategy (lighting: manual, EMS, occ. sensors, dimmers, daylighting, etc.; HVAC: thermostat, EMS, etc.)

Appendix 2 presents the final on-site audit data collection instrument.

Site Audit Weighting

To account for differences in segments and usage strata between the premises receiving site visits and the sample frame, we developed a two-step weighting scheme similar to the weighting scheme described above for the C&I telephone survey.

Similar to the C&I telephone survey, we developed and applied weights to ensure that the telephone survey results are representative of the population of premises in CLC's commercial and industrial sector. The site visit findings in this report are weighted to account for the following factors:

1) Differences in the distribution of customer counts by usage group within our sample compared with the sample frame (i.e., customer base), since we oversampled premises with high usage to collect information on electricity-using equipment typically only found in large facilities. For example, chillers are typically only found in large facilities and to collect enough information on this type of equipment, we needed to oversample large facilities (i.e., those with usage over 1,000 MWh/year).
2) Differences in the distribution of customer counts by segment, to account for variations in survey response rates by segment.

As with the C&I telephone survey, the sample weight is a product of the segment weight and the usage weight. After developing the site visit weights, we evaluated the weights for undesirable unequal weighting effects and found none. The weights applied to the C&I telephone survey results presented in this report are shown in the Sample Weight column in Table 2-20.

Table 2-20. C&I Site Visit Sample Weights

Usage Stratum	Segment	Population Count[a]	Responses	Sample Weight
<125 MWh/Year	Small Retail	2,436	20	1.3691
<125 MWh/Year	Office	2,248	16	1.5402
<125 MWh/Year	Restaurant	867	10	0.7842
<125 MWh/Year	Government or Education	1,094	12	0.7347
<125 MWh/Year	Lodging/Hospitality	3,372	15	1.9146
<125 MWh/Year	Health Services	663	5	0.9216
<125 MWh/Year	Grocery, Convenience or Large Retail	256	4	0.4370
<125 MWh/Year	Automotive, Warehouse/ Distribution or Industrial	2,505	21	1.1815
<125 MWh/Year	Other Commercial	2,060	9	2.0574
125 - 1000 MWh/Year	Small Retail	84	1	0.3429
125 - 1000 MWh/Year	Office	45	1	0.3858
125 - 1000 MWh/Year	Restaurant	163	5	0.1964
125 - 1000 MWh/Year	Government or Education	163	2	0.1840
125 - 1000 MWh/Year	Lodging/Hospitality	141	5	0.4796
125 - 1000 MWh/Year	Health Services	54	2	0.2308
125 - 1000 MWh/Year	Grocery, Convenience or Large Retail	98	4	0.1095

Usage Stratum	Segment	Population Count[a]	Responses	Sample Weight
125 - 1000 MWh/Year	Automotive, Warehouse/ Distribution or Industrial	84	4	0.2959
125 - 1000 MWh/Year	Other Commercial	104	3	0.5153
>1000 MWh/Year	Small Retail	0	0	--
>1000 MWh/Year	Office	2	0	--
>1000 MWh/Year	Restaurant	1	0	--
>1000 MWh/Year	Government or Education	31	6	0.0405

>1000 MWh/Year	Health Services	10	2	0.0508
>1000 MWh/Year	Grocery, Convenience or Large Retail	29	2	0.0241
>1000 MWh/Year	Automotive, Warehouse/ Distribution or Industrial	0	0	--
>1000 MWh/Year	Other Commercial	0	0	--
Total		16,521	150	

[a] The population count for the <125 MWh/year usage stratum includes the Bottom 5% usage stratum

2.2.4 Manual Adjustments

In addition to adjusting phone survey results with information from the site visits, we also made some manual adjustments to the final data.

Square Footage

Square footage is a key input into the potential model. We asked each phone survey respondent about the size of their business in square feet and also collected this information during our on-site visits. Although telephone survey interviewers prompted respondents to give their best estimate, 37% of customers were still unable to estimate the square footage of their business. In these cases, we used the site visit estimate if available. Additionally, our initial review of the phone survey responses found that many of the estimates were not accurate. The telephone survey adjustment methodology used for many questions did not work in this case because the square footage estimates from the site visits may also have been incorrect, either from auditor error or from being provided by the same contact at the site who supplied the erroneous first estimate. Instead we used an alternate adjustment method consisting of randomly selecting a sample of 50 sites and researching the exact square footage of each site to develop an error correction factor of 93% to apply to the population. To find the square footage of these properties, we used public property records,[33] as well as aerial and satellite photographs along with a web-based application designed to obtain the square footage of a building from these photos.

Equipment Information

Whenever possible and reasonable, the site visit auditors collected detailed information (e.g., efficiency level of central air conditioning systems (SEER) and horsepower of motors) for the equipment found onsite. In cases where it was impossible to determine this information

[33] We used tax records found on the Massachusetts Office of Geographic Information (MassGIS) online mapping tool. (http://maps.massgis.state.ma.us/map_ol/oliver.php)

onsite, we used to the model number, collected during the site visit, to research this information following the site visit.[34]

2.3 Potential Modeling

2.3.1 General Methodology

Description of Model

We developed a CLC-specific potential model that estimates the electric energy and capacity saving potential in CLC's service territory. The model embeds CLC-specific inputs with respect to measure characteristics, equipment penetration and saturation, and measure adoption assumptions. We developed a flexible potential model structure that can produce the outputs and level of disaggregation specified by CLC – at the sector level (C&I, residential, and low income), for key market segments, etc. – and that allows for future modification of key model parameters by CLC staff to test different scenarios during the program planning process.

The scope of the study included development of three levels of potential: technical potential, economic potential, and achievable potential. They are defined as follows:

- Technical Potential: For each market,[35] the measure procuring the most energy savings per unit is selected. The technical potential is defined as the electricity savings from these measures multiplied by the theoretical maximum number of units per year.
- Economic Potential: For each market, the cost-effective measure procuring the most energy savings per unit is selected. The economic potential is defined as the electricity savings from these measures multiplied by the theoretical maximum number of units per year.
- Achievable Potential: The achievable potential is defined as the electricity savings from cost-effective measures adjusted by several factors to represent the potential that could be achieved through ambitious and comprehensive programs/initiatives.

Key concepts used in the estimation of potential are briefly described below.

- Inputs: The model requires several inputs at the measure level (e.g., energy and capacity savings, costs, effective useful life, net-to-gross factors, load profile, etc.), as

[34] In some cases, to minimize the time on-site and disruption to customers, auditors only collected the model numbers of equipment knowing that other nameplate information could be researched later. Auditors collected efficiency and capacity information for approximately 85% of systems onsite and looked up the other 15% after the visit.

[35] We use the words "market" or "market size" to describe the number of baseline equipment or buildings in a given segment that capture the opportunity for specific energy-efficient measures. For example, the number of sockets with incandescent bulbs in the non-seasonal residential sector would be an example of a "market" for CFLs or LEDs.

well as other inputs such as avoided costs, rates, electricity forecasts, markets, and initiatives.[36]

- Units per Year (theoretical maximum): Using inputs and calculations such as market size and growth, measure type, and natural replacement rates of existing equipment, the maximum number of units that could be replaced or installed per year is calculated.
- Cost-Effectiveness: The model calculates two types of cost-effectiveness ratios. Both tests can be calculated at the measure, initiative, segment, sector, and portfolio level.
  - The **Total Resource Cost test (TRC)** is used to screen measures for the economic and achievable potentials. A positive TRC result (net present value higher than zero or cost-benefit ratio higher than one) indicates that the energy efficiency measure (or initiative) will produce reductions in energy costs, as well as non-energy benefits, that are greater than the costs of implementing that measure (or initiative).
  - The **Participant Cost Test (PCT)** is an input for measure adoption rates. A positive PCT result means that the participant of an energy efficiency initiative will receive benefits – including energy bill savings and non-energy benefits – that are higher than net costs (i.e., the cost of the measure minus incentives received by the participant).
- Base Adoption Rate: The base adoption rate for determining the achievable potential is calculated using the cost-effectiveness of measures from the participants' point of view and levels of market barriers.
- Competing Measures: At the achievable potential level, multiple cost-effective measures can compete with each other for the same market. In that case, each measure is attributed a share of the overall market, based on its base adoption rate compared to other measures. An example would be CFL and LED bulbs competing for the same sockets where incandescent lighting is currently used. If both are cost-effective, both will be included in the achievable potential.
- Cumulative Annual Savings: Cumulative savings are calculated for each potential type and each year, using incremental savings potentials. Savings from individual measures are removed from the cumulative savings at the end of their effective useful life (EUL). For instance, a measure installed in Year 1 and with a EUL of two years would be removed from the cumulative potential starting in Year 3.
- Aggregate Results and Reporting: Measure-level energy and capacity savings, costs, and benefits are aggregated and can be displayed by sector, segment, end-use, measure-type, or initiative. Costs are reported from both the program administrator's and the service territory's perspectives. The program administrator's costs do not

[36] Initiatives are sub-components of programs that target specific opportunities. For instance, the Residential New Construction, Residential Multi-Family Retrofit, and Residential Behavior/Feedback initiatives are all part of the Residential Whole House Program.

include the participants' share of costs (i.e., costs that are not covered by incentives), nor do they include any adjustments for early retirement measures.

The following sections present more detailed descriptions of the modeling methodology. It should be noted that the rest of the methodology discussion focuses on achievable potential as it is the study's primary focus.

Sectors and Segments

The model reflects three different sectors and 13 segments, as detailed in Table 2-21 below. Measure inputs are differentiated by segment (e.g., lighting savings vary by commercial segment according to reported hours of use and seasonality adjustments). Results are reported at both the sector and segment levels.

Table 2-21. Sector and Segment Definition for Potential Model

Sector	Segment
Residential	Non-seasonal
	Seasonal
Low Income	Low Income
C&I	Small Retail
	Office
	Restaurant
	Government or Education
	Lodging/Hospitality
	Health Services
	Multifamily or Rental Housing
	Grocery, Convenience or Large Retail
	Other Commercial
	Automotive, Warehouse/Distribution or Industrial

End-Uses

The model includes 12 different end-uses, listed in Table 2-22 below (with examples of associated measures).

Table 2-22. End-Uses Included in Potential Model

End-Use	Examples of Measures
Lighting	LED light bulbs, lighting controls, efficient linear lighting
HVAC (Heating, Ventilation, Air Conditioning)	Thermostats, heat pumps, air conditioning units
Motors	Furnace fan motors, pool pumps, C&I ventilation & process motors
Refrigeration	Refrigerators, freezers, vending machine misers
Food Services	Ovens, dishwashers, fryers

Hot Water	Heat pump water heaters, low flow showerheads, spray rinse valves
Appliances	Clothes dryers
Products	Smart strips, TVs, Dehumidifiers
Behavior	Feedback, opt-In behavioral, basic educational measures
Envelope	Insulation, air sealing
CHP (Combined Heat and Power)	Combined heat and power
Other	Retro-commissioning, advanced energy analytics, cable boxes

Measures

We used the 2012 Massachusetts Technical Reference Manual (TRM) (Program Years 2013-2015) as a starting point for the list of measures to be included in this study. Amongst other factors, the expected relative importance of measures in CLC's potential was used to make decisions on aggregating TRM measures or breaking them out into sub-measures. As an example, lighting measures in the TRM are much more detailed than weatherization measures. We bundled measures mainly across initiatives that offer the same measure, using either assumptions for the most prevalent initiative or weighted averages for measure inputs.

The following measure categories were excluded from the scope of this study:

- Demand Response
- Fuel Switching
- Renewables
- Gas-saving measures that are covered by other PA's natural gas initiatives, which may also have an electric impact.

In addition to TRM measures, CLC expressed interest in investigating and screening new measures that are not currently offered in Massachusetts (as reflected by the TRM). We followed the process described below to identify new measures:

1. We reviewed a total of 13 Technical Reference Manuals to identify measures that are not already included in the Massachusetts TRM and are not currently offered by CLC programs.
2. We reviewed the program tracking database of an Emerging Technology program in California (which had close to 200 projects) to identify up-and-coming measures that currently have low market adoption rates but may evolve as a result of product development growth and market awareness for future implementation.
3. We reviewed a list of measures provided by the Massachusetts Technical Advisory Committee (MTAC).

After systematically considering new measures, we found that CLC already has a nearly complete suite of measures available within their portfolio. Many "missing" measures where in fact already included in CLC's initiatives as "custom measures" and were added to our list. We selected new electric measures for inclusion in this study based on the likelihood that they may represent a significant potential during the study period.

Table 2-23 lists new measures included in the study.

Table 2-23. New Measures Included in Potential Model

Residential / Low Income
Whole-House Fan
Residential Behavioral Opt-in[A]
Room Air Conditioning Recycling[B]
C&I
Linear LEDs without Ballast Change
Ultra High Efficiency Roof Top Units
Advanced Controller for Roof Top Units
Smart Thermostat (Cooling)
Advanced Refrigeration for Supermarkets – Glass Door Retrofits
Advanced Refrigeration for Supermarkets – Floating Head Pressure Control
Strip Curtains
Retro-commissioning and Advanced Energy Analytics
Advanced Lighting Controls
Early Replacement of Cable Boxes
Combined Heat and Power

A The Cape Light Compact has previously received information that might question the viability of this type of program, given the size of the population and its ability to participate in an initiative like this one.

B The Compact has previously offered room air conditioning recycling; however, because it is not currently being offered, it is referenced as a new measure here.

Calculation of Achievable Potential

As defined above, the achievable potential is defined as the electricity savings from cost-effective measures multiplied by the theoretical maximum number of units per year, the base adoption rates, the market share adjustments for competing measures, and other adjustments such as market applicability factors[37] and uptake factors.

We used adoption curves, based on the Department of Energy (DOE) adoption model, to determine the base adoption rate for each measure, by segment.[38] These curves provide a formula for relating customer cost-effectiveness to adoption rates, given different levels of market barriers. The DOE model is grounded in a qualitative assessment of market barriers and the calculation of a cost-benefit ratio to estimate the maximum achievable market penetration for energy efficient products. Based on this approach, measure cost-effectiveness and perceived barriers are the two primary factors affecting adoption rates. In our model, both

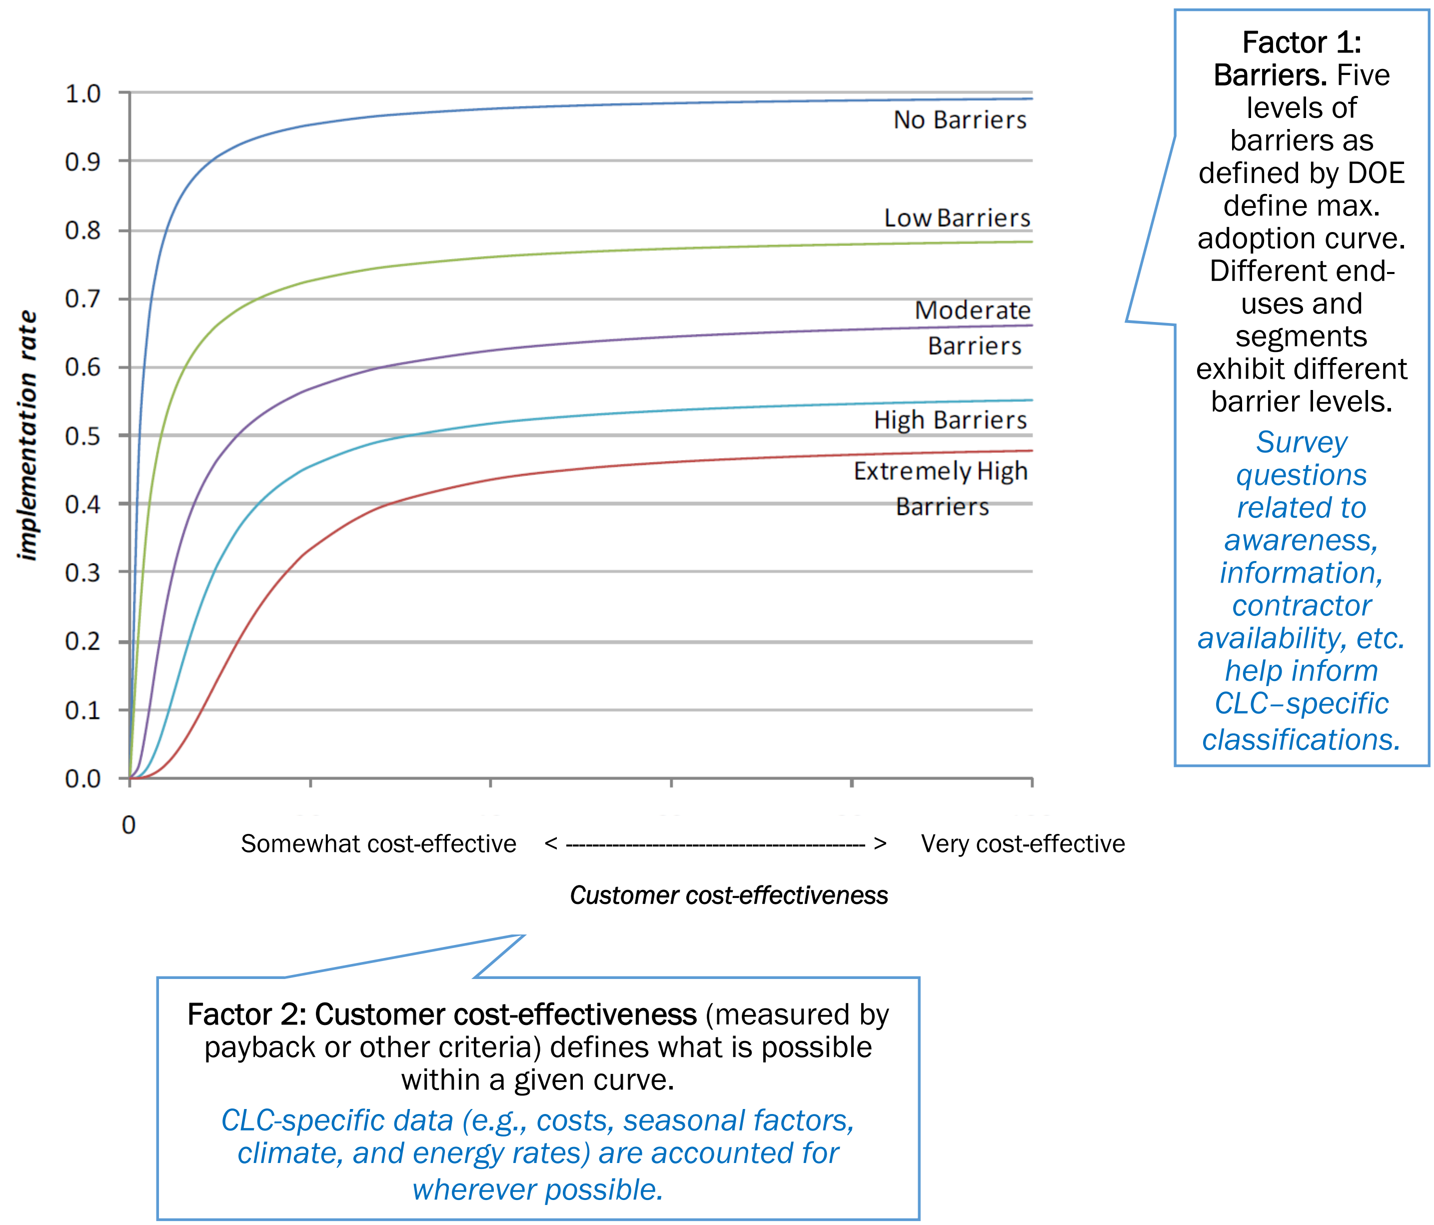
[37] Market applicability factors adjust the potential of some measures to account for specific technical barriers that prevent the application of that measure in a share of the potential market.

[38] DOE uses this model in several regulatory impact analyses. An example can be found in http://www.regulations.gov/contentStreamer?objectId=090000648106c003&disposition=attachment&contentType=pdf, section 17-A.4.

market barriers and the cost-effectiveness ratios encompass several CLC-specific inputs (see also Table 2-24, later in this section).

Figure 2-2 presents a schematic view of adoption curves.

Figure 2-2. US DOE Adoption Curves



The main steps for determining the adoption rate for each measure/segment are:

1. Selection of a curve, based on barriers level and benefit-cost criteria. Both barrier levels and the benefit-cost criteria (net present value vs simple payback period) were determined using survey inputs.

2. Calculation of customer cost-effectiveness, using the model's inputs, including measure characteristics (costs, savings, EUL, etc.), energy rates, and the incentive levels offered by modeled initiatives.
3. Calculation of the adoption rate, based on the selected curve and the cost-effectiveness value.

While our approach to determining the adoption rate is based on the US DOE model, we investigated the need for a few refinements: the choice of the cost-benefit criteria and short-term and long term adjustments. These refinements are described below.

Cost-Benefit Criteria

The DOE model assumes that participants make their decisions based on a benefit-cost ratio calculated using discounted values. While this may be true for more sophisticated customers (large institutional and C&I customers), many customers use much simpler decision criteria, including the payback period. This has implications on the choice of measures by the model, since the payback period ignores the value of money over time as well as any impacts after the break-even point has been reached. Thus, using the payback period, short-term benefits are favored over long-term benefits, creating a bias in favor of measures with a short effective useful life.[39]

To determine which cost-benefit criteria should be used for this study, the surveys gathered information on the criteria actually used by customers. Based on survey responses, we used the PCT ratio for the C&I sector (we did not observe clear differences by C&I segment) and the Simple Payback Period (SPP) for the Residential and Low Income sectors.

As a result, for the residential and low income sectors, we converted the DOE adoption curves to equivalent curves reflecting payback periods, based on discounted values. We assumed an average effective useful life of 15 years and used CLC's discount rate.

Short-term Adjustment

The DOE model determines the percentage of the informed market that will accept an energy efficiency measure based on the barrier level and the cost-effectiveness ratio – this is the "adoption rate" discussed above. The informed market is defined as the portion of the market that is aware and informed about the energy efficiency measure. Low awareness limits implementation of measures.

Furthermore, some programs may be limited in their ability to quickly increase participation after available rebates are increased because of delivery limitations. A good example would be a home retrofit program that requires skilled auditors and contractors: increasing capacity necessitates the enrollment and training of additional program vendors, which could take some time.

[39] Let's suppose a 3-year simple payback criteria is used by a customer. This means that a measure has to pay for itself within this 3-year period, regardless of its useful life. A measure with a payback of 4 years and a useful life of 20 years would be very cost-effective using a PCT ratio (with a cost-effectiveness ratio of approximately 3.5), but would be rejected using a simple payback criteria. On the other hand, a measure that is barely cost-effective (PCT ratio of 1) but has a very short useful life would be included.

These two factors, measure awareness and program delivery structure, can limit program participation, especially during the first few years, and result in lower participation than the maximum achievable implementation rates as calculated using the DOE model.

For this study, we made short-term adjustments to measure adoption on a case-by-case basis, using professional judgment. We adjusted few measures given that overall model results are within reasonable reach of the actual 2013-15 Plan.

Long-term Adjustment

The DOE model is based on the assessment of market barriers at a given point in time. These barriers are then assumed to remain static. In reality, barriers can be lowered in the long run, especially if programs use enabling strategies. Examples of enabling strategies include financing, labeling, and workforce training. For programs, measures, or market segments where specific barriers are prevalent, targeted strategies could, and likely would, be put in place.[40]

However, because the barrier levels, estimated using survey results, are already low (ranging from "low" to "moderate" for most of them), we only made long-term adjustment for LEDs in the residential sector to reflect anticipated evolving technology and better consumers' knowledge.

Chained Measures

Chained measures are measures that are installed in combination with one another. Chained measures require an adjustment in savings because the total savings of these measures is less than the sum of the savings of each individual measure. For example, if a customer installs a heat pump water heater as well as low flow showerheads and faucet aerators, the savings from the low flow showerheads and faucet aerators are smaller than if they were installed in a home with a less efficient water heater (less energy is lost for the same amount of wasted water). The adjustment to the chained measures' savings are calculated based on the different measures in the chain and entered for each individual measure.

CLC-Specific Adjustments

A key aspect of this study was to incorporate CLC-specific factors that differentiate CLC from the rest of Massachusetts.

The most important adjustment to measure inputs in this study was to account for seasonality. A large share of residential customers (31.7%), as well as many C&I customers (especially in the Restaurant and Lodging/Hospitality segments), show reduced occupancy or hours of operation, especially during the winter. Some customers even shut down completely during that period. Reduced activity is also observed during the spring and autumn seasons. For this study, we adjusted energy savings, peak savings, and load shapes to account for seasonality using survey and site visit data. The seasonality adjustment factors were calculated for each major end-use, taking into account the requirement to maintain a minimum temperature in

[40] Higher incentives are already implicitly taken into account in the cost-effectiveness ratio (higher incentives result in lower paybacks and higher Participant Cost Test ratios). To prevent double-counting, no adjustment have been made to market barriers because of higher incentives.

buildings to prevent freezing conditions. Reduced savings due to seasonality impact cost-effectiveness of measures, thus screening out some measures for specific segments and reducing adoption rates of remaining measures for segments with a strong seasonal profile.[41]

We also considered several other CLC-specific characteristics, such as business types and size, building stock, milder climate, and measure cost when developing the model's inputs.

Table 2-24 (next page) summarizes CLC-specific factors that were considered and how they were addressed in the model.

[41] In addition to the savings adjustment, we also increased market barriers for the opt-in behavioral measure in the Residential seasonal segment. Because this measure is more demanding, we expect that customers with secondary homes, presumably on leisure time, would show less interest.

Table 2-24. CLC-Specific Factors Considered in Potential Model

Factors Considered	Model addresses this through...					Notes
	Baseline Equipm. / Usage	Barriers	Costs	Savings	Other	
Residential						
Seasonality A sizable proportion of the population and housing stock is seasonal, which means (a) they may use less energy compared to similarly-sized non-seasonal houses, (b) the savings they could get from a measure may be less, (c) the payback period may be longer, (d) they may have a different set of priorities for home improvements, or (e) CLC may have more limited time period and channels to intervene/promote programs.	✔	✔		✔		Seasonal and non-seasonal are treated as separate segments, with separate annual usage assumptions (based on actual data and survey) and measure characterization (from baseline study). We also adjusted savings for measures affected by seasonality, to reflect factors such as lower HOU. Our survey didn't find significant differences in barrier levels between seasonal and non-seasonal customers, so we did not adjust barriers with the only exception of opt-in behavioral, as this measure requires much more involvement than the other measures.
Age of population The CLC customer base is thought to be older than statewide average. This may result in lower likelihood to invest in EE (ROI calculus is off, fixed income, etc).		✔				Any lower likelihood to adopt EE measures as a result of age was captured in the barrier survey and is therefore reflected in the adoption curves.

Factors Considered	Model addresses this through...					Notes
	Baseline Equipm. / Usage	Barriers	Costs	Savings	Other	
Building stock CLC believes that stock is newer than the rest of the state. That means that pre-weatherization barriers may be low (e.g., knob and tube wiring), and there may be many 1- or 2-story homes that are relatively easy to insulate and work on. Additionally, many 3-season homes are converted to 4 season homes, which presents lots of opportunity. However, this means that the required upgrades are significant, and it's possible that customers would rather renovate the kitchen or bath than spend the incremental dollars for high efficiency.	✔	✔				CLC-specific information on insulation levels and barriers levels were collected and integrated in the potential study.
Commercial						
Seasonal business cycles Cash flow for some business owners is concentrated in a few months of the year. Seasonable businesses have a smaller window of opportunity to actually complete EE retrofits. CLC has a narrow window to approach them to discuss the programs and EE retrofits that are available to them. Seasonality also affects savings - for businesses that are closed during the winter and much of the spring and fall, the payback period may be longer.		✔		✔		The model uses a weighted average of barrier levels by segment (including both seasonal and non-seasonal customers). We also adjusted savings to account for reduced hours of operation and/or shutdowns during the off-peak seasons.

Factors Considered	Model addresses this through...					Notes
	Baseline Equipm. / Usage	Barriers	Costs	Savings	Other	
Business types Lots of retail, hospitality, and government buildings,[42] and relatively few office. Business owners whose income is tied to tourism may be more reluctant to spend on EE in the off season because they have a hard time forecasting how business will be next season.		✔				Since barriers levels are determined for each market segment, and modeling is performed at the segment level, the overall potential model results appropriately represent barriers for CLC's mix of businesses.
For many segments, commercial businesses are generally smaller than businesses in the rest of MA.	✔			✔		Each segment's average and total annual consumption is reflected in the measure characterization, which reflects any difference in equipment penetration/saturation (and equipment size, where relevant) related to small business size.
Building stock Many commercial operations are in structures originally built as residential, creating significant issues with measure applicability. CLC, along with the statewide programs in general, has limited commercial measure offerings for these building types as compared to the average MA commercial customer (though residential measures are offered).	✔				✔	We moved customers who are clearly "residential commercial" (as identified by CLC) into the residential study. Still, there is a fair number of small, house-like structures in other segments. The characteristics of these businesses are reflected in the measure characterisation and baseline equipment.

[42] Note that CLC pays 100% incentives for all projects in government buildings.

Factors Considered	Model addresses this through...					Notes
	Baseline Equipm. / Usage	Barriers	Costs	Savings	Other	
All Sectors						
Climate The climate is milder on the Cape and Vineyard relative to the rest of the state, so weather-dependent measures may have lower savings (and a longer payback)				✔		Savings have been adjusted using Cape Cod weather normals where relevant.

Model Calibration

Model calibration ensures that the overall estimated consumption levels determined by the model are in line with utility electricity forecasts. For this study, because of the amount and quality of primary data, model calibration is not as critical as for other potential studies that must rely on secondary sources to make broad assumptions on equipment saturation and building characteristics. The comprehensive primary data on penetration, saturation, and characteristics of equipment and buildings in each sector and segment greatly reduces the chance of underestimating or overestimating the load forecast because the modeled baseline does not fit the actual baseline and real consumption.

In the residential and low income sectors, we used annual energy consumption levels by equipment type – obtained through regression analyses of actual electric accounts as well as secondary sources – to ensure that our overall estimated consumption matches the electricity forecast for these sectors.

In the C&I sector, this approach would be too onerous due to the complexity and diversity of equipment and buildings. As both the potential markets and the baseline equipment were well defined due to extensive primary research, those elements were not deemed critical. We therefore used indirect approaches, including verification of lighting densities and average floor area, to validate our primary data.

2.3.2 Inputs and Assumptions

Measure Characterization

For existing measures, we reviewed measure assumptions (savings estimates or algorithms, cost, effective useful life, etc.) and assessed if they adequately reflect CLC’s service territory and customer base.

We based savings assumptions on the Massachusetts TRM, where possible. For measures with algorithm-based or custom savings, we used primary data and engineering algorithms, historical program data, or program impact evaluations to derive the required inputs to calculate the savings. We also used evaluation results and participation data to validate measure assumptions.

Savings include other fuels impacts (oil, gas, propane). These other fuels savings or added consumption do not directly affect electric potential results (no “kWh-equivalent” savings/reductions were used) but are considered when calculating measure cost-effectiveness and may positively or negatively impact measure screening and adoption rates.

As discussed above, we made adjustments to savings for residential customers and C&I segments with high seasonality profiles. These adjustments were made for each major end-use, based on survey and site visit occupancy results and operational profiles during unoccupied periods use. For the C&I sector, this was supplemented with a billing analysis, to identify the proportion of businesses within a segment with seasonal consumption patterns. We derived seasonal adjustments from those results for winter peak and off-peak as well as summer peak and off-peak consumption. Overall energy and peak savings were adjusted accordingly.

We used CLC-specific incremental costs wherever those costs were available. For measures where only statewide cost assumptions were available, we considered making an adjustment to account for the difference between statewide and CLC costs. However, we did not find evidence of materially higher CLC costs, based on a comparison of CLC costs with other MA jurisdiction (where available), as well as a comparison of construction cost indexes for CLC's service territory versus the rest of MA. Thus, we made no CLC-specific adjustments.

Non-energy impacts (often referred to as "externalities"), as quantified in the Massachusetts' TRM,[43] are monetized in the potential model. Because they directly affect the cost-benefit ratio results, there is no need to adjust market barriers to account for non-energy impacts.

Types of measure

The model uses four types of measures: replacement on burnout (ROB), early retirement (ER), addition (ADD), and new construction/installation (NEW). Each of these measure types requires a different approach for determining the maximum yearly units available for potential calculations, as detailed in Table 2-25.

Table 2-25. Types of Measures Used in Potential Model

Measure Type	Description	Market Base	Yearly Units Calculation
Replace On Burnout (ROB)	Existing units are replaced by efficient units after they fail *Example: Replacing incandescent bulbs by LEDs*	Existing Units	Market/Effective Useful Life (EUL) *The EUL is set at a minimum of 6 years to spread installations over the potential study period. Alternate EULs can be used to calculate yearly units if baseline units have a different EUL than efficient units.*
Early Replacement (ER)	Existing units are replaced by efficient units before burnout *Example: Early replacement of functional but inefficient refrigerators*	Existing (Old) Units	Market (old units)/6 (study period) *The market is defined as the number of old units, not the total number of units (e.g., old refrigerators that could be retired early, not all existing refrigerators).*
Addition (ADD)	An EE measure is applied to existing equipment or structures	Existing Units	Market/6 (study period)

43 Non-energy impacts are values that are estimated after the measures have been implemented, and as such may not represent exactly what consumers perceive as non-energy impacts at the time of investment decision-making. Our analyses using the potential model indicate, however, that non-energy impacts have a very small effect on results, meaning that this effect would not have a significant impact on potential results.

Measure Type	Description	Market Base	Yearly Units Calculation
	Example: Adding controls to existing lighting systems, adding insulation to existing buildings		
NEW	Measures not related to existing equipment *Example: new construction, installing a new heat pump (not replacing an existing heat pump)*	Custom	Market *Market base is measure-specific and defined as new units per year*

Early Retirement

Early retirement refers to efficiency measures (and program strategies) that seek to replace functional equipment before the end of its useful life. Refrigerator replacement is a common measure that falls into this category, but early retirement can also apply to any other equipment including other appliances, HVAC systems, and lighting.

In addition to the yearly unit calculations explained above, the first cost for early retirements is adjusted to reflect true economic costs. This adjustment is required because early retirements defer the need for new capital investment in the future. Assuming, for example, that there is an initial investment to buy a refrigerator in year 1 and this refrigerator would have been replaced anyway in year 5, the future investment that would have taken place in year 5 is now pushed forward in the future because the new fridge will last 15 years (instead of 5 years for the old fridge). Because the value of money decreases with time, there is an economic benefit in deferring future investments.[44]

We use the following formula to adjust costs for early retirements, which calculates the difference between the discounted values of two streams of investments:

$$PV = (C - incr)\left\{1 + \frac{1}{(1+dr)^{eul} - 1}\right\}\left\{1 - \frac{1}{(1+dr)^{erp}}\right\} + incr$$

Where:

PV = present value of initial cost and deferred future costs

[44] Note that because of this adjustment, the economic cost used by the model might be lower than the incentive in some cases.

C = initial capital cost

incr = Incremental cost (cost of efficient vs baseline unit)

dr = discount rate

eul = effective useful life of new unit

erp = early replacement period (remaining effective useful life of old unit)

During the initial "early retirement" period, the energy consumption of the new, efficient unit is compared to the old, retired unit to calculate savings. After the initial period, the new efficient unit is usually compared to a new "baseline" unit with standard efficiency. This "dual baseline" approach is widely used to calculate savings and cost-effectiveness for early retirement measures. However, in Massachusetts, the "single baseline" approach (constant savings for the full EUL) is still in use. As a result, CLC requested that this study use the single baseline approach to make CLC's potential results comparable to those of other MA program administrators. This single baseline approach for savings has no impact on the method we use for economic costs described above.

Economic Parameters

The potential model incorporates several key economic parameters:

- The **cost-effectiveness** framework used in this study follows the Department's directive in Energy Efficiency Guidelines (D.P.U. 08-50-A), as well as the "BCR Model" used internally by CLC. Before building the potential model, we ensured that our core calculations replicated the results of the BCR Model.
- **Avoided costs** in this study reflect the latest available information from the 2015 study by the Avoided-Energy-Supply-Component (AESC) Study Group.
- **Electricity rates**, used for participant cost-effectiveness calculations, are based on energy and capacity avoided costs for the wholesale portion, and on marginal retail rates for the retail portion. We assumed that the retail portion would grow at the same rate as the energy portion in the long term, reflecting pressures on the grid from renewable energy and aggressive EE targets. For non-electric fuel types (gas, oil, and propane), we used the avoided costs as a proxy of future fuel prices.
- We used a **real discount rate** of 0.44%, based on 2014 10-years Treasury rates.

Baseline Potential Markets

Markets are largely determined by our primary data collection. The surveys and site visits collected existing equipment and building characteristics in CLC's service area. We used this information to quantify baseline equipment and building components to which energy efficient measures can be applied.

For new equipment (e.g., heat pumps that do not replace existing heat pumps), we conducted additional interviews with contractors to estimate the annual market size.

We estimated new construction in the residential sector using the "Annual New Privately-Owned Residential Building Permits (Estimates with Imputation)" from the U.S. Census Bureau. We extrapolated total 2013 building permits for Barnstable and Dukes counties into the future using a 4.6% annual growth rate, based on the observed 2009-2013 growth.

We estimated new construction in the commercial sector using a 2013 market assessment of Cape Cod, prepared by the Chesapeake Group for the Cape Cod Commission.[45] We used the total market growth for retail goods and services (0.12% per year over the next 10 years) as a starting point for evaluating the C&I New Construction market. We set a growth rate three times higher (0.37%) for health services, which the report (qualitatively) identified as a segment with higher growth potential because of the aging population. We then adjusted other segments to 0.09% in order to keep the added square footage per year at the same level (i.e., at an average overall growth rate of 0.12% per year).

We used the new square footage (about 126,000 square feet per year, estimated based on an average annual growth rate of 0.12%) for the advanced lighting design measure, and the annual growth rate (0.09% to 0.37%) for all the other markets except CHP and early retirement measures (i.e., T12 and motors).

[45] The Chesapeake Group (c.2013), "Market Assessment of Cape Cod, Massachusetts".

3. Summary of Key Penetration and Saturation Results

A primary purpose of this portion of the study was to determine the penetration and saturation of key electricity-using equipment in homes and businesses. These two concepts are defined as follows:

- **Penetration:** A percentage representing the proportion of customers that have one or more of a particular piece of equipment. It is calculated by dividing the number of customers with one or more of a piece of equipment by the total number of customers responding to that question. For example, non-seasonal residential customers had an LED penetration rate of 49%, compared to only 21% of seasonal residential customers and 8% of low income customers.
- **Saturation:** A number representing how many of a particular piece of equipment exist, on average, among all customers. It is calculated by dividing the total number of a particular piece of equipment by the total number of customers responding to that question (regardless of whether they reported having the equipment or not). This ratio is at least equal to, but generally higher than the corresponding penetration of the equipment, because some customers will have more than one of the equipment. For example, the saturation rate of LEDs in non-seasonal homes was 5.1 LED bulbs on average across all non-seasonal homes, compared to an average of 1.5 LED bulbs across all seasonal residential customer homes and less than one across all low income homes.

Table 3-1 presents key equipment penetration and saturation data collected in the 2014 Residential Energy Use Survey and adjusted, where necessary, by site visit results. In some cases (footnoted), penetration and saturation data is based directly on site visit data. Penetration and saturation results are presented for the three study segments: residential seasonal (Res-S), non-seasonal (Res-NS), and low income (LI). The full adjusted results of the 2014 Residential Energy Use Survey are presented in Volume 2 of this report.

[d] Includes only showerheads and aerators served by electric water heating

4. Overall Potential Results

We estimate CLC's total achievable energy efficiency potential for the six-year period from 2016-2021 to be 246 annual GWh and 62 MW.[47] Achievable potential represents 51% of economic potential and 36% of technical potential. On average over the six-year period, achievable energy savings represent 1.98% of CLC annual forecasted sales. These savings would cost CLC $220 million (incentive and non-incentive program costs), an average of $37 million per year or $0.895/kWh.[48] The total cost (including the participants' net cost) amounts to $246 million (in 2016 dollars) for the six-year period. All of the 2016-2021 proposed investments are cost-effective, with a Total Resource Cost (TRC) ratio of 3.6 and a Program Administrator Cost (PAC) ratio of 2.8.

Table 4-1 summarizes these results for the six-year period 2016-2021, as well as for each of the next two three-year planning periods. Table 4-2 provides these results by sector.

Table 4-1. Key Potential Results – All Sectors, by Period

	2016-2021		2016-2018		2019-2021	
Potential (Total)	GWh	MW	GWh	MW	GWh	MW

Total Resource Cost Test	3.6		3.6		3.6	
Program Administrator Cost Test	2.8		2.8		2.9	

[47] These findings reflect the best information and assumptions available as of April 2015. Cape Light Compact and the Opinion Dynamics/Dunsky team plan to refresh these results, prior to the September Three Year Plan draft filing, to incorporate any newly available evaluation findings, as well as updates to non-incentive program costs.

[48] This compares to a projected average cost of $0.794/kWh during the 2013-2015 Three Year Plan Cycle. It should be noted that per kWh projected costs are relatively high for CLC due to a number of territory-specific reasons, including the small base of large C&I customers and the seasonal nature of many homes and businesses.

Table 4-2. Key 2016-2021 Potential Results by Sector

	All Sectors		Residential		Low Income		C&I

Table 4-3 and Table 4-4 detail annual achievable potentials as a percentage of sales, by year and sector, for the first three-year period and the second three-year period, respectively.

Table 4-3. Achievable Potential as a Percentage of Forecasted Energy Sales – 2016 to 2018

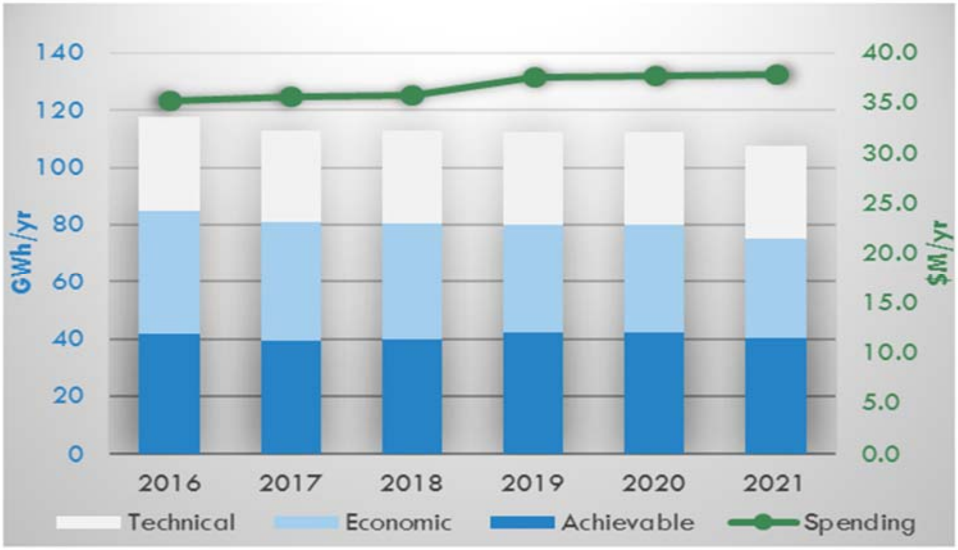
	2016	2017	2018	2016-2018
Residential	2.06%	1.80%	1.79%	1.88%
Low Income	2.39%	2.05%	2.04%	2.16%
Commercial	1.94%	2.00%	2.04%	1.99%
All Sectors	**2.02%**	**1.89%**	**1.90%**	**1.94%**

Table 4-4. Achievable Potential as a Percentage of Forecasted Energy Sales – 2019 to 2021

	2019	2020	2021	2019-2021
Residential	2.00%	2.01%	1.87%	1.96%
Low Income	2.18%	2.19%	2.12%	2.16%
Commercial	2.07%	2.11%	2.07%	2.09%
All Sectors	**2.03%**	**2.06%**	**1.96%**	**2.02%**

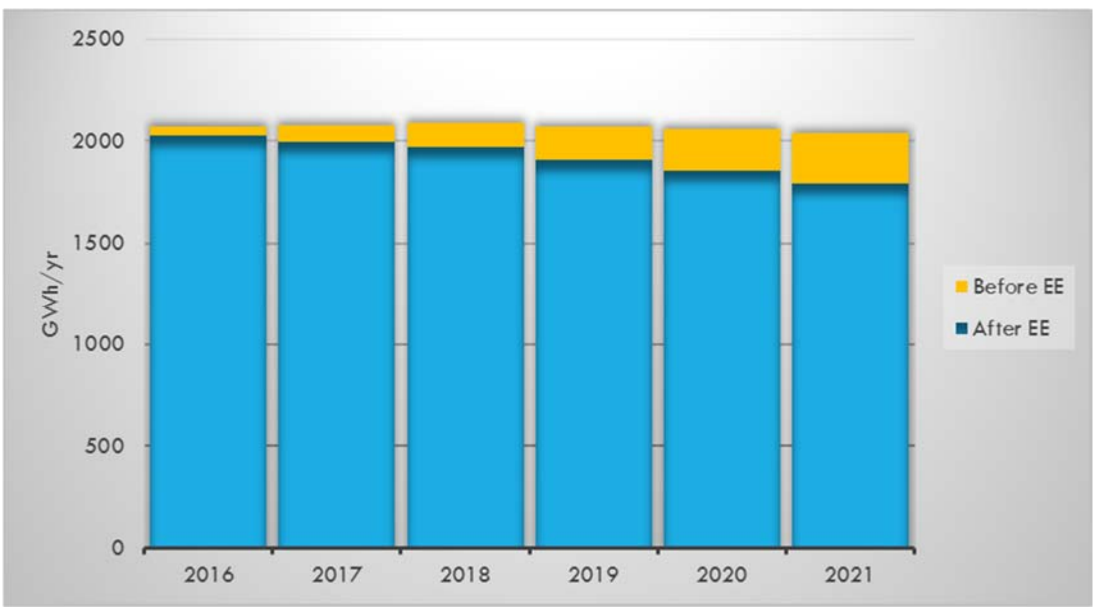
Figure 4-1 presents annual GWh savings for the three types of potential, as well as annual spending required to meet the achievable potential. The increase in spending during the second three-year period (2019–2021) is due to higher LED uptake, which results from an assumption of decreasing market barriers. While savings from LEDs are higher for that period, they are counterbalanced by somewhat lower savings for other measures.

Figure 4-1. Annual Savings and Spending



Eversource forecasts slightly declining energy sales, before energy efficiency (EE) efforts, over the six-year period, with total sales of 2,041 GWh in 2021 compared to 2,071 in 2016. With EE efforts at the level of the achievable potential, energy sales would decline faster, with 2021 sales amounting to 1,796 GWh, a drop of nearly 12% from 2016 sales (Figure 4-2).

Figure 4-2. Impact of Achievable Potential on Annual Sales

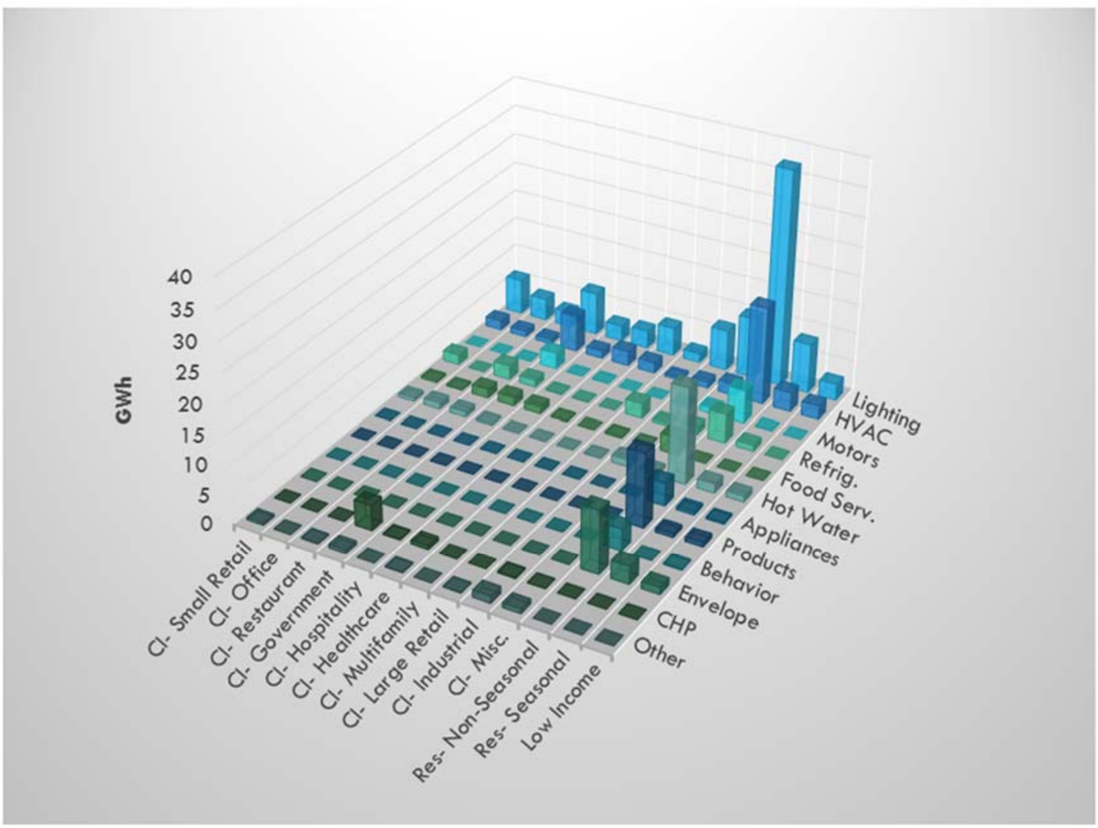


4.1 Results by Sector and End-Use

Over half of the achievable potential comes from the Residential Sector (54%). The Commercial & Industrial (C&I) Sector accounts for 42% of potential and the Low Income Sector for only 4%. The dominance of the Residential Sector, compared to C&I, reflects the economic structure of CLC's service territory, in which residential kWh sales comprise a higher proportion of CLC's total annual kWh sales (56%) than the statewide average (37%). The small contribution of the Low Income Sector is in line with the sector's number of accounts and annual energy sales (3%). (See Figure 4-3.)

Achievable potential associated with seasonal residential customers is rather low, even though they account for almost one-third (32%) of residential homes on Cape Cod and Martha's Vineyard and 23% of residential sector usage. This is mainly due to seasonal occupancy and its effect on annual savings (i.e., lower hours of use resulting in lower savings for the same measure). Some measures also do not pass the TRC test for seasonal customers because of reduced savings. Likewise, seasonality also has an effect on the commercial potential result, especially for segments such as hospitality and restaurants. Serving seasonal customers yields lower than average savings and higher cost per kWh because of lower hours of use.

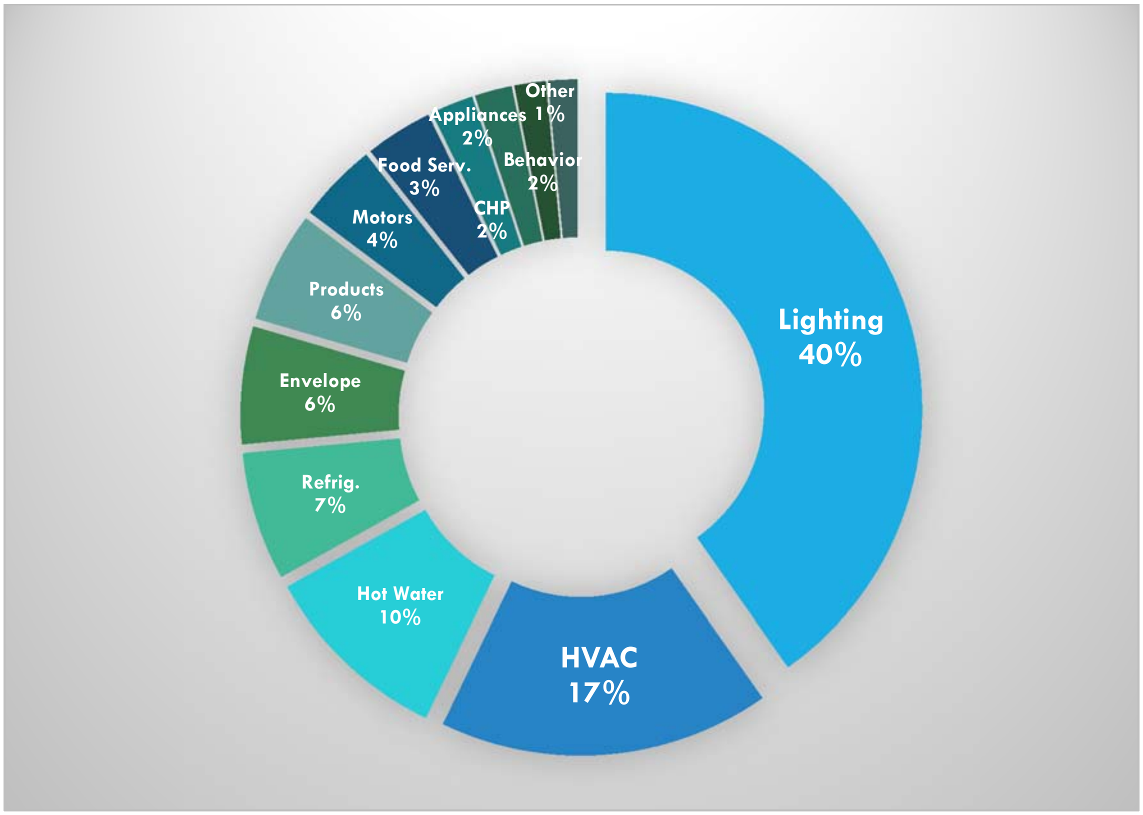
Figure 4-3. Six-Year Cumulative Achievable Potential (GWh)



The main end-use contributing to achievable potential is lighting (40%). Other significant end-uses are HVAC (17%), hot water (10%), refrigeration (7%), building envelope (6%), and products[49] (6%). (See Figure 4-4.)

[49] Including electronics, smart strips, and dehumidifiers.

Figure 4-4. Achievable Potential by End-Use



4.2 Top Five Measures

Three of the top five measure categories (across all sectors combined) are lighting measures, reflecting the large share of lighting savings in the overall achievable potential. LED bulbs are by far the highest energy-saving measure category, contributing 52.9 GWh of savings (22% of total achievable potential) over the six-year period. Linear lighting savings also include some savings from LED technology. Some potential for CFL savings remains, assuming that CLC continues to promote CFLs through its programs. CFLs and LEDs currently compete with each other for several types of baseline sockets/fixtures.

Hot water and building envelope measures also account for a substantial share of overall potential.

Table 4-5 summarizes the potential contribution by the top five measure categories, by sector.

Table 4-5. 2016-2021 Savings for Top Five Measure Categories by Sector

Rank	All Sectors		Residential		Low Income		C&I	
	Measure	GWh	Measure	GWh	Measure	GWh	Measure	GWh
1	LED Bulbs	52.9	LED Bulbs	28.6	Air Conditioning	2.0	LED Bulbs	22.4
2	Hot Water	18.4	CFL Bulbs	17.4	LED Bulbs	1.9	Linear Lighting	14.0
3	CFL Bulbs	18.3	Building Envelope	13.6	Building Envelope	1.2	Lighting Control	12.7
4	Building Envelope	14.8	Hot Water	13.5	CFL Bulbs	0.9	Refrigeration	10.0
5	Linear Lighting	14.0	Heat Pumps	11.6	Hot Water	0.8	Food service	9.1

4.3 Combined Heat & Power

Table 4-6 presents the annual potential results with and without Combined Heat & Power (CHP) in the C&I sector. C&I CHP has a relatively small impact on the overall achievable potential results, contributing only 5.4 GWh, or 2%, over the six-year period. A large part of the technical potential is not cost-effective with current inputs and assumptions, and high barriers result in a low adoption rate. When removing C&I CHP, the annual achievable potential drops from 1.98% to 1.93% of sales.

Table 4-6. Comparison of 2016-2021 Cumulative Achievable Potential: With and without C&I Combined Heat & Power

Potential	With C&I CHP		Without C&I CHP	
	GWh	MW	GWh	MW
Technical	675	163	494	126
Economic	480	117	447	114
Achievable	246	62	240	61

4.4 Comparison to Three Year Plan

In its April 30th 2015 draft of the Three-Year Plan for 2016-2018, CLC established a portfolio-wide savings goal of 156.3 GWh. This goal is 29% higher than our estimated achievable potential of 120.8 GWh for the same period.

When comparing CLC's published goal to our potential estimate, it is important to remember that the potential study is not meant to be a direct forecast of claimable savings, because some of the assumptions and inputs used to estimate potential are different from those used for setting goals and claiming savings. In particular, a key objective of our potential study was to reflect the unique circumstances of CLC's service territory and customer base, including the effects on achievable savings of having a large share of seasonal customers. To this end, we collected a wealth of primary data which is reflected in the potential study results. In contrast, the Massachusetts goal setting and savings claiming process requires consistency with TRM assumptions. As a result, the potential study results reflect certain CLC-specific information that is not mirrored in CLC's goals.

Further analysis of potential study results and Plan goals identified C&I upstream lighting as a key programmatic area where results are different: The April 30th Three-Year Plan estimates savings of 40.9 GWh from C&I upstream lighting whereas the potential model only estimates 8.7 GWh. The main drivers of this difference are assumptions about (1) the mix of baseline (replaced) bulbs (i.e., incandescent vs CFL units); (2) the size (wattage) of the baseline (replaced) bulbs; and (3) hours of use. The potential study used primary data for all of these factors, which showed:

1. higher penetration of CFL bulbs;[50]
2. lower wattage of baseline (replaced) bulbs; and
3. lower weekly hours of use during normal business operations

These differences lead to significantly lower savings estimates in the potential study compared to those used for planning purposes.

Another, but smaller, difference comes from consideration of seasonality in the potential study. While businesses on the Cape generally have shorter weekly hours of use during normal business weeks, which is reflected in the hours of use adjustment above, a number of businesses also have an additional reduction in their hours of operation during the off-peak season, especially winter.

In addition to differences stemming from the use of primary data, chaining – i.e., reduced savings from cumulative effects – also has an important effect because of high adoption rates for lighting controls in the potential study (resulting from high cost-effectiveness for these measures). When new lighting equipment is installed together with controls, the savings are smaller than the sum of each measure alone. Finally, small differences in net-to-gross and realization rate assumptions result in a negligible effect on savings compared to the Plan.

Table 4-7 below details the key differences in assumptions for C&I upstream lighting, and their impacts on 2016-2018 savings.

Table 4-7. Impact of Assumptions on Upstream Lighting Results

DESCRIPTION	Potential Study 3-Year Model (GWh)[51]	Increase /decrease (GWh)	Increase /decrease (% change)	3-Year Plan (GWh)
Base scenario (Potential Model)	8.7	---	---	40.9
Adjustment for seasonal customers removed	9.2	+0.5	+6%	
Hours of use adjusted to 3,901 per year (statewide assumption)	12.6	+3.4	+37%	
Mix of baseline incandescent/CFL set to 75%/25% for Type A bulbs	19.3	+6.7	+53%	

[50] For the potential study, we determined the mix of CFL versus incandescent bulbs being replaced using site visit and survey information, as well as natural replacement rates. This value is significantly different from the statewide TRM assumption.

[51] This column shows cumulative GWh from each assumption change.

Net-to-gross and realization rate factors set to same values as the 2016-18 CLC Plan	19.2	-0.1	-1%	
Chaining adjustment removed	25.3	+6.2	+32%	
Size of bulbs (watt difference between baseline and efficient bulbs for Type A bulbs) set to same value as CLC Plan	35.1	+9.8	+39%	

Using statewide assumptions and removing CLC-specific adjustments for C&I upstream lighting would increase our estimated C&I achievable potential by 26.5 GWh, from 52.5 GWh to 79.0 GWh. These additional 26.5 GWh would increase our estimated total achievable potential from 120.8 GWh to 147.3 GWh, in turn increasing the achievable potential as a percentage of sales from 1.94% in the base case to 2.36%. It should be noted, however, that even with these adjustments to C&I upstream lighting, Plan goals are not perfectly comparable to the achievable potential estimated in this study. The potential model also uses CLC-specific assumptions in the other sectors (residential and low income), which we did not vary for this analysis. However, the different assumptions for C&I upstream lighting can explain a significant portion of the difference between Plan goals and our estimated achievable potential.

4.5 Sensitivity Analysis

We conducted a sensitivity analysis to assess uncertainty regarding the 6-year GWh savings potential, using the following ranges:

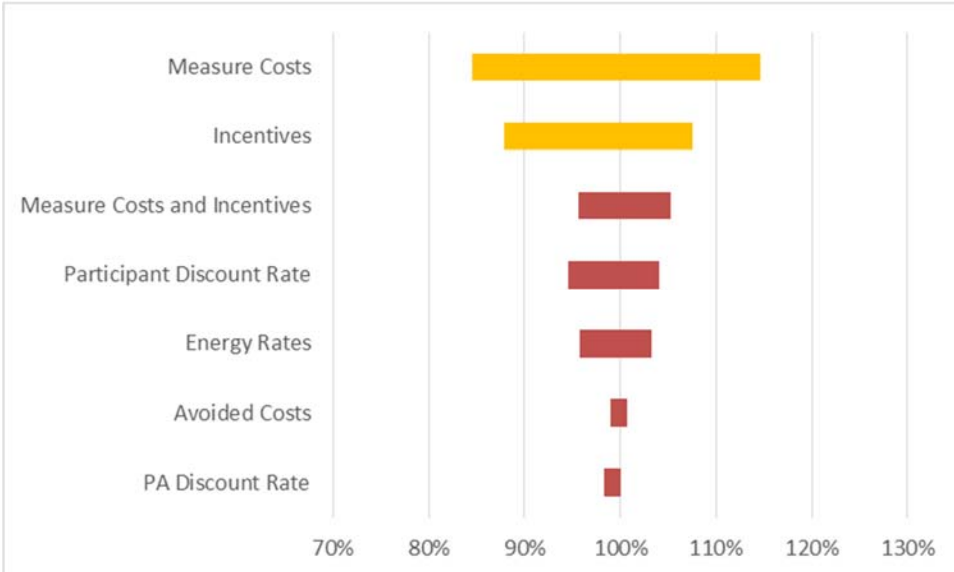
- Program administrator discount rate: 0% to 4%
- Participant discount rate: 0% to 10%
- Measure costs, incentives, energy rates, and avoided costs: -20% to +20%

Figure 4-5 presents the results of these analyses, as the percentage of savings under the lower and upper bounds for each factor, compared to the base scenario.

The potential model appears sensitive to measure costs and to incentives, because moving just one of these two parameters creates a discrepancy between costs and incentives (see orange bars in graph below). In reality, incentives are largely endogenous as they can be adjusted to evolving costs. As the graphic shows, adjusting measure costs and incentives at the same time (red bar) produces far less variability in results.

The potential savings appear robust, as all tested factors produce a variability of less than 20% compared to the base scenario.

Figure 4-5. 6-Year GWh Savings and Variability (Base Scenario = 100%)



4.6 Detailed Results

The following tables present additional detail on the results of the potential study, by type of potential, sector, segment, and end-use.

Table 4-8. Technical, Economic, and Achievable Potential by Year (GWh)

5. Residential Potential Results

CLC's annual achievable energy efficiency potential for the residential sector is estimated at 131 GWh and 29 MW for the six-year period from 2016 to 2021. Achievable potential represents 54% of economic potential and 31% of technical potential. On average, achievable energy savings amount to 1.92% of CLC annual sales to the sector. These savings would cost CLC $135 million (incentive and non-incentive program costs), an average of $23 million per year. The total cost (including the participants' net cost) amounts to $159 million for the six-year period. These investments are cost-effective, with a Total Resource Cost (TRC) ratio of 3.0 and a Program Administrator Cost (PAC) ratio of 2.5. Table 5-1 summarizes these results.

Table 5-1. Key Potential Results – Residential Sector, by Period

	2016-2021		2016-2018		2019-2021

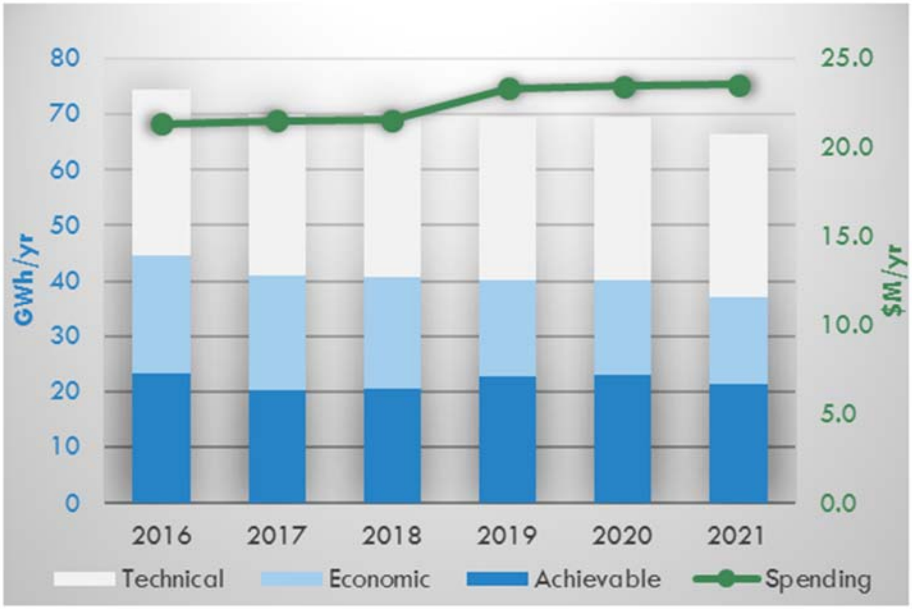
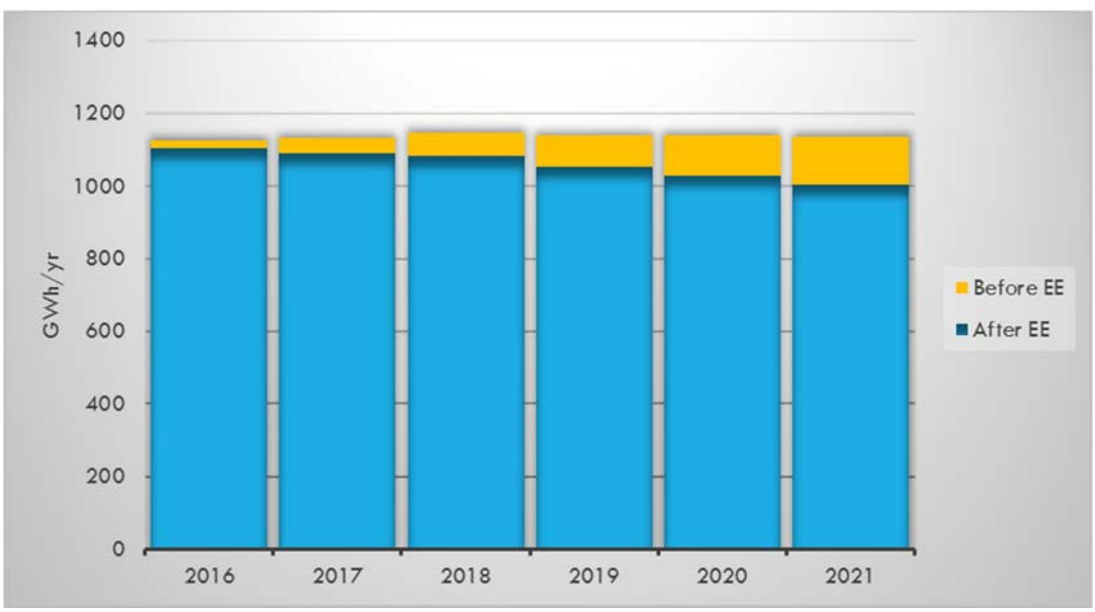
Figure 5-1 presents annual GWh savings for the three types of potential, as well as annual spending required to meet the achievable potential. As noted for the overall potential, the increase in spending during the second three-year period (2019–2021) is due to higher LED uptake, which results from an assumption of decreasing market barriers. While savings from LEDs are higher for that period, they are counterbalanced by somewhat lower savings for other measures.

Figure 5-1. Annual Savings and Spending for Residential Sector



Eversource forecasts slightly increasing energy sales for the residential sector, before energy efficiency (EE) efforts, over the six-year period, with total sales of 1,136 GWh in 2021 compared to 1,125 in 2016. With EE efforts at the level of the achievable potential, energy sales would decline, with 2021 sales amounting to 1,005 GWh, a drop of 11.5% from 2016 sales (Figure 5-2).

Figure 5-2. Impact of Achievable Potential on Annual GWh Residential Sales



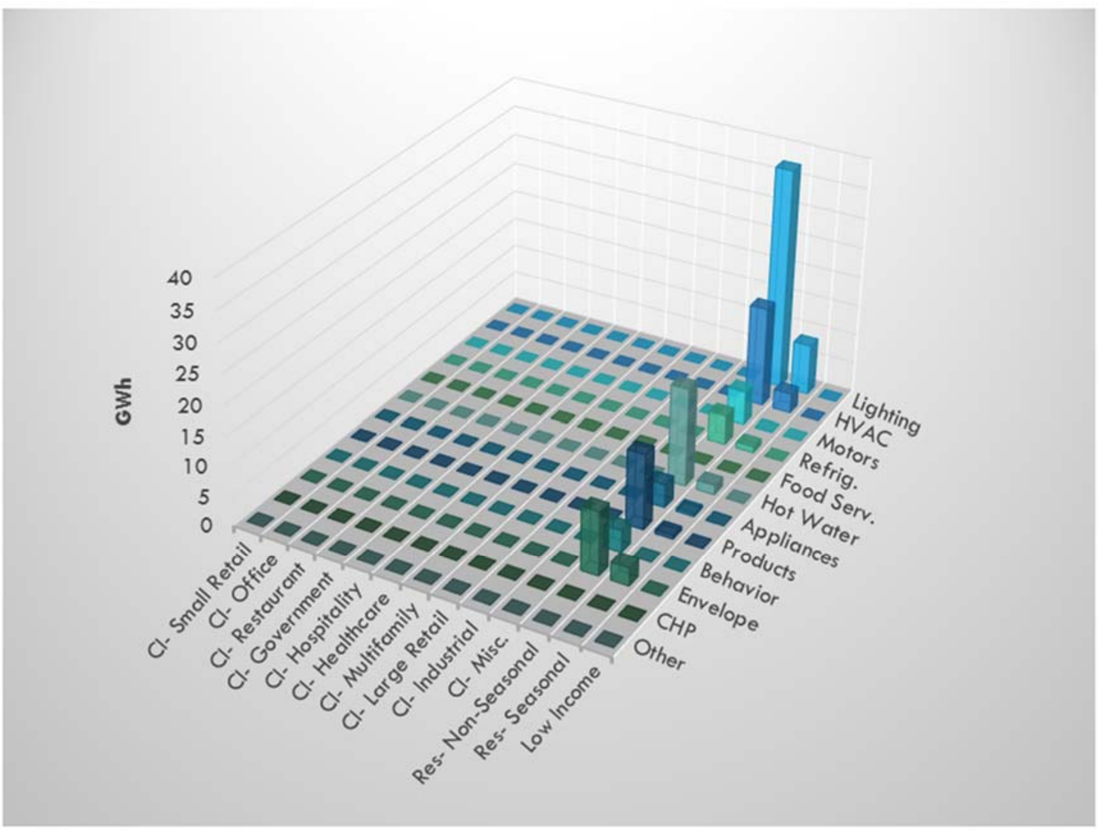
5.1 Results by Segment and End-Use for Residential Sector

Achievable potential associated with seasonal residential customers is rather low compared to non-seasonal residential customers. Over the six-year period, we estimate achievable energy savings of 2.14% of energy sales for non-seasonal customers and 1.19% of energy sales for seasonal customers.

This low potential is mainly due to the effect of seasonal occupancy on annual savings (i.e., lower hours of use resulting in lower savings for the same measure compared to non-seasonal customers). Several measures also do not pass the TRC for seasonal customers because of reduced savings, including important measures such as ENERGY STAR Homes - New Construction, heat pumps with lower efficiency levels, heat pump water heaters, and smaller LED bulbs that replace CFLs. Finally, because energy savings also affects the economics from the customer's point of view, lower Participant Cost Test (PCT) ratios will translate into lower adoption rates.

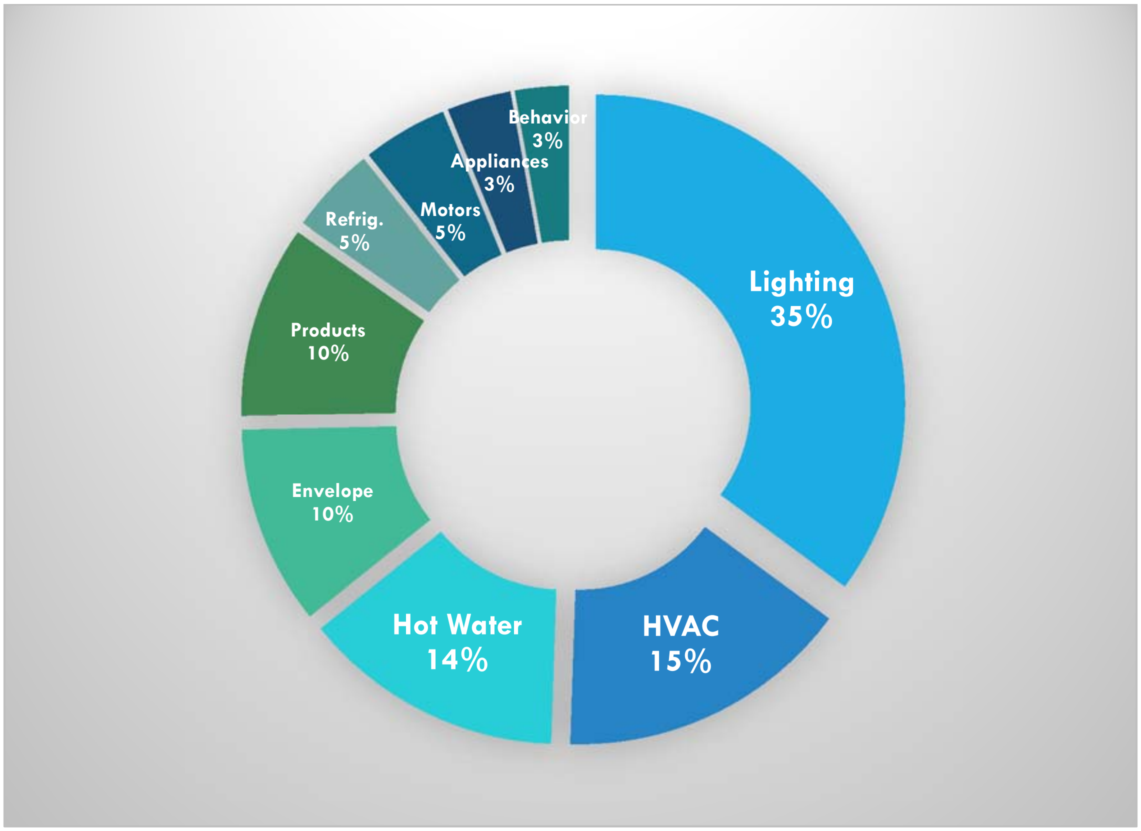
As can be seen on Figure 5-3, there are significant differences in the achievable savings patterns between seasonal and non-seasonal customers due to these factors.

Figure 5-3. 2016-2021 Cumulative Achievable Savings (GWh) for Residential Sector



The main end-uses contributing to achievable potential in the residential sector are lighting (35%), HVAC (15%) and hot water (14%). Other significant end-uses are building envelope (10%) and products (10%) (Figure 5-4).

Figure 5-4. 2016-2021 Achievable Potential by End-Use for Residential Sector



5.2 Top Five Measures for Residential Sector

The two top residential measures categories are lighting measures, reflecting the large share of lighting savings in the overall achievable potential. LED bulbs are the highest energy-saving measure, contributing 28.6 GWh of savings (22% of total achievable potential for the residential sector) over the six-year period, followed by CFL bulbs at 17.4 GWh (13%). CFLs and LEDs are competing with each other for several types of baseline sockets/fixtures.

Building envelope (13.6 GWh) and hot water (13.5 GWh) measures also account for a substantial share of overall potential.

Finally, heat pumps, including both new additions and replacements on burnout, are estimated to contribute 11.6 GWh to the six-year achievable potential.

Table 5-2. 2016-2021 Savings for Top Five Measure Categories in the Residential Sector

Rank	Measure	GWh
1	LED Bulbs	28.6
2	CFL Bulbs	17.4
3	Building Envelope	13.6
4	Hot Water	13.5
5	Heat Pumps	11.6

6. Low Income Potential

CLC's annual achievable energy efficiency potential for the low income sector is estimated at 9 GWh and 3 MW for the six-year period from 2016 to 2021. Achievable potential represents 41% of economic potential and 29% of technical potential. On average, achievable energy savings amount to 2.16% of CLC annual sales to the sector. These savings would cost CLC $10 million (incentive and non-incentive program costs), an average of $2 million per year. The total cost (including the participants' net cost) amounts to $11 million for the six-year period. These investments are cost-effective, with a Total Resource Cost (TRC) ratio of 4.2 and a Program Administrator Cost (PAC) ratio of 2.9. Table ES-1 summarizes these results.[52]

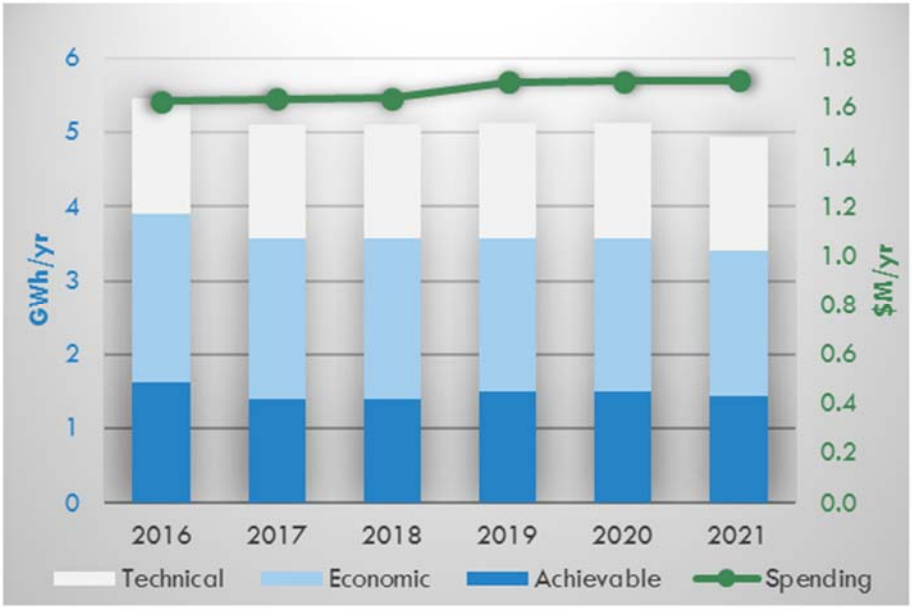
Table 6-1. Key Potential Results – Low Income Sector, by Period

	2016-2021		2016-2018		2019-2021	
Potential (Total)	GWh	MW	GWh	MW	GWh	MW
Technical	31	12	16	6	15	6
Economic	22	10	11	5	11	5
Achievable	9	3	4	2	4	1
Potential (Yearly)	GWh	MW	GWh	MW	GWh	MW
Technical	5.1	2.0	5.2	2.0	5.1	2.0
Economic	3.6	1.7	3.7	1.7	3.5	1.7
Achievable	1.5	0.6	1.5	0.7	1.5	0.5
Achievable as % of Sales	2.16%		2.16%		2.16%	
Cost						
Total (millions)	$11		$5		$5	
CLC (millions)	$10		$5		$5	
CLC Cost/kWh	$1.134		$1.112		$1.156	
Cost-Effectiveness						
Total Resource Cost Test	4.2		4.1		4.2	
Program Administrator Cost Test	2.9		2.9		3.0	

Figure 6-1 presents annual GWh savings for the three types of potential, as well as annual spending required to meet the achievable potential. Similar to the residential sector, the increase in spending during the second three-year period (2019–2021) is due to higher LED uptake over that period.

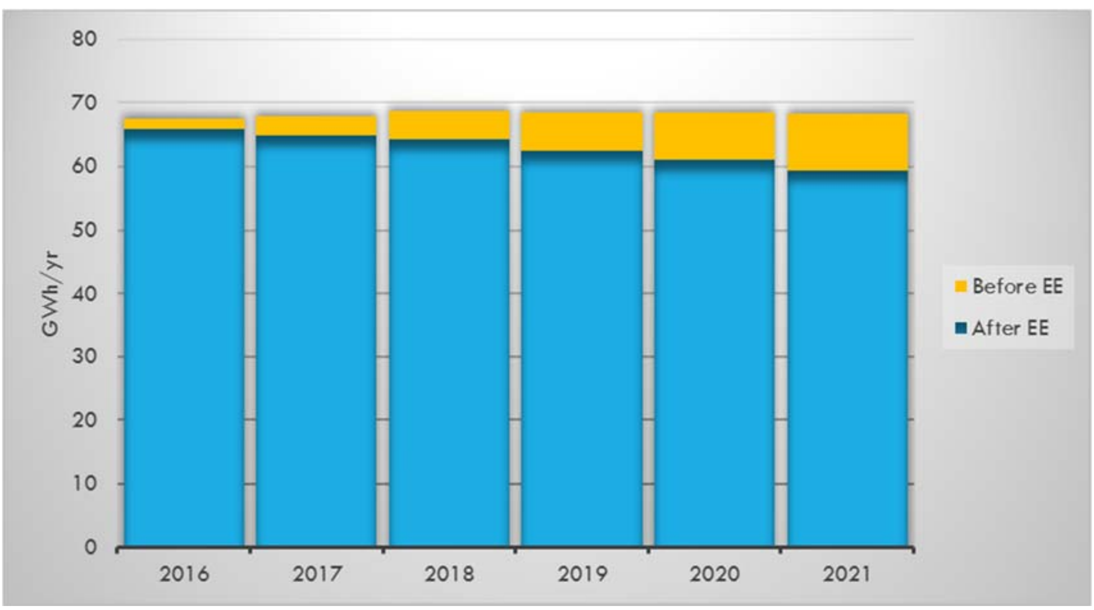
[52] Note that the indicated budget allocation for low income programs in the Potential Model is not 10% of the overall CLC budget, as required by Massachusetts Statute. In order to meet the statutory 10% requirement, CLC may need to expend additional budget without corresponding savings.

Figure 6-1. Annual Savings and Spending for the Low Income Sector



Eversource forecasts slightly increasing energy sales for the low income sector, before energy efficiency (EE) efforts, over the six-year period, with total sales of 68.2 GWh in 2021 compared to 67.6 in 2016. With EE efforts at the level of the achievable potential, energy sales would decline, with 2021 sales amounting to 59.4 GWh, a drop of nearly 9% from 2016 sales (Figure 6-2).

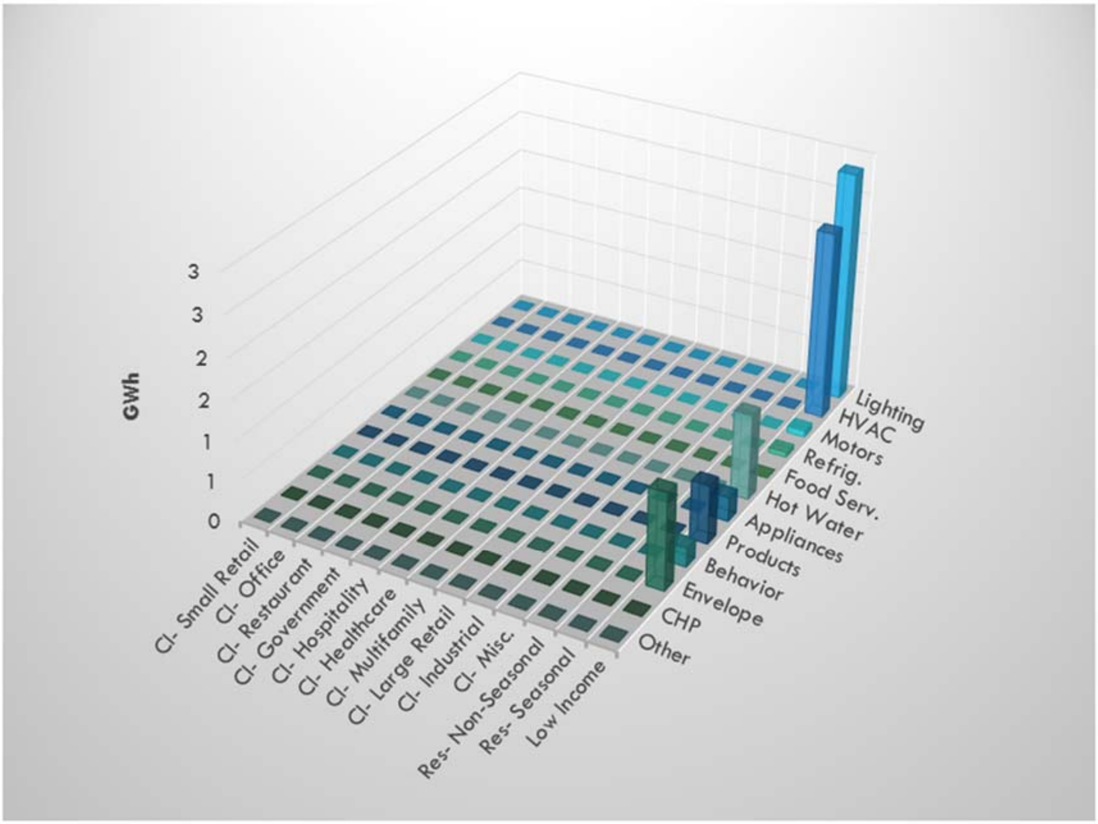
Figure 6-2. Impact of Achievable Potential on Annual Low Income GWh Sales



6.1 Results by End-Use for Low Income Sector

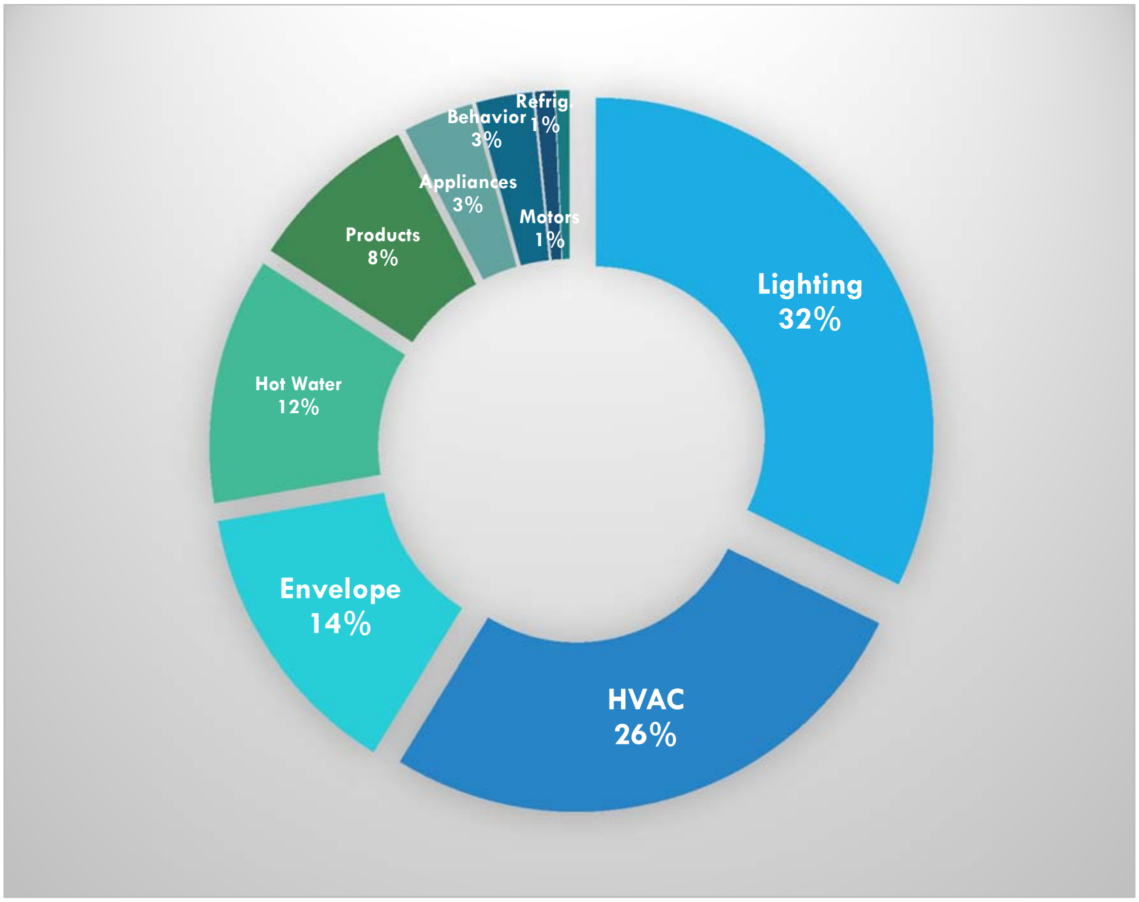
The small contribution of the Low Income Sector to overall achievable potential (4%) is in line with the sector's number of accounts and annual energy sales. This sector is not affected by seasonality, unlike the Residential and C&I sectors.

Figure 6-3. 2016-2021 Cumulative Achievable Savings (GWh) for the Low Income Sector



The main end-uses contributing to achievable potential are lighting (32%) and HVAC (26%). Other significant end-uses are building envelope (14%), and hot water (12%) (Figure 6-4).

Figure 6-4. 2016-2021 Achievable Potential by End-Use for the Low Income Sector



6.2 Top Five Measures for Low Income Sector

Two of the top five measure categories are lighting measures, reflecting the large share of lighting savings in the overall achievable potential. Air conditioning is the highest energy-saving measure, followed closely by LED bulbs. The importance of air conditioning saving potentials for the low income sector can be explained by the higher penetration of room air conditioning units compared to the residential sector, and by the existence of an income dependent initiative for room AC replacements. On the other hand, lighting savings are lower for the low income sector because low income households have fewer lightbulbs on average, and a larger proportion of them have already been replaced by CFLs. There still remains some potential for CFL savings, assuming that CLC continues to promote them through its programs. As noted above, CFLs and LEDs currently compete with each other for several types of baseline sockets/fixtures.

Hot water and building envelope measures also account for a substantial share of overall potential.

Table 6-2. 2016-2021 Savings for Top Five Measures in the Low Income Sector

Rank	Measure	GWh
1	Air Conditioning	2.0
2	LED Bulbs	1.9
3	Building Envelope	1.2
4	CFL Bulbs	0.9
5	Hot Water	0.8

7. Commercial & Industrial Potential Results

CLC's annual achievable energy efficiency potential for the commercial and industrial (C&I) sector is estimated at 106 GWh and 30 MW for the six-year period 2016 to 2021. Achievable potential represents 49% of economic potential and 47% of technical potential. On average, achievable energy savings amount to 2.04% of CLC annual sales to the sector. These savings would cost CLC $75 million (incentive and non-incentive program costs), an average of $13 million per year. The total cost (including the participants' net cost) amounts to $77 million for the six-year period. These investments are cost-effective, with a Total Resource Cost (TRC) ratio of 4.8 and a Program Administrator Cost (PAC) ratio of 3.4. Table ES-1 summarizes these results.

Table 7-1. Key Potential Results – C&I Sector, by Period

	2016-2021		2016-2018		2019-2021	
Potential (Total)	GWh	MW	GWh	MW	GWh	MW
Technical	224	66	113	33	111	33
Economic	214	61	108	31	106	30
Achievable	106	30	53	15	53	15
Potential (Yearly)	GWh	MW	GWh	MW	GWh	MW
Technical	37.4	11.0	37.6	11.0	37.1	11.0
Economic	35.7	10.2	36.1	10.3	35.3	10.2

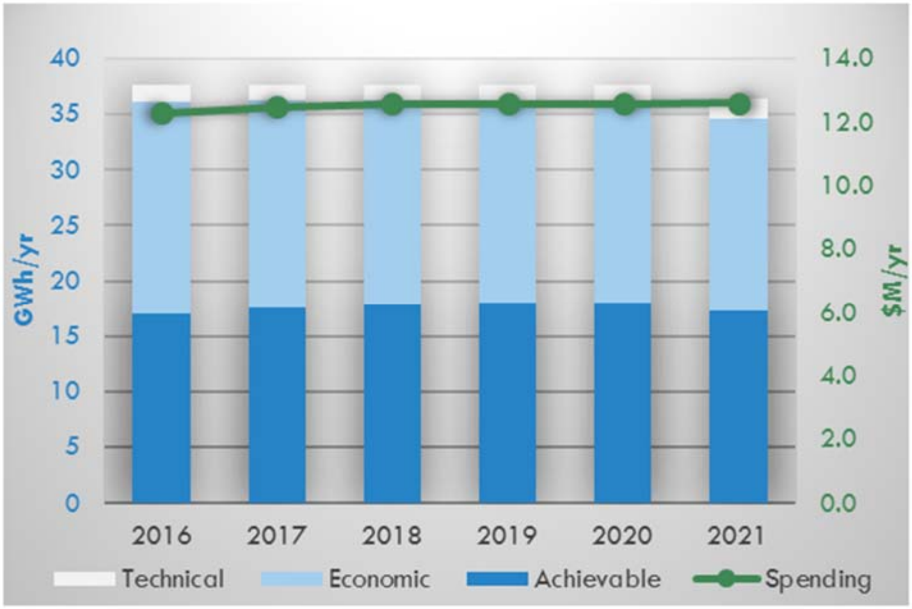
Cost-Effectiveness						
Total Resource Cost Test	4.8		4.9		4.8	
Program Administrator Cost Test	3.4		3.4		3.4	

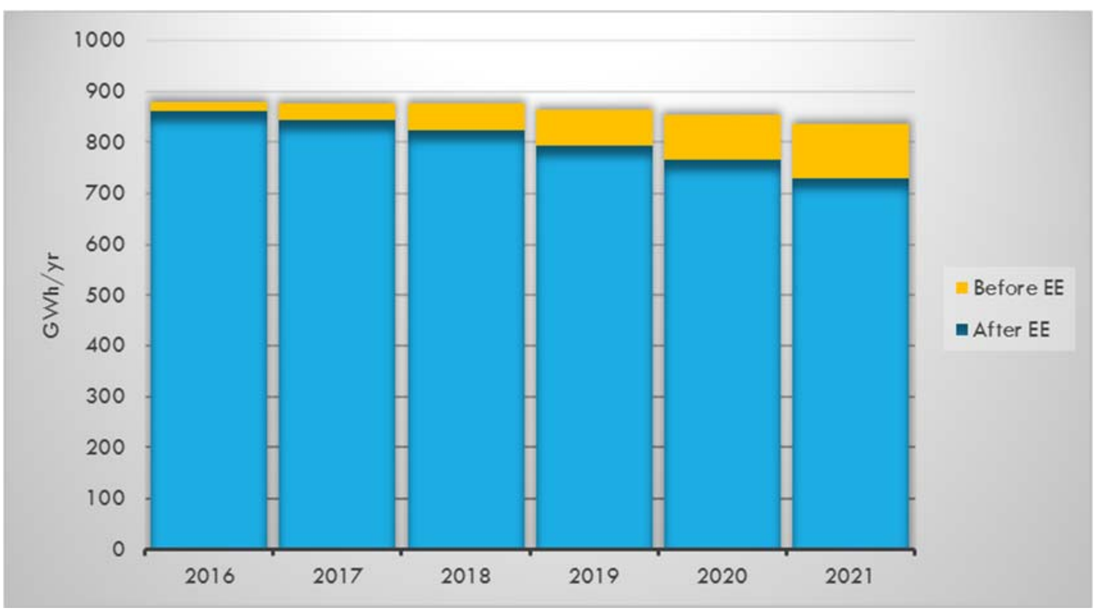
Figure 7-1 presents annual GWh savings for the three types of potential, as well as annual spending required to meet the achievable potential. Both spending and savings are rather flat during the six-year period.

Figure 7-1. Annual Savings and Spending for the C&I Sector



Eversource forecasts declining energy sales for the C&I sector, before energy efficiency (EE) efforts, over the six-year period, with total sales of 837 GWh in 2021 compared to 879 in 2016. With EE efforts at the level of the achievable potential, energy sales would decline faster, with 2021 sales amounting to 731 GWh, a drop of nearly 17% from 2016 sales (Figure 7-2).

Figure 7-2. Impact of Achievable Potential on Annual C&I GWh Sales

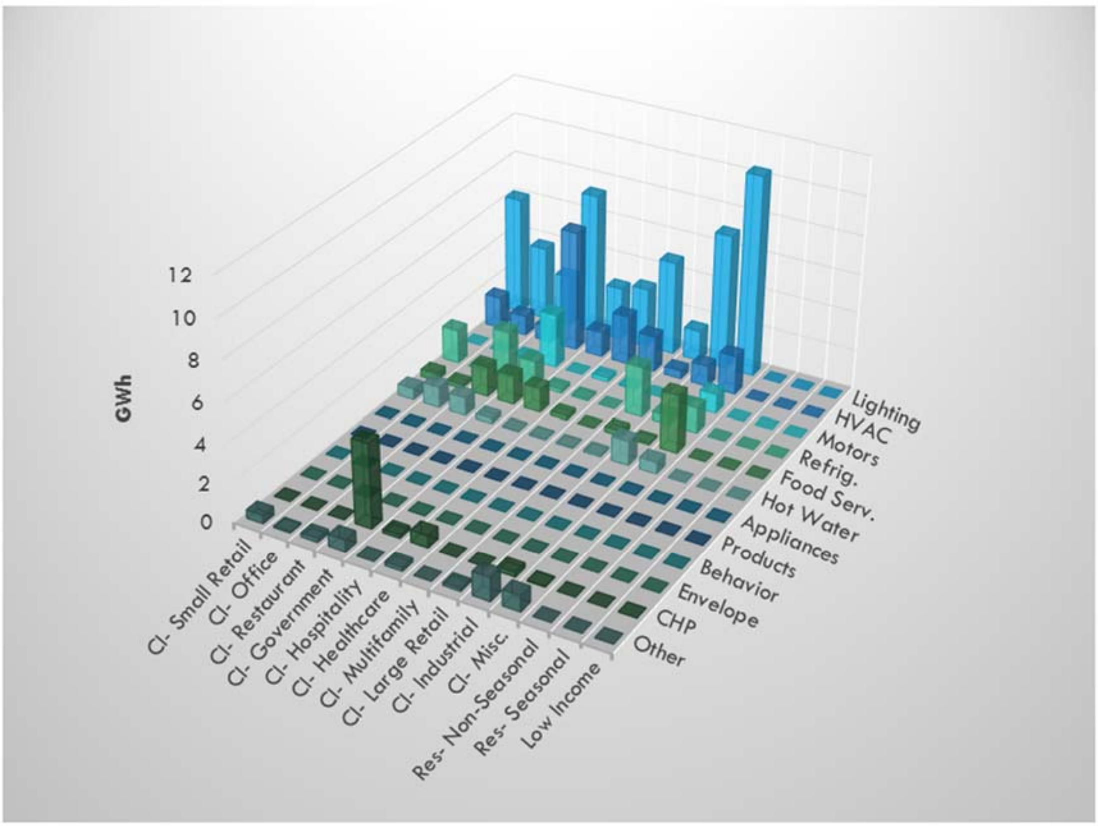


7.1 Results by Segment and End-Use for C&I Sector

The C&I sector accounts for 42% of the overall achievable potential. The relatively small contribution of the C&I sector, which compares to 57% of statewide C&I savings for the 2016-18 period, reflects the economic structure of Cape Cod and Martha's Vineyard. CLC's non-residential customer base is dominated by small businesses, with very few large commercial or industrial customers. This structure results in lower potential from the C&I sector as well as higher cost per kWh saved, as it is more expensive to serve smaller customers.

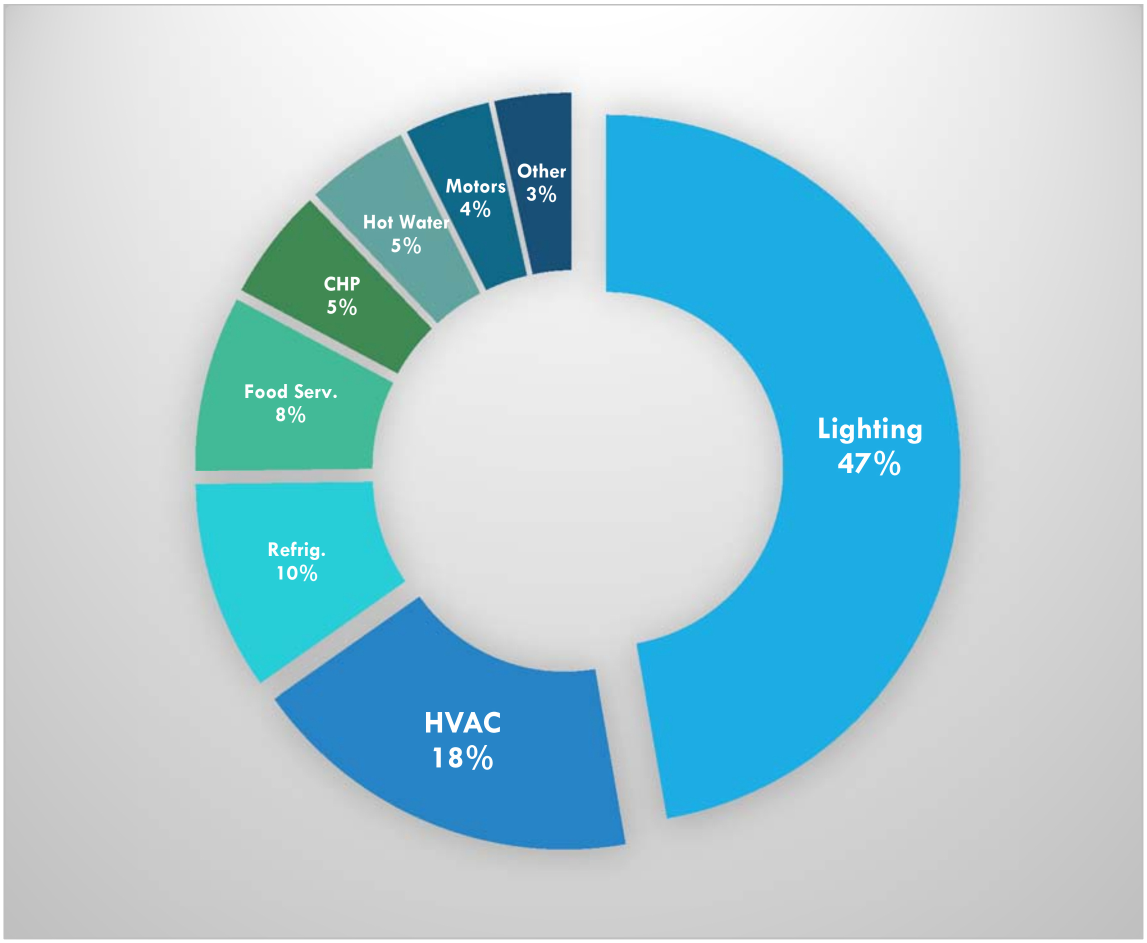
Achievable potential of the C&I sector is affected by seasonality, especially for the Restaurant and Hospitality segments. A large proportion of businesses have reduced hours of operation and/or occupancy during the off-peak season, and some even shut down completely during the winter.

Figure 7-3. 2016-2021 Cumulative Achievable Savings (GWh) for the C&I Sector



The main end-uses contributing to achievable potential are lighting (47%) and HVAC (18%). Other significant end-uses, which are specific to the C&I sector, are refrigeration (10%) and food service equipment (8%) (Figure 7-4).

Figure 7-4. 2016-2021 Achievable Potential by End-Use for C&I



7.2 Top Five Measures for C&I Sector

Three of the top five measure categories are lighting measures, reflecting the large share of lighting savings in the overall achievable potential. LED bulbs are by far the highest energy-saving measure, contributing 22.4 GWh of savings (21% of total achievable potential for the C&I sector) over the six-year period. Linear lighting savings also include some savings from LED technology.

Refrigeration and food service equipment also account for a substantial share of overall potential.

Table 7-2. 2016-2021 Savings for Top Five Measure Categories in the C&I Sector

Rank	Measure	GWh
1	LED Bulbs	22.4
2	Linear Lighting	14.0
3	Lighting Control	12.7
4	Refrigeration	10.0
5	Food service	9.1

DNV·GL

National Grid Massachusetts Energy Efficiency Potential Study

FINAL

Prepared by KEMA, Inc.

October 26, 2015

Table of Contents

Tables

Figures

1. EXECUTIVE SUMMARY

In 2014, National Grid Massachusetts (National Grid) engaged DNV GL to assess the potential for electric and natural gas energy and electric demand savings from company-sponsored commercial and industrial demand side management (DSM) programs. The method used for estimating potential is a "bottom-up" approach, in which energy efficiency costs and savings are assessed at the customer segment and energy efficiency measure level. For cost-effective measures (based on the Total Resource Cost (TRC) test), achievable savings potential is estimated as a function of measure economics, rebate levels, and program marketing and education efforts. The modeling approach was implemented using a National Grid specific Excel model which allows for efficient integration of large quantities of measure, building, and economic data to determine energy efficiency potential.

1.1 Methodology

DNV GL leveraged its proprietary model, DSM ASSYST™, in order to develop a dynamic, transparent, user-friendly, Excel-based model that allows National Grid staff to update certain predetermined fields as new information and/or program parameters arise. Wherever possible, National Grid specific data were used as inputs to the model. The model was populated with data collected from National Grid customers through Wave 1 and a portion of Wave 2 of the Massachusetts Existing Building Market Characterization C&I Customer On-site Assessments (EM&V Project 41),[1] previous state-wide and National Grid specific evaluation efforts, the Massachusetts Technical Reference Manual, National Grid's internal documents and tracking data and other secondary sources.

The analysis has a starting year of 2015 and uses that year as its calibration year, assuming that 2015 costs and savings are similar to available 2014 savings. Results from 2016 onward are presented so as to accurately reflect a start date that is consistent with the 2016 to 2018 planning period. In this document DNV GL shows a three-year forecast for the 2016 to 2018 planning period and a longer term 10-year forecast from 2016 to 2025.

Three basic types of energy efficiency potential were estimated in this study:

- **Technical potential:** The complete penetration of all measures analyzed in applications where they were deemed technically feasible from an engineering perspective. Technical potential is a purely theoretical estimate of potential, as it ignores cost effectiveness, measure turnover and other barriers that might inhibit measure adoption. The size of the technical potential hinges primarily on the list of measures being evaluated: An expansive measure list with many cutting-edge but not currently cost effective technologies would have a much higher technical potential than one with a more restrictive list of measures known to be cost effective in at least some applications.
- **Economic potential:** The technical potential of those energy efficiency measures that are cost-effective when compared to supply-side alternatives. It should be noted that the potential captured in economic potential includes all possible measure installations regardless of the timing of the installation, i.e., all potential savings across all time periods

[1] The Massachusetts Existing Building Market Characterization – C&I Customer On-site Assessments (EM&V Project 41) is a two year study and includes two waves of on-site data collection. Wave 1 data collection was completed in December 2014 and included 350 sites, Wave 2 data collection began in January 2015 and is anticipated to include 450 sites and is slated to be complete in late 2015. A total of 257 National Grid electric sites were included in this study and a total of 207 gas sites were included (the majority of which were National Grid serviced sites with the only exception being industrial sites which included sites from all Massachusetts gas PAs).

modeled are counted in this number. At this stage, the analysis leverages the TRC test to determine which measures have a TRC value above a certain threshold (in the case of National Grid this is 1.0). Any measures with a TRC below this threshold are dropped from the analysis at this point. The modeling effort addresses competing measures at a variety of levels. Retrofit and replace-on-burnout approaches to the same measures are addressed through market segmentation. Beyond that, the research team utilizes a supply curve approach to avoid double counting of savings, in which measures are ranked by cost-effectiveness and assumed to be implemented in that order. For measures in direct competition (that is, one or the other may be installed, but not both), the study applies the most cost effective measure, then evaluates the second measure based on its marginal cost and savings relative to the first.

- **Achievable program potential:** The amount of savings that would occur in response to specific marketing and measure incentive levels. Here, timing of the measure installation becomes a factor for the modeled savings. In this study DNV GL looked at the potential available under three scenarios - a business-as-usual (BAU) scenario where overall incentives levels paid in 2015 are used going forward as well as two additional funding scenarios: 25 percent increase over those BAU levels (25 Percent Plus scenario) and a 75 percent increase (75 Percent Plus scenario).[2] Program energy and peak-demand savings, as well as program cost effectiveness, were assessed under all three funding scenarios. The National Grid study also provides an estimate of naturally occurring savings, i.e., those savings that are projected to result from normal market forces in the absence of any intervention by utility sponsors. These savings are not included in the estimate of achievable program potential.[3] While economic potential is based on a TRC test screening, measure adoption for achievable potential and naturally occurring is based on the measure benefit/cost ratio from the customer perspective.

1.2 Model Assumptions & Limitations

In order to best understand and interpret the results of this analysis, the reader should first have a solid understanding of the assumptions and limitations of the model used for this study. Each of these is presented in Table 1-1 along with an assessment of the effect on the model outputs. Most importantly, it should be noted that the model used in this analysis is primarily intended to give National Grid a realistic picture of savings potential during the 2016 to 2018 time frame under current technology, program and market conditions, this was an intentional choice made by the project team. Therefore, the study takes a more conservative stance when modeling energy efficiency potential.

---

[2] The 25 percent plus and 75 percent plus scenarios reflect a percentage increase of the incentives already paid to the customer, capping at 100 percent of incremental measure cost to be paid in customer incentives. Increasingly, customer incentives in National Grid's service territory are paid in cents per kWh.

[3] Naturally occurring are free riders or non-participants that would have installed the measure without program assistance. The calculation for naturally occurring parallels that for program savings. Both look at adoption as a function of the measure benefit cost (B/C) ratio from the customer perspective, but the B/C ratio used to calculate naturally occurring excludes the incentive, while the B/C ratio used to calculate adoption under the program includes it. The difference in savings between the two adoption scenarios represents the estimated net program savings.

Table 1-1: Model Assumptions & Limitations

Assumption/ Limitation	Notes	Effect on Model Results
Conservative Approach to New Technologies	The new technologies that are included in the study are commercially available and most have been included in National Grid's programs, although in relatively small numbers to date and often as Custom measures. This approach is a result of a decision made by the DNV GL and National Grid teams to take a conservative approach when modeling emerging technologies so as to best represent those technologies that will be market-ready during the 2016 to 2018 time frame.	Reduces Savings Estimates
No CHP or Streetlighting Measures	Both CHP and streetlighting measures are not accounted for in the model. National Grid is aware of this limitation and has adjusted estimates of three year savings goals accordingly.	Reduces Savings Estimates
Limited Range of Policy Interventions	The model design allows for a limited range of policy interventions – specifically increased marketing and/or incentive levels.	Limits the ability to model increased (or decreased) program support and new program designs
Assumes static measure efficiency over time	The modeling effort does not address incremental improvements in energy efficiency due to the ongoing evolution and gradual improvement of existing technologies. These improvements will lead to increased energy efficiency potential over time.	Reduces Savings Estimates
Does not address ongoing tightening of equipment and building standards	The modeling effort does not address the ongoing tightening of equipment and building standards (beyond those known to be effective within the study period), which will lead to a decrease in energy efficiency potential over time. The improvements in energy-efficient technologies provide opportunities for additional program savings over a static base-case technology. However, as the market matures, codes and standards are tightened to raise base-case efficiency, and the result is subsequent reduction in program savings opportunities to levels that were available prior to the improvements in technology efficiency.	The effects of gradual technology improvement and ongoing tightening of codes and standards offset each other over the long term.

1.3 Results

1.3.1 Overall Cumulative Energy Efficiency Savings – Electric Energy and Demand Savings

Table 1-2 shows the results of the achievable analysis as compared to base consumption[4], technical potential, and economic potential for the 2016 to 2018 time frame. For this time period, technical potential is estimated at 4,710 GWh per year by 2018. Economic potential is estimated at 4,533 GWh by 2018. BAU achievable potential is 686 GWh, or approximately 15 percent of economic potential. For the 75 Percent Plus scenario, this potential increases to 867 GWh and 19 percent of economic potential. Economic potential for energy savings is estimated to be 36% percent of base 2018 energy use, while achievable potentials range from six percent of base usage in the BAU case to seven percent of base energy use in the 75 Percent Plus case (averaging between 2 and 2.3 percent each year). Keep in mind that these results exclude 2015 program savings and naturally occurring savings.

Table 1-2: Three Year Cumulative Annual Electric Potential (2016-2018) – GWh

Sector	2018 Base Energy Use	Three Year Cumulative Annual Potential - GWh					
		Technical Potential	Economic Potential	BAU Scenario (Net)	25% Plus Scenario (Net)	75% Plus Scenario (Net)	Naturally Occurring

Cumulative Program Costs-Real, $ Million		NA	NA	$216	$270	$356	NA

There are several reasons for the observed drop off between technical and economic potential and achievable potential including slow turnover rates for replace-on-burnout measures, retrofit "procrastination" (where customers wait before implementing a new measure), market barriers (not related to measure costs), hard-to-reach (or change-resistant) customers, the effects of codes and standards, and the fact that economic potential captures savings regardless of timing while achievable savings take into account measure turnover and other factors that affect the timing of measure installation over the modeled time frames.

[4] The model provides independent estimates of base consumption, however for these tables DNV GL presents National Grid's own forecast data so as to create a more direct comparison to the savings estimates presented in the draft 2016-2018 three year energy efficiency program plan.

Table 1-3 shows the same results for the 2016 to 2025 time frame. A similar drop-off between economic potential and achievable potential estimates is observed under this time frame as well. It should be noted, that this is not outside of the range normally observed by DNV GL and in fact is in line with recent potential efforts in states with similar longevity and program support as Massachusetts.[5]

Table 1-3: Ten Year Cumulative Annual Electric Potential (2016-2025) – GWh

Cumulative Program Costs- Real, $ Million		NA	NA	$573	$689	$895	NA

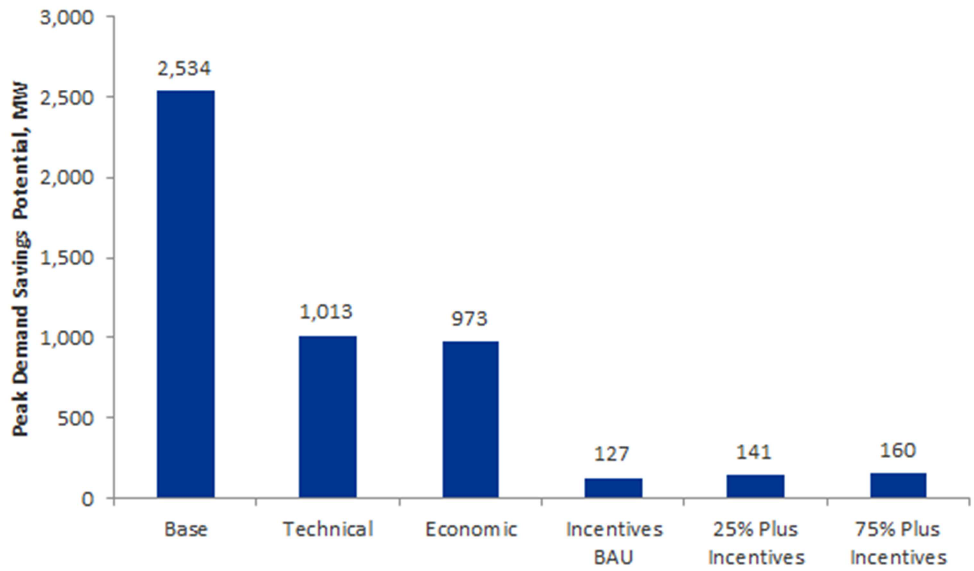
Cumulative peak demand savings potential estimates for both the 3-year and 10-year periods are provided in the figures below.[6]

Technical potential is estimated at 1,013 MW for the 3-year period while economic potential is estimated at 973 MW. Cumulative achievable program potential ranges between 127 MW in the BAU case up to 160 MW in the 75 Percent Plus incentive case. Economic potential for peak demand savings is estimated to be 38 percent of base peak demand and achievable potentials range from five percent of base peak demand in the BAU case up to six percent of base peak demand in the 75 Percent Plus incentive case (averaging between 1.7 and 2 percent each year).

[5] The current California potential study being conducted by Navigant shows a precipitous drop in potential in the commercial sector in 2018 and a gradual decline in industrial potential. Navigant, 2015 California Potential and Goals Study, Draft Results Presentation to DAWG, March 17, 2015. http://www.cpuc.ca.gov/NR/rdonlyres/1D3525C7-7145-4AD5-80A8-55515B066223/0/2015PGStudyMarch17DAWGPublicWorkshop.pdf. Slides 7 and 9.

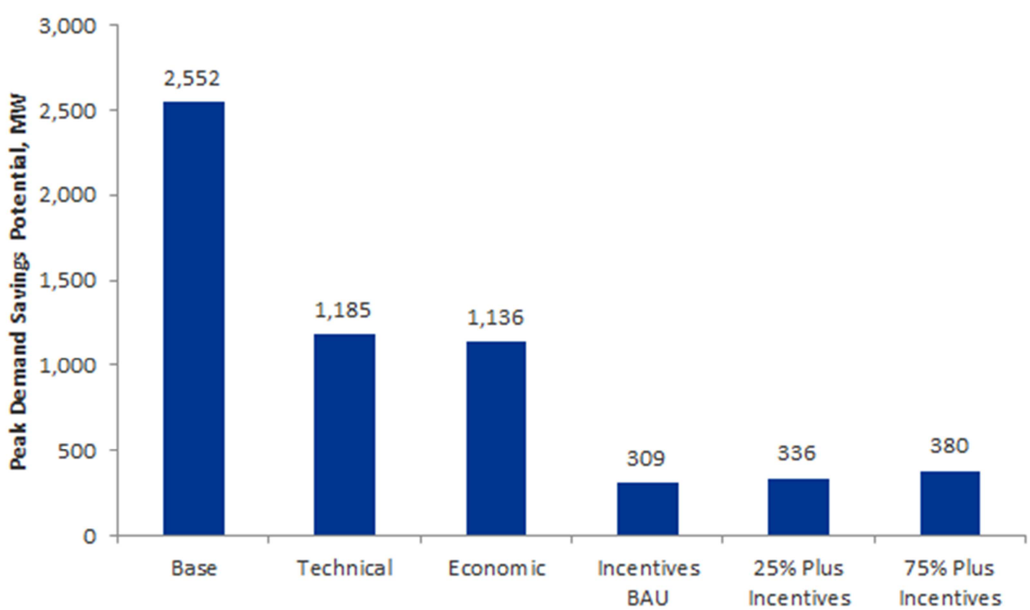
[6] The estimates of peak demand savings are from the installation of energy efficiency measures and do not include demand savings from demand response technologies such as direct load control or dynamic pricing.

Figure 1-1: Estimated Peak Demand Savings Potential, 2016-2018



Technical potential is estimated at 1,185 MW summer coincident peak savings for the 10-year period. Economic potential is estimated at 1,136 MW for the 10-year period. For the 10-year period, cumulative achievable program potential ranges between 380 MW in the 75 Percent Plus incentive case down to 309 MW in the BAU case. Economic potential for peak demand savings is estimated to be 37 percent of base 2025 peak demand; achievable potentials range from 10 percent of base peak demand in the BAU case to 12 percent of base peak demand in the 75 Percent Plus incentive case.

Figure 1-3: Estimated Peak Demand Savings Potential, 2016-2025



1.3.2 Overall Cumulative Energy Efficiency Savings - Natural Gas Savings

Table 1-4 shows the results of the achievable analysis as compared to base consumption, technical potential, and economic potential for the 2016 to 2018 time frame. BAU achievable potential is 12,063 thousand therms, or approximately seven percent of economic potential. For the 75 Percent Plus scenario, this potential increases to 17,606 thousand therms and 10 percent of economic potential. Economic potential for energy savings is estimated to be 30 percent of base 2018 energy use while achievable potentials range from two percent of base usage in the BAU case to three percent of base energy use in the 75 Percent Plus case (averaging between 0.7 and 1 percent each year).

Table 1-4. Three Year Cumulative Annual Gas Potential (2016-2018)

Sector	2018 Base Energy Use	Three Year Cumulative Annual Potential – thousand therms					
		Technical Potential	Economic Potential	BAU Scenario (Net)	25% Plus Scenario (Net)	75% Plus Scenario (Net)	Naturally Occurring
Commercial	512,915	184,472	158,672	10,363	13,038	15,221	949
Savings % of Base		**36%**	**31%**	**2%**	**3%**	**3%**	**0.2%**

1.4 Interpreting the Results

While the DNV GL team recognizes that the results of this modeling effort are lower than anticipated, based on DNV GL's experience, the numbers are reasonable given the landscape of the Massachusetts energy efficiency programs and the assumptions made in the model. As noted above, DNV GL and National Grid made assumptions regarding the availability of new technologies and program designs that were in line with National Grid's expectations for the 2016 to 2018 time frame which limited the potential for savings from innovative program design or the introduction of new technologies that are further from being market-ready. This decision was made intentionally so that the study would best represent the technology, program and market conditions during the 2016–2018 program period.

In addition to the model assumptions, there are two key factors that are leading to lower estimates of potential savings:

1. The maturity of National Grid's energy efficiency programs causes awareness among the participant population to be already quite high. Put more simply, much of the "low hanging fruit" is gone in National Grid's territory, while simultaneously there is not an anticipated disruptive change (either in new technology or program design) during the 2016 to 2018 time frame.
2. The saturation of retrofit upgrades during earlier years of the model result in a noted decline over time in the annual energy savings. Put another way, as retrofits are completed, there are fewer opportunities going forward.

Additional detail on the DNV GL team's assessment of the results of the model is presented in Section 5.4 of this report.

2. INTRODUCTION

National Grid retained DNV GL to conduct a demand side management (DSM) market potential study which was based on existing and proposed commercial and industrial customer end-use energy efficiency measures and programs. The study provides estimates of potential energy and peak demand savings from energy efficiency measures in National Grid's Massachusetts service territory, including technical, economic, and achievable program potential. This study covers two time periods, years 2016 to 2025 and years 2016 to 2018. The 2016 to 2018 time period covers the forthcoming 3-year planning cycle for Massachusetts and is of particular interest. Analyses of electric and natural gas measures in both the commercial and industrial sectors were performed to arrive at potential estimates.

2.1 Overview

National Grid's primary objective in conducting this potential study is to obtain realistic estimates of achievable commercial and industrial electric and gas energy efficiency potential for years 2016 to 2018 for use during the forthcoming 3-year planning cycle. Secondary objectives include the creation of a dynamic, transparent, user-friendly, Excel-based model that allows National Grid staff to update certain predetermined fields as new information and/or program parameters arise as well as the use of National Grid specific data wherever possible to populate the model.

In support of these goals, DNV GL developed a modified version of its DSM Assyst model built to National Grid's specifications. The model was used to estimate electric energy and demand savings and natural gas savings potentials for National Grid's commercial and industrial (C&I) customers for both a 10-year period beginning with 2016 and for the next 3-year planning period of 2016 to 2018. The model was populated with data collected from National Grid customers through the Massachusetts Existing Building Market Characterization – C&I Customer On-site Assessments (EM&V Project 41) being conducted under the statewide C&I evaluation contract. Additional model inputs came from pervious Massachusetts statewide and National Grid specific evaluation efforts, the Massachusetts Technical Reference Manual, National Grid's internal documents and data, and other secondary sources.

2.2 Study Approach

The energy efficiency potential portion of the study involved identifying and developing baseline end-use and measure data and developing estimates of future energy efficiency impacts under varying levels of program effort.

DNV GL performed a baseline characterization that identified the types and approximate sizes of the various market segments that are the most likely sources of DSM potential in National Grid's service territory. These characteristics then served as inputs to a modeling process that incorporated National Grid's energy-cost parameters and specific energy efficiency measure characteristics (such as costs, savings, and existing penetration estimates) to provide more detailed potential estimates.

This study provides thorough and transparent documentation of model inputs and calculations used for estimating technical, economic, and achievable potential. The research team estimated technical, economic, and achievable program potential for the commercial and industrial sectors, with a focus on energy efficiency impacts through 2018 and 2025.

It should be noted that the primary focus of the modeling effort is to provide National Grid with a realistic picture of the achievable program savings during the 2016 to 2018 time frame. As a result the team made specific assumptions regarding the program, technology and market conditions that would best represent the 2016 to 2018 period, including the exclusion of new technologies that are not likely to be cost-effective and market ready during the 2016 to 2018 time frame; the exclusion of estimates of CHP or streetlighting measures; and a similar program design as seen during the 2013-2015 program cycle.

2.3 Organization of the Report

The remainder of this report is organized as follows:

- Section 3 provides a brief overview of the data collection activities conducted for this study. Full results for EM&V Project 41 data is provided in a separate report that presents the detailed results of on-sites that were conducted to develop inputs used in the market potential models.
- Section 4 discusses the methodology and concepts used to develop the technical, economic, and achievable potential estimates.
- Section 5 provides results of the analysis and a discussion and interpretation of the model results.

3. DATA COLLECTION AND DEVELOPMENT

This section describes the efforts used by DNV GL to develop data inputs for this potential study. The main sources of these data were the Massachusetts Commercial and Industrial Customer On-site Assessment, and information provided by National Grid including: National Grid 2013 non-residential customer billing data, CoreLogic property information, data provided by the National Grid staff, and other secondary data sources.

3.1 Developing the Measure List

The team developed the measure list for the study to include efficiency measures currently commercially available, including measures currently offered through National Grid's current programs as well as measures offered through other utility programs. The measure list was intentionally designed to be conservative, focusing on technologies with well-documented costs and savings that were known to be available in the region. This approach mitigated the uncertainty associated with unproven technologies, but may underestimate potential to the extent that some of those technologies may eventually become mainstream, especially in the later years of ten-year time frame. The research team believes that impact is negligible in the 2016 to 2018 period, as the new technologies are unlikely to gain sufficient foothold in the market to have a significant impact in just three years.

The research team did evaluate a number of emerging technologies for inclusion in the model. These were:

- Advanced Rooftop Controls
- Advanced Lighting Controls
- Comprehensive lighting design
- Ventilation Controls for High Outside Air Use Facilities
- Data Center Optimization
- Cold Weather Heat Pumps
- Rooftop Unit Automated Fault Detection
- Kitchen Exhaust Demand Control Ventilation
- Phase Change Materials

Of these, advanced rooftop controls, advanced lighting controls, and rooftop automated fault detection were explicitly included in the model. The research team believed that the savings from kitchen exhaust demand control ventilation and ventilation controls for high outside air facilities were captured under a more broadly defined demand control ventilation measure. Small data center optimization was initially included, but dropped, along with large data center optimization, at National Grid's direction, because they felt that data center measures were more appropriately captured under the model's custom measures. Cold-weather heat pumps do not have enough of a track record in the marketplace to develop a good estimate of savings or feasibility, and the initial screening of the technology indicated relatively low savings potential. Similarly, phase-change materials have little track record on which to base savings or estimate costs, and the initial review suggested that savings potential was low.

Included in the measure list are a number of custom measures for each sector:

- Commercial electric: Custom lighting, custom cooling, custom building shell, custom ventilation, custom refrigeration, and custom operations and maintenance
- Industrial electric: Custom compressed air, custom drives, custom water/wastewater, custom process heating, custom process cooling, custom other process
- Commercial gas: Custom boiler, custom furnace, custom other heat, custom water heating
- Industrial gas: Custom boiler, custom furnace, custom process heating, custom HVAC

These were intended to represent highly customer-specific measures and uncommon measures not explicitly included in the model. DNV GL believes that these measures are sufficient to represent the early phases of commercialization for technologies that were not explicitly included in the model.

3.2 National Grid-Specific Data Collection Efforts

The Massachusetts Program Administrators engaged DNV GL to collect end-use saturation data from non-residential customers, through the Massachusetts C&I Customer On-site Assessment (EM&V Project 41), to be used to inform the Massachusetts PAs energy efficiency programs. Data collected via this study include building characteristics, occupant characteristics, and the penetration and usage of various measures and end uses throughout the PAs' service territories. Those primary data collected from EM&V Project 41 that were specific to National Grid were combined with other secondary data sources to fully populate the data inputs required for the potential study modeling efforts. Table 3-1 presents the percent of each model input type that comes from the data collected via EM&V Project 41. The number of incomplete factors from this project is low, at 29 percent. This is due to the fact that the incomplete factors are measure specific and therefore the number of questions that would have been required for the on-site survey to address all these data points would have made the surveys unacceptably time consuming and costly.

Table 3-1: Percent of Model Inputs by Type from Project 41

Model Input Type	% of Inputs from P41
Applicability Factor (% of floor space for which the measure is applicable)	88%
Technical Saturations (units* per square foot)	62%**
Incomplete Factor (% of applicable floor space without the efficiency measure already installed)	29%

*"Units," in the context of the tech saturation, are the units in which costs are specified. If costs are in tons, tech saturations are tons per square foot; if costs are per horsepower, tech saturations are HP per square foot.

**An additional 24% of the technology saturations were "by definition." For example, if costs were expressed per square foot of building area, the tech saturation is always one (one building square foot per building square foot). Other costs were expressed per kWh saved, which the research team calculated internally from other model inputs (percent savings and base energy use per square foot). Only 14 percent of technology saturations were from other sources.

The first and second waves of primary data collection resulted in enough National Grid specific data to inform the commercial electric, commercial gas, and industrial electric potential models. There were not enough National Grid specific data to inform the industrial gas potential model. This was a result of the primary data collection being based on a sample of electric accounts, with no specific targeting of gas accounts. After discussion with National Grid, the analysis team decided to include industrial gas data collected in other PA territories as part of the study. Table 3-2 provides a breakdown of the completed sites used in the analysis by commercial building type for customers to whom National Grid is an electric or gas provider. Table 3-3 provides a breakdown of completed Manufacturing/Industrial sites used in the analysis by fuel type and National Grid/non-National Grid, where applicable.

Table 3-2: Breakdown of Utilized EM&V Project 41 Commercial Site Visits

Building Type	Commercial Electric	Commercial Gas
Campuses	9	6

Retail	30	17
Warehouse	9	3
Total	*231*	*168*

Table 3-3: Breakdown of Utilized EM&V Project 41 Industrial Site Visits

Program Administrator	Industrial Electric	Industrial Gas
National Grid	26	13
Non-National Grid	N/A	26
Total	*26*	*39*

3.3 Additional Data Sources

In addition to EM&V Project 41, DNV GL used additional data sources to inform certain inputs of the potential study model that could not be ascertained through the aforementioned data collection efforts. This section outlines those sources, and how they were used in the modeling process.

3.3.1 Measure Data

Several secondary data sources provided insight on measure-level energy usage and savings potential, measure costs and lifetimes, and the current penetration of various efficiency measures. DNV GL reviewed a variety of data sources for this information with the aim to find data that was specific to

National Grid's service territory or geographic location as much as possible. The sources listed below provided information for these inputs:

- EIA Commercial Buildings Energy Consumption Survey (CBECS)
- National Grid 2013 and 2014 Program Tracking Data
- Massachusetts Technical Reference Manuals (TRMs) including the 2013-2015 Plan TRM, and 2013 and 2014 Report TRMs.
- Professional judgment of DNV GL analysts and engineers with experience in National Grid's service territory
- National Grid and Massachsetts PA EM&V Results
- Gas Networks studies
- TRMs from other states

3.3.2 Economic Data

Economic inputs from National Grid's service territory were used to provide a more accurate picture of the monetary cost and benefits associated with energy efficiency. National Grid provided data to support the following model requirements:

- Inflation Rate
- Utility Discount Rate
- Avoided Energy and Demand Cost Forecasts from the 2015 Avoided Energy Supply Component Study (2015 AESC).
- Retail Electric and Gas Rate Forecasts

3.3.3 Building Data

National Grid's Customer Analytics group provided a wealth of detailed customer information. They matched customer data to tax record information and data from other sources to identify building types with greater accuracy than that provided by the NAICS codes in the customer billing database. In particular, the tax record data provided building square footage, which allowed the analysis team to develop estimates of energy intensity by building type. As energy use per square foot is a key input to the model, having the information at this level of resolution and accuracy enhanced the overall accuracy of the potential estimates.

The total energy use from the customer analytics data accounted for only about 2/3 of National Grid's total energy sales for both gas and electric, for reasons the analysis team was unable to resolve with customer analytics staff. The team extrapolated the breakdown of energy use across building types from the customer analytics sample to the entire population, and estimated square footage for the missing customers by assuming that the energy intensity was the same (by building type) for the missing customers as for the customer analytics sample. The resulting forecast aligned with National Grid's load forecast.

3.3.4 Program Budgets

As part of the potential modeling process, past and projected program budgets were used to as a starting point for the achievable potential analysis which estimates the market penetration of measures as a function of marketing, incentive levels and other factors.[7] To help calibrate the achievable modeling efforts, past National Grid program budgets were used to gauge the range of program costs in the National Grid's service territory. Specifically, marketing and administrative dollars were two inputs into the model that were derived from National Grid's 2014 Plan Year Report Benefit Cost Model provided to DNV GL. Table 3-4 outlines the data that DNV GL reviewed for this effort.

Table 3-4: National Grid 2014 Plan Year Report Budget Summary Definitions

National Grid Screening Model Budget Summary	DNV GL Funding Designation
A001 - Program Planning & Administration	Admin
A002 - Marketing	Marketing
A003 - Customer Incentive	Incentive dollars
A004 - Sales, Tech Assist & Training	Marketing
A005 - Evaluation & Market Research	Admin

[7] The methodology of calculation measure penetration is described in more detail in Section 4 and Appendix A

4. ENERGY EFFICIENCY METHODS

This section provides a brief overview of the concepts, methods, and scenarios used to conduct this study.

4.1 Characterizing the Energy Efficiency Resource

Energy efficiency has been characterized for some time now as an alternative to energy supply options, such as conventional power plants that produce electricity from fossil or nuclear fuels. In the early 1980s, researchers developed and popularized the use of a conservation supply-curve paradigm to characterize the potential costs and benefits of energy conservation and efficiency. Under this framework, technologies or practices that reduced energy use through efficiency were characterized as making the energy saved available to meet other demands, and could therefore be thought of as a resource and plotted on an energy supply curve. The energy efficiency resource paradigm argued simply that the more energy efficiency or "nega-watts"[8] produced, the fewer new plants would be needed to meet end-users' power demands.

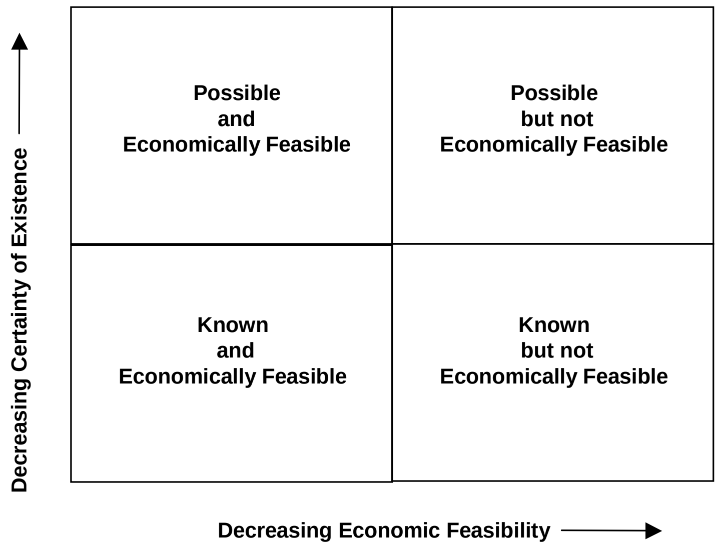
4.2 Defining Energy Efficiency Potential

Energy efficiency potential studies became popular throughout the utility industry from the late 1980s through the mid-1990s. This period coincided with the advent of what was called least-cost or integrated resource planning (IRP). Energy efficiency potential studies became one of the primary means of characterizing the resource availability and value of energy efficiency within the overall resource planning process.

Like any resource, there are a number of ways in which the energy efficiency resource can be estimated and characterized. Definitions of energy efficiency potential are similar to definitions of potential developed for finite fossil fuel resources, like coal, oil, and natural gas. For example, fossil fuel resources are typically characterized along two primary dimensions: the degree of geological certainty with which resources may be found, and the likelihood that extraction of the resource will be economic. This relationship is shown conceptually in Table 4-1.

[8] Term coined by environmental scientist Amory Lovins in 1989.

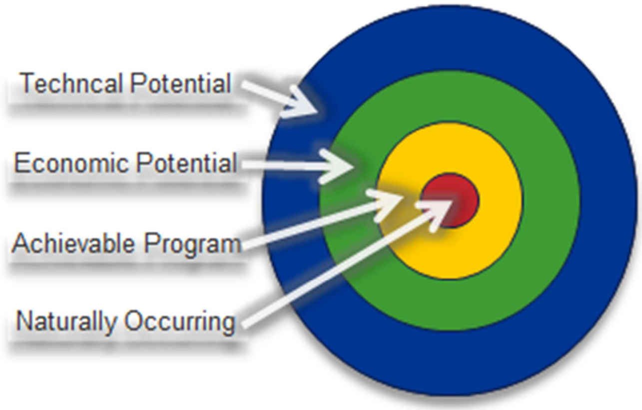
Table 4-1: Conceptual Framework for Estimates of Fossil Fuel Resources



Somewhat analogously, this energy efficiency potential study defines several different *types* of energy efficiency *potential*, namely technical, economic, achievable program, and naturally occurring. These potentials are shown conceptually in Figure 4-1 and described below.

- **Technical potential** is defined in this study as the *complete* penetration of all measures analyzed in applications where they were deemed *technically* feasible from an *engineering* perspective.
- **Economic potential** refers to the *technical potential* of those energy conservation measures that are cost effective when compared to supply-side alternatives.
- **Achievable program potential** refers to the amount of savings that would occur in response to specific program funding and measure incentive levels. Savings associated with program *achievable potential* are savings that are projected beyond those that would occur naturally in the absence of any market intervention.
- **Naturally occurring potential** refers to the amount of savings estimated to occur as a result of normal market forces; that is, in the absence of any utility or governmental intervention.

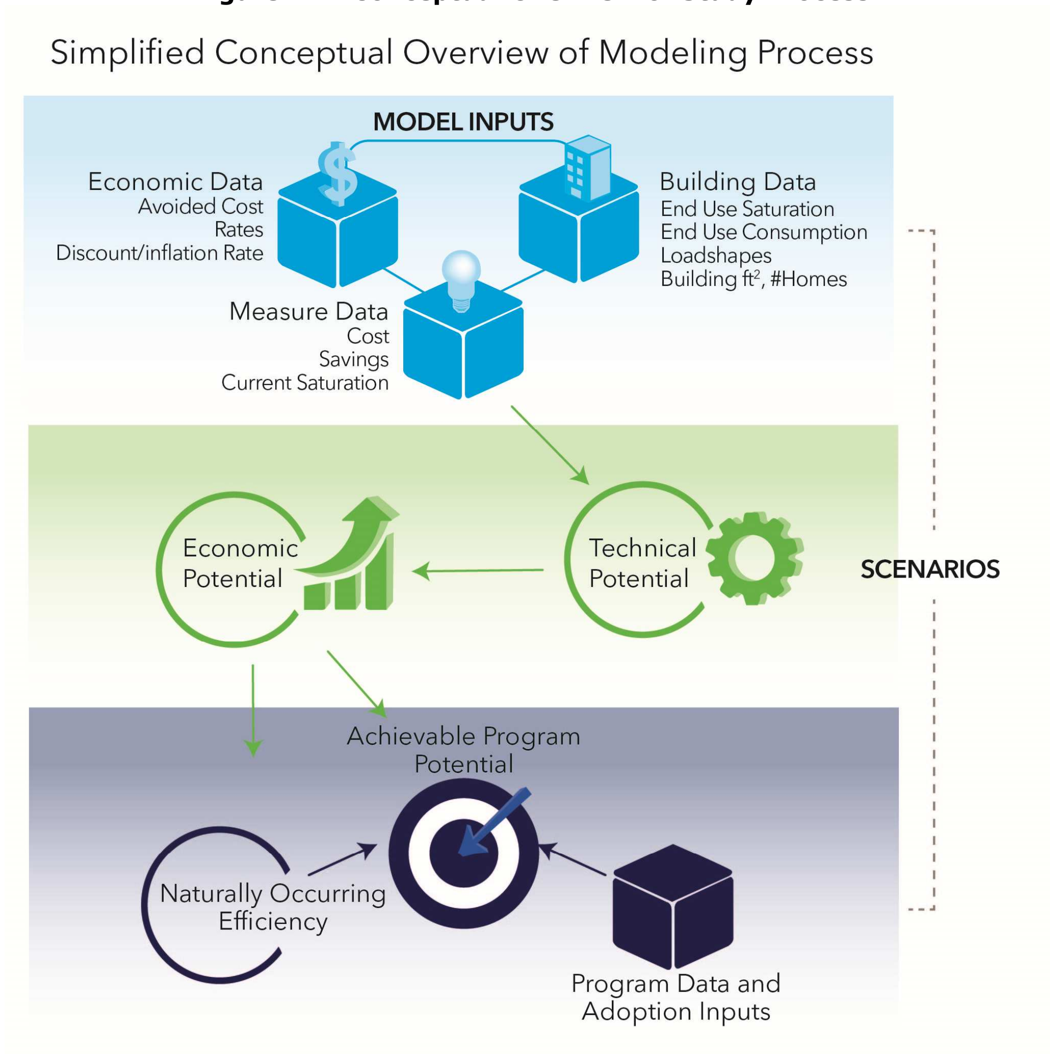
Figure 4-1: Conceptual Relationship among Energy Efficiency Potential Definitions



4.3 Summary of Analytical Steps Used for the Energy Efficiency Potential

The crux of this study involves carrying out a number of basic analytical steps to produce estimates of the energy efficiency potentials introduced above. The basic analytical steps for this study are shown in relation to one another in Figure 4-2. The bulk of the analytical process for this study was carried out in a model developed by DNV GL for conducting energy efficiency potential studies. Details on the steps employed and analyses conducted are described in Appendix A. The study integrates technology-specific engineering and customer behavior data with utility market saturation data, load shapes, rate projections, and marginal costs into an easily updated data management system.

Figure 4-2: Conceptual Overview of Study Process



The key steps implemented in this study are:

Step 1: Develop Initial Input Data

- Develop a list of energy efficiency measure opportunities to include in scope. In this step, an initial draft measure list was developed and provided to National Grid. The final measure list was developed after incorporating comments.
- Gather and develop technical data (costs and savings) on efficient measure opportunities. Data on measures were gathered from a variety of sources. Measure inputs are provided in Appendix E.
- Gather, analyze, and develop information on building characteristics, including total square footage, energy consumption and intensity by end use, end-use consumption load patterns by time of day and year (i.e., load shapes), market shares of key electric consuming equipment, and market shares of energy efficiency technologies and practices. Section 5 of this report describes the baseline data developed for this study.
- Collect data on economic parameters: avoided costs, electricity rates, discount rates, and inflation rate. These inputs are provided in Appendix C of this report.

Step 2: Estimate Technical Potential and Develop Supply Curves

- Match and integrate data on efficient measures to data on existing building characteristics to produce estimates of technical potential and energy efficiency supply curves.

Step 3: Estimate Economic Potential

- Match and integrate measure and building data with economic assumptions to produce indicators of costs from different viewpoints (e.g., societal and consumer).
- Account for interaction and competition between measures. Measures are assumed to be implemented in order of cost-effectiveness, with the most cost-effective measures implemented first. If subsequent measures are mutually exclusive with previous measures (for example, CFL and LED lamps competing for the same socket), the subsequent measure is evaluated on its marginal costs and marginal savings compared to the more cost-effective measure.
- Estimate total economic potential. Note that at this stage of the analysis, program-related costs are not factored into the cost-effectiveness screening. Thus, the results reflect the theoretical estimate of the measure impacts, while disregarding the mode of delivery. In addition, this step does not take into account natural measure turnover and instead assumes that all available measure installations occur immediately in year one.

Step 4: Estimate Achievable Program and Naturally Occurring Potentials

- Screen initial measures for inclusion in the program analysis. This screening may take into account factors such as natural measure turnover, cost effectiveness, potential market size, non-energy benefits, market barriers, and potentially adverse effects associated with a measure. For this study, measures were screened using the total-resource-cost test, with the exclusion of program marketing and administrative costs.
- Gather and develop estimates of program costs (e.g., for administration and marketing) and historic program savings.
- Develop estimates of customer adoption of energy efficiency measures as a function of the economic attractiveness of the measures, barriers to their adoption, and the effects of program intervention.
- Estimate achievable program and naturally occurring potentials and associated program costs.

Step 5: Scenario Analyses

- Recalculate potentials under alternate program scenarios. These scenarios relate to different levels of incentives offered to participants for energy efficiency measures. See Appendix A for further discussion on how program scenarios were run.

4.4 Estimating Achievable Potential

At the core of the achievable analysis is an adoption model that applies equally to the program and naturally occurring analyses. Whether as a result of natural market forces or aided by a program intervention, the rate at which measures are adopted are modeled is a function of the following factors:

- The availability of the adoption opportunity as a function of capital equipment turnover rates and changes in building stock over time
- Customer awareness of the efficiency measure
- The cost-effectiveness of the efficiency measure
- Market barriers associated with the efficiency measure.

The paragraphs below provide an overview of the adoption approach. The modeling approach is discussed in greater detail in Appendix A.

4.4.1 Availability

A crucial part of the model is a stock accounting algorithm that handles capital turnover and stock decay over a period of up to 20 years. In the first step of the achievable potential method, the model calculates the number of customers for whom each measure will apply. The input to this calculation is the total floor space available for the measure from the technical potential analysis, i.e., the total floor space multiplied by the applicability, not complete, and feasibility factors described previously. This is referred to as the eligible stock. The stock algorithm keeps track of the amount of floor space available for each efficiency measure in each year based on the total eligible stock and whether the application is new construction, retrofit, or replace-on-burnout.[9]

Retrofit measures are available for implementation by the entire eligible stock. The eligible stock is reduced over time as a function of adoptions[10] and building decay.[11] Replace-on-burnout measures are available only on an annual basis, approximated as equal to the inverse of the service life.[12] The annual portion of the eligible market that does not accept the replace-on-burnout measure does not have an opportunity again until the end of the service life.

New construction applications are available for implementation in the first year. Those customers that do not accept the measure are given subsequent opportunities corresponding to whether the measure is a replacement or retrofit-type measure.

[9] Replace-on-burnout measures are defined as the efficiency opportunities that are available only when the base equipment turns over at the end of its service life. For example, a high-efficiency chiller measure is usually only considered at the end of the life of an existing chiller. By contrast, retrofit measures are defined to be constantly available, for example, application of a window film to existing glazing.

[10] That is, each square foot that adopts the retrofit measure is removed from the eligible stock for retrofit in the subsequent year, and remains out of the eligible stock until the end of the measure's useful life.

[11] Buildings do not last forever. An input to the model is the rate of decay of the existing floor space. Floor space typically decays at a very slow rate.

[12] For example, a base-case technology with a service life of 15 years is only available for replacement to a high-efficiency alternative each year at the rate of 1/15 times the total eligible stock. For example, the fraction of the market that does not adopt the high-efficiency measure in year *t* will not be available to adopt the efficient alternative again until year *t* + 15.

4.4.2 Awareness

In the modeling framework, customers cannot adopt an efficient measure merely because there is stock available for conversion. Before they can make the adoption choice, they must be aware and informed about the efficiency measure. Thus, in the second stage of the process, the study calculates the portion of the available market that is informed. An initial user-specified parameter sets the initial level of awareness for all measures. Incremental awareness occurs in the model as a function of the amount of money spent on awareness/information building and how costly it is to reach each customer.

The study also controls for information retention. An information decay parameter in the model is used to control for the percentage of customers that will retain program information from one year to the next. Information retention is based on the characteristics of the target audience and the temporal effectiveness of the marketing techniques employed.

4.4.3 Adoption

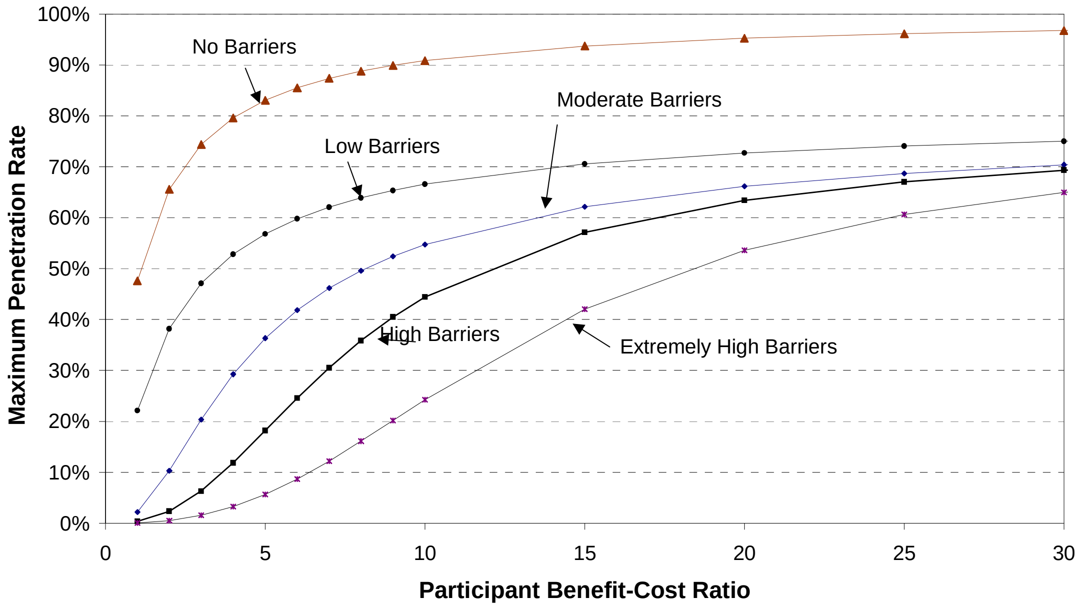
The portion of the total market that is available and informed can now face the choice of whether or not to adopt a particular measure. Only those customers for whom a measure is available for implementation (stage 1) and, of those customers, only those who have been informed about the program/measure (stage 2), are in a position to make the implementation decision.

In the third stage of the penetration process, the study calculates the fraction of the market that adopts each efficiency measure as a function of the participant test, which a benefit-cost ratio that compares the present value of customer bill savings to the present value of participant costs.

The study uses measure implementation curves to estimate the percentage of the informed market that will accept each measure based on the participant's benefit-cost ratio. The study provides enough flexibility so that each measure in each market segment can have a separate implementation rate curve.

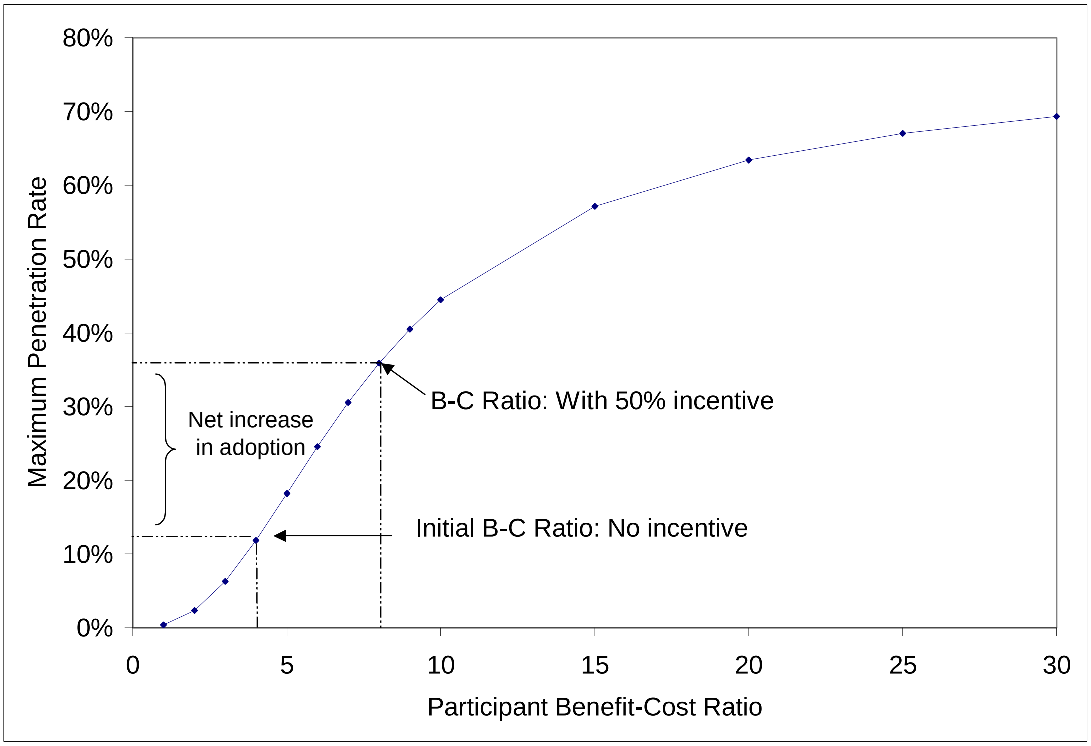
Figure 4-3 shows examples of the form of the adoption curve used in the model. The different curves represent different levels of market barriers. The research team calibrated the curves used in the model (by changing parameters representing market barriers) to produce base year program results that are calibrated to actual measure implementation results associated with National Grid's commercial efficiency programs over the past several years. Different curves are used to reflect different levels of market barriers for different efficiency measures.

Figure 4-3. Primary Measure Implementation Curves Used in Adoption Model



The study estimates adoption under both naturally occurring and program intervention situations. There are only two differences between the naturally occurring and program analyses. First, in any program intervention case in which measure incentives are provided, the participant benefit-cost ratios are adjusted based on the incentives. Thus, if an incentive that pays 20 cents per kWh saved is applied in the program analysis, the participant benefit-cost ratio will increase, since the incentive offsets part of the cost. The effect on the amount of adoption estimated will depend on where the pre- and post-incentive benefit-cost ratios fall on the curve. This effect is illustrated in Figure 4-4.

Figure 4-4. Illustration of Effect of Incentives on Adoption Level as Characterized in Implementation Curves



5. ENERGY EFFICIENCY RESULTS

5.1 Energy Efficiency Baseline Analysis

This section presents a baseline analysis of energy use in National Grid Massachusetts' service territory. The purpose of this analysis is to provide a breakout of energy use by sector, building type and end use to provide a foundation for estimating demand side management /energy efficiency potentials.

5.1.1 Commercial End-Use Saturations - Electricity

As stated above, most (91 percent) of the equipment saturations (percent of commercial square footage having a specific end use) were calculated from the results of EM&V Project 41, using National Grid data. The exceptions are parking garage lighting, where the team used saturations from a 2012 DNV GL study conducted in Minnesota, and miscellaneous equipment, which were assumed to have 100 percent saturation. Four other saturations (office ventilation, and three lighting types in "other" buildings) were increased from the P41 values based on expert judgment, as they produced overall energy distributions inconsistent with the expectations of National Grid program staff.

The saturations used in the analysis are shown in Table 5-1. In some cases, the saturations may seem mutually inconsistent, such as when the saturations across lighting types add up to more than 100%. Any particular building area may be illuminated by more than one type of lighting, for example an office area with both fluorescent troffers and desk lamps designed for screw-based lamps. The study also accounts for the number of lamps of each particular type per applicable square foot (called the technology saturation, which can be thought of as an equipment density). The combination of the saturations below with the equipment densities gives a complete picture of the mix of equipment.

Table 5-1: Commercial Electric End-Use Saturations by Base Measure

End-use Saturations	Cam-pus	Educa-tion	Food Sales	Food Service	Health care	Hosp-itals	Lodg-ing	Office	Other	Public Assem-bly	Retail	Ware-house

5.1.2 Commercial End-Use Saturations - Natural Gas

Most (92 percent) of the gas equipment saturations (percent of commercial square footage having a specific end use) were calculated from the results of EM&V Project 41, using National Grid data. The exception is miscellaneous gas uses, where the research team used saturations from a 2012 DNV GL study conducted in Minnesota. The saturations used in the analysis are shown in Table 5-2.

Table 5-2: Commercial Natural Gas End-Use Saturations by Base Measure

5.1.3 Commercial End-Use Energy Intensities

The second major component of the baseline analysis is end-use energy intensity for each type of base equipment. This is the energy consumed per square foot of floor space having that equipment type. When used in the model, this is multiplied by the saturation-weighted floor space, not total floor space.

National Grid's Customer Analytics Group was able to provide detailed information about the building activity and floor space associated with each customer account for electricity and for industrial gas. This data was assembled from a variety of data sources, including property tax information. DNV GL used this data to calculate total building square feet and total electricity and natural gas use by building type, and from those overall energy intensities by building type. While the Customer Analytics data only accounted for about 2/3 of total non-residential electricity use, 80 percent of industrial gas use, and 17 percent of commercial gas use, the research team assumed that the energy intensity for the missing customers was similar to those of the customers for which there was data.

This overall energy intensity provided a calibration target against which to calibrate the end-use energy intensities. In order for the baseline analysis to represent National Grid's non-residential loads, the saturation-weighted end-use energy intensities for each building type had to add up to the overall target energy intensities.

To help with the breakout by end-use, DNV GL conducted building simulations of nine building prototypes using EnergyPlus, from which the research team calculated end-use energy intensities for the prototypes. In few cases were these intensities used directly in the model, as the team needed to ensure consistency with the target energy intensities. However, the team did rely on the simulations to guide allocations of energy between different end uses.

5.1.3.1 Electric

Table 5-3 shows the end-use electricity intensities for the commercial sector by base measure. Remember that these represent the energy use per square feet for businesses that have that end-use (for example, chiller annual kWh for non-Residential square feet with chillers). Because the saturation for each type of equipment is different, these values are not additive unless weighted by the equipment saturations. The bottom row of the table, whole building, corresponds to the overall target energy intensities from the Customer Analytics data.

Table 5-3: Commercial Electric End-Use Energy Intensities (kWh/sq ft with end-use)

5.1.3.2 Natural Gas

Customer Analytics data for commercial natural gas customers accounted for only 17 percent of commercial use. DNV GL therefore turned to a straightforward billing analysis to break out gas use by building type, relying on the NAICS codes in the billing data to identify building activity. Lacking any other data on square footage, however, the research team did use the energy intensities developed from the Customer Analytics data set to extrapolate to the population.

Table 5-4 shows the natural gas end-use energy intensities for the commercial sector by base measure. As with electric, these represent the energy use per square feet for businesses that have that end-use. Because the saturation for each type of equipment is different, these values are not additive unless weighted by the equipment saturations. The bottom row of the table, whole building, corresponds to the overall target energy intensities from the Customer Analytics data.

Table 5-4: Commercial Natural Gas End-Use Energy Intensities (kBtu/sq ft with end-use)

5.1.4 Commercial Energy Use - Electricity

Energy use was calculated as the product of the number of square feet by building type, equipment saturation, and the end-use energy intensity. Energy use by building type and end-use is shown in Table 5-5. The breakdown is calibrated so that the resulting total energy use, 9,081,305 MWh, corresponds to National Grid's commercial load forecast.

The square footage by building type was developed from the Customer Analytics data discussed above. As previously noted the Customer Analytics data set represented only about 2/3 of the total energy use, and researchers assumed that the missing floor space had a similar distribution and similar energy intensities to the included customers. DNV GL used available data on total energy sales in conjunction with the energy intensities to extrapolate total square footage.

Table 5-5: Commercial Electric Floor Space (1000 sq ft) and Energy Use (MWh) by Building Type and End-Use

	Campus	Edu-cation	Food Sales	Food Service	Health-care	Hos-pitals	Lodging	Office	Other	Public Assem-bly	Retail	Wareho use	Total

Figure 5-1 and Figure 5-2 show the breakout of commercial electricity use by building type and end use, respectively.

Figure 5-1: Commercial Electric Energy Use by Building Type (GWh)

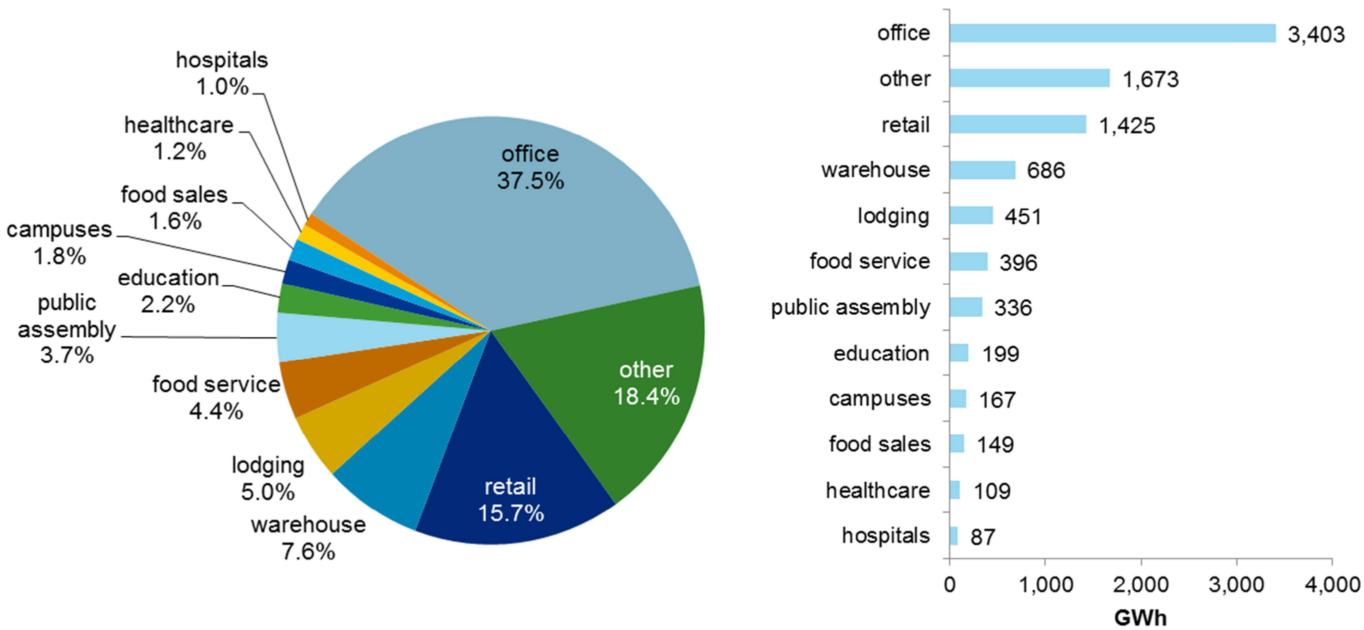

Figure 5-2: Commercial Electric Energy Use by End-Use (GWh)

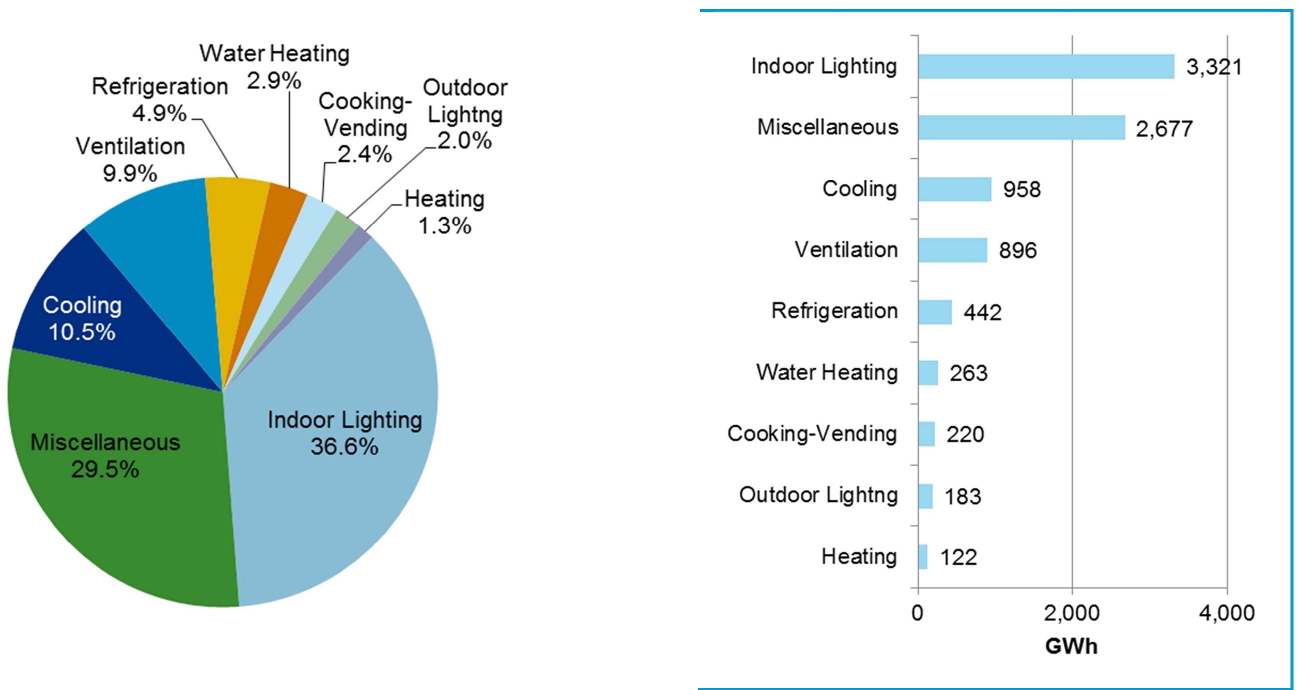

5.1.5 Commercial Energy Use - Natural Gas

Natural gas use was calculated as the product of the number of square feet by building type, equipment saturation, and the end-use energy intensity. Energy use by building type and end-use is shown in Table 5-6. The breakdown is calibrated so that the resulting total energy use, 410,958,773 therms, corresponds to the commercial portion of sales from National Grid's billing database.

The square footage by building type was developed from the Customer Analytics data discussed above. As previously noted the Customer Analytics data set represented only a very small share (17 percent) of the total natural gas use in the commercial sector. However, alternative sources for data on floor space (such as using data from the Department of Energy's Commercial Building Energy Consumption Survey) did not offer any higher level of reliability. Lacking better data, researchers assumed that the missing floor space had similar energy intensities to the included customers. DNV GL used available data on total energy sales from the billing data in conjunction with the energy intensities to extrapolate total square footage.

5.1.6 Commercial Electric Peak Demand

Annual 8,760 hourly data from National Grid was combined with end-use load shape data from DNV GL's end-use databases to allocate annual energy usage by building type into time-of-use (TOU) periods. Commercial summer peak demand intensities (kW per square foot) are shown in Table 5-7, and estimates of total summer peak demand by segment and end use are summarized in Table 5-8.

Table 5-7: Commercial Electric Demand Intensity by Building Type and End Use (kW/sq ft)

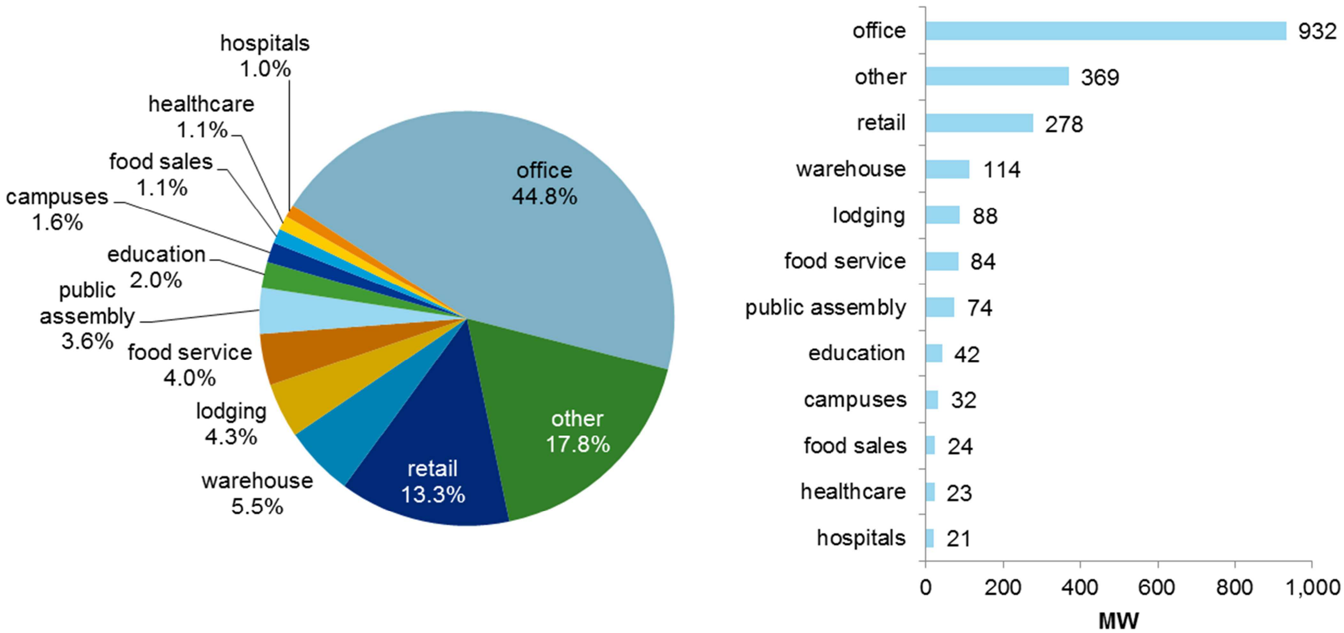

Figure 5-6: Commercial Peak Demand by End-Use (MW)

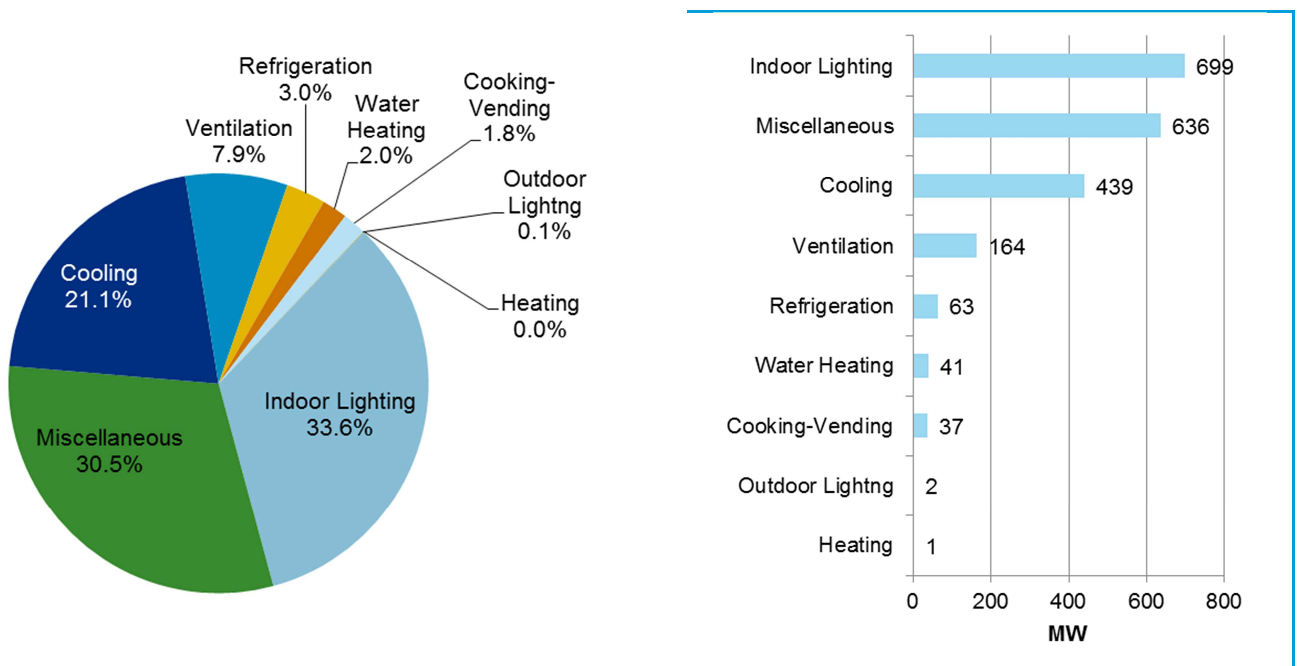

5.1.7 Industrial Baseline

The sample size of industrial buildings from Project 41 did not support statistically reliable estimates at the industry level. Without data to support a breakout, DNV GL analyzed industry as a single category for this study. National Grid's industrial electric customer mix includes a variety of industries including computers and electronics, plastics, fabricated metals, and food production.

5.1.7.1 Industrial Equipment Saturations - Electricity

The equipment saturations (percent of industrial square feet having an end use) were calculated primarily from the results of the EM&V Project 41 on-sites, using National Grid data. The exception was other process, which DNV GL drew from an on-site study conducted in Minnesota in 2012. The resulting saturations are shown in Table 5-9.

Table 5-9: Summary of Industrial Electric Equipment Saturations

	Saturation
Base Compressed Air	63.6%
Base Non-Cycling refrigerated air dryer	24.6%
Base <5 HP drive/fan/motor	35.0%
Base 6-20 HP drive/fan/motor	32.1%

5.1.7.2 Industrial Equipment Saturations - Natural Gas

The equipment saturations (percent of industrial square feet having an end use) were calculated primarily from the results of the EM&V Project 41 on-sites, using National Grid data. The exception was CHP, which is not analyzed in the study but is included to get a complete picture of how natural gas is being used in the industrial sector (CHP total energy use is from an Energy Information Administration source and is independent of the saturation). The resulting saturations are shown in Table 5-10.

Table 5-10: Summary of Industrial Natural Gas Equipment Saturations

Base Other	25%
Base Whole Facility	100%

5.1.7.3 Industrial End-Use Energy Intensities - Electricity

Table 5-11 shows the end-use electricity intensities (EUIs) for the industrial sector by base measure. EUIs were developed from a variety of sources. Some were developed using a bottom-up approach based on wattage (lighting) or horsepower (motors), hours of use, load factors, and equipment densities from the EM&V Project 41 surveys. For process end uses, DNV GL relied on data from the 2013 Manufacturer End-Use Consumption Survey (MECS) conducted by the Energy Information Administration.

As with commercial, the end-use energy intensities apply to floor space identified as having the measure, and are applied to saturation-weighted square footage rather than total square footage.

Table 5-11: Industrial Electric End-Use Energy Intensities (kWh per End-Use Square Foot)

	kwh/sq ft
Base Compressed Air	1.35
Base Non-Cycling refrigerated air dryer	0.05

Base HVAC	0.98
Base CHP	2.19
Base Other	0.30
Base Whole Facility	2.00

5.1.7.5 Industrial Building Stock and Energy Use - Electricity

DNV GL used the 2010 MECs data to estimate the energy use by end use. The resulting total energy use, 3,154,169 MWh, corresponds to National Grid's commercial load forecast. As shown in Figure 5-7, motors and drives account for the largest portion of industrial sector electricity consumption.

As with the commercial sector, DNV GL used the data from Customer Analytics to estimate industrial floor space.

Table 5-13: Industrial Electric Floor Space (1000 sq ft) and Energy Use (GWh) by End-Use

	All Industrial
1000 sq ft	168,943
	MWh
Base Compressed Air	145,166

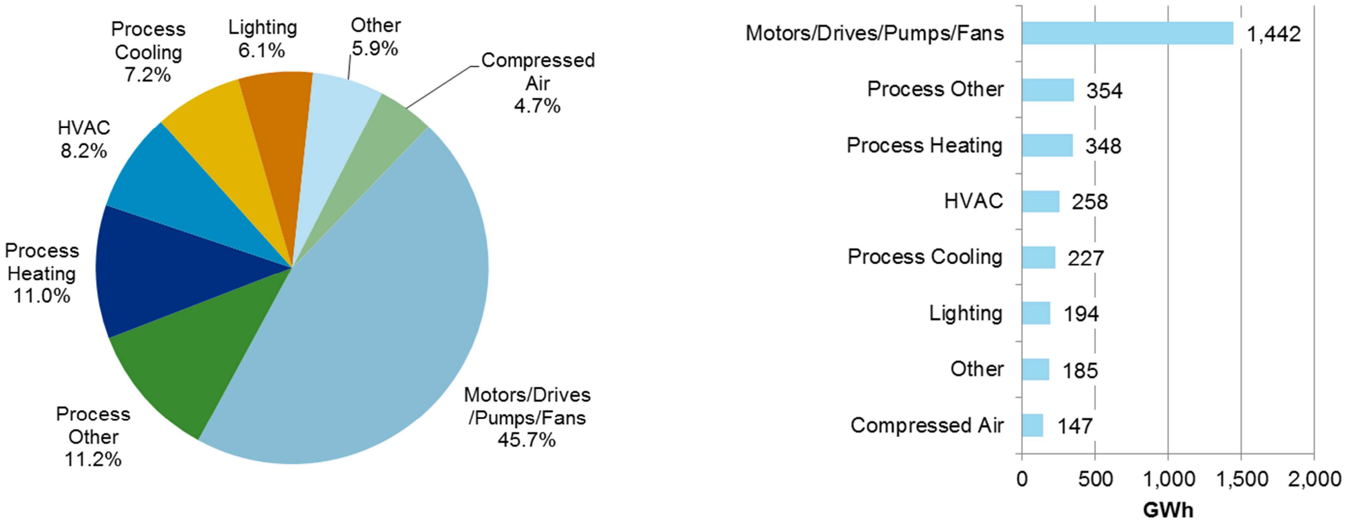
Figure 5-7: Industrial Electric Energy Use by End-Use (GWh)



5.1.7.6 Industrial Building Stock and Energy Use - Natural Gas

DNV GL used the 2010 MECs data to estimate the energy use by end use. The resulting total energy use, 65,247,603 therms, corresponds to the industrial portion of sales from National Grid's billing database. As shown in Figure 5-8, process heat accounts for the majority of industrial sector electricity consumption.

As with the commercial sector, DNV GL used the data from Customer Analytics to estimate industrial floor space. In contrast to the commercial gas sector, the Customer Analytics data accounted for a large share (81 percent) of industrial natural gas use.

Table 5-14: Industrial Natural Gas Floor Space (1000 sq ft) and Energy Use (Therms) by End-Use

	All Industrial

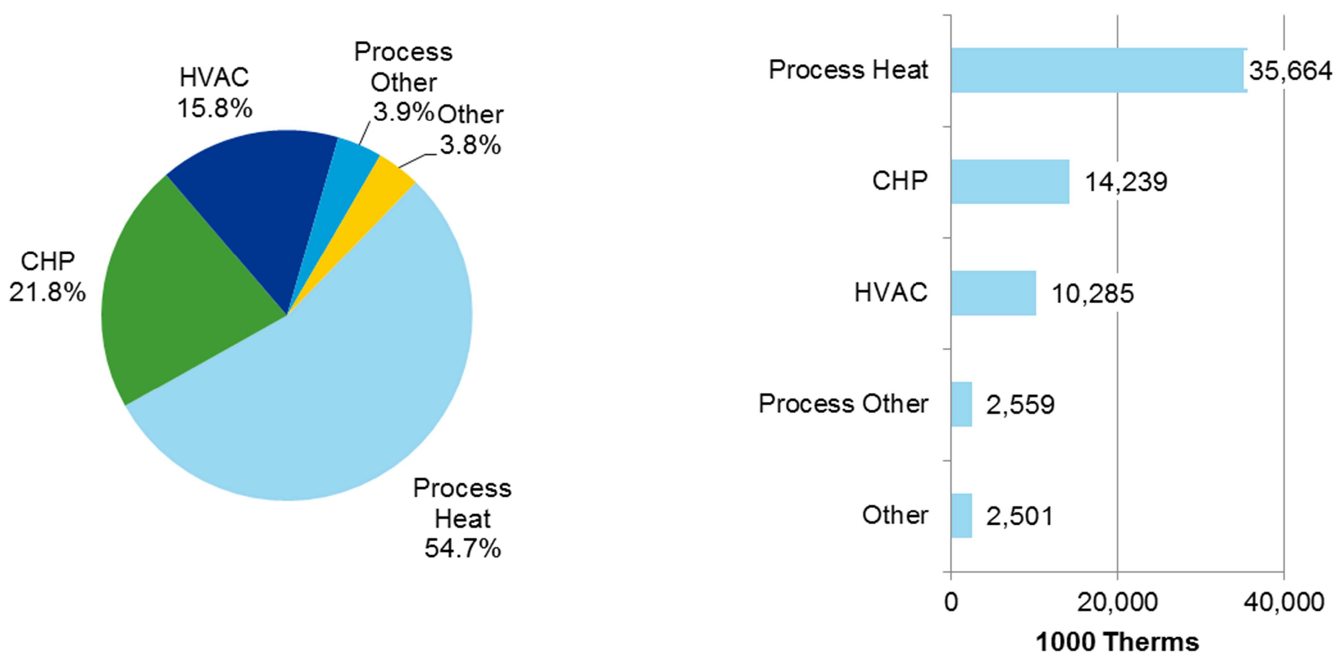
Base Whole Facility	65,247,603

Figure 5-8: Industrial Energy Use by End-Use (Thousand Therms)



5.1.7.7 Industrial Electric Peak Demand

Similar to the commercial sector, National Grid's annual hourly 8,760 load data was combined with non-residential end-use load shapes from DNV GL's end-use databases to allocate annual energy usage to time-of-use (TOU) periods. DNV GL also used the load shape data to develop factors relating peak demand to average energy by TOU period, then used these factors to convert summer peak period energy use to summer peak demand. Non-residential peak demand intensity (kw per square foot) is summarized in Table 5-15, and overall peak demand by end use is summarized in Table 5-16.

5.2 Technical and Economic Potential Results

This section contains a summary of findings from the analysis of technical and economic savings potential of electric energy efficiency efforts in National Grid's Massachusetts service territory. Technical potential is defined as the complete and immediate penetration of all measures analyzed in applications where they were deemed technically feasible from an engineering perspective. Economic potential is defined as the technical potential of those energy conservation measures that are cost-effective when compared to supply-side alternatives. All measures with a TRC greater than one are considered to have economic potential.

In the bottom-up modeling approach, analysts first estimate technical potential for energy savings by integrating key measure and market segment parameters using the following equation:

Equation 1: Technical Potential of an Efficient Measure

$$\text{Technical Potential of Efficient Measure} = \text{Total sq. ft. or \# of Dwellings} \times \text{Base Case Equipment EUI or UEC} \times \text{Applicability Factor} \times \text{Not Complete Factor} \times \text{Feasibility Factor} \times \text{Savings Factor}$$

Where:

- Square feet is the total floor space for all buildings in the market segment.
- Base case equipment Energy Use Intensity (EUI) is the energy used per square foot by each base case technology in each market segment. This is the consumption of the energy-using equipment that the efficient technology replaces or affects. For example, if the

efficient measure were a screw-based LED lamp replacing a screw-based CFL, the base EUI would be the annual kWh per square foot of an equivalent CFL.

- Applicability factor is the fraction of the floor space that is applicable for the efficient technology in a given market segment; for the example above, the percentage of floor space lit by CFLs. This input was developed through results of the Project 41 on-site surveys and Baseline Analysis.
- Not complete factor is the fraction of applicable floor space that has not yet been converted to the efficient measure; that is, one minus the fraction of floor space that already has the EE measure installed. DNV GL relied on the results of the Project 41 on-site surveys to estimate this value when possible and utilized other recent saturation surveys and internal databases for other measures not included in the saturation surveys.
- Feasibility factor is the fraction of the applicable floor space that is technically feasible for conversion to the efficient technology from an engineering perspective. DNV GL engineers familiar with National Grid’s service territory reviewed these values to ensure they were consistent with National Grid’s building stock.
- Savings factor is the reduction in energy consumption resulting from application of the efficient technology. DNV GL estimated energy savings through the use of sources including Massachusetts Technical Resource Manual (TRM), other regionally appropriate TRMs, National Grid’s program tracking data, Motor Master International, the IAC Database, and other engineering calculations.

Technical potential for peak demand reduction is calculated analogously.

Economic potential is then assessed by first developing a supply-curve analysis to eliminate double counting of measure savings. On a market segment and end-use/technology basis, measures are stacked in order of cost-effectiveness, and the energy consumption of the system being affected by the efficiency measures decreases as each measure is applied. For example, if a low wattage high performance T8 lamp is more cost effective that installing occupancy sensors, then the study assumes that the lamp measure is implemented first. The savings for the occupancy sensors are then calculated as the measure being installed on the higher efficiency lamp, rather than the base lamp. Each subsequent measure takes into account the savings of the measures that preceded it. The combined savings of the lamp and occupancy sensor are the same, regardless of the implementation order, assuming both are installed. But once the first, more cost-effective, measure is installed, the less cost-effective measure may no longer pass the TRC test and would not count toward economic potential.

In addition to the question of measure ordering, some measures compete directly with each other for the same opportunity, such as screw-based CFLs and LEDs competing for the same sockets. These measures are also ordered by cost effectiveness, but in this case the less cost-effective measure is reassessed on the margin, based on the marginal costs and savings relative to the higher efficiency measure. For example, if the CFL is more cost effective, the research team then looks at the price premium of the LED compared to the CFL, and the additional savings of the LED relative to the CFL, and calculates a new TRC ratio. If the less cost-effective measure still passes the TRC test on the margin, it is included in economic potential. But note that this methodology only attributes the marginal savings to the LED, while the bulk of the savings (in this example) would be attributed to the CFL, even though it is the LED that is ultimately installed in the socket.

After eliminating double counting of savings, the benefits and costs associated with a given measure and market segment are compared using the TRC test. Measures with a TRC ratio greater than 1.0 will be passed on to the achievable potential analysis.

5.2.1 Overall Technical and Economic Potential - Electric

In this section, DNV GL present the technical and economic potential results for all electric measures considered in the study. Figure 5-10 and Figure 5-11 present the overall estimates of total technical and economic potential for electrical energy and peak demand savings for National Grid for the 2016 to 2018 and 2016 to 2025 time periods.

Figure 5-10. Estimated Electrical and Technical Economic Potential, 2016-2018

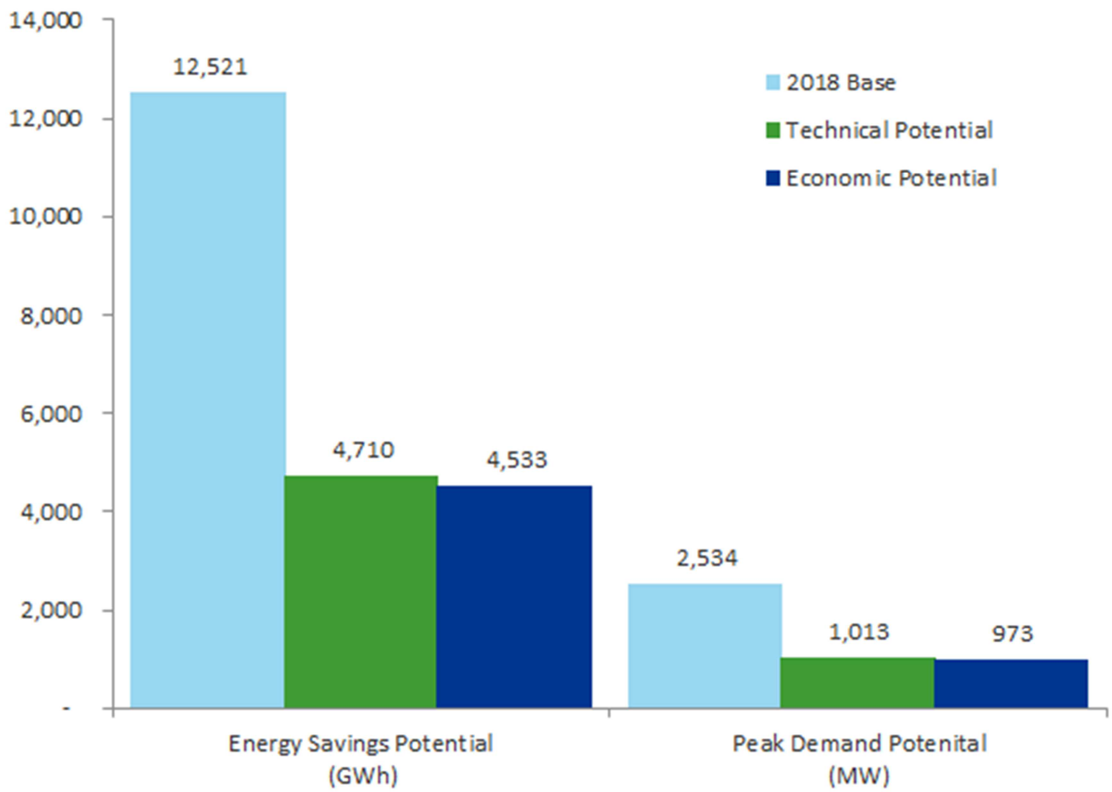

Figure 5-11: Estimated Electric Technical and Economic Potential, 2016-2025

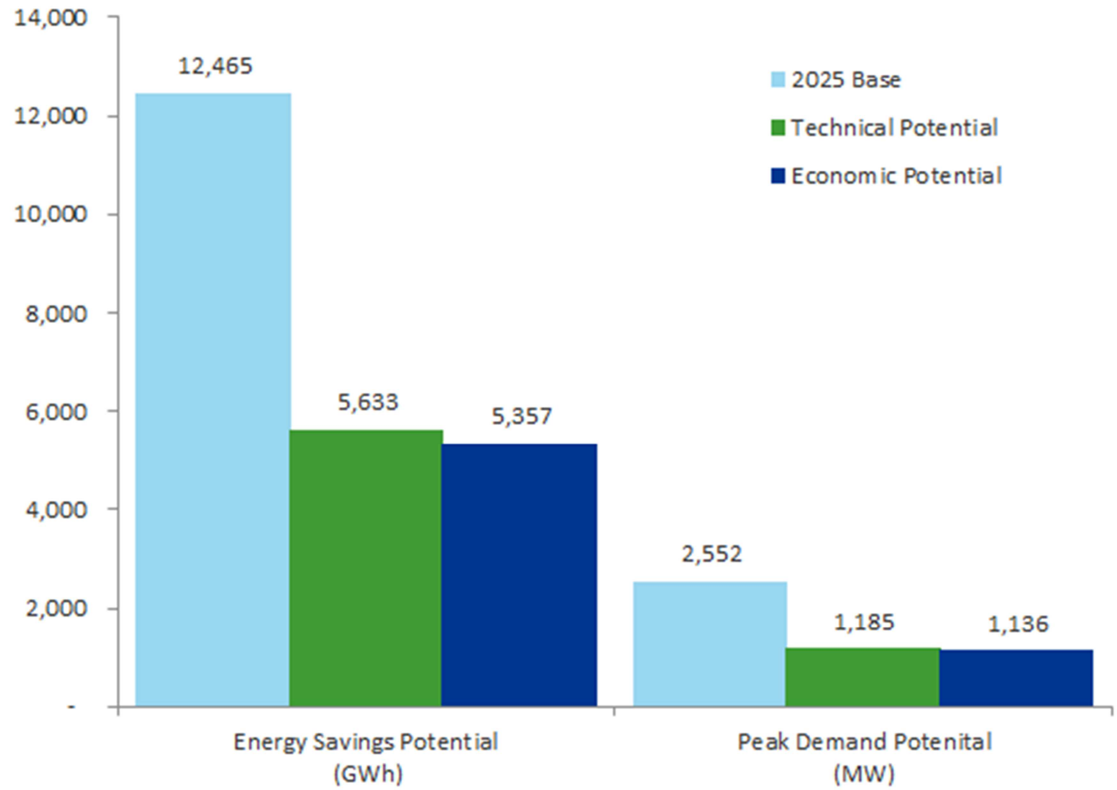

Table 5-17 and Table 5-18 show technical and economic potential for energy and demand for the 2016 to 2018 time frame, respectively. The values of both energy savings and peak-demand reductions are incorporated into the measure TRC test.

- **Energy Savings:** Technical potential is estimated at 4,710 GWh per year, and economic potential at 4,533 GWh per year by 2018 (about 38 and 36 percent of base 2018 usage, respectively).
- **Peak-Demand Savings:** Technical potential is estimated at 1,013 MW and economic potential at 973 MW by 2018 (about 24 and 23 percent of base 2018 demand, respectively).

Table 5-17: Estimated Technical and Economic Usage Savings Potential, 2016-2018 – Electric

Sector	2018 Base Usage (GWh)	Technical Potential (GWh)	Technical as Percent of Sector Base	Economic Potential (GWh)	Economic as Percent of Sector Base
Commercial	9,318	3,881	42%	3,792	41%

Industrial	399	95	24%	82	21%
Total	**2,534**	**1,013**	**40%**	**973**	**38%**

Table 5-19 and Table 5-20 show technical and economic potential for energy and demand for the 2016 to 2025 time frame, respectively. The values of both energy savings and peak-demand reductions are incorporated into the measure TRC test.

- **Energy Savings:** Technical potential is estimated at 5,633GWh per year, and economic potential at 5,357GWh per year by 2025 (about 45 and 43 percent of base 2025 usage, respectively).
- **Peak-Demand Savings:** Technical potential is estimated at 1,185 MW and economic potential at 1,136 MW by 2025 (about 39 and 37 percent of base 2025 demand, respectively).

Table 5-19: Estimated Technical and Economic Usage Savings Potential, 2016-2025 - Electric

5.2.2 Overall Technical and Economic Potential - Gas

Figure 5-12 and Figure 5-13 presents the overall estimates of total technical and economic potential for natural gas energy savings for National Grid for the 2016 to 2018 and 2016 to 2025 time periods.

Figure 5-12. Estimated Natural Gas Savings Potential, 2016-2018

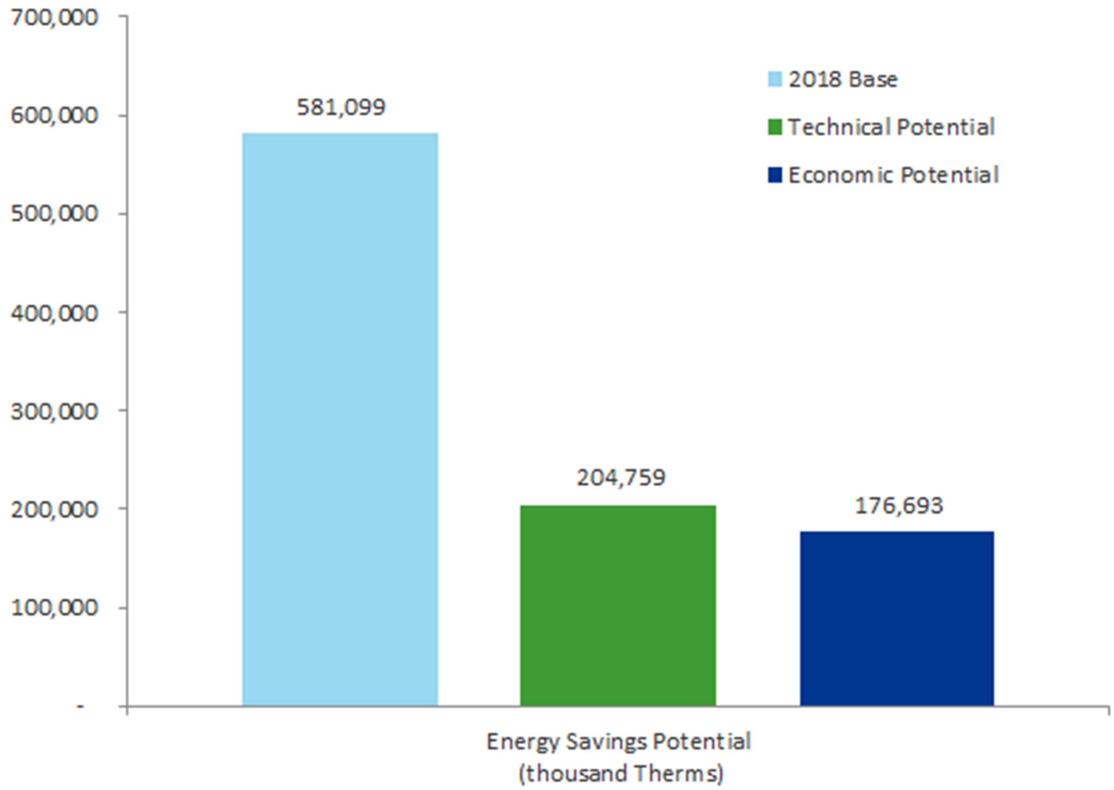

Figure 5-13. Estimated Natural Gas Technical and Economic Potential, 2016-2025

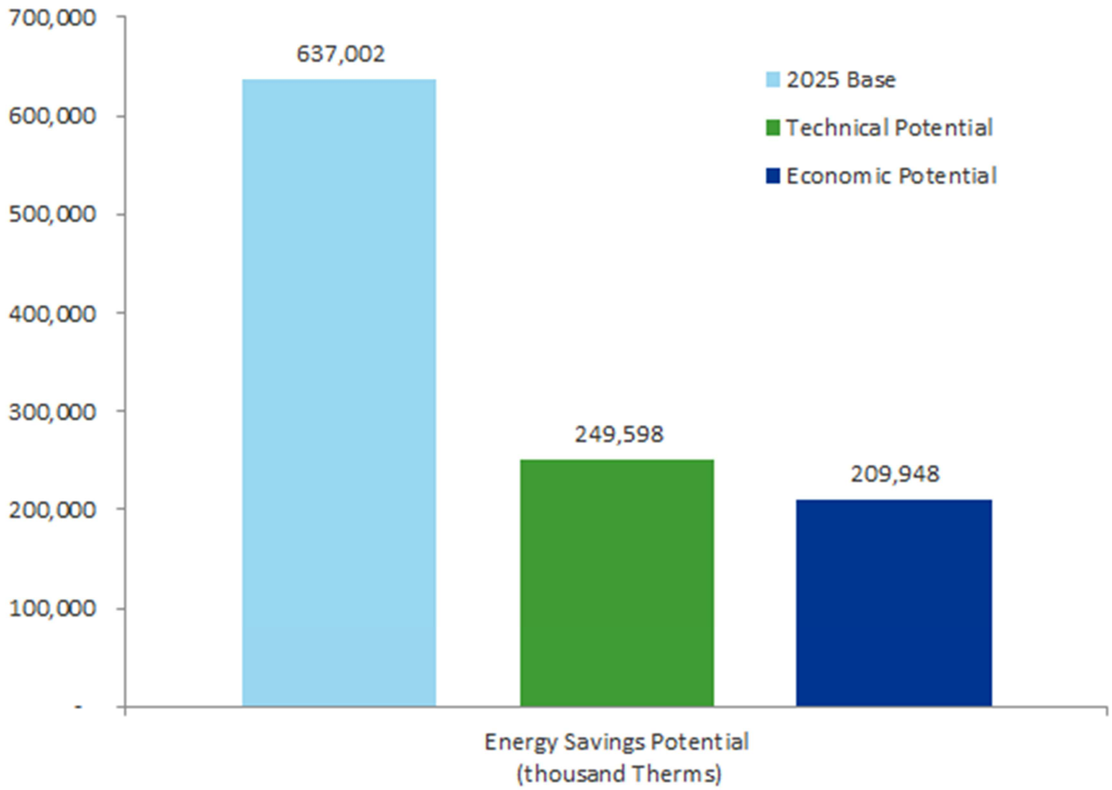

Table 5-21 and Table 5-22 show technical and economic potential for gas. The values of the energy savings are incorporated into the measure TRC test. Technical potential is estimated at 204,759 thousand therms per year, and economic potential at 176,693 thousand therms per year by 2018 (about 35 and 30 percent of base 2018 usage, respectively).

Table 5-21. Estimated Technical and Economic Demand Savings Potential, 2016-2018 – Natural Gas

5.2.3 Base Case Technical and Economic Potential Detail

This section describes technical and economic potential in more detail, and further describes potentials by sector, state, building type, and by end use.

5.2.3.1 Potentials by Sector – Electric

Figure 5-14 and Figure 5-15 present the sector (commercial vs. industrial) breakdown of technical and economic potential as compared to the total base consumption and demand in 2018, while Figure 5-16 and Figure 5-17 present the same information for the ten year time frame.

Figure 5-14: Technical and Economic Potential Energy Savings by Sector, 2016-2018 – Electric

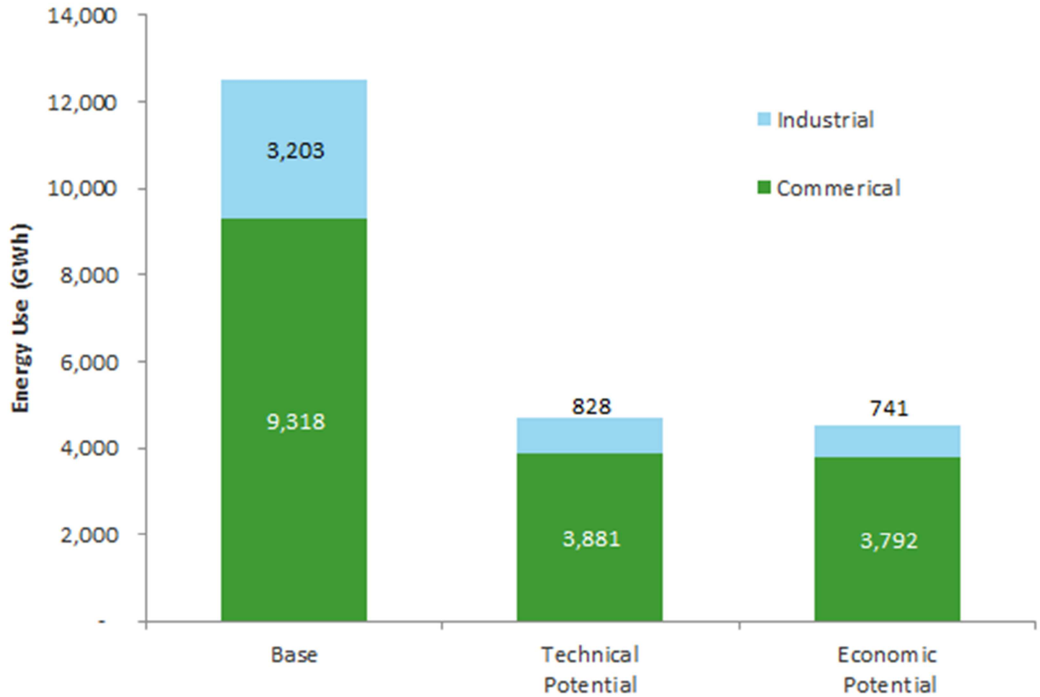

Figure 5-15: Technical and Economic Potential Peak Demand Savings by Sector, 2016-2018 – Electric

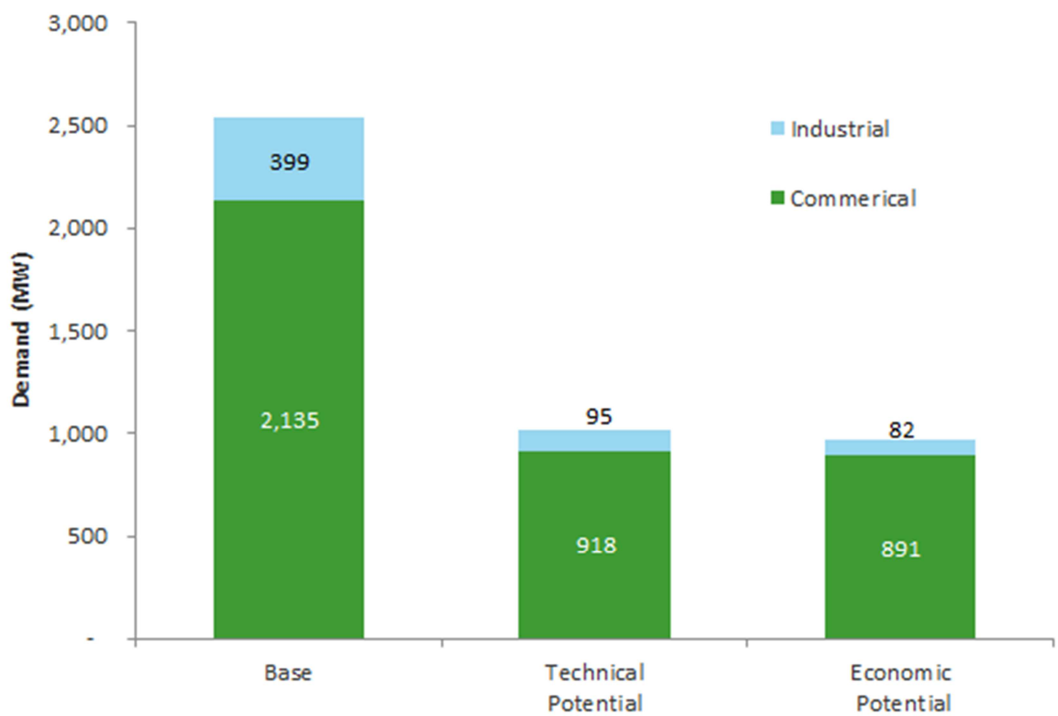

Figure 5-16: Technical and Economic Potential Energy Savings by Sector, 2016- 2025 - Electric

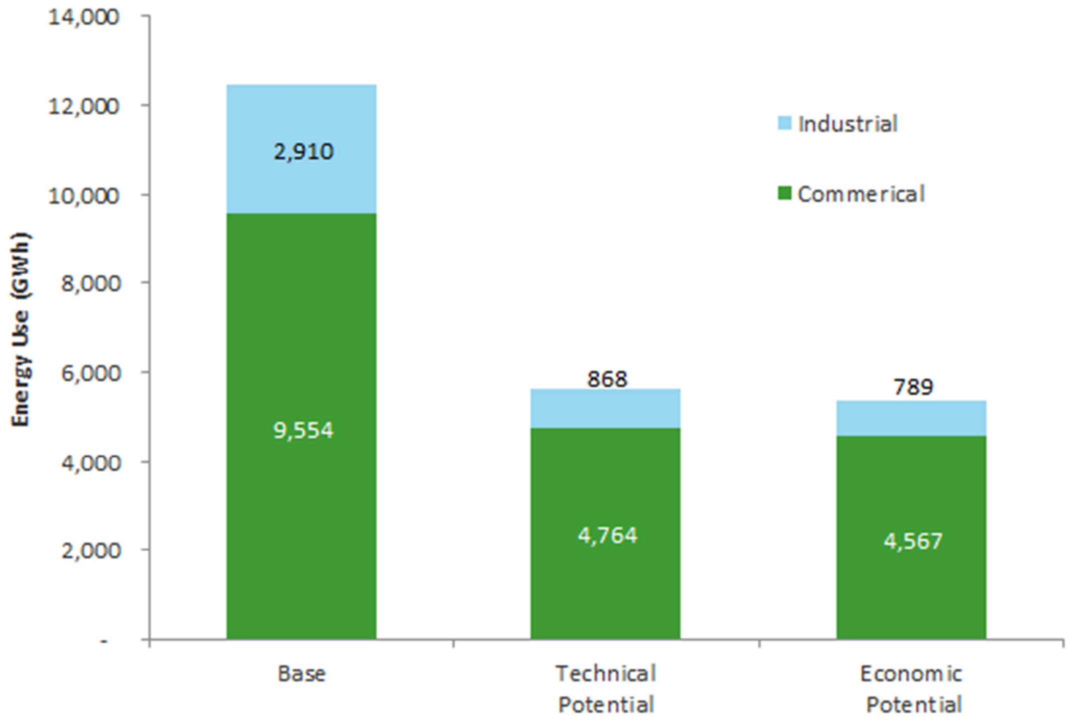

Figure 5-17: Technical and Economic Potential Demand Savings by Sector, 2016-2025 - Electric

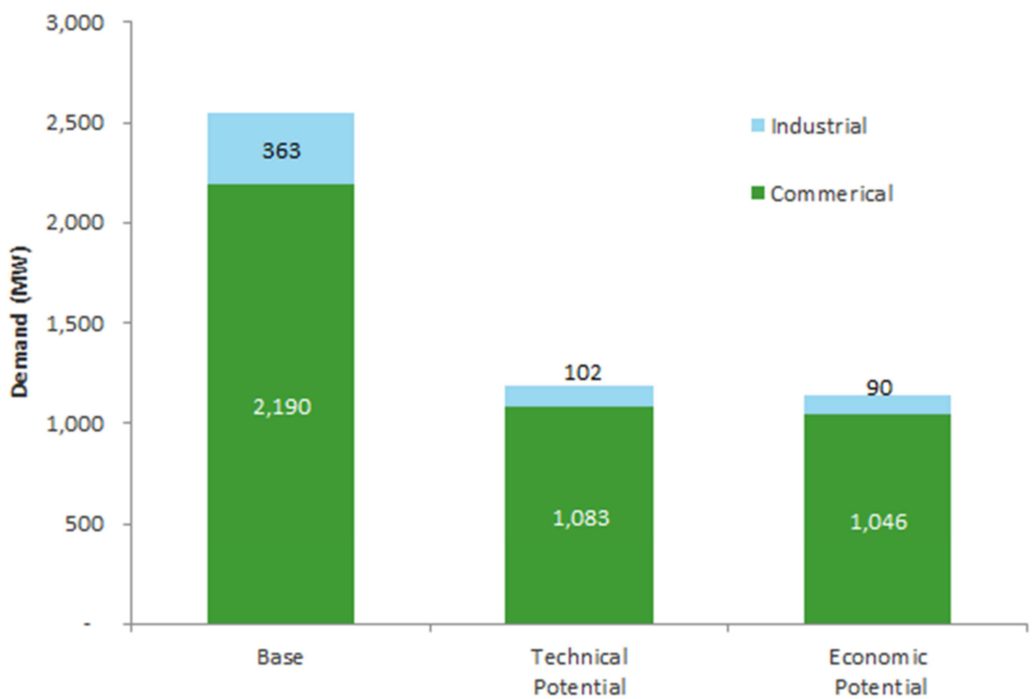

Table 5-23 and Table 5-24 show the contribution of technical and economic potential from each sector for 2018, also broken down by retrofit ("existing") versus new construction/replace on burnout/normal replacement markets ("new"). These tables also compare the potential savings of each sector to base consumption.

Table 5-23: Technical and Economic Potential Energy Savings by Sector and Vintage, 2016-2018 – Electric

Sector Type	2018 Base Energy Usage (GWh)	Technical Potential (GWh)	Technical as Percent of Sector Base	Economic Potential (GWh)	Economic as Percent of Sector Base
Commercial Existing	7,037	3,043	43%	3,017	43%

5.2.3.2 Potentials by Sector – Natural Gas

The figures below present the sector (commercial vs. industrial) breakdown of technical and economic potential as compared to the total base consumption in 2018 and 2025, respectively.

Figure 5-18. Technical and Economic Potential Energy Savings by Sector, 2016-2018 – Natural Gas

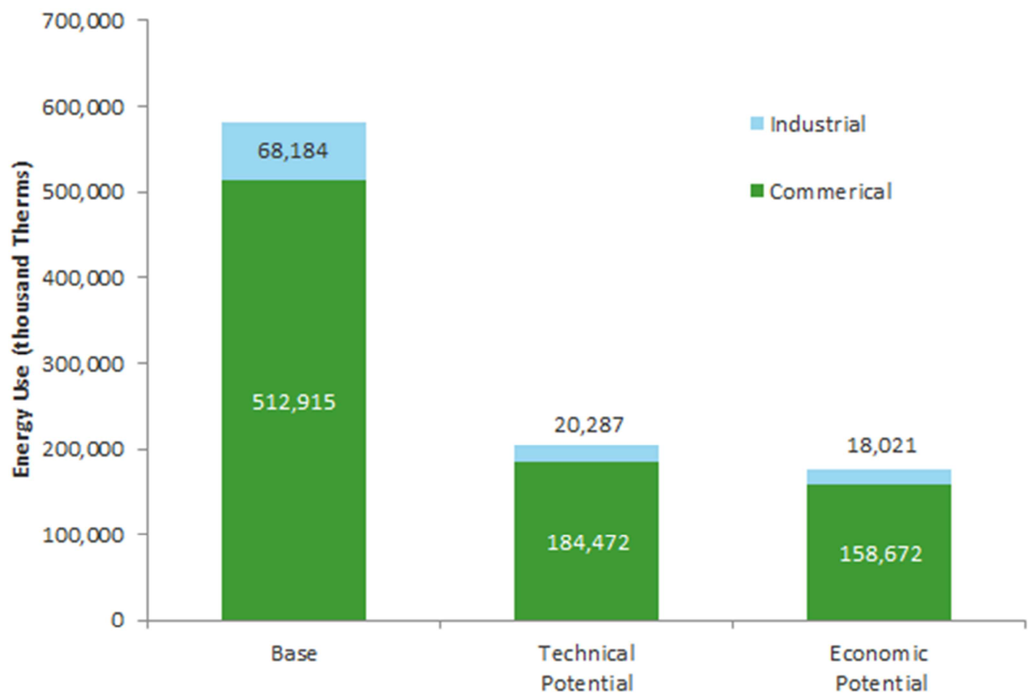

Figure 5-19. Technical and Economic Potential Energy Savings by Sector, 2016- 2025 – Natural Gas

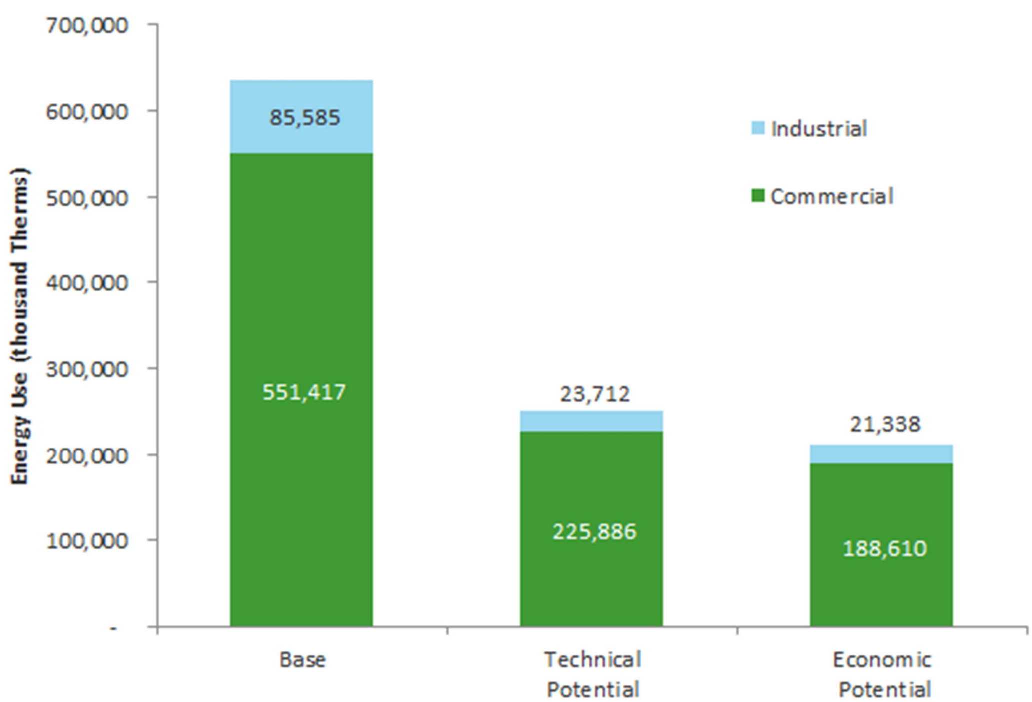

Table 5-27 and Table 5-28 show the contribution of technical and economic potential from each sector for 2018 and 2025, respectively, which are also broken down by retrofit versus new construction/ replace on burnout/normal replacement markets. These tables also compare the potential savings of each sector to base consumption. The commercial sector has higher technical and economic energy savings potential in relation to base energy use than does the industrial sector.

Table 5-27. Technical and Economic Potential Energy Savings by Sector Type, 2015-2018 – Natural Gas (thousand therms)

Sector Type	2018 Base Energy Usage (thousand therms)	Technical Potential (thousand therms)	Technical as Percent of Sector Base	Economic Potential (thousand therms)	Economic as Percent of Sector Base

5.2.3.3 Potentials by Building Type - Electric

This section presents technical and economic potential by commercial building type to provide more detail about where potential savings exist in National Grid's service territory.

Figure 5-20 and Figure 5-21 show the building type breakdown of commercial and industrial potential for 2018. Here, the industrial sector is included as a building type. Industrial buildings account for about 14 percent of the economic energy and 8 percent of the economic demand potential, while offices account for about 31 percent of the economic energy and 48 percent of the economic demand potential. This is followed by other (miscellaneous) buildings (13 percent of energy and 18 percent of demand potential). All other building types account for less than 10 percent of energy and demand potential.

Figure 5-20: Energy Savings Potential by Building Type, 2016-2018

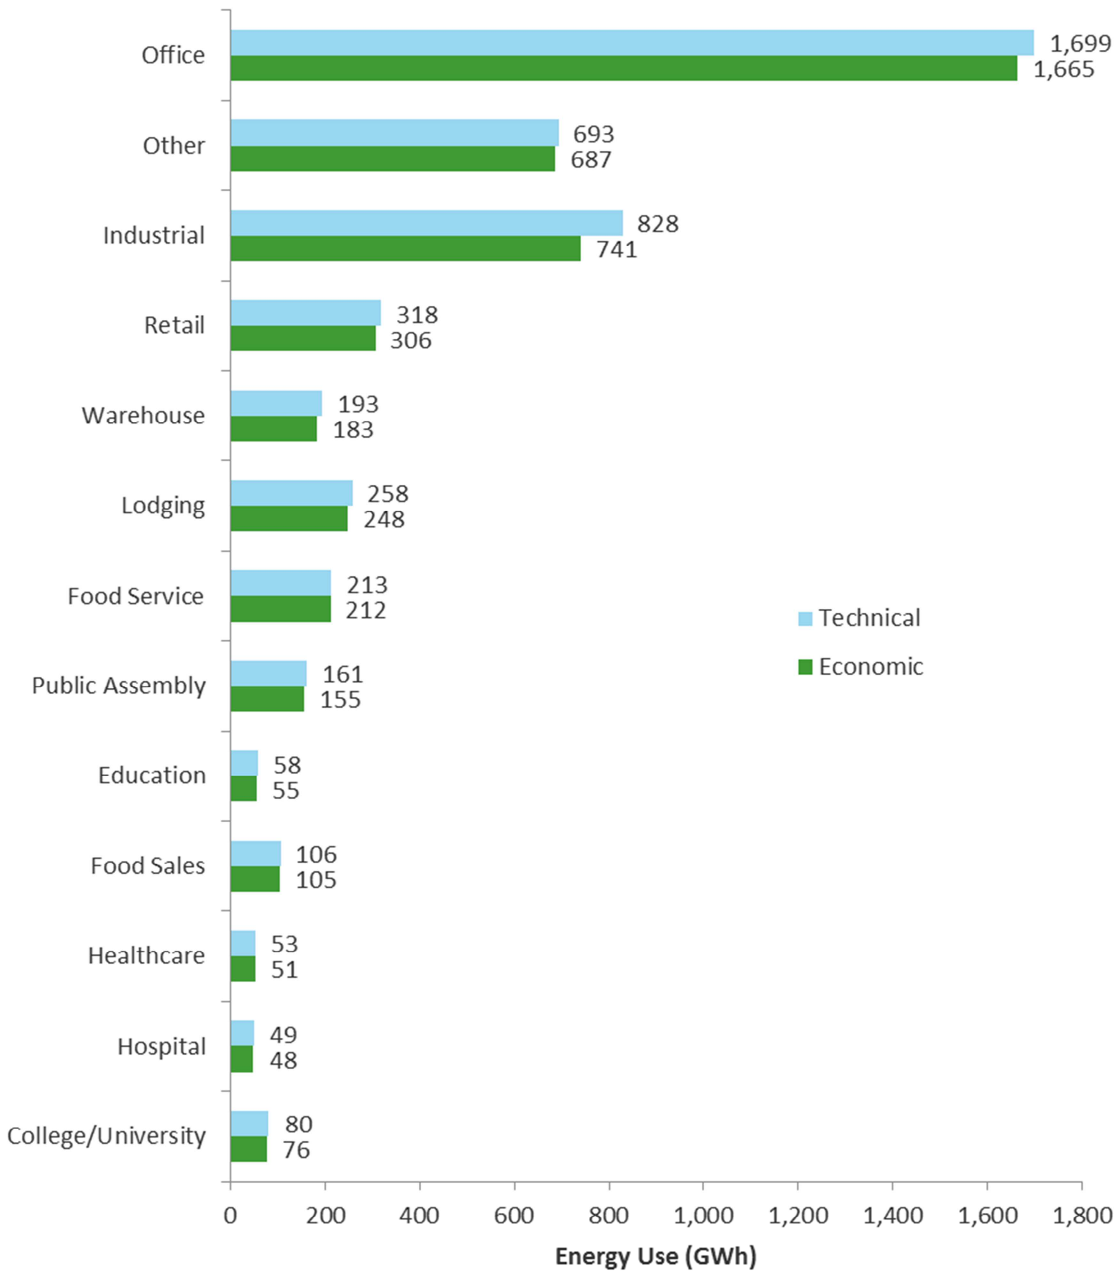

Figure 5-21: Demand Savings Potential by Building Type, 2016-2018

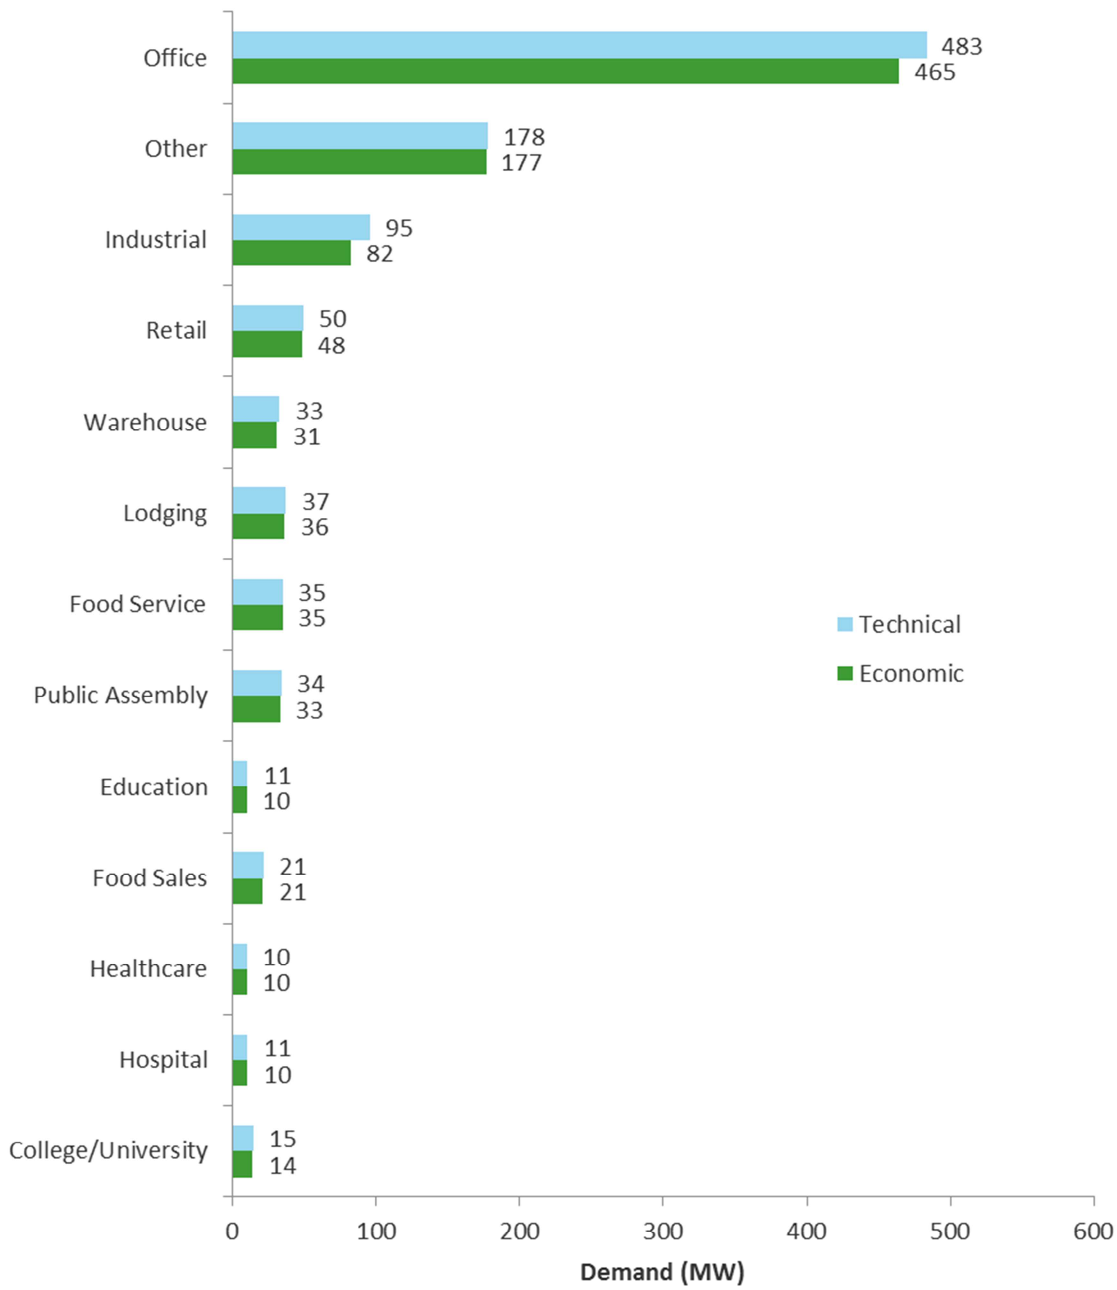

Table 5-29 shows the building type breakdown of commercial and industrial potential for 2018.

Table 5-29: Energy and Demand Savings Potential by Building Type, 2018.

Building Type	Energy (GWh)		Demand(MW)	
	Technical	Economic	Technical	Economic
College/University	80	76	15	14

5.2.3.4 Potential by Building Type – Natural Gas

This section presents technical and economic potential by commercial building type to provide more detail about where potential gas savings exist in National Grid's service territory. Figure 5-24 shows the building type breakdown of commercial and industrial gas potential for 2018. Here, the industrial sector is included as a building type. Industrial buildings account for about 10 percent of the economic energy potential, while offices account for about 41 percent of the economic energy potential. This is followed by retail buildings, which account for 13 percent of economic energy potential. All other building types account for 36 percent of economic energy potential.

Figure 5-24. Natural Gas Energy Savings Potential by Building Type, 2016-2018

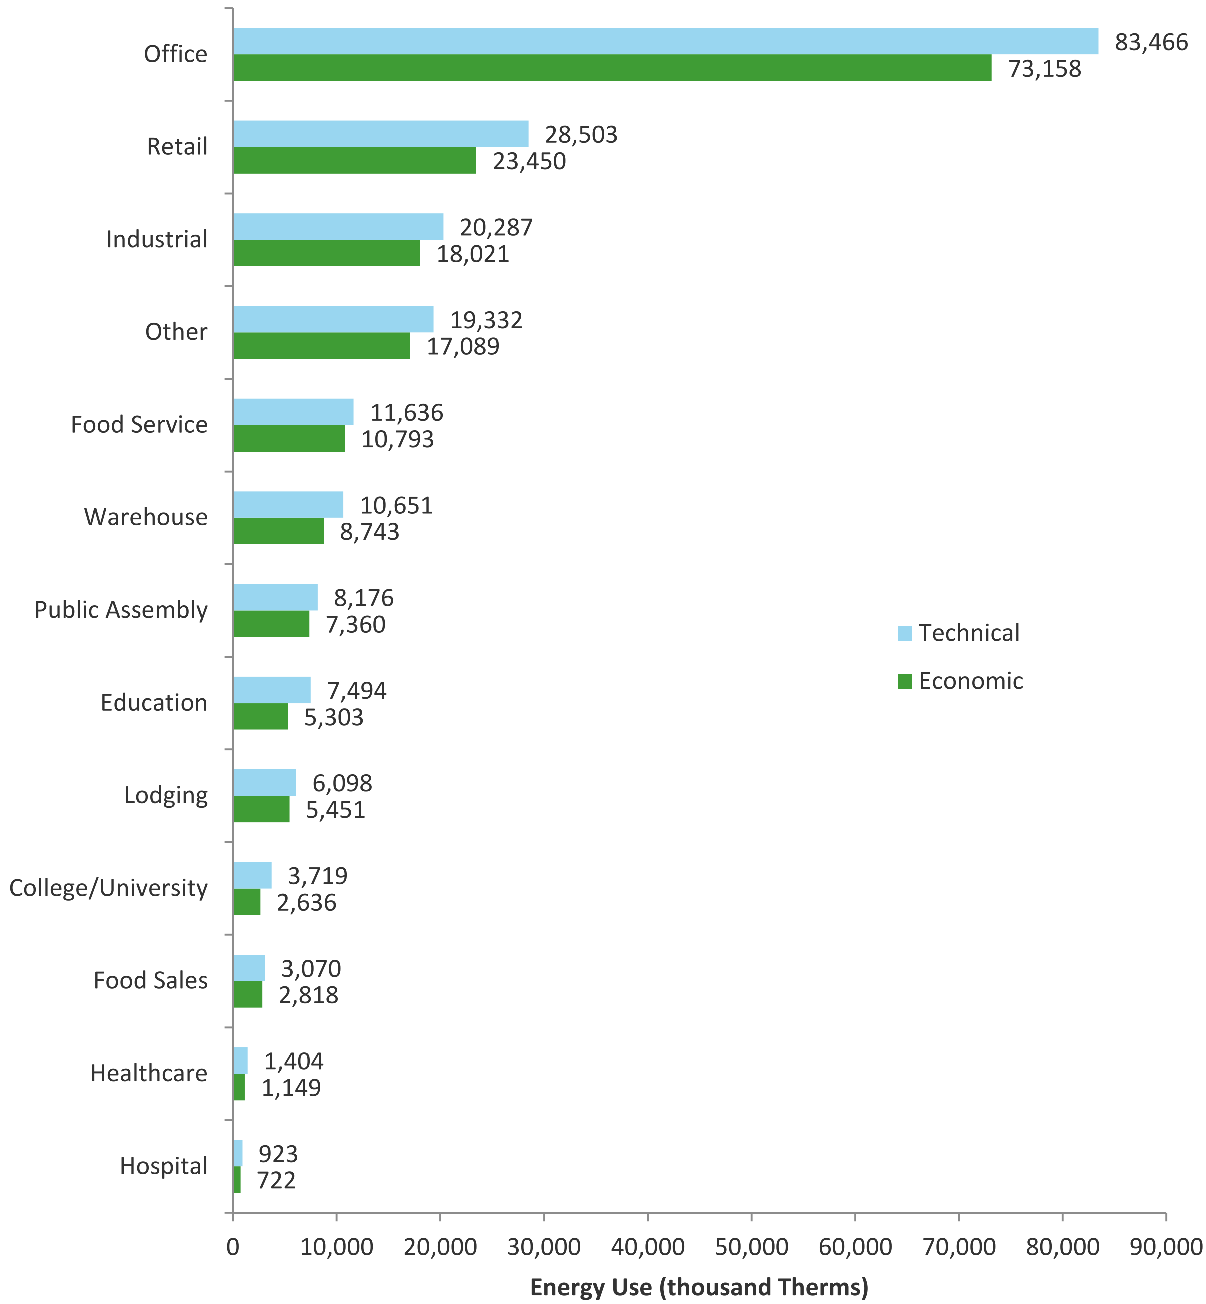

Table 5-31 shows the building type breakdown of commercial and industrial gas potential for 2018.

Table 5-31. Natural Gas Energy Savings Potential by Building Type, 2018

Building Type	Energy (thousand therms)	
	Technical	Economic
Hospital	923	722
Healthcare	1,404	1,149
Food Sales	3,070	2,818
College/University	3,719	2,636

Total	**249,598**	**209,948**

5.3 Achievable (Program) Potential

This section provides a high-level summary of the achievable potential analysis, based on the results of the technical and economic potential analyses. The detailed outputs of the achievable analysis are included in the appendices.

In contrast to the technical and economic potential estimates which are based on measure-level costs and savings, the estimates of achievable potential take into account market conditions such as awareness and other factors that affect the adoption of efficiency measures. As further described in Section 4.4, the method of estimating measure adoption takes into account market barriers and program incentives and reflects actual consumer and business implicit discount rates. This portion of the analysis also includes program marketing and administrative budgets as they impact the savings potential and are used in the analysis of the total resource cost and other cost benefit tests.

In this analysis, achievable potential refers to the amount of savings that would occur in response to one or more specific program interventions. Gross or total market savings shown in this section includes net savings and savings attributable to program free-riders – those customers who would have installed the measure in the absence of the program. Net or program savings associated with program potential are savings that are projected beyond those that would occur naturally in the absence of any market intervention.

The achievable analysis typically begins by calibrating budgets and savings to recent program results.[13] Based on input from National Grid staff, DNV GL set incentives as a specified cents per kWh saved by end-use and implementation type, based on National Grid's 2014 program data. In National Grid's current programs, lighting incentives are implemented in this way, while other measures are still incented at a percent of incremental cost (industrial for example pays 50 percent of incremental cost for retrofit measures and 75 percent for new and replace-on-burnout measures). The research team used the cents per kWh approach because National Grid intends to move in that direction for all its programs, but the mismatch between the modeling approach and actual practice in 2014 (the calibration year) made it difficult to line the results up perfectly with the results of the 2014 program. Because the research team was attempting to match National Grid's current programs, this is referred to as the business-as-usual (BAU) scenario.

Because achievable potential depends on the type and degree of intervention applied, per the direction of National Grid, DNV GL also developed potential estimates under two alternative funding scenarios: a 25 Percent Plus and 75 Percent Plus scenario with each scenario defined as follows:

- 25 Percent Plus: Increased customer incentives, expressed as dollars per kWh of savings, by 25 percent, not to exceed 100 percent of incremental costs. In the commercial model, 36 percent of measures capped out at 100 percent incentives under this scenario; in the industrial model 27 percent did. The average incentive (as a percent of incremental cost) paid under the scenario in 2016 was 72 percent for commercial and 79 percent for industrial.
- 75 Percent Plus: Increase customer incentives by 75 percent over the base costs, again not to exceed 100 percent of incremental costs. A 75 percent increase pushes most measures to the 100 percent cap. In the commercial model, 45 percent of measures capped out at 100 percent incentives under this scenario; in the industrial model 42 percent did. The average incentive paid under the scenario in 2016 was 81 percent for commercial and 91 percent for industrial.

DNV GL estimated program energy and peak demand savings under each scenario for the 2016 to 2025 and 2016 to 2018 period.

5.3.1 Electric

Table 5-33 presents the overall results of the electric energy efficiency potential analysis for the 2016 to 2018 period. Technical, economic, and achievable (program) potential estimates, to the extent possible, exclude customers who do not pay a systems benefit charge.[14] The research team accomplished this by omitting the floor space for these customers from the building stock estimates used in the analysis.

13 The calibration stage only includes measures that can be mapped to National Grid programs. All cost-effective measures are included in the funding scenario analyses.

14 Customers who do not pay a benefit charge are not eligible to participate in National Grid's DSM programs and were, to the extent possible, excluded from the technical, economic and program savings analyses.

Table 5-33: Summary of Cumulative Electric Energy Efficiency Savings, 2016-2018

Energy Efficiency 2016-2018	Technical Potential	Economic Potential	Achievable Program Savings Potential: Business as Usual	Achievable Program Savings Potential: 25% Plus Incentives	Achievable Program Savings Potential: 75% Plus Incentives	Naturally Occurring Savings Potential
Energy Savings-GWh	4,710	4,533	686	761	867	34

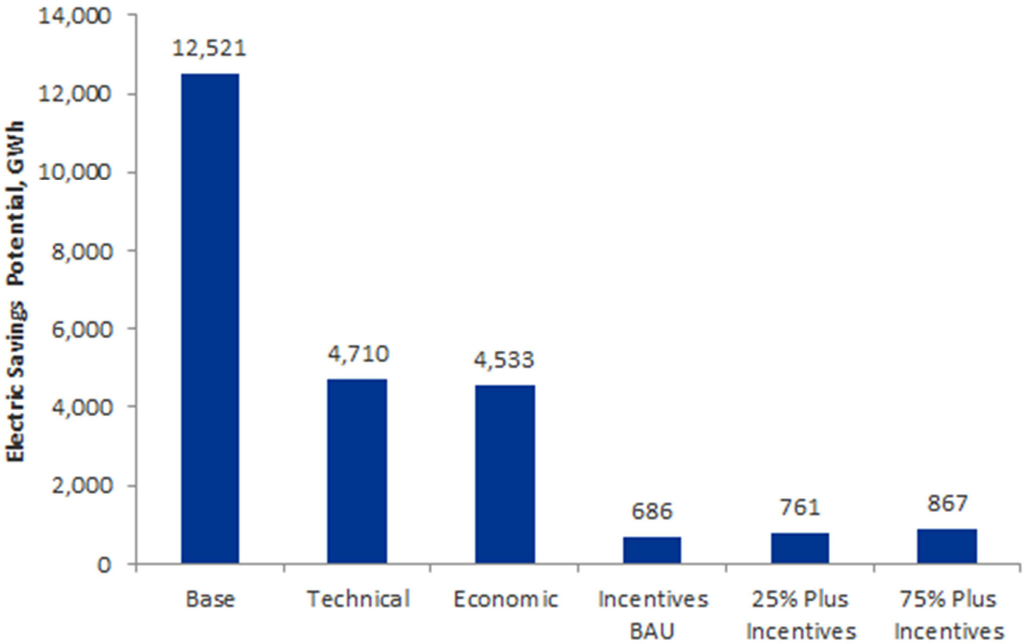
Savings % of Base		**45%**	**43%**	**13%**	**14%**	**16%**	**1%**

Estimates of electric energy savings potential are presented in the figures below. These savings reflect cumulative annual potential savings over both the 3-year and 10-year period. This can also be looked at as the annual savings potential of all installations through 2018 and 2025 respectively.

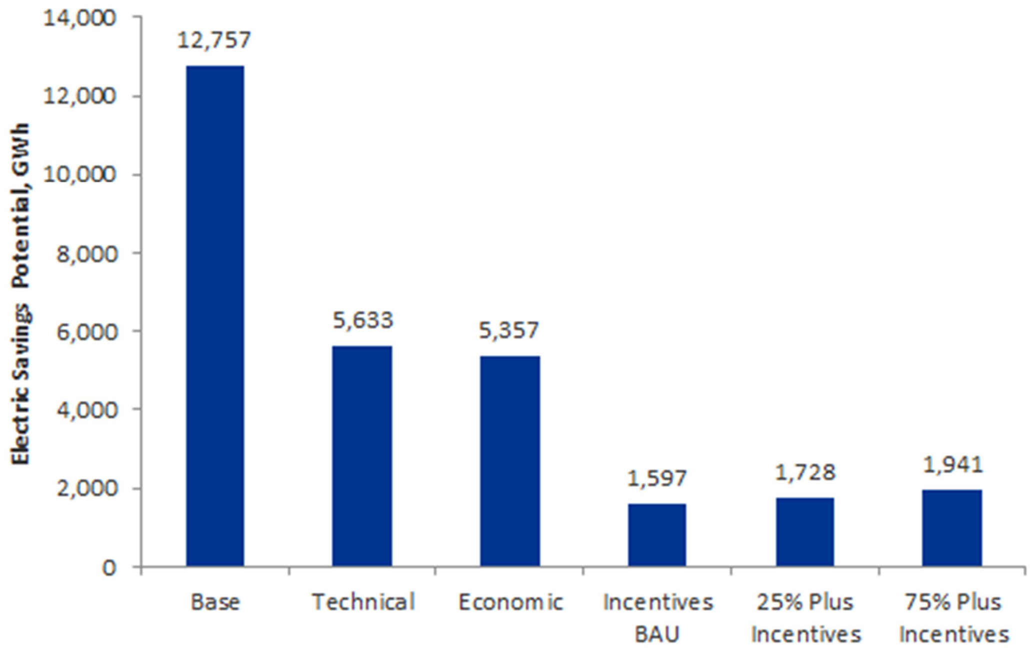
Under the 2016 to 2018 time period, technical potential is estimated at 4,710 GWh per year by 2018. Economic potential is estimated at 4,533 GWh by 2018. Achievable program potentials range between 867 GWh per year in the 75 Percent Plus scenario to 686 GWh per year for the BAU scenario. Economic potential for energy savings is estimated to be 36% percent of base 2018 energy use, while achievable potentials range from six percent of base usage in the BAU case to seven percent of base energy use in the 75 Percent Plus case.

Figure 5-26: Estimated Electric Energy Efficiency Savings Potential, 2016-2018



Under the ten-year period, technical potential is estimated at 5,633 GWh per year by 2025 and economic potential is estimated at 5,357 GWh by 2025. Achievable program potentials range between 1,941 GWh per year by 2025 in the 75 Percent Plus scenario to 1,597 GWh per year for the BAU scenario. Economic potential for energy savings is estimated to be 43% percent of base 2025 energy use. For the 2016 to 2025 year period, achievable potentials range from 13 percent of base usage in the BAU case to 16 percent of base energy use in the 75 Percent Plus case.

Figure 5-27: Estimated Electric Energy Efficiency Savings Potential, 2016-2025

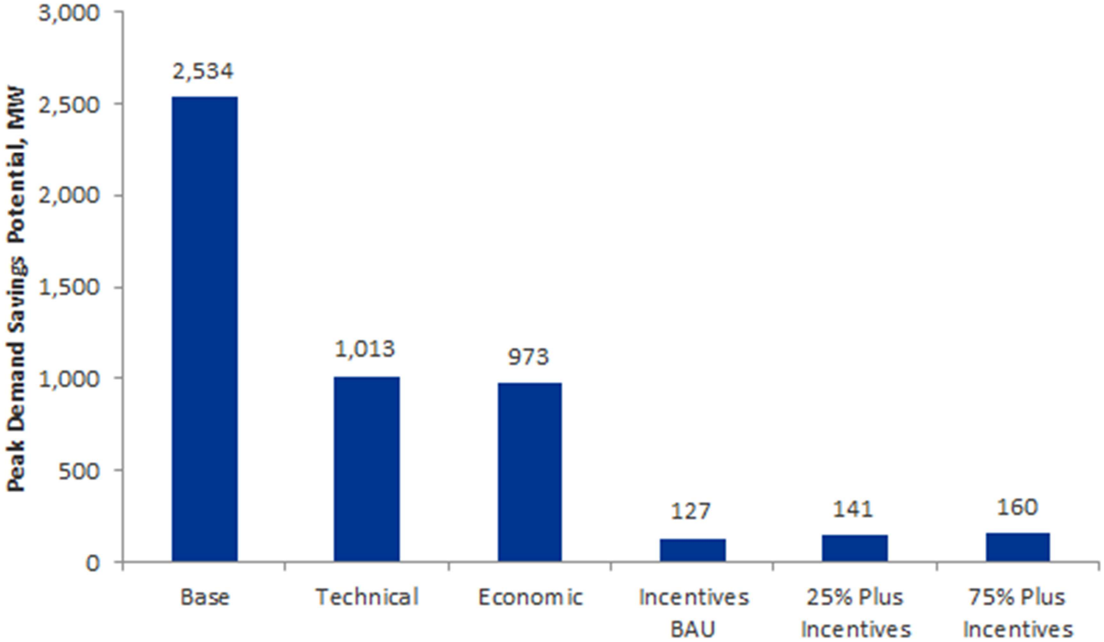


Cumulative peak demand savings potential estimates for both the 10-year and 3-year periods are provided in the figures below.[15]

Technical potential is estimated at 1,013 MW for the 3-year period while economic potential is estimated at 973 MW. Cumulative achievable program potential ranges between 160 MW in the 75 Percent Plus incentive case down to 127 MW in the BAU case. Economic potential for peak demand savings is estimated to be 38 percent of base peak demand and achievable potentials range from five percent of base peak demand in the BAU case to six percent of base peak demand in the 75 Percent Plus incentive case.

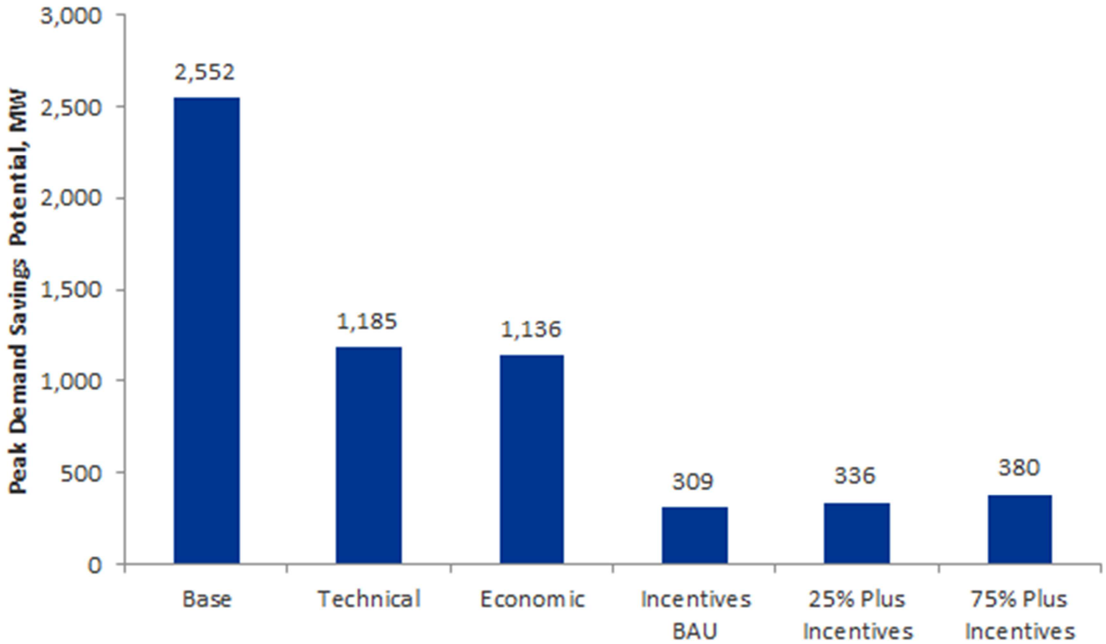
[15] The estimates of peak demand savings are from the installation of energy efficiency measures and do not include demand savings from demand response technologies such as direct load control or dynamic pricing.

Figure 5-28: Estimated Peak Demand Savings Potential, 2016-2018



Technical potential is estimated at 1,185 MW for the 10-year period. Economic potential is estimated at 1,136 MW for the 10-year period. For the 10-year period, cumulative achievable program potential ranges between 380 MW in the 75 Percent Plus incentive case down to 309 MW in the BAU case. Economic potential for peak demand savings is estimated to be 37 percent of base 2025 peak demand; achievable potentials range from 10 percent of base peak demand in the BAU case to 12 percent of base peak demand in the 75 Percent Plus incentive case.

Figure 5-3: Estimated Peak Demand Savings Potential, 2016-2025



5.3.2 Natural Gas

Table 5-37 presents the overall results of the electric energy efficiency potential analysis for the 2016 to 2018 time frame.

Table 5-37. Summary of Cumulative Gas Energy Efficiency Savings, 2016-2018

Energy Efficiency 2016-2018	Technical Potential	Economic Potential	Achievable Program Savings Potential: Business as Usual	Achievable Program Savings Potential: 25% Plus Incentives	Achievable Program Savings Potential: 75% Plus Incentives	Naturally Occurring Savings Potential

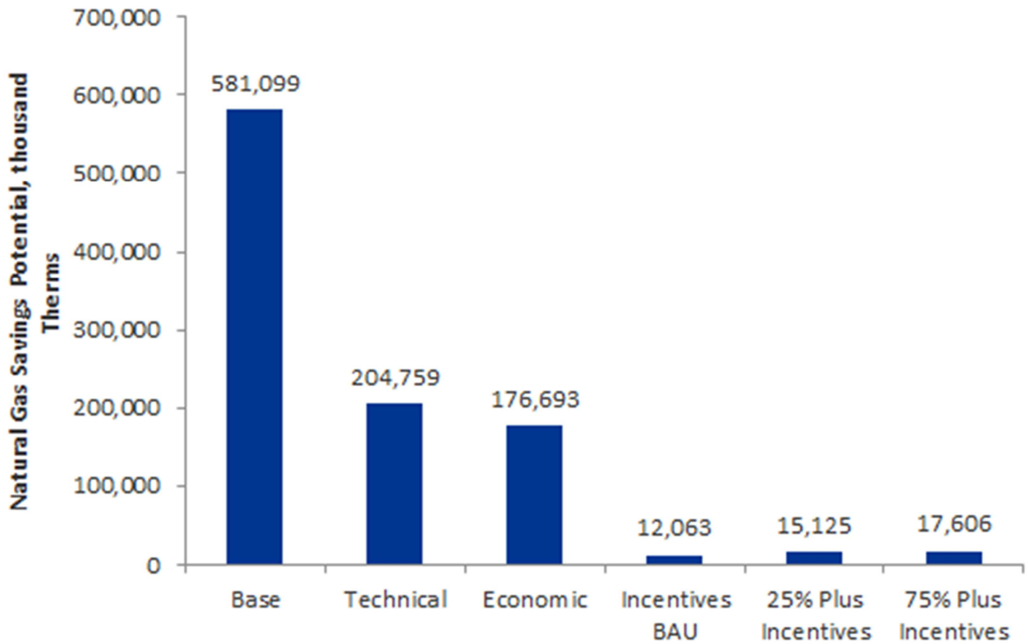
Savings % of Base		**28%**	**25%**	**6%**	**7%**	**8%**	**0.3%**
Total	637,003	249,598	209,948	31,318	37,867	43,250	3,445
Savings % of Base		**39%**	**33%**	**5%**	**6%**	**7%**	**0.5%**

Estimates of natural gas energy savings potential are presented in the figures below. These savings reflect cumulative annual potential gas savings over the 3-year and 10-year period. This can also be looked at as the annual savings potential of all installations through 2018 and 2025 respectively.

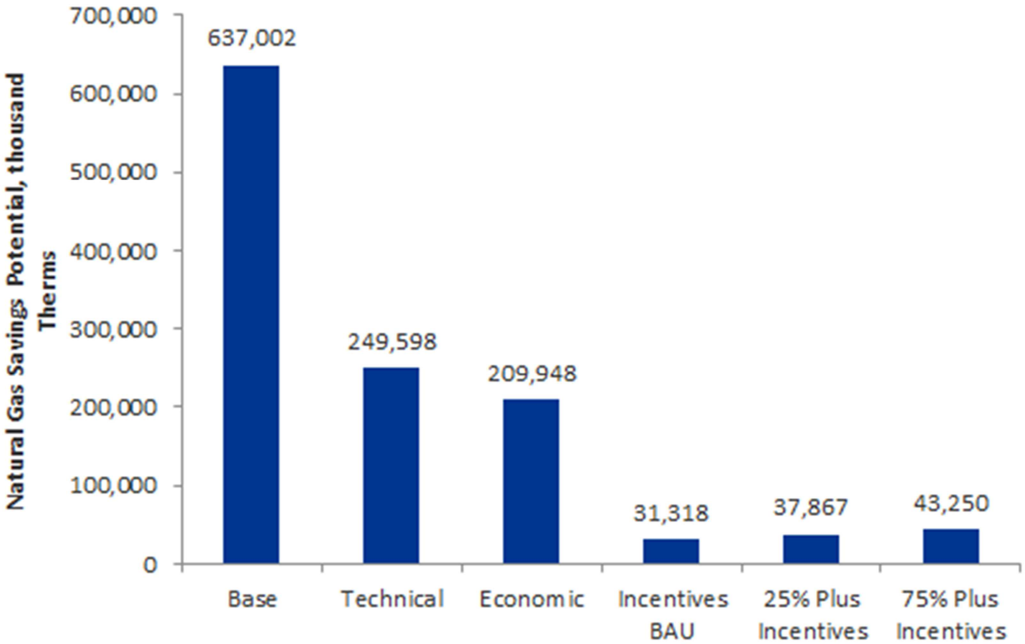
Under the three-year time frame, technical potential is estimated at 204,759 thousand therms per year by 2018. Economic potential is estimated at 176,693 thousand therms by 2018. Achievable program potentials range between 12,063 thousand therms per year for the BAU scenario to 17,606 thousand therms per year by 2018 in the 75 Percent Plus scenario. Economic potential for energy savings is estimated to be 30 percent of base 2018 energy use while achievable potentials range from two percent of base usage in the BAU case to three percent of base energy use in the 75 Percent Plus case.

Figure 5-29. Estimated Gas Energy Efficiency Savings Potential, 2016-2018



Under the 2016 to 2025 time frame, technical potential is estimated at 249,598 thousand therms per year by 2025 and economic potential is estimated at 209,948 thousand therms by 2025. Achievable program potentials range between 31,318 thousand therms per year for the BAU scenario to 43,250 thousand therms per year by 2025 in the 75 Percent Plus scenario. Economic potential for energy savings is estimated to be 33 percent of base 2025 energy use. For the 2016 to 2025 year period, achievable potentials range from 5 percent of base usage in the BAU case to 7 percent of base energy use in the 75 Percent Plus case.

Figure 5-30. Estimated Gas Energy Efficiency Savings Potential, 2016-2025



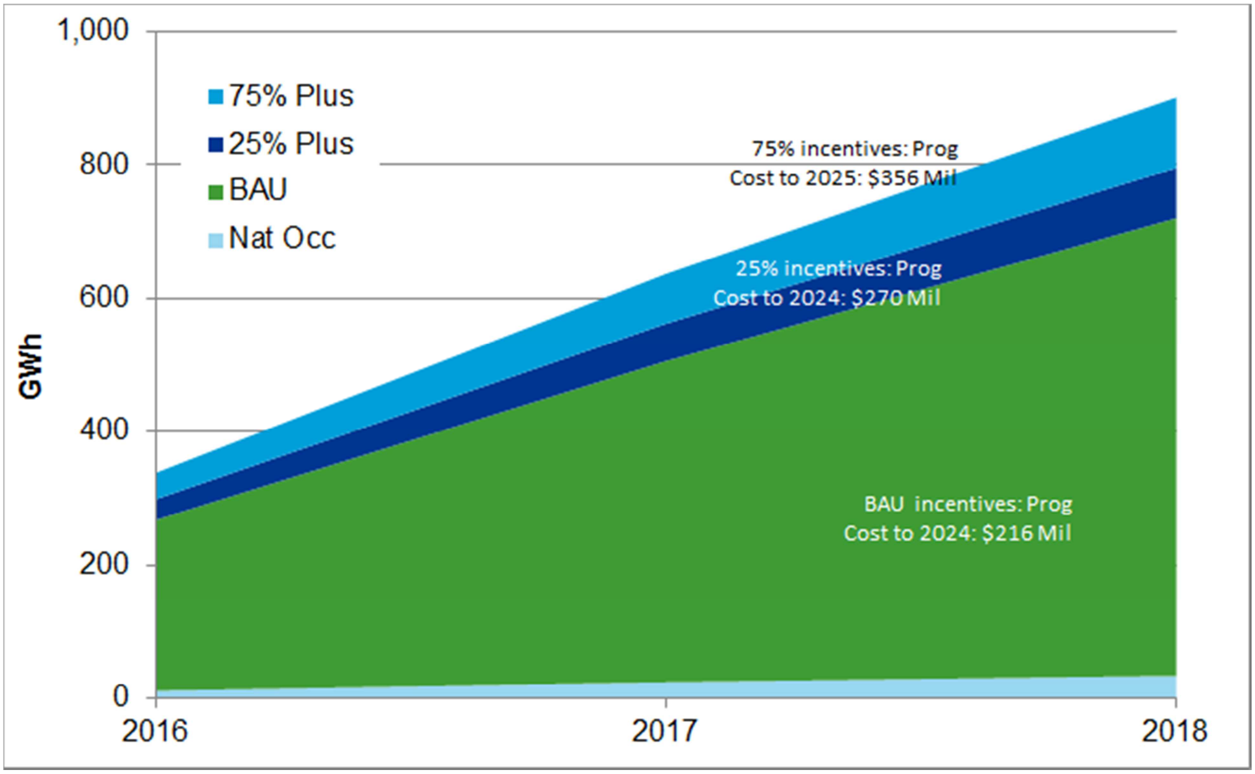
5.3.3 Achievable (Program) Potential – Detailed Results - Electric

5.3.3.1 2016 to 2018 Time Frame

Figure 5-31 shows the estimates of achievable potential savings over the 2016 to 2018 time frame. As shown in this figure, by 2018 cumulative net[16] energy savings are projected to be 720 GWh under the BAU scenario, 795 GWh under the 25 Percent Plus scenario and 901 GWh under the 75 Percent Plus scenario. In each scenario, savings increase over time. A breakdown of the program costs can be seen below.

[16] Throughout this section, *net* refers to savings beyond those estimated to be naturally occurring; that is, from customer adoptions that would occur in the absence of any programs or standards.

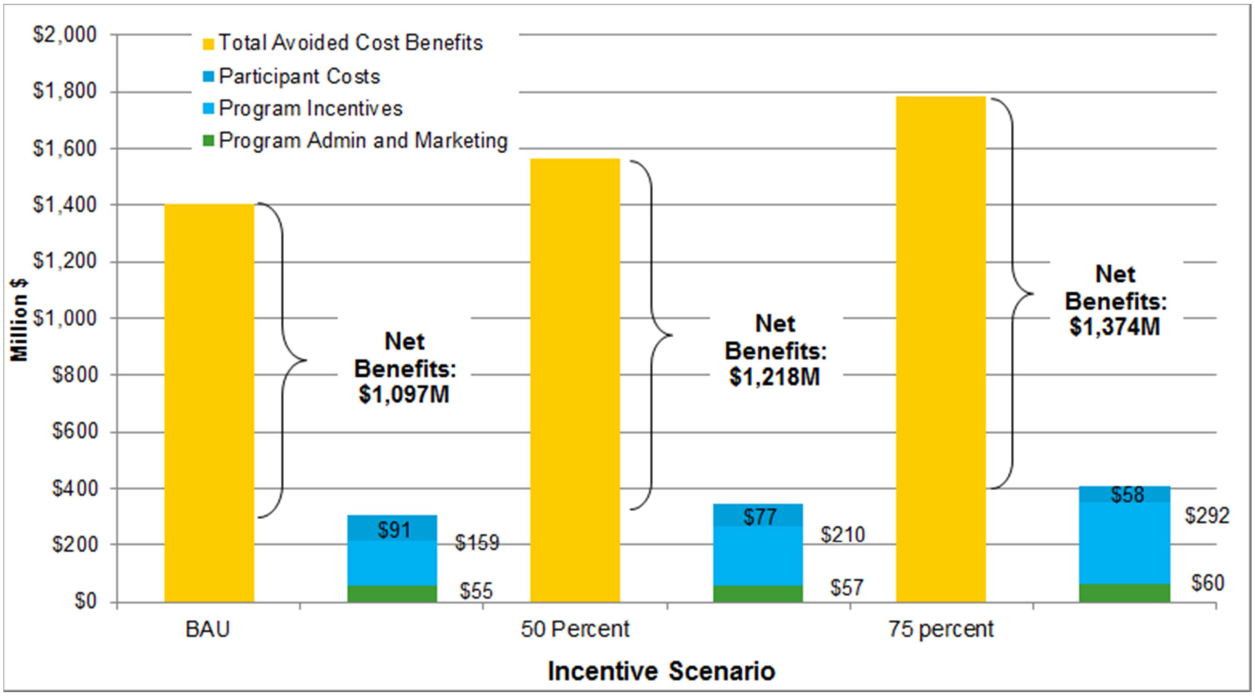
Figure 5-31: Achievable Electric Energy Savings (GWh): All Evaluated Sectors



The present value of program costs (including program incentives and program admin and marketing) is $216 million under the BAU scenario, $270 million under the 25 Percent Plus scenario and $356 million under the 75 Percent Plus scenario for the 3-year period.[17]

[17] It should be noted that a portion of all participant costs are negative costs due to free-riders. As the participant cost get closer to zero for all participants, as is the case with the 75% percent plus scenario, the negative costs become visible, therefore it is reasonable to see the negative participant costs of $5M and $1M in the ten-year and three-year time periods respectively.

Figure 5-32: Benefits and Costs of Energy Efficiency Savings—2016-2018*



* Present value of benefits and costs over measure lifetimes; nominal discount rate is 2.78 percent, inflation rate is 2.22 percent.

The present value of total avoided cost benefits is $1,402 million under the BAU scenario, $1,561 million under the 25 Percent Plus and $1,784 million under the 75 Percent Plus for the 3-year period. The present value of net avoided cost benefits for the 3-year period is $1,097 million under the BAU scenario, $1,218 million under 25 Percent Plus and $1,374 million under 75 Percent Plus.

Key results of the efficiency scenario forecasts from 2016 to 2018 are summarized in Table 5-41 . Gross cumulative savings include naturally occurring savings, while Net program savings include savings net of naturally occurring savings.

Table 5-41: Summary of Achievable Potential Results—2016-2018*

Result - Programs	Program Scenario:		
	BAU	25% Plus	75% Plus
Gross Cumulative Annual Energy Savings - GWh	720	795	901
Gross Cumulative Annual Peak Demand Savings - MW	133	147	166
Net Cumulative Annual Energy Savings - GWh	686	761	867
Net Cumulative Annual Peak Demand Savings - MW	127	141	160
Program Costs - Real, $ Million (sum 3-year cost, not discounted)			
Administration	$11	$13	$16
Marketing	$45	$45	$45
Incentives	$160	$212	$295
Total	$216	$270	$356
PV 3-year Avoided Costs	$1,402	$1,561	$1,784
PV 3-year Annual Program Costs (Adm/Mkt)	$55	$57	$60
PV 3-year Net Measure Costs	$250	$286	$349
Net Benefits (PV 3-year)	$1,097	$1,218	$1,374
TRC Ratio	4.6	4.5	4.4

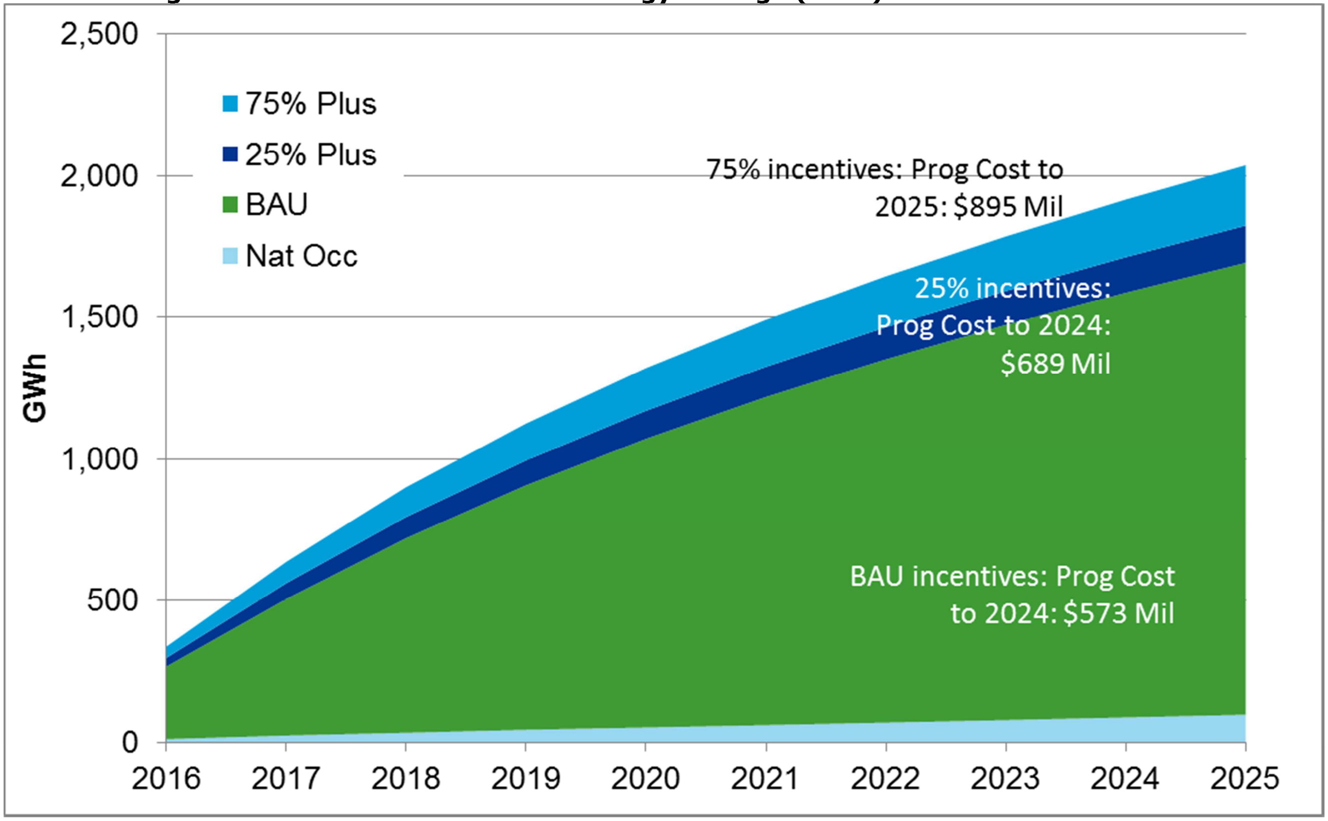
*PV (present value) of benefits and costs is calculated over measure lifetimes for 2016-2018 program years, nominal discount rate = 2.78 percent, inflation rate = 2.22 percent; GWh and MW savings are cumulative through 2018.

5.3.3.2 2016 to 2025 Time Frame

Figure 5-33 shows the estimates of achievable potential savings over time. As shown in this figure, by 2025 cumulative annual net[18] energy savings are projected to be 1,597 GWh under the BAU scenario, 1,728 GWh under the 25 Percent Plus scenario and 1,941 GWh under the 75 Percent Plus scenario. In each scenario, savings increase over time. A breakdown of the program costs can be seen in Figure 5-34 below.

[18] Throughout this section, *net* refers to savings beyond those estimated to be naturally occurring; that is, from customer adoptions that would occur in the absence of any programs or standards.

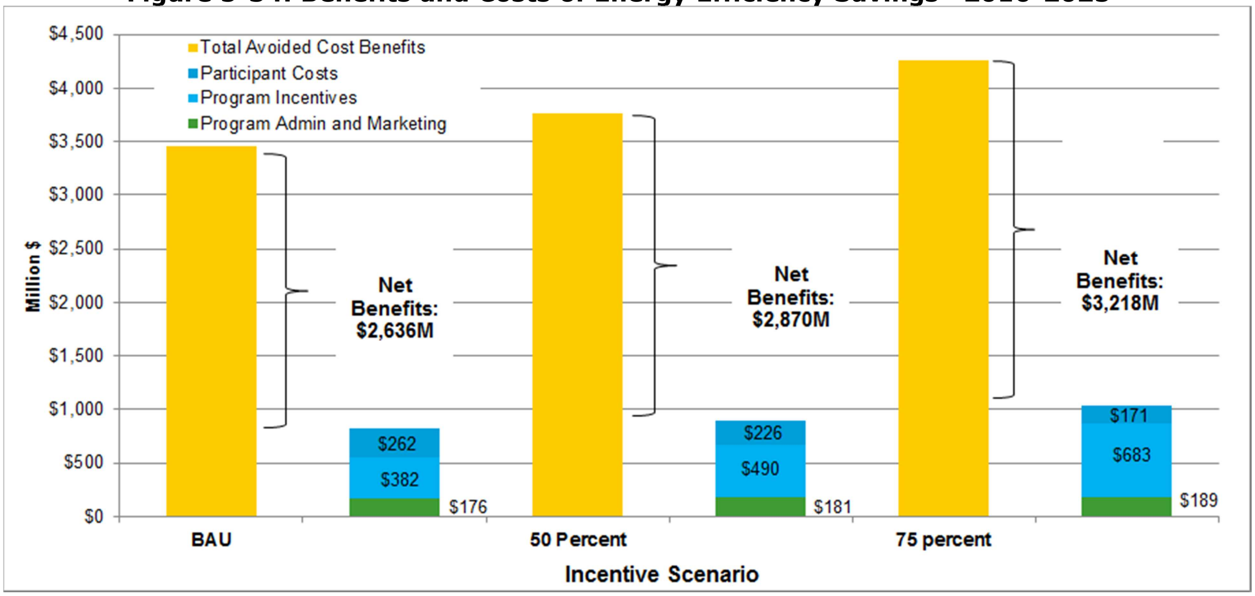
Figure 5-33: Achievable Electric Energy Savings (GWh): All Evaluated Sectors



As incentive levels increase between program scenarios, the costs to administer and market the program also increase from additional programmatic activity. Increased incentives also affect participant costs as the incremental cost participants must pay per measure has decreased as a result of the higher incentives. It is also important to note that although the level of naturally occurring savings does not change between scenarios, program free riders receive the same incentives payments as program participants.

Figure 5-34 depicts the estimated costs and benefits under each funding scenario from 2016 to 2025. The present value of program costs (including program incentives and program administration, marketing) is $558 million under the BAU scenario, $671 million under the 25 Percent Plus scenario and $872 million under the 75 Percent Plus scenario.

Figure 5-34: Benefits and Costs of Energy Efficiency Savings—2016-2025*



* Present value of benefits and costs over measure lives; nominal discount rate is 2.78 percent, inflation rate is 2.22 percent.

The present value of total avoided cost benefits is $3,456 million under the BAU scenario, $3,767 million under the 25 Percent Plus scenario and $4,261 million under the 75 Percent Plus scenario. Finally, all scenarios have positive net benefits: the present value of net avoided cost benefits, i.e., the difference between total avoided cost benefits and total costs (which include participant costs in addition to program costs) for the 10-year period is $2,636 million under the BAU scenario, $2,870 million under the 25 Percent Plus scenario and $3,218 million under the 75 Percent Plus scenario.

Each of the funding scenarios are cost-effective based on the TRC test The TRC benefit-cost ratios for National Grid's service territory are 4.2 for the BAU scenario, 4.2 for the 25 Percent Plus scenario and 4.1 under the 75 Percent Plus scenario.

Key results of the efficiency scenario forecasts from 2016 to 2025 are summarized in Table 5-42. Gross cumulative savings include naturally occurring savings, while Net savings include savings net of naturally occurring savings.

Table 5-42: Summary of Achievable Potential Results—2016-2025*

Result - Programs	Program Scenario:		
	BAU	25% Plus	75% Plus
Gross Cumulative Annual Energy Savings - GWh	1,695	1,825	2,038
Gross Cumulative Annual Peak Demand Savings - MW	325	352	396
Net Cumulative Annual Energy Savings - GWh	1,597	1,728	1,941
Net Cumulative Annual Peak Demand Savings - MW	309	336	380
Program Costs - Real, $ Million (sum 10-year cost, not discounted)			
Administration	$33	$38	$46
Marketing	$149	$149	$149
Incentives	$392	$503	$701
Total	$573	$689	$895
PV 10-year Avoided Costs	$3,456	$3,767	$4,261
PV 10-year Annual Program Costs (Adm/Mkt)	$176	$181	$189
PV 10-year Net Measure Costs	$644	$716	$854
Net Benefits (PV 10-year)	$2,636	$2,870	$3,218
TRC Ratio	4.2	4.2	4.1

*PV (present value) of benefits and costs is calculated over the life of each measure for 2016-2025 program years, nominal discount rate = 2.78 percent, inflation rate = 2.22 percent; GWh and MW savings are per year, but reflect the cumulative effects of program efforts through 2025.

5.3.3.3 Breakdown of Achievable Electric Potential by Sector

Cumulative achievable potential estimates by sector for the period of 2016 to 2025 and the period 2016 to 2018 are presented in Figure 5-36 through Figure 5-37. These figures compare the industrial and commercial sector results for each funding scenario.

Under the program assumptions developed for this study, achievable energy savings under each scenario are highest for the commercial sector during both time periods. Peak demand savings under all scenarios are also highest for the commercial sector.[19]

[19] The estimates of peak demand savings are from the installation of energy efficiency measures and do not include demand savings from demand response technologies such as direct load control or dynamic pricing.

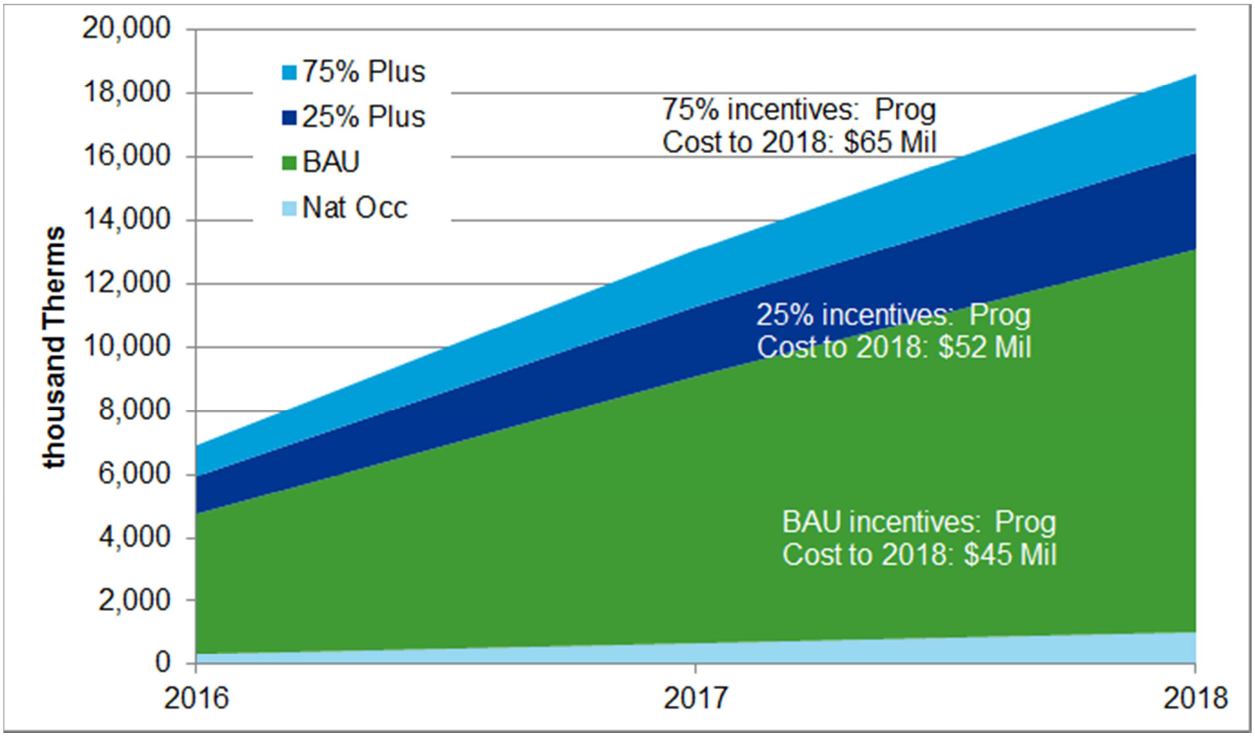
5.3.4 Achievable (Program) Potential – Detailed Results - Natural Gas

5.3.4.1 2016 to 2018 Time Frame

Figure 5-39 shows the estimates of achievable potential savings over the 2016 to 2018 time frame. As shown in this figure, by 2018 cumulative net gas savings are projected to be 24,126 thousand therms under the BAU scenario, 30,249 thousand therms under the 25 Percent Plus scenario, and 35,211 thousand therms under the 75 Percent Plus scenario. In each scenario, savings increase over time. A breakdown of the program costs can be seen below.

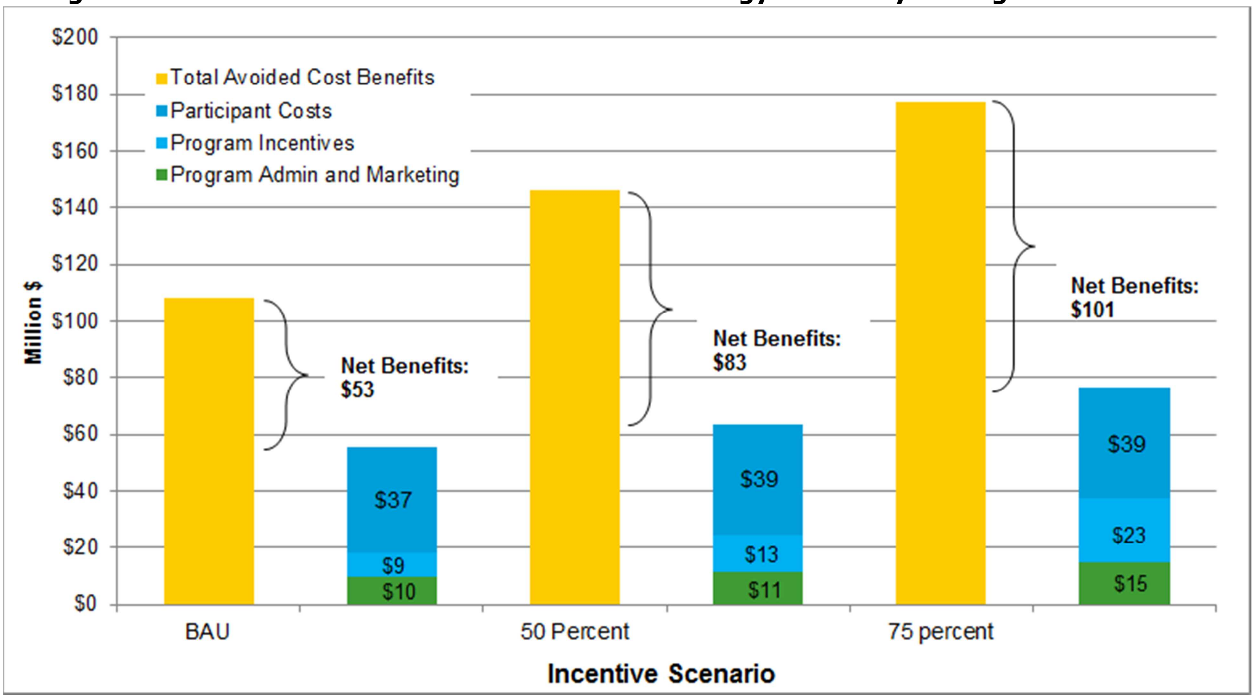
Figure 5-39. Achievable Natural Gas Energy Savings (thousand therms): All Evaluated Sectors



The present value of program costs (including program incentives and program admin and marketing) is $45 million under the BAU scenario, $52 million under the 25 Percent Plus scenario and $65 million under the 75 Percent Plus scenario for the 3-year period.[20]

[20] It should be noted that a portion of all participant costs are negative costs due to free-riders. As the participant cost get closer to zero for all participants, as is the case with the 75% percent plus scenario, the negative costs become visible, therefore it is reasonable to see the negative participant costs of $5M and $1M in the ten-year and three-year time periods respectively.

Figure 5-40. Benefits and Costs of Natural Gas Energy Efficiency Savings—2016-2018*



* Present value of benefits and costs over measure lives; nominal discount rate is 2.78 percent, inflation rate is 2.22 percent.

The present value of total avoided cost benefits is $108 million under the BAU scenario, $146 million under the 25 Percent Plus and $177 million under the 75 Percent Plus for the 3-year period. The present value of net avoided cost benefits for the 3-year period is $53 million under the BAU scenario, $83 million under 25 Percent Plus and $101 million under 75 Percent Plus.

Key results of the efficiency scenario forecasts from 2016 to 2018 are summarized in Table 5-43.

Table 5-43. Summary of Achievable Natural Gas Potential Results—2016-2018*

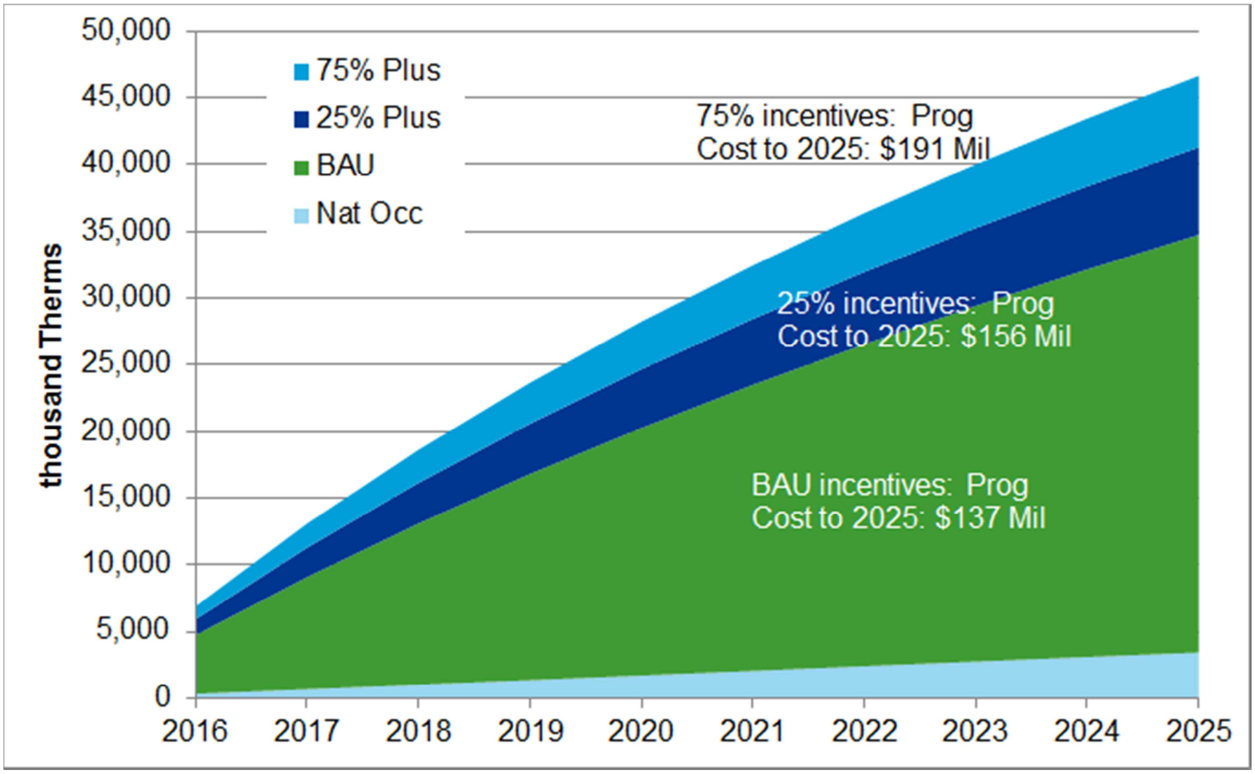
Result – Programs	Program Scenario:		
	BAU	25% Plus	75% Plus
Gross Cumulative Annual Energy Savings – thousand therms	13,087	16,148	18,629
Net Cumulative Annual Energy Savings – thousand therms	12,063	15,125	17,606
Program Costs - Real, $ Million (sum 3-year cost, not discounted)			
Administration	$5	$6	$8
Marketing	$18	$18	$18
Incentives	$22	$28	$39
Total	$45	$52	$65
PV 3-year Avoided Costs	$108	$146	$177
PV 3-year Annual Program Costs (Adm/Mkt)	$10	$11	$15
PV 3-year Net Measure Costs	$46	$52	$61
Net Benefits (PV 3-year)	$53	$83	$101
TRC Ratio	1.9	2.3	2.3

*PV (present value) of benefits and costs is calculated over the life of each measure for 2016-2018 program years, nominal discount rate = 2.78 percent, inflation rate = 2.22 percent; therms savings are cumulative through 2018.

5.3.4.2 2016 to 2025 Time Frame

Figure 5-41 shows the estimates of achievable potential gas savings over time. As shown in this figure, by 2025 cumulative annual net energy savings are projected to be 31,318 thousand therms under the BAU scenario, 37,867 thousand therms under the 25 Percent Plus scenario, and 1,941 GWh under the 75 Percent Plus scenario. In each scenario, savings increase over time. A breakdown of the program costs can be seen in Figure 5 10 below.

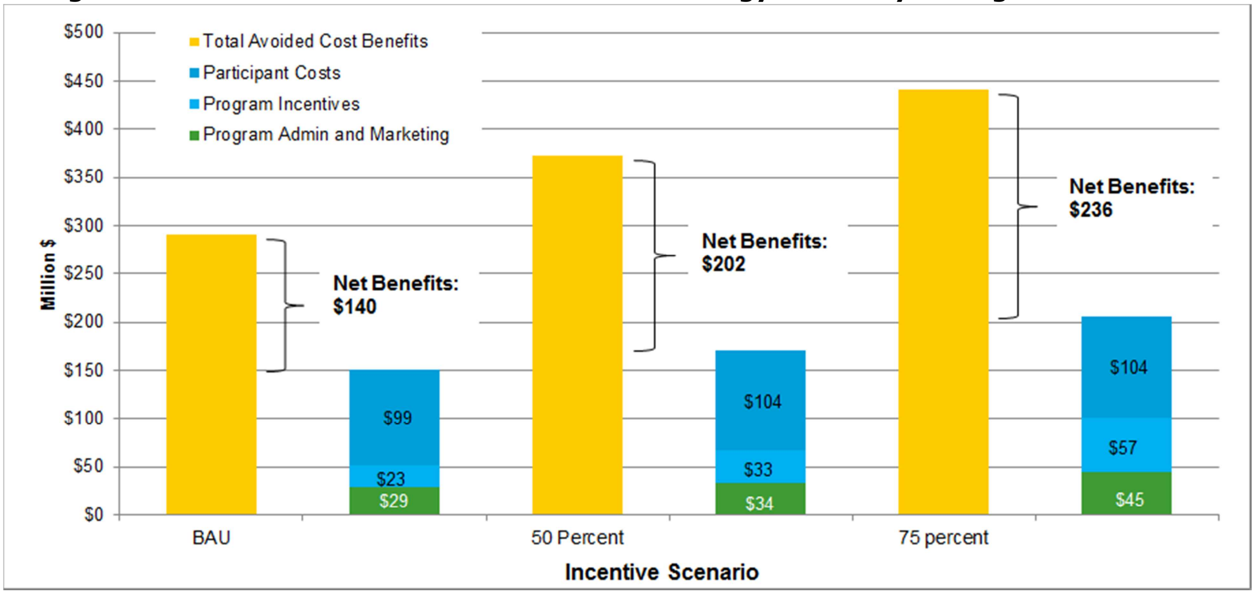
Figure 5-41. Achievable Natural Gas Energy Savings (thousand therms): All Evaluated Sectors



As incentive levels increase between program scenarios, the costs to administer and market the program also increase from additional programmatic activity. Increased incentives also affect participant costs as the incremental cost participants must pay per measure has decreased as a result of the higher incentives. It is also important to note that although the level of naturally occurring savings does not change between scenarios, program free riders receive the same incentives payments as program participants.

Figure 5-42 depicts the estimated costs and benefits under each funding scenario from 2016 to 2025. The present value of program costs (including program incentives and program administration, marketing) is $52 million under the BAU scenario, $67 million under the 25 Percent Plus scenario and $102 million under the 75 Percent Plus scenario.

Figure 5-42. Benefits and Costs of Natural Gas Energy Efficiency Savings—2016-2025*



* Present value of benefits and costs over measure lives; nominal discount rate is 2.78 percent, inflation rate is 2.22 percent.

The present value of total avoided cost benefits is $291 million under the BAU scenario, $373 million under the 25 Percent Plus scenario and $441 million under the 75 Percent Plus scenario. Finally, all scenarios have positive net benefits: the present value of net avoided cost benefits, i.e., the difference between total avoided cost benefits and total costs (which include participant costs in addition to program costs) for the 10-year period is $140 million under the BAU scenario, $202 million under the 25 Percent Plus scenario and $236 million under the 75 Percent Plus scenario.

Each of the funding scenarios are cost-effective based on the TRC test The TRC benefit-cost ratios for National Grid's service territory are 1.9 for the BAU scenario, 2.2 for the 25 Percent Plus scenario and 2.1 under the 75 Percent Plus scenario.

Key results of the efficiency scenario forecasts from 2016 to 2018 are summarized in Table 5-44.

Table 5-44. Summary of Achievable Natural Gas Potential Results—2016-2025*

Result - Programs	Program Scenario: BAU	Program Scenario: 25% Plus	Program Scenario: 75% Plus
Gross Cumulative Annual Energy Savings – thousand therms	34,762	41,312	46,695
Net Cumulative Annual Energy Savings – thousand therms	31,318	37,867	43,250
Program Costs - Real, $ Million (sum 10-year cost, not discounted)			
Administration	$15	$17	$23
Marketing	$61	$61	$61
Incentives	$60	$77	$107
Total	$137	$156	$191

PV 10-year Annual Program Costs (Adm/Mkt)	$29	$34	$45
PV 10-year Net Measure Costs	$122	$137	$161
Net Benefits (PV 10-year)	$140	$202	$236
TRC Ratio	1.9	2.2	2.1

*PV (present value) of benefits and costs is calculated over the life of each measure for 2016-2025 program years, nominal discount rate = 2.78 percent, inflation rate = 2.22 percent; therms savings are cumulative through 2025.

5.3.4.3 Breakdown of Achievable Natural Gas Potential by Sector

Cumulative achievable potential estimates by sector for gas for the period of 2016 to 2025 and the period 2016 to 2018 are presented in Figure 5-43 and

Figure 5-44. These figures compare the industrial and commercial sector results for each funding scenario. Under the program assumptions developed for this study, achievable energy savings under each scenario are highest for the commercial sector during both time periods. Peak demand savings under all scenarios are also highest for the commercial sector.

Figure 5-43. Net Achievable Natural Gas Energy Savings (2016-2018) by Sector—thousand Therms per Year

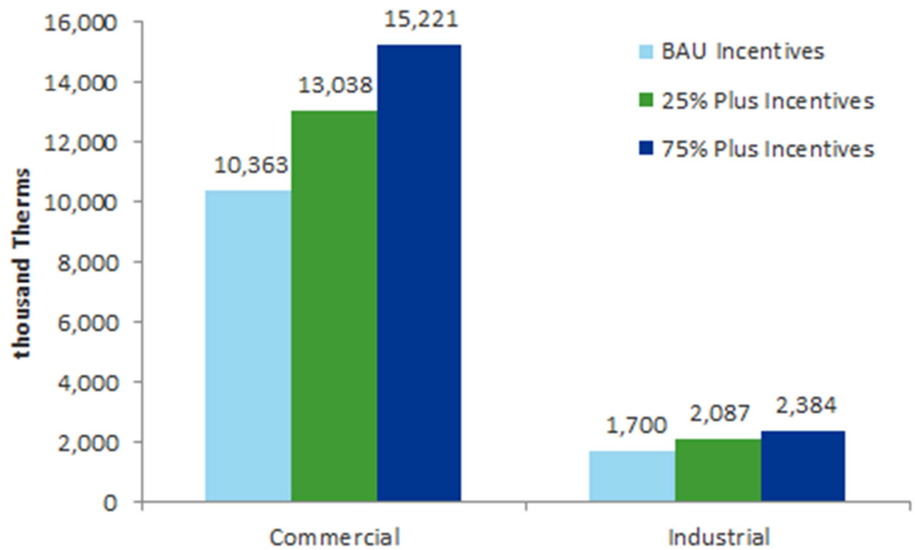

Figure 5-44. Net Achievable Natural Gas Energy Savings (2016-2025) by Sector—thousand therms per year

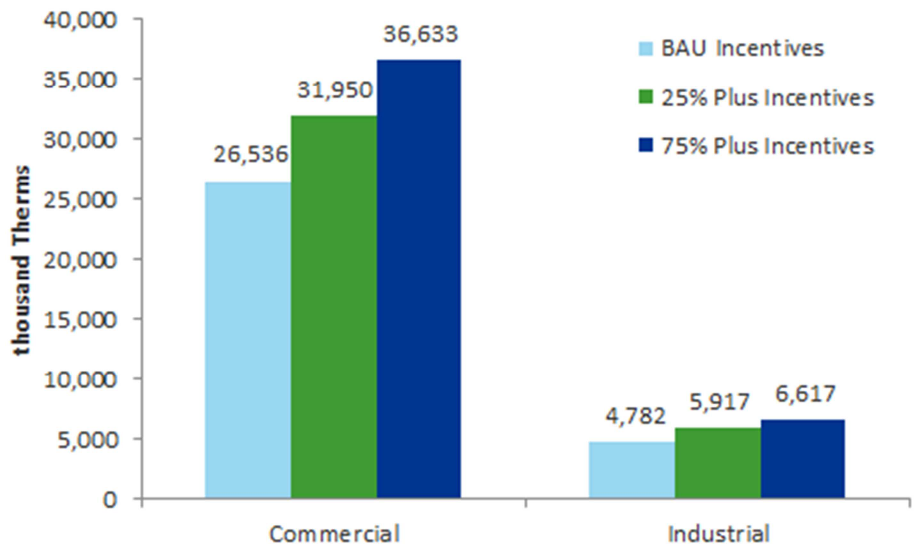

5.3.5 Top 20 Saving Measures - Electric

Table 5-45 and Table 5-46 show the top 20 electricity measures ranked by net achievable energy savings for the commercial and industrial sectors, respectively. The savings shown are annual savings for 2016, the first year of the forecast period.

Upstream LEDs replacing incandescents have the highest savings in the commercial sector. While incandescents represent only a small share of the screw-based lighting stock, Project 41 found them in many commercial buildings (see saturation in Table 5-1), though in smaller numbers than CFLs. That remaining stock, the high per-unit savings, combined with the short lifetime (and therefore rapid turnover) of incandescents, results in high savings for this measure in the early years of the forecast. Upstream LEDs are followed closely by occupancy sensors.

Table 5-45: Top 20 Commercial Electric Measures for 2016 Net Energy Savings

Rank	Measure	MWh
1	Upstream LEDs (base Incandescent 72W)	42,109
2	Occupancy Sensors	25,092
3	RET 4L4' Low Watt High Performance T8 (83 W)	23,057
4	Retrocommissioning/Building tune up	20,972
5	Custom Lighting	9,912
6	Upstream LEDs (base CFL spiral 23W)	8,413
7	High Bay T5 HO (240W)	8,143
8	Variable Speed Drive Control, 5 HP	7,088
9	RET LED Troffer	6,207
10	Advanced Lighting Design (High Performance Lighting R/R) - 25% Savings	6,113
11	Upstream 4L4' LED Tube	5,873
12	Advanced Lighting Controls	5,343
13	High Bay LED Lighting	4,897
14	ROB DX Packaged System, EER=10.8, 30 tons	3,919
15	Commissioning	2,888
16	New Construction 30% better than code	2,621
17	RTU VSD	2,462
18	RET 4L4' LED Tube	2,373
19	New Construction 15% better than code	2,095
20	New Construction 50% better than code	2,089

In the industrial analysis, electric drive injection molders, which have been a large part of National Grid's programs for many years, has the highest savings, followed by variable speed drive control for large (100 HP and larger) motors.

Table 5-46: Top 20 Industrial Electric Measures for 2016 Net Energy Savings

Rank	Measure	MWh
1	Electric Drive Injection Molder (Plastics)	13,901
2	Variable speed drive control (100+ hp)	9,570
3	Occupancy Sensor, 4L4' Fluorescent Fixtures	3,991
4	High Bay T5 HO (240W)	3,691
5	Custom Measures--Drives (100+ hp)	2,643
6	Variable speed drive (pumps)	1,785
7	RET 4L4' Low Watt High Performance T8 (83 W)	1,711
8	Variable speed drive control (51-100 hp)	1,456
9	Upstream 4L4' LED Tube	973
10	Custom Measures--Other Process	929
11	High Bay LED Lighting	811
12	Custom Measures--Process Heating	674
13	Custom Measures--Drives, (6-20 hp)	628
14	Custom Compressed Air	601
15	Custom Measures--Drives (51-100 hp)	514
16	Variable Speed Drive Control, (6-20 hp)	424
17	Motors- System Optimization and sizing (100+ hp)	371
18	Upstream 4L4' Low Watt High Performance T8 (83 W)	369
19	Water/Wastewater Custom Projects	355
20	High Efficiency Air Compressors	331

5.3.6 Top 20 Saving Measures - Natural Gas

Table 5-47 and Table 5-48 show the top 20 natural gas measures ranked by net achievable energy savings for the commercial and industrial sectors, respectively. The savings shown are annual savings for 2016, the first year of the forecast period.

Retrocommissioning has the highest savings in the commercial sector, followed by air side heat recovery systems.

Table 5-47: Top 20 Commercial Natural Gas Measures for 2016 Net Energy Savings

Rank	Measure	1000 therms
1	Retrocommissioning	1,177,049
2	Installation of Air Side Heat Recovery Systems	483,461
3	Installation of Energy Management Systems (EMS)	312,821
4	Steam traps	300,379
5	Boiler Controls	238,357
6	High Efficiency Condensing Boiler 95% efficiency	137,298
7	Custom Boiler	106,627
8	Custom Other Heat	101,208
9	Custom Water Heating-high standby loss	97,449
10	Condensing unit heaters	94,178
11	Programmable communicating thermostat	82,055
12	Refrigeration heat recovery - space conditioning	75,553
13	Energy Star Steamer	71,240
14	Stack Heat Exchanger	68,213
15	Condensing Water Heater (gas, 95% thermal efficiency)	59,342
16	DHW Pipe Insulation - high standby loss (as % of load)	58,776
17	Insulation of Pipes	54,350
18	Energy Star Fryer	45,910
19	Hot water temperature reset	45,281
20	Insulation (ceiling)	39,611

In the industrial analysis, custom process heating has the highest savings, followed by improved furnace combustion efficiency.

Table 5-48: Top 20 Industrial Natural Gas Measures for 2016 Net Energy Savings

Rank	Measure	1000 therms
1	Custom (Base Process Heating)	145,799
2	Improved Furnace Combustion Efficiency/Oxygen enrichment	74,077
3	Boiler reset controls (Base Steam Boiler)	37,671
4	Process heat recovery	36,502
5	Process integration	30,743
6	Upgrading to steam blanchers (Food)	29,472
7	Improve ceiling insulation	25,863
8	Steam trap improvement/maintenance/monitoring	23,857
9	Improved boiler pipe insulation (Base Steam Boiler)	21,420
10	Custom (Base Other Process)	19,711
11	Custom (Base HVAC)	16,671
12	Improved insulation on steam lines	16,238
13	Direct contact water heating (low temperature only)	13,963
14	Resize charging openings or add a movable door on furnace	12,567
15	EMS install	9,836
16	Boiler reset controls (Base Hot Water Boiler)	7,770
17	Efficient drying systems	5,356
18	Blowdown heat recovery (Base Steam Boiler)	5,007
19	Improved boiler pipe insulation (Base Hot Water Boiler)	4,554
20	Condensing Boiler (>300,000 Btu/h) (EF>90%) (Th. Eff. >=90%)	3,289

5.4 Interpreting the Results

This section presents the DNV GL team's assessment of the drivers behind the results of the model. While the research team recognizes that the results are lower than anticipated, DNV GL does feel that the numbers are reasonable given the landscape of the Massachusetts energy efficiency programs and the assumptions made in the model. In addition, the analysis specifically includes assumptions about the technology, program and market conditions that are intended to best represent the 2016 to 2018 time frame which was of most interest to National Grid.

5.4.1.1 National Grid's Program Landscape

For the last six years, National Grid has faced and achieved aggressive energy savings goals. In addition, National Grid's own energy efficiency programs have existed for decades. Together, this has led to both high program awareness and saturation within National Grid's territory. Put more simply, the availability of wide-spread cost-effective measures in National Grid's territory is diminishing. Without a disruptive change either in new technology or program design on the horizon during the 2016 to 2018 time frame, the results of the modeling effort are not surprising.

5.4.1.2 Market Saturation of Retrofit Measures

When the total BAU achievable results are disaggregated and reviewed year by year across 2016 to 2025, there is a noted decline over time in the annual BAU achievable energy savings as a percentage of base consumption as shown in Figure 5-45 (electric) and Figure 5-46 (gas) below. One of the main drivers for this drop is the treatment of retrofit upgrades over the study period. The decline is the result of front-loading one-time retrofit savings, which saturates the market and reduces opportunities for retrofit savings going into the future. In addition, the modeling effort intentionally uses a conservative approach and does not count on speculative changes in technologies and markets to produce savings that may or may not come to pass. In reality, this decline in savings would be at least partially offset by new technologies not reviewed in this analysis entering the market (or existing technologies becoming more cost effective).

Figure 5-45: Total BAU Achievable Electric Energy Savings as a % of 2025 Base Consumption

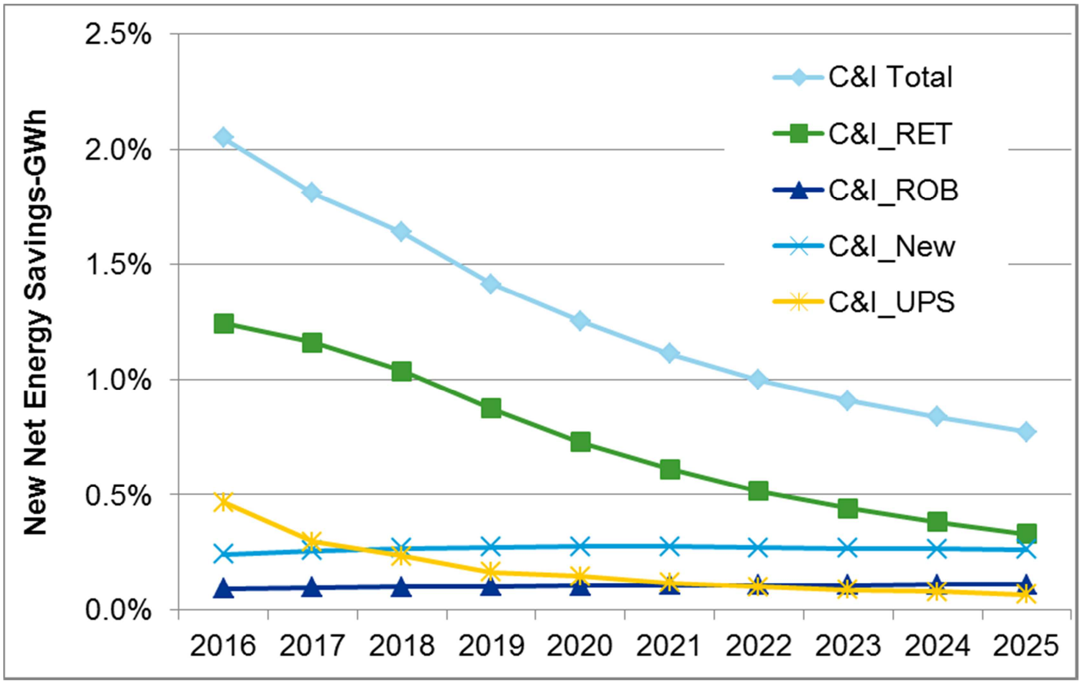

Figure 5-46. Total BAU Achievable Natural Gas Energy Savings as a % of 2025 Base Consumption

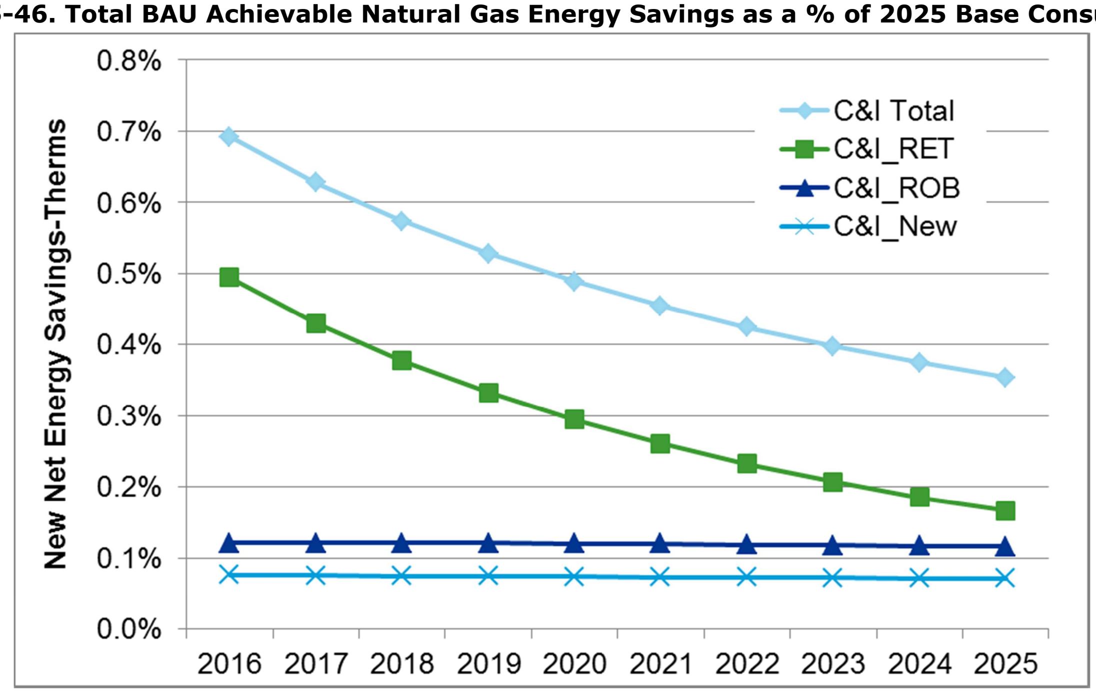

It should be noted that retrofit is the largest contributor to savings, as well as the main driver of the slope of the line. Other program measures (e.g. new construction) have a more constant stream of savings, but retrofit measures saturate the market early and decline much faster than other programs, despite the study including a number of measures that are relatively new to the market and have low current saturations. The reason for this early saturation is that retrofit opportunities are available immediately, as installations do not need to wait for the base measure to reach the end of its lifetime before it can be updated. With greater program effort, retrofit savings can be front-loaded, but without additional measures, the total area under the curve will be the same. Because of this, the study assumes that a majority of the retrofit measures are being implemented during the earlier years, while replace on burn-out measures and new construction measures experience a continuous stream over the 10-year period of the model.

5.4.1.3 Conservative Estimates of New Technologies

One way that programs compensate for the decline in annual accomplishments due to rapid saturation of retrofit measures is to support new measures and/or new technologies. The DNV GL team does incorporate several new technologies in the model, including but not limited to:

- Advanced rooftop controls
- Advanced lighting controls
- Comprehensive lighting design
- Rooftop unit automated fault detection (limited applicability)
- Multiple catch-all custom measures that can capture new technologies not explicitly modeled.

In addition to the new technologies that are included in the model, the DNV GL team reviewed a number of additional technologies and program approaches for inclusion in the study (see section 3.1), but did not include them either due to lack of credible costs and savings data or because the technology or program approach was considered to be too nascent to be viable in the near term. Instead, the new technologies that are included in the study are commercially available and most have been included in National Grid's programs, although in relatively small numbers to date. The limited inclusion of emerging technologies is a result of a decision made by the DNV GL and National Grid teams to take a conservative approach, and not include technologies that were not yet commercialized (or near commercialization). There were several reasons for this decision, most importantly to ensure that the estimates for the 2016 to 2018 time frame were based on measures that were likely to be available in the market during the next three-year plan. A more aggressive approach to modeling new technologies would potentially have seen more savings coming from new technologies in future years of the model.

A more complete discussion of the new technologies considered is included in Section 3.1.

5.4.1.4 Lighting Baselines/Lifetimes

The EM&V Project 41 Wave 1 on-sites found a screw-based lamp distribution of 18 percent incandescent, 71 percent CFL, and 11 percent LED. Incandescents last less than a year with typical commercial or industrial usage, so turnover is rapid. While to date, National Grid program evaluations have found that upstream LEDs have mostly replaced incandescents, the small and shrinking share of incandescents suggests that this practice will change in the near future. DNV GL's analysis predicts (and other evidence of LED adoption supports) that incandescent lamps will be rapidly replaced with LEDs over the next couple years, leaving the upstream program with the less fruitful opportunity of replacing CFLs with LEDs (or possibly lower efficiency LEDs with higher efficiency LEDs). Less fruitful, because not only are the savings smaller going from a CFL to an LED, but also because CFLs last longer than incandescents and will turn over more slowly.

5.4.1.5 Exclusion of CHP & Streetlighting

Another reason for lower than expected achievable savings is due to the fact that both CHP and streetlighting measures are not addressed in the study. While the CHP measure accounts for 9.6% of gross C&I Retrofit kWh savings and 6.4% of gross C&I total kWh savings according to the 2013-2015 Electric Screening Model, CHP projects do not follow an easily modeled path, instead showing up in very unpredictable and "lumpy" waves over a 10-year time frame. In addition, the more predictable, smaller scale 1-to-5 kW CHP system projects are still a long way off from being a cost-effective measure. Finally, in early discussions with National Grid, their program implementation team felt that it had a solid understanding of the CHP projects in the pipeline over the next few years. For these reasons, the DNV GL team determined (along with National Grid) that it was not necessary to include CHP in the study. The team followed a similar decision making process when deciding not to include streetlighting as a measure in the study.

5.4.1.6 Comparison to Other Potential Studies

Finally, while the results of the study show a lower than expected achievable potential result, it should be noted that in comparison to other potential studies conducted recently, National Grid is within the "ball park" of findings DNV GL is seeing in other jurisdictions with a similar history of energy efficiency programs as Massachusetts. Table 5-49 provides the results of the achievable scenarios for several of these additional potential studies.

Table 5-49: 10-Year Achievable Scenarios (percent of base) from other recent Potential Studies

Study	BAU	Low-Case	High-Case
Electric Results			
National Grid 2015 Potential Study	13%	14%	16%
CPUC 2015 Potential Study[21]	9%	NA	NA
Vermont Public Service 2013 Potential Study[22]	NA	NA	19%
Xcel Energy 2012 Potential Study[23]	9%	10%	11%
Idaho Power 2012 Potential Study (Comm'l)[24]	9%	NA	NA
Idaho Power 2012 Potential Study (Ind'l)[25]	9%	NA	NA
Natural Gas Results			
National Grid 2015 Potential Study	5%	6%	7%
CPUC 2015 Potential Study[26]	3%	NA	NA
Xcel Colorado DSM Market Potential (Gas results)[27]	NA	3%	7%

It should be noted that the achievable scenarios in Table 5-49 for the other utilities were approached differently than what was done for National Grid. For example, the scenarios for Xcel were for incentives that covered 50% and 75% of the total cost for each measure. Although this difference makes comparing the results not quite apples to apples, it does provide context for the range of achievable energy savings other utilities similar to National Grid have seen for their 10 year potential studies.

National Grid Massachusetts Energy Efficiency Potential Study Appendices

FINAL

Prepared by KEMA, Inc.

October 26, 2015

APPENDICES

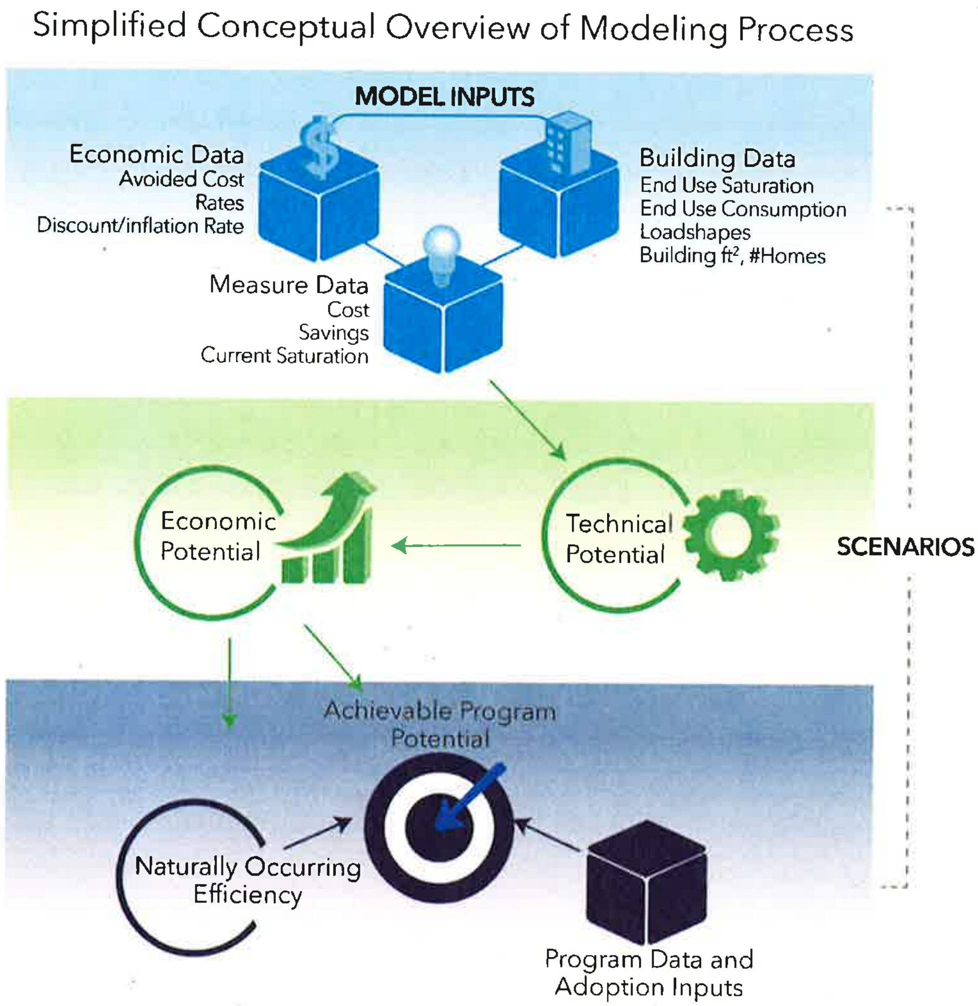
A. DETAILED METHODOLOGY

In this appendix DNV GL presents and discusses our basic methodology for conducting market potential studies.

A.1 Overview of DSM Forecasting Method

The crux of this study involves carrying out a number of basic analytical steps to produce estimates of the energy efficiency potentials introduced above. The basic analytical steps for this study are shown in relation to one another in Figure A-1. The bulk of the analytical process for this study was carried out in a model developed by DNV GL for conducting energy efficiency potential studies. The study integrates technology-specific engineering and customer behavior data with utility market saturation data, load shapes, rate projections, and marginal costs into an easily updated data management system.

Figure A-1: Conceptual Overview of Study Process



The key steps implemented in this study are:

Step 1: Develop Initial Input Data

- Develop a list of energy efficiency measure opportunities to include in scope. In this step, an initial draft measure list was developed and provided to National Grid. The final measure list was developed after incorporating comments.
- Gather and develop technical data (costs and savings) on efficient measure opportunities. Data on measures were gathered from a variety of sources. Detail on measure inputs is provided in Appendix D.
- Gather, analyze, and develop information on building characteristics, including total square footage, energy consumption and intensity by end use, end-use consumption load patterns by time of day and year (i.e., load shapes), market shares of key electric consuming equipment, and market shares of energy efficiency technologies and practices.

- Collect data on economic parameters: avoided costs, electricity rates, discount rates, and inflation rate. These inputs are provided in Appendix C of this report.

Step 2: Estimate Technical Potential and Develop Supply Curves

- Match and integrate data on efficient measures to data on existing building characteristics to produce estimates of technical potential and energy efficiency supply curves.

Step 3: Estimate Economic Potential

- Match and integrate measure and building data with economic assumptions to produce indicators of costs from different viewpoints (e.g., societal and consumer).
- Account for interaction and competition between measures. Measures are assumed to be implemented in order of cost-effectiveness, with the most cost-effective measures implemented first. If subsequent measures are mutually exclusive with previous measures (for example, CFL and LED lamps competing for the same socket), the subsequent measure is evaluated on its marginal costs and marginal savings compared to the more cost-effective measure.
- Estimate total economic potential. Note that at this stage of the analysis, program-related costs are not factored into the cost-effectiveness screening. Thus, the results reflect the theoretical estimate of the measure impacts, while disregarding the mode of delivery. In addition, this step does not take into account natural measure turnover and instead assumes that all available measure installations occur immediately in year one.

Step 4: Estimate Achievable Program and Naturally Occurring Potentials

- Screen initial measures for inclusion in the program analysis. This screening may take into account factors such as natural measure turnover, cost effectiveness, potential market size, non-energy benefits, market barriers, and potentially adverse effects associated with a measure. For this study, measures were screened using the total-resource-cost test, with the exclusion of program marketing and administrative costs.
- Gather and develop estimates of program costs (e.g., for administration and marketing) and historic program savings.
- Develop estimates of customer adoption of energy efficiency measures as a function of the economic attractiveness of the measures, barriers to their adoption, and the effects of program intervention.
- Estimate achievable program and naturally occurring potentials and associated program costs.

Step 5: Scenario Analyses

- Recalculate potentials under alternate program scenarios. These scenarios relate to different levels of incentives offered to participants for energy efficiency measures.

Provided below is additional discussion of DNV GL's modeling approaches for technical, economic, and achievable DSM forecasts.

A.1.1 Estimate Technical Potential and Develop Energy-Efficiency Supply Curves

Technical potential refers to the amount of energy savings or peak demand reduction that would occur with the *complete* penetration of all measures analyzed in applications where they were deemed *technically* feasible from an *engineering* perspective. Total technical potential is developed from estimates of the technical potential of individual measures as they are applied to discrete market segments (commercial building types, residential dwelling types, etc.).

A.1.1.1 Core Equation

The core equation used to calculate the energy technical potential for each individual efficiency measure, by market segment, is shown below (using a commercial example):[1]

$$\text{Technical Potential of Efficient Measure} = \text{Total Square Feet} \times \text{Base Case Equipment EUI} \times \text{Applicability Factor} \times \text{Not Complete Factor} \times \text{Feasibility Factor} \times \text{Savings Factor}$$

where:

Square feet is the total floor space for all buildings in the market segment. For a residential analysis, the **number of dwelling units** is substituted for square feet.

Base-case equipment EUI is the energy used per square foot by each base-case technology in each market segment. This is the consumption of the energy-using equipment that the efficient technology replaces or affects. For example, if the efficient measure were a CFL, the base EUI would be the annual kWh per square foot of an equivalent incandescent lamp. For the residential analysis, unit energy consumption (UECs), energy used per dwelling, are substituted for EUIs.

Applicability factor is the fraction of the floor space (or dwelling units) that is applicable for the efficient technology in a given market segment; for the example above, the percentage of floor space lit by incandescent bulbs.

Not complete factor is the fraction of applicable floor space (or dwelling units) that has not yet been converted to the efficient measure; that is, (1 minus the fraction of floor space that already has the EE measure installed).

Feasibility factor is the fraction of the applicable floor space (or dwelling units) that is technically feasible for conversion to the efficient technology from an *engineering* perspective.

Savings factor is the percent reduction in energy consumption resulting from application of the efficient technology.

Technical potential for peak demand reduction is calculated analogously.

---

[1] Note that stock turnover is not accounted for in our estimates of technical and economic potential, stock turnover *is accounted for* in our estimates of achievable potential. Our definition of technical potential assumes instantaneous replacement of standard-efficiency with high-efficiency measures.

An example of the core equation is shown in Table A-1 for the case of a prototypical 4-lamp 4-foot standard T-8 lighting fixture, which is replaced by a 4-lamp 4-foot premium T-8 fixture in the office segment of a large utility service territory.

Table A-1
Example of Technical Potential Calculation—Replace 4-Lamp 4-Foot Standard T-8s with 4-Lamp 4-Foot Premium T-8s in the Office Segment of a Utility Service Territory
(Note: Data are illustrative only)

Technical Potential of Efficient Measure	=	Total square feet	×	Base Case Equipment UEC	×	Applicability Factor	×	Not Complete Factor	×	Feasibility Factor	×	Savings Factor
57 million kWh		195 million		5.74		0.34		0.95		1.00		0.16

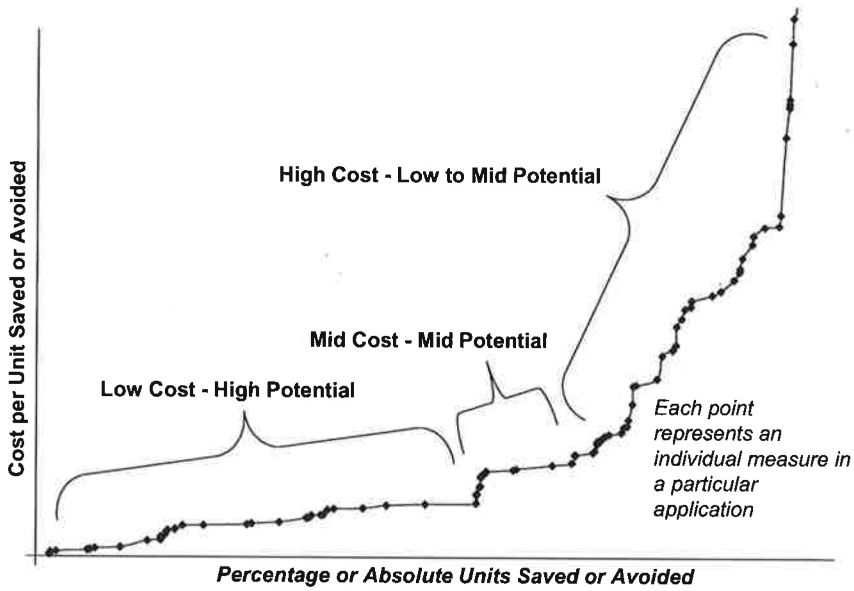
Technical EE potential is calculated in two steps. In the first step, all measures are treated independently; that is, the savings of each measure are not marginalized or otherwise adjusted for overlap between competing or synergistic measures. By treating measures independently, their relative economics are analyzed without making assumptions about the order or combinations in which they might be implemented in customer buildings. However, the total technical potential across measures cannot be estimated by summing the individual measure potentials directly. The cumulative savings cannot be estimated by adding the savings from the individual savings estimates because some savings would be double counted. For example, the savings from a measure that reduces heat gain into a building, such as window film, are partially dependent on other measures that affect the efficiency of the system being used to cool the building, such as a high-efficiency chiller; the more efficient the chiller, the less energy saved from the application of the window film.

A.1.1.2 Use of Supply Curves

In the second step, cumulative technical potential is estimated using an EE supply curve approach.[2] This method eliminates the double-counting problem. In Figure A-2, DNV GL presents a generic example of a supply curve. As shown in the figure, a supply curve typically consists of two axes—one that captures the cost per unit of saving a resource or mitigating an impact (e.g., $/kWh saved or $/ton of carbon avoided) and the other that shows the amount of savings or mitigation that could be achieved at each level of cost. The curve is typically built up across individual measures that are applied to specific base-case practices or technologies by market segment. Savings or mitigation measures are sorted on a least-cost basis, and total savings or impacts mitigated are calculated incrementally with respect to measures that precede them. Supply curves typically, but not always, end up reflecting diminishing returns, i.e., as costs increase rapidly and savings decrease significantly at the end of the curve.

[2] This section describes conservation supply curves as they have been defined and implemented in numerous studies. Readers should note that Stoft 1995 describes several technical errors in the definition and implementation of conservation supply curves in the original and subsequent conservation supply curve studies. Stoft concludes that conservation supply curves are not "true" supply curves in the standard economic sense but can still be useful (albeit with his recommended improvements) for their intended purpose (demonstration of cost-effective conservation opportunities).

Figure A-2: Generic Illustration of EE Supply Curve



As noted above, the cost dimension of most EE supply curves is usually represented in dollars per unit of energy savings. Costs are usually annualized (often referred to as "levelized") in supply curves. For example, EE supply curves usually present levelized costs per kWh or kW saved by multiplying the initial investment in an efficient technology or program by the "capital recovery rate" (CRR):

$$\text{CRR} = \frac{d}{1-(1+d)^{-n}}$$

where *d* is the real discount rate and *n* is the number of years over which the investment is written off (i.e., amortized).

Thus,

Levelized Cost per kWh Saved = Initial Cost x CRR/Annual Energy Savings

Levelized Cost per kW Saved = Initial Cost x CRR/Peak Demand Savings

The levelized cost per kWh and kW saved are useful because they allow simple comparison of the characteristics of EE with the characteristics of energy supply technologies. However, the levelized cost per kW saved is a biased indicator of cost-effectiveness because all of the efficiency measure costs are arbitrarily allocated to peak savings.

Returning to the issue of EE supply curves, Table A-2 shows a simplified numeric example of a supply curve calculation for several EE measures applied to commercial lighting for a hypothetical population of buildings. What is important to note is that in an EE supply curve, the measures are sorted by relative cost—from least to most expensive. In addition, the energy consumption of the system being affected by the efficiency measures goes down as each measure is applied. As a result, the savings attributable to each subsequent measure decrease if the measures are interactive. For example, the occupancy sensor measure shown in Table A-2 would save more at less cost per unit saved if it were applied to the base-case consumption before the T8 lamp and electronic ballast combination. Because the T8 electronic ballast combination is more cost-effective, however, it is applied first, reducing the energy savings potential for the occupancy sensor. Thus, in a typical EE supply curve, the base-case end-use consumption is reduced with each unit of EE that is acquired. Notice in Table A-2 that the total end-use GWh consumption is recalculated after each measure is implemented, thus reducing the base energy available to be saved by the next measure.

Table A-2 shows an example that would represent measures for one base-case technology in one market segment. These calculations are performed for all of the base-case technologies, market segments, and measure combinations in the scope of a study. The results are then ordered by levelized cost and the individual measure savings are summed to produce the EE potential for the entire sector.

In the next subsection, DNV GL discusses how economic potential is estimated as a subset of the technical potential.

Table A-2
Sample Technical Potential Supply Curve Calculation for Commercial Lighting
(Note: Data are illustrative only)

Measure	Total End Use Consumption of Population (GWh)	Applicable, Not Complete and Feasible (1000s of ft^2)	Average kWh/ft^2 of population	Savings %	GWh Savings	Levelized Cost ($/kWh saved)
Base Case: T12 lamps with Magnetic Ballast	425	100,000	4.3	N/A	N/A	N/A
1. T8 w. Elec. Ballast	425	100,000	4.3	21%	89	$0.04
2. Occupancy Sensors	336	40,000	3.4	10%	13	$0.11
3. Perimeter Dimming	322	10,000	3.2	45%	14	$0.25
With all measures	309		3.1	27%	116	

A.1.2 Estimation of Economic Potential

Economic potential is typically used to refer to the technical potential of those energy conservation measures that are cost effective when compared to either supply-side alternatives or the price of energy. Economic potential takes into account the fact that many EE measures cost more to purchase initially than do their standard-efficiency counterparts. The incremental costs of each efficiency measure are compared to the savings delivered by the measure to produce estimates of energy savings per unit of additional cost. These estimates of EE resource costs can then be compared to estimates of other resources such as building and operating new power plants.

A.1.2.1 Cost Effectiveness Tests

To estimate economic potential, it is necessary to develop a method by which it can be determined that a measure or program is economic. There is a large body of literature that debates the merits of different approaches to calculating whether a public purpose investment in EE is cost effective (Chamberlin and Herman 1993, RER 2000, Ruff 1988, Stoft 1995, and Sutherland 2000). DNV GL usually utilizes the total resource cost (TRC) test to assess cost effectiveness and in addition, National Grid's own cost-effectiveness testing utilizes the TRC test. The TRC is a form of societal benefit-cost test. Other tests that have been used in analyses of program cost-effectiveness by EE analysts include the utility cost, ratepayer impact measure (RIM), and participant tests. The California Standard Practice Manual (CASPM) discusses the tests in detail and presents a good primer for a basic understanding. Before discussing the TRC test and how it is typically used in our DSM forecasts, DNV GL presents below a brief introduction to the basic tests as described in the CASPM:[3]

- Total Resource Cost Test—The TRC test measures the net costs of a demand-side management program as a resource option based on the total costs of the program, including both the participants' and the utility's costs. The test is applicable to conservation, load management, and fuel substitution programs. For fuel substitution programs, the test measures the net effect of the impacts from the fuel not chosen versus the impacts from the fuel that is chosen as a result of the program. TRC test results for fuel substitution programs should be viewed as a measure of the economic efficiency implications of the total energy supply system (gas and electric). A variant on the TRC test is the societal test. The societal test differs from the TRC test in that it includes the effects of externalities (e.g. environmental, national security), excludes tax credit benefits, and uses a different (societal) discount rate.
- Participant Test—The participant test is the measure of the quantifiable benefits and costs to the customer due to participation in a program. Since many customers do not base their decision to participate in a program entirely on quantifiable variables, this test cannot be a complete measure of the benefits and costs of a program to a customer.
- Utility (Program Administrator) Test—The program administrator cost test measures the net costs of a demand-side management program as a resource option based on the costs incurred by the program administrator (including incentive costs) and excluding any net costs incurred by the participant. The benefits are similar to the TRC benefits. Costs are defined more narrowly.
- Ratepayer Impact Measure Test—The ratepayer impact measure (RIM) test measures what happens to customer bills or rates due to changes in utility revenues and operating costs caused by the program. Rates will go down if the change in revenues from the program is greater than the change in utility costs. Conversely, rates or bills will go up if revenues collected after program implementation are less than the total costs incurred by the utility in

[3] These definitions are direct excerpts from the California Standard Practice Manual, October 2001.

implementing the program. This test indicates the direction and magnitude of the expected change in customer bills or rate levels.

The key benefits and costs of the various cost-effectiveness tests are summarized in Table A-3.

Table A-3
Summary of Benefits and Costs of California Standard Practice Manual Tests

Test	Benefits	Costs
TRC Test	Generation, transmission and distribution savings Participants avoided equipment costs (fuel switching only)	Generation costs Program costs paid by the administrator Net participant measure costs
Participant Test	Bill reductions Incentives Participants avoided equipment costs (fuel switching only)	Bill increases Participant measure costs
Utility (Program Administrator) Test	Generation, transmission and distribution savings	Generation costs Program costs paid by the administrator Incentives
Ratepayer Impact Measure Test	Generation, transmission and distribution savings Revenue gain	Generation costs Revenue loss Program costs paid by the administrator Incentives

Generation, transmission and distribution savings (hereafter, energy benefits) are defined as the economic value of the energy and demand savings stimulated by the interventions being assessed. These benefits are typically measured as induced changes in energy consumption, valued using some mix of avoided costs. Electricity benefits are valued using three types of avoided electricity costs: avoided distribution costs, avoided transmission costs, and avoided electricity generation costs.

Participant costs are comprised primarily of incremental measure costs. Incremental measure costs are essentially the costs of obtaining EE. In the case of an add-on device (say, an adjustable-speed drive or ceiling insulation), the incremental cost is simply the installed cost of the measure itself. In the case of equipment that is available in various levels of efficiency (e.g., a central air conditioner), the incremental cost is the excess of the cost of the high-efficiency unit over the cost of the base (reference) unit.

Administrative costs encompass the real resource costs of program administration, including the costs of administrative personnel, program promotions, overhead, measurement and evaluation, and shareholder incentives. In this context, administrative costs are not defined to include the costs of various incentives (e.g., customer rebates and salesperson incentives) that may be offered to encourage certain types of behavior. The exclusion of these incentive costs reflects the fact that they are essentially transfer payments. That is, from a societal perspective they involve offsetting costs (to the program administrator) and benefits (to the recipient).

A.1.2.2 Use of the Total Resource Cost to Estimate Economic Potential

We use the TRC test in two ways in our model. First, the team develops an estimate of economic potential by calculating the TRC of individual measures and applying the methodology described below. Second, the team develops estimates of whether different program scenarios are cost effective.

Economic potential can be defined either inclusively or exclusively of the costs of programs that are designed to increase the adoption rate of EE measures. In many of our projects, DNV GL defines economic potential to exclude program costs. DNV GL does so primarily because program costs are dependent on a number of factors that vary significantly as a function of program delivery strategy. There is no single estimate of program costs that would accurately represent such costs across the wide range of program types and funding levels possible. Once an assumption is made about program costs, one must also link those assumptions to expectations about market response to the types of interventions assumed. Because of this, the team believes it is more appropriate to factor program costs into our analysis of program potential. Thus, our definition of economic potential is that portion of the technical potential that passes our economic screening test (described below) exclusive of program costs. Economic potential, like technical potential, is a theoretical quantity that will exceed the amount of potential the team estimates to be achievable through current or more aggressive program activities.

As implied in Table A-3 and defined in the CASPM 2001, the TRC focuses on resource savings and counts benefits as utility-avoided supply costs and costs as participant costs and utility program costs. It ignores any impact on rates. It also treats financial incentives and rebates as transfer payments; i.e., the TRC is not affected by incentives. The somewhat simplified benefit and cost formulas for the TRC are presented in Equations A-1 and A-2 below.

Equation A-1

$$\text{Benefits} = \sum_{t=1}^{N} \frac{\text{Avoided Costs of Supply}_{p,t}}{(1+d)^{t-1}}$$

Equation A-2

$$\text{Costs} = \sum_{t=1}^{N} \frac{\text{Program Cost}_t + \text{Participant Cost}_t}{(1+d)^{t-1}}$$

Where:

d = the discount rate
p = the costing period
t = time (in years)
n = 20 years

A nominal discount rate is typically used in the analysis, as inflation is taken into account separately.

The avoided costs of supply are calculated by multiplying measure energy savings and peak demand impacts by per-unit avoided costs by costing period. Energy savings are allocated to costing periods and peak impacts estimated using load shape factors.

As noted previously, in the measure-level TRC calculation used to estimate economic potential, program costs are excluded from Equation A-2. Using the supply curve methodology discussed previously, measures are ordered by TRC (highest to lowest) and then the economic potential is calculated by summing the energy savings for all of the technologies for which the marginal TRC test is greater than 1.0. In the example in Table A-4, the economic potential would include the savings for measures 1 and 2, but exclude saving for measure 3 because the TRC is less than 1.0 for measure 3. The supply curve methodology, when combined with estimates of the TRC for individual measures, produces estimates of the economic potential of efficiency improvements. By definition and intent, this estimate of economic potential is a theoretical quantity that will exceed the amount of potential the team estimates to be achievable through program activities in the final steps of our analyses.

Table A-4: Sample Use of Supply Curve Framework to Estimate Economic Potential (Note: Data are illustrative only)

Measure	**Total End Use Consumption of Population (GWh)**	**Applicable, Not Complete and Feasible Sq.Feet (000s)**	**Average kWh/ft^2 of population**	**Savings %**	**GWh Savings**	**Total Resource Cost Test**	**Savings Included in Economic Potential?**
Base Case: T12 lamps with Magnetic Ballast	425	100,000	4.3	N/A	N/A	N/A	N/A
1. T8 w. Elec. Ballast	425	100,000	4.3	21%	89	2.5	Yes
2. Occupancy Sensors	336	40,000	3.4	10%	13	1.3	Yes
3. Perimeter Dimming	322	10,000	3.2	45%	14	0.8	No
Technical Potential with all measures				27%	116		
Economic Potential with measures for which TRC Ratio > 1.0				24%	102		

A.1.3 Estimation of Program and Naturally Occurring Potentials

In this section DNV GL presents the method we employ to estimate the fraction of the market that adopts each EE measure in the presence and absence of EE programs. DNV GL defines:

- Program potential as the amount of savings that would occur in response to one or more specific market interventions
- Naturally occurring potential as the amount of savings estimated to occur as a result of normal market forces, that is, in the absence of any utility or governmental intervention.

Our estimates of program potential are typically the most important results of the modeling process. Estimating technical and economic potentials are necessary steps in the process from which important information can be obtained; however, the end goal of the process is better understanding how much of the remaining potential can be captured in programs, whether it would be cost-effective to increase program spending, and how program costs may be expected to change in response to measure adoption over time.

A.1.3.1 Adoption Method Overview

We use a method of estimating adoption of EE measures that applies equally to be our program and naturally occurring analyses. Whether as a result of natural market forces or aided by a program intervention, the rate at which measures are adopted is modeled in our method as a function of the following factors:

- The availability of the adoption opportunity as a function of capital equipment turnover rates and changes in building stock over time
- Customer awareness of the efficiency measure
- The cost-effectiveness of the efficiency measure
- Market barriers associated with the efficiency measure.

In many of our projects, only measures that pass the measure-level TRC test are put into the penetration module for estimation of customer adoption.

A.1.3.2 Availability

A crucial part of the model is a stock accounting algorithm that handles capital turnover and stock decay over a period of up to 20 years. In the first step of our achievable potential method, the team calculates the number of customers for whom each measure will apply. The input to this calculation is the total floor space available for the measure from the technical potential analysis, i.e., the total floor space multiplied by the applicability, not complete, and feasibility factors described previously. DNV GL calls this the eligible stock. The stock algorithm keeps track of the amount of floor space available for each efficiency measure in each year based on the total eligible stock and whether the application is new construction, retrofit, or replace-on-burnout.[4]

Retrofit measures are available for implementation by the entire eligible stock. The eligible stock is reduced over time as a function of adoptions[5] and building decay.[6] Replace-on-burnout measures are

[4] Replace-on-burnout measures are defined as the efficiency opportunities that are available only when the base equipment turns over at the end of its service life. For example, a high-efficiency chiller measure is usually only considered at the end of the life of an existing chiller. By contrast, retrofit measures are defined to be constantly available, for example, application of a window film to existing glazing.

[5] That is, each square foot that adopts the retrofit measure is removed from the eligible stock for retrofit in the subsequent year, and remains out of the eligible stock until the end of the measure's useful life.

[6] Buildings do not last forever. An input to the model is the rate of decay of the existing floor space. Floor space typically decays at a very slow rate.

available only on an annual basis, approximated as equal to the inverse of the service life.[7] The annual portion of the eligible market that does not accept the replace-on-burnout measure does not have an opportunity again until the end of the service life.

New construction applications are available for implementation in the first year. Those customers that do not accept the measure are given subsequent opportunities corresponding to whether the measure is a replacement or retrofit-type measure.

A.1.3.3 Awareness

In our modeling framework, customers cannot adopt an efficient measure merely because there is stock available for conversion. Before they can make the adoption choice, they must be aware and informed about the efficiency measure. Thus, in the second stage of the process, the model calculates the portion of the available market that is informed. An initial user-specified parameter sets the initial level of awareness for all measures. Incremental awareness occurs in the model as a function of the amount of money spent on awareness/information building and how costly it is to reach each customer.

The model also controls for information retention. An information decay parameter in the model is used to control for the percentage of customers that will retain program information from one year to the next. Information retention is based on the characteristics of the target audience and the temporal effectiveness of the marketing techniques employed.

A.1.3.4 Adoption

The portion of the total market this is available and informed can now face the choice of whether or not to adopt a particular measure. Only those customers for whom a measure is available for implementation (stage 1) and, of those customers, only those who have been informed about the program/measure (stage 2), are in a position to make the implementation decision.

In the third stage of our penetration process, the model calculates the fraction of the market that adopts each efficiency measure as a function of the participant test. The participant test is a benefit-cost ratio that is generally calculated as follows:

Equation A-3

$$\text{Benefits} = \sum_{t=1}^{N} \frac{\text{Customer Bill Savings (\$)}_t}{(1+d)^{t-1}}$$

Equation A-4

$$\text{Costs} = \sum_{t=1}^{N} \frac{\text{Participant Costs (\$)}_t}{(1+d)^{t-1}}$$

Where:

[7] For example, a base-case technology with a service life of 15 years is only available for replacement to a high-efficiency alternative each year at the rate of 1/15 times the total eligible stock. For example, the fraction of the market that does not adopt the high-efficiency measure in year *t* will not be available to adopt the efficient alternative again until year *t* + 15.

d = the discount rate
t = time (in years)
N = measure lifetime

The bill reductions are calculated by multiplying measure energy savings and customer peak demand impacts by retail energy and demand rates.

The model uses measure implementation curves to estimate the percentage of the informed market that will accept each measure based on the participant's benefit-cost ratio. The model provides enough flexibility so that each measure in each market segment can have a separate implementation rate curve. The functional form used for the implementation curves is:

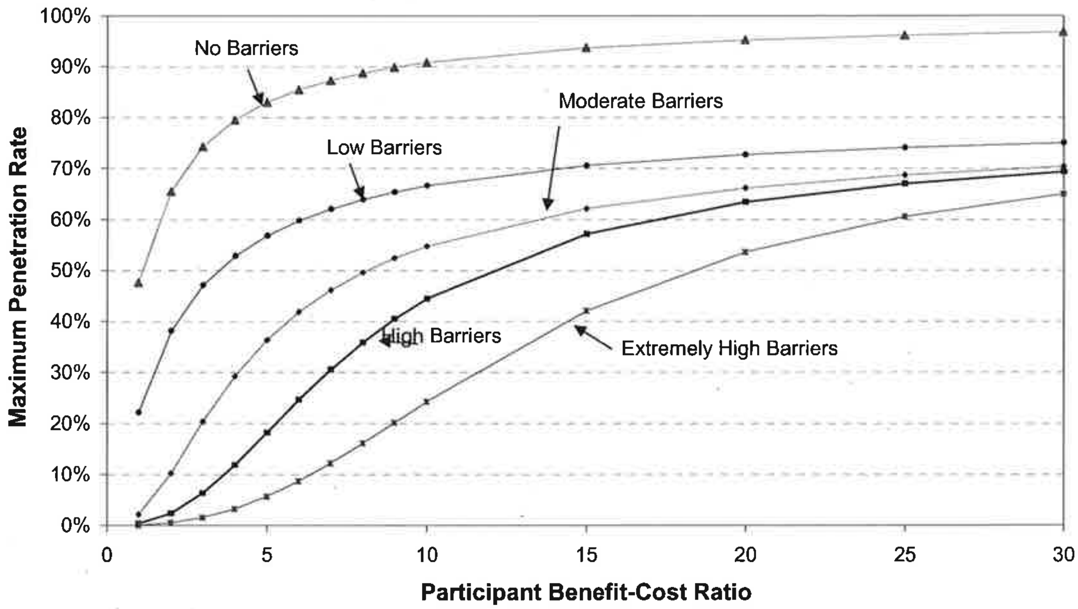
$$y = \frac{a}{\left(1 + e^{-\ln\frac{x}{4}}\right) \times \left(1 + e^{-c\ln(bx)}\right)}$$

where:

y = the fraction of the market that installs a measure in a given year from the pool of informed applicable customers;
x = the customer's benefit-cost ratio for the measure;
a = the maximum annual acceptance rate for the technology;
b = the inflection point of the curve. It is generally 1 over the benefit-cost ratio that will give a value of 1/2 the maximum value; and
c = the parameter that determines the general shape (slope) of the curve.

The primary curves utilized in our model are shown in Figure A-3. These curves produce base year program results that are calibrated to actual measure implementation results associated with major IOU commercial efficiency programs over the past several years. Different curves are used to reflect different levels of market barriers for different efficiency measures. A list of market barriers is shown in Table A-5. It is the existence of these barriers that necessitates program interventions to increase the adoption of EE measures.

Figure A-3: Primary Measure Implementation Curves Used in Adoption Model



Note that for the moderate, high barrier, and extremely high curves, the participant benefit-cost ratios have to be very high before significant adoption occurs. This is because the participant benefit-cost ratios are based on a 15-percent discount rate. This discount rate reflects likely adoption if there were no market barriers or market failures, as reflected in the no-barriers curve in the figure. Experience has shown, however, that actual adoption behavior correlates with implicit discount rates several times those that would be expected in a perfect market.[8]

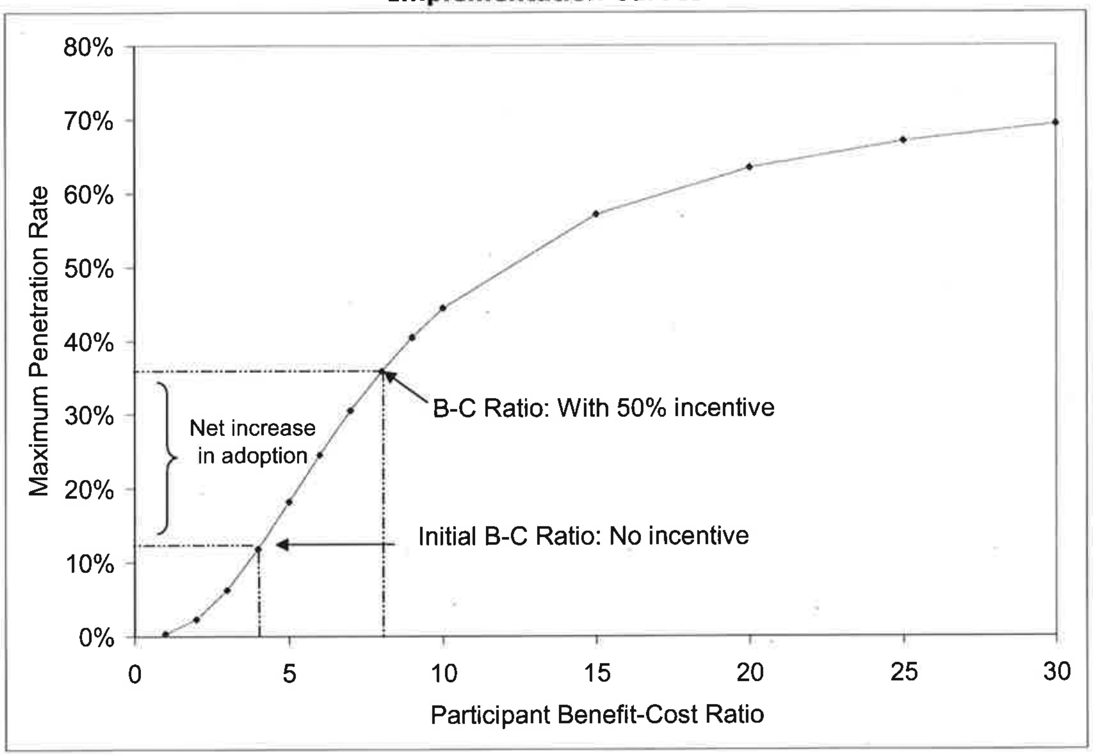
[8] For some, it is easier to consider adoption as a function of simple payback. However, the relationship between payback and the participant benefit-cost ratio varies depending on measure life and discount rate. For a long-lived measure of 15 years with a 15-percent discount rate, the equivalent payback at which half of the market would adopt a measure is roughly 6 months, based on the high barrier curve in Figure 2-3. At a 1-year payback, one-quarter of the market would adopt the measure. Adoption reaches near its maximum at a 3-month payback. The curves reflect the real-world observation that implicit discount rates can average up to 100 percent.

Table A-5: Summary Description of Market Barriers from Eto, Prahl, Schlegel 1997

Barrier	Description
Information or Search Costs	The costs of identifying energy-efficient products or services or of learning about energy-efficient practices, including the value of time spent finding out about or locating a product or service or hiring someone else to do so.
Performance Uncertainties	The difficulties consumers face in evaluating claims about future benefits. Closely related to high search costs, in that acquiring the information needed to evaluate claims regarding future performance is rarely costless.
Asymmetric Information and Opportunism	The tendency of sellers of energy-efficient products or services to have more and better information about their offerings than do consumers, which, combined with potential incentives to mislead, can lead to sub-optimal purchasing behavior.
Hassle or Transaction Costs	The indirect costs of acquiring EE, including the time, materials and labor involved in obtaining or contracting for an energy-efficient product or service. (Distinct from search costs in that it refers to what happens once a product has been located.)
Hidden Costs	Unexpected costs associated with reliance on or operation of energy-efficient products or services - for example, extra operating and maintenance costs.
Access to Financing	The difficulties associated with the lending industry's historic inability to account for the unique features of loans for energy savings products (i.e., that future reductions in utility bills increase the borrower's ability to repay a loan) in underwriting procedures.
Bounded Rationality	The behavior of an individual during the decision-making process that either seems or actually is inconsistent with the individual's goals.
Organization Practices or Customs	Organizational behavior or systems of practice that discourage or inhibit cost-effective EE decisions, for example, procurement rules that make it difficult to act on EE decisions based on economic merit.
Misplaced or Split incentives	Cases in which the incentives of an agent charged with purchasing EE are not aligned with those of the persons who would benefit from the purchase.
Product or Service Unavailability	The failure of manufacturers, distributors or vendors to make a product or service available in a given area or market. May result from collusion, bounded rationality, or supply constraints.
Externalities	Costs that are associated with transactions, but which are not reflected in the price paid in the transaction.
Non-externality Pricing	Factors other than externalities that move prices away from marginal cost. An example arises when utility commodity prices are set using ratemaking practices based on average (rather than marginal) costs.
Inseparability of Product Features	The difficulties consumers sometimes face in acquiring desirable EE features in products without also acquiring (and paying for) additional undesired features that increase the total cost of the product beyond what the consumer is willing to pay.
Irreversibility	The difficulty of reversing a purchase decision in light of new information that may become available, which may deter the initial purchase, for example, if energy prices decline, one cannot resell insulation that has been blown into a wall.

The model estimates adoption under both naturally occurring and program intervention situations. There are only two differences between the naturally occurring and program analyses. First, in any program intervention case in which measure incentives are provided, the participant benefit-cost ratios are adjusted based on the incentives. Thus, if an incentive that pays 50 percent of the incremental measure cost is applied in the program analysis, the participant benefit-cost ratio for that measure will double (since the costs have been halved). The effect on the amount of adoption estimated will depend on where the pre- and post-incentive benefit-cost ratios fall on the curve. This effect is illustrated in Figure A-4.

Figure A-4: Illustration of Effect of Incentives on Adoption Level as Characterized in Implementation Curves



In many of our projects achievable potential EE forecasts are developed for several scenarios, ranging from base levels of program intervention, through moderate levels, up to an aggressive EE acquisition scenario. Uncertainty in rates and avoided costs are often characterized in alternate scenarios. The final results produced are annual streams of achievable program impacts (energy and demand by time-of-use period) and all societal and participant costs (program costs plus end-user costs).

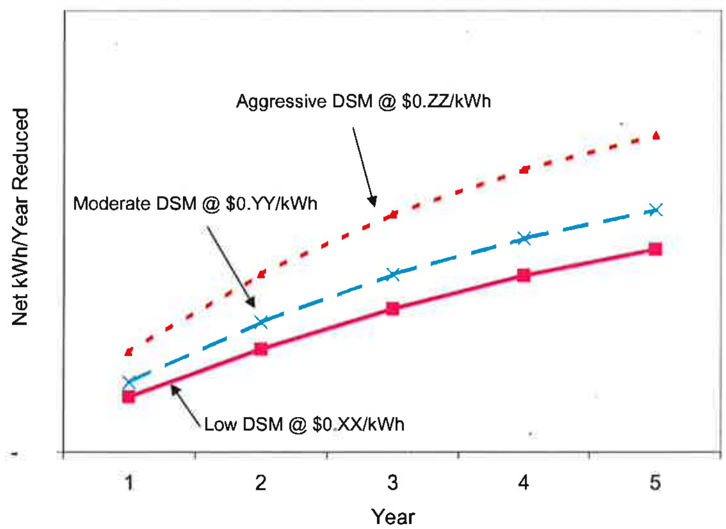
A.1.4 Scenario Analyses

Achievable potential forecasts can be developed for multiple scenarios. For example, program savings can be modeled under low levels of program intervention, through moderate levels, up to an aggressive DSM acquisition scenario. Uncertainty in rates and avoided costs can be characterized in alternate scenarios as well. The final results produced will be annual streams of achievable DSM program impacts (energy and demand by time-of-use period) and all societal and participant costs. An example of the types of outputs that have been produced for similar studies in the past is shown in Table A-6 and Figure A-5.

Table A-6: Example Format of Achievable Potential Outputs

DSM Program Output	2015	20016	20017	etc.
Annual Energy Savings (kWh)				
Net Annual Energy Savings (kWh)				
Peak Demand Savings (kW)				
Net Peak Demand Savings (kW)				
Annual Program Costs				
Supplemental Customer Costs				

Figure A-5: Example of DSM Scenario Outputs



A.1.5 Measure "Bundles" for Complex End Uses

Although potential can be estimated through measure-specific analyses for many sectors and end uses, there are some cases where the measure-specific approach becomes problematic because of the complexity or heterogeneity of the base-case energy systems being addressed. Two key examples are industrial processes and some aspects of residential and commercial new construction.

In the industrial case, there may be dozens or even hundreds of individual measures that can be applied to industrial processes throughout the population of industrial facilities in a service territory; however, analyzing each of these opportunities, though possible, is impractical within a resource and time-constrained study such as this one.

In the case of new construction, the problem is sometimes that an equipment substitution paradigm does not fit the real-world circumstances in which efficiency levels are improved. For example, in commercial lighting, virtually all new buildings tend to have electronic ballasts and T-8 lamps, as well as CFLs or LEDs, and other high-efficiency components. However, the overall lighting system efficiency can often be increased by using these same components in smarter designs configurations or by combining with other features such as daylighting.

For both of these situations, our approach on recent related work has been to bundle multiple individual efficiency measures into somewhat simplified efficiency levels. For example, lighting levels for commercial new construction might be set at 10- and 20-percent improvement over those required by building codes. Similarly, for industrial compressed air systems, the team has bundled savings opportunities into three levels where both savings and costs increase with each level. The team then estimates an incremental cost for achieving each of the efficiency levels.

Once the levels efficiency are specified in terms of costs and savings, they are run through the modeling system as if they were individual measures. Thus, cost-effectiveness indicators are calculated for each level, those that pass the TRC are included in the achievable potential forecasting, and adoption is modeled using the same process as described above. Although the team recommends using this approach for complex end uses because it creates a manageable forecasting process, care must be taken in developing the levels and recognizing that this approach results in some aggregation bias.

B. GLOSSARY

Achievable potential: The amount of savings that would occur in response to specific marketing levels and measure incentive levels. Savings associated with program potential are savings that are projected beyond those that would occur naturally in the absence of any market intervention.

Applicability factor: The percentage of the building stock that has a particular type of equipment or for which an efficiency measure applies. For example, the applicability factor for a tankless electric water heater (compared to a base standard electric water heater) is the percentage of homes with electric water heaters. The applicability factor for high-efficiency clothes washers as an electric water heating measure is the percentage of homes with electric water heating that also have a clothes washer. For base measures, this is sometimes referred to as the equipment saturation.

Business-as-usual (BAU): Represents a continuation of current activities or trends. For utility programs, it denotes a scenario in which program marketing and administrative budgets are kept constant in real terms, and incentive levels are kept constant.

Baseline analysis: Characterizes how baseline energy consumption breaks down by sector, building type, and end use.

Base measure: The equipment against which an efficiency measure is compared.

C&I: commercial and industrial.

CBECS: EIA Commercial Buildings Energy Consumption Survey

CFL: compact fluorescent lamp.

Coincidence factor: Utility coincidence factors are the ratio of actual demand reduction at utility peak to the gross of maximum demand reduction. These factors vary by market segment or building type, end use, measure and by time-of-use period.

Cumulative annual: Savings occurring in a particular year that are due to cumulative program activities up to that year. For example, if a program installs one high-efficiency widget in year 1 of the program, two in year 2, and five in year 3, the cumulative annual savings in year three would be the savings accruing on all eight surviving units in place in year 3, regardless of what year they were installed. Cumulative annual savings does account for equipment retirement. In the example above, widgets are assumed to have an effective useful life of more than three years. If the equipment in the above example were measures that only have a two-year effective useful life, the year 1 measures would have retired at the end of year 2, so only the units sold in years 2 and 3 would contribute to year 3 cumulative annual savings.

Demand-side management (DSM): An electric system must balance the supply of electricity with the demand for electricity. Demand-side management (DSM) programs focus on managing the demand side of this balance through energy-efficiency and load management to reduce the need for supply.

DOE: Department of Energy.

Economic potential: The technical potential of those energy conservation measures that are cost effective when compared to supply-side alternatives. This scenario counts the savings of all cost effective energy conservation measures regardless of the predicted time of installation, i.e. all potential savings are counted in year one.

Effective useful life (EUL): A measure of the typical lifetime of an efficiency measure. Technically, it is the age at which half of the units have failed and half survive. In DNV GL's National Grid model, all measures are assumed to remain in place until the end of their effective useful lives and then retire.

Energy-use intensity (EUI): Energy use per unit of building stock for a specific end use. For example, the EUI for commercial electric heating is the amount of electricity used for heating divided by the number of square feet of floor space that are electrically heated. EUI differs from EI in that it accounts for the equipment type's saturation. If the saturation of the equipment type is low, the EI will be much lower than the EUI.

Energy intensity (EI): Energy use per unit of building stock. For example, the EI for commercial electric heating is the amount of electricity used for heating divided by the total square feet. EI differs from EUI in that it does not account for the saturation of the equipment. If the saturation for the equipment type is low, EI will be much lower than the EUI.

EUI adjustment factor: Because equipment efficiencies can change over time independent of program activities, due to either naturally occurring technological changes or external intervention, such as appliance standards, the efficiency of new equipment may differ from the typical efficiency of the equipment stock. The EUI adjustment factor is the ratio of new standard efficiency equipment's energy use to the average energy use of units in the equipment stock.

Feasibility factor: The fraction of the applicable floor space, or households, that is technically feasible to convert to a DSM technology, from an engineering perspective.

Free rider: A program participant who would have invested in an energy efficiency measure even without the intervention of the program. Free riders add to program costs but do not contribute to net energy savings.

Free-rider energy savings: The subset of naturally occurring energy savings for which the utility pays incentives or provides other program benefits. These savings are included in gross program savings but not in net program savings.

Gross program savings: The total savings for all measures installed under the program, including those that would have been installed even without program intervention (free riders). Gross program savings equals net program savings minus free ridership savings.

Horsepower (HP): A metric for the rated work a motor can perform.

HVAC: heating, ventilation and air conditioning. These space-conditioning measures are often discussed as a group and are referred to by the abbreviation HVAC.

Incomplete factor: The fraction of the applicable floor space which has not yet been converted to the particular energy-efficiency technology.

Incremental cost: The additional cost required to purchase an efficiency measure compared to base equipment.

kW: kilowatts, 1,000 watts. A measure of electric power or electricity demand.

kWh: kilowatt-hour. A measure of electrical energy.

LED: light-emitting diode. LEDs are semiconductor light sources. They have been in use for decades as indicator lights; they are increasingly being used for general-purpose lighting. They are highly efficient compared to incandescent lamps.

MW: megawatt, one million watts. A measure of electric power or electricity demand.

MWh: megawatt-hour, equal to 1,000 kWh. A measure of electrical energy.

NAICS: The North American Industry Classification System is the standard used by Federal statistical agencies in classifying business establishments for the purpose of collecting, analyzing, and publishing statistical data related to the U.S. business economy.

Naturally occurring energy savings: The amount of savings estimated to occur as a result of normal market forces, that is, in the absence of any utility or governmental intervention.

Net program savings: Program savings above and beyond naturally occurring levels. Net savings exclude free-rider energy savings.

Net-to-gross: The ratio of net program savings to gross program savings.

Program potential: This term is used interchangeably with achievable potential.

Replace on burnout (ROB): A measure that is installed when the previous equipment reaches the end of its useful life. ROB measures penetrate the market gradually as the existing stock of equipment turns over due to equipment age and eventual failure.

Retrofit: A measure that is installed to achieve energy savings independent of the condition of the existing equipment. This includes measures that affect the energy use of other equipment, such as insulation to reduce heating costs. It also includes replacing equipment with higher efficiency equipment before the end of existing equipment's useful life, for example replacing T12 fluorescent lighting in an office with higher efficiency T8s. Retrofits can be done at any time and therefore have the potential to penetrate the market more quickly than ROB measures.

Technical potential: The savings that would result from complete penetration of all analyzed measures in applications where they were deemed technically feasible, from an engineering perspective.

Technology saturation: A factor that relates the cost units used in the model for a measure to its savings units. For example, the cost of a chiller may be expressed in dollars per ton, though the savings are in kWh per square foot. The technology saturation then represents the number of tons of cooling per square foot.

Time-of-use (TOU) period: The study can analyze energy use by up to six time-of-use periods. These periods are used to characterize the relationship between energy and peak demand, which varies over both season and time of day, and to capture differences in avoided costs and rates over different time periods. TOU periods usually capture differences between summer/winter and peak/off-peak but can also capture shoulder season, mid-peak, or super peak demand, depending on the needs of a utility.

Total resource cost test (TRC): A benefit-cost test that compares the value of avoided energy production and power plant construction to the costs of energy efficiency measures and the program activities necessary to deliver them. The values of both energy savings and peak-demand reductions are incorporated in the TRC test.

UEC: unit energy consumption.

D. MEASURE INPUTS

The following tables present the measure inputs to the model, including base technology end-use energy and demand intensities, measure costs and lifetimes, applicability factors, incomplete factors, feasibility factors, and technology saturations.

The applicabilities for whole building new construction measures are designed to segment the market in a way that avoids double counting of savings. In new construction, we have both individual measures paralleling the approach to existing buildings (for example, a low wattage high performance T8 fixture). We also have whole building measures that could encompass many individual measures, including low wattage high performance T8s. We first segment the market into the portion getting whole building treatment and that getting individual measure treatment. Then, within the whole building segment, we divide the floor space into that getting 15 percent savings, 30 percent savings, 50 percent savings, and 70 percent savings, with progressively smaller shares going to the more aggressive savings levels. The way these measures are modelled applies a single costs that applies to all buildings of a given type (e.g. offices), and this segmentation recognizes that different buildings will face different costs in achieving the various levels of savings, and that as a result not all building will find it equally cost effective to pursue a 50 or 70 percent saving.

O. **Unique Service Area Challenges Presentations**

berkshire gas
A UIL HOLDINGS COMPANY

THE BERKSHIRE GAS COMPANY

2016-2018 ENERGY EFFICIENCY PLAN

UIL HOLDINGS CORPORATION

D.P.U. 15-160 to D.P.U. 15-169
Three-Year Plan 2016-2018
October 30, 2015
Exhibit 1, Appendix O - Part 1 (Berkshire)

Quick Summary

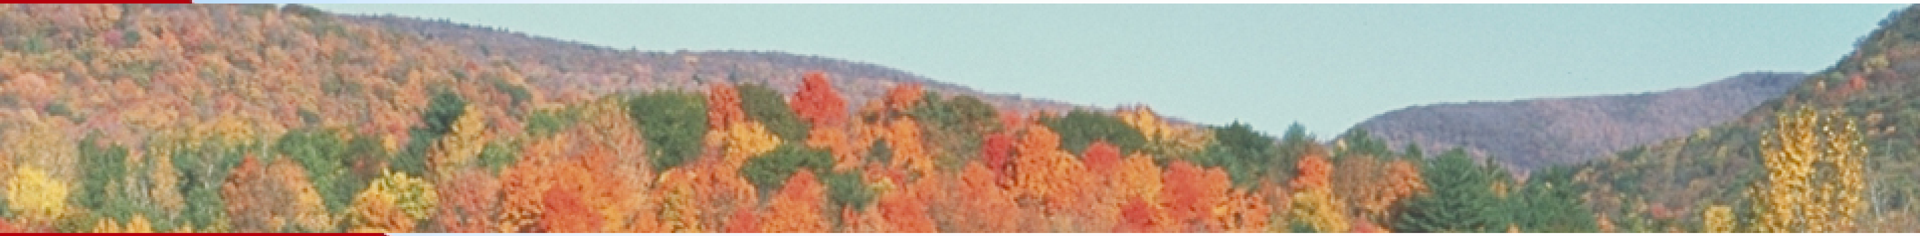
- **Unique Territory**
  - Covers two non-contiguous rural areas, making in-the-field efficiencies challenging
  - Company serves 20 cities and towns with combined population of 190,000
- **Unique Customers**
  - Berkshire Gas serves approx. 32,000 heating customers, approx. 5000 commercial customers, only 2% are large C&I
  - Large C&I customers account for only 0.31% of heating customers, yet they contribute 45 % to annual portfolio savings goals
  - Many customers use readily available and low cost alternative fuel sources, such as wood, rather then taking advantage of our energy efficiency programs
- **Economy**
  - In the past few years, the Company experienced certain plants or parts of plants closing, moving or simply shutting down
  - Some commercial customers have been uncertain about the future of some satellite locations in the area, making it challenging for them to commit to energy efficiency projects
- **Budget increase since 2010**
  - Berkshire's 2016 energy efficiency budget is more than double its 2010 budget

UIL HOLDINGS CORPORATION

berkshire gas
A UIL HOLDINGS COMPANY

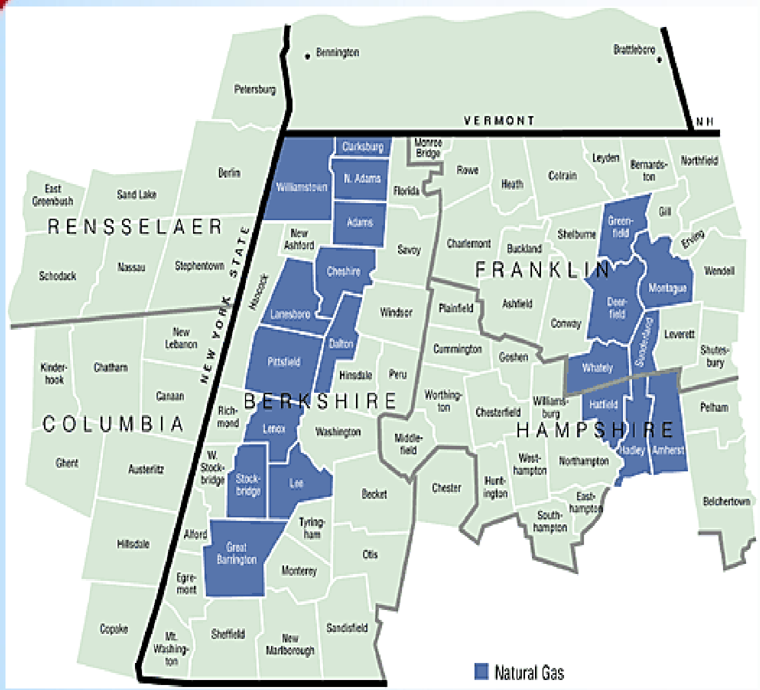
What Makes Berkshire's Territory Unique?

- Berkshire Gas serves approximately 32,000 heating customers
- Located in pastoral western Massachusetts, an area renowned for its natural beauty
- This unique geographic area presents unique challenges
- There is a small commercial & industrial (C&I) customer base
- Out of 5,000 commercial customers, only 2% (about 100) are large C&I customers
- Large C&I customers account for only 0.31% of all heating customers yet they contribute 45% to the annual portfolio savings goal
- In the past few years, the Company experienced certain plants or parts of plants closing, moving or simply shutting down.



UIL HOLDINGS CORPORATION

Service Territory Challenges



- Berkshire's service territory covers two non-contiguous rural areas, making in-the-field efficiencies challenging
- Berkshire Gas serves 20 cities and towns with a combined population of 190,000
- 40% or 8 of these municipalities are Green Communities that have actively pursued energy efficiency opportunities
- For three decades, The Center for EcoTechnology, Berkshire's current residential lead vendor, has promoted sustainability and increased awareness of energy efficiency in Berkshire County and the Pioneer Valley
- These efforts increase the challenge of identifying cost-effective energy efficiency opportunities

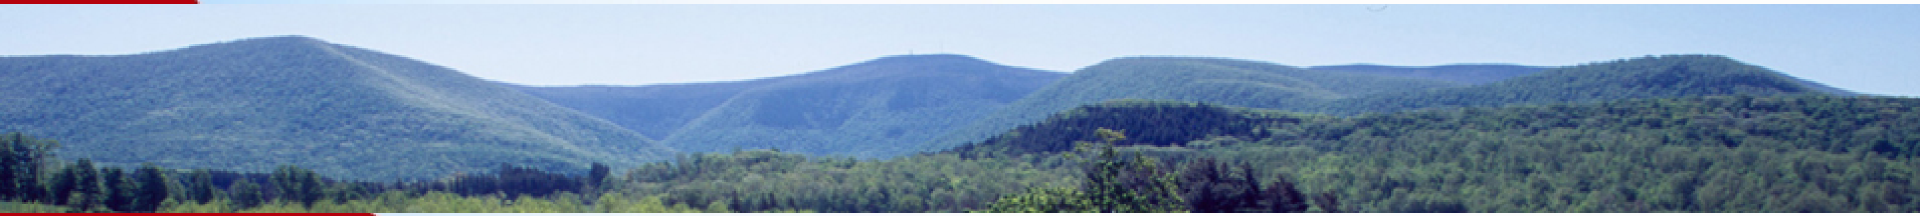
UIL HOLDINGS CORPORATION

ADDITIONAL BACKGROUND

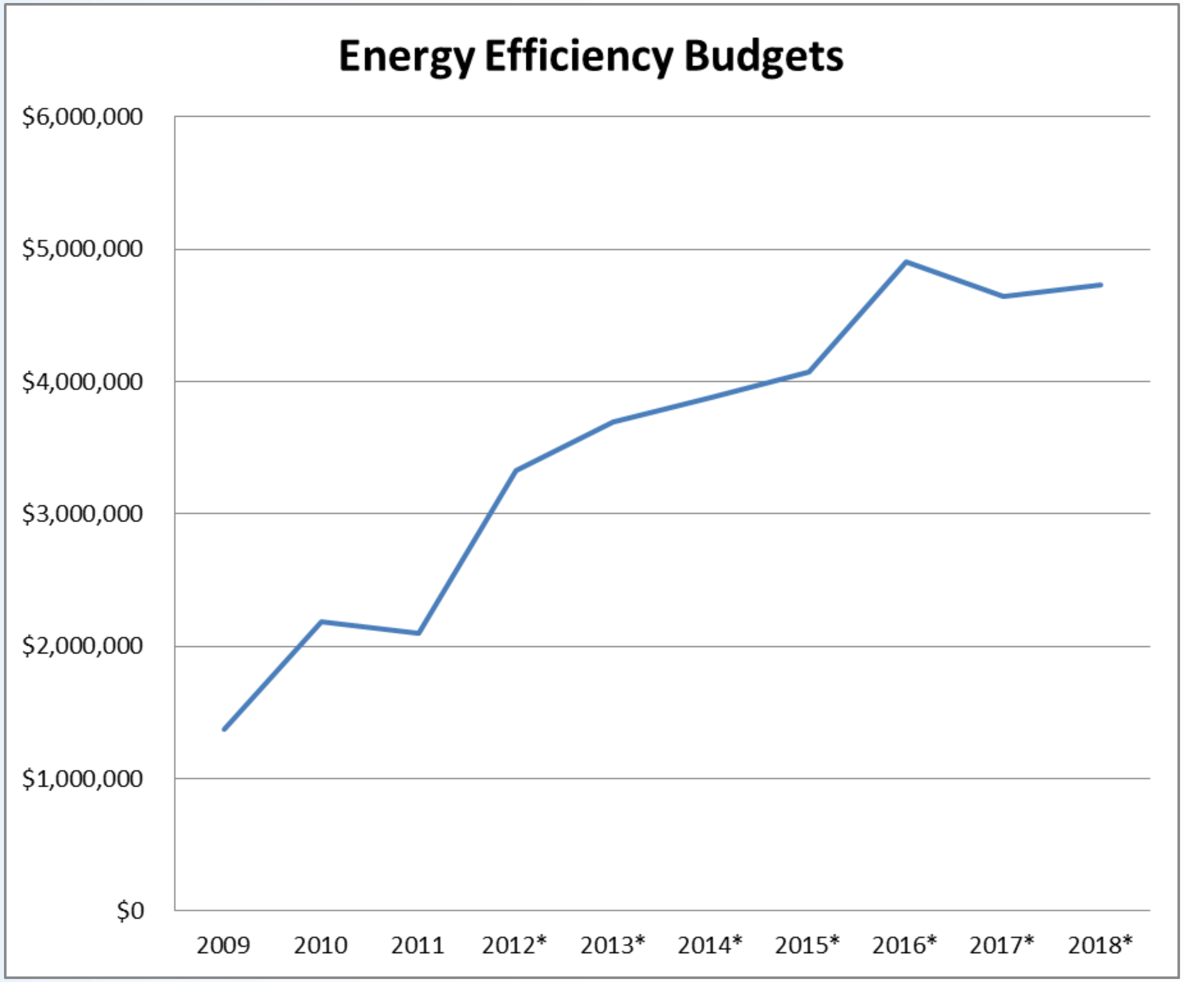
berkshire® gas

A UIL HOLDINGS COMPANY

- Challenging economic conditions have not turned around as rapidly as eastern MA.
- The previous 3- Year Plan was built on the premise that the economy would bounce back at the end of the third year.
- Of our 30,450 residential heating customers,18% or 5,553 are Low-Income heating customers.
- Many customers use readily available and low cost alternative fuel sources, such as wood or wood pellets, rather than taking advantage of our energy efficiency programs.
- During 2015 the gas companies experienced evaluation study results that have been a significant factor in reducing annual savings goals.
- The new avoided gas costs for 2016 are lower than the previous study by some 21%



UIL HOLDINGS CORPORATION



UIL HOLDINGS CORPORATION

What's Driving Berkshire's Costs/Benefits?

berkshire® gas
A UIL HOLDINGS COMPANY

- Residential
  - New Multifamily realization rate of 60% down from 100%
  - The higher commercial and residential building code with higher baseline efficient equipment results in less fuel savings available for custom measures.

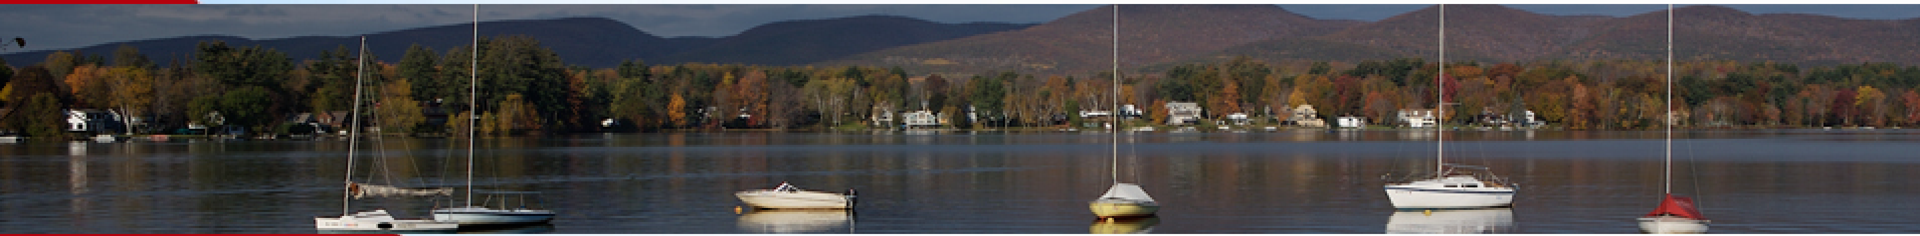
UIL HOLDINGS CORPORATION

D.P.U. 15-160 to D.P.U. 15-169
Three-Year Plan 2016-2018
October 30, 2015
Exhibit 1, Appendix O - Part 1 (Berkshire)
Page 7 of 9

Other Cost/Benefit Drivers

Commercial & Industrial

- New NTG numbers decreased WH savings from 103% to 62% (lost 40% of savings).
- Thermostat savings cut 50%, i.e. 77 therms to 32
- Lower gas prices contributing to yet even longer payback periods



THE FUTURE

- Fully committed to providing the best possible energy efficiency programs and services to our customers.
- Fully committed to continuing to be a valuable and trusted partner in the Western Massachusetts community and building on the Company's many years of excellent service
- Fully committed to continuing to collaborate with fellow PAs to identify best practices and better understand differences driving costs and savings relative to other Pas
- Fully committed to continuing our successful integration efforts with our electric PA partners

Liberty Utilities℠

Massachusetts Energy Efficiency Programs
2016-2018 Plan Background

September 25, 2015

Key Takeaways

- The economy in Greater Fall River is in dire condition.
- Businesses continue to be recruited to other states and foreign countries. Perceived pro-business climate elsewhere.
- Company has been informed of concerns that more stringent Codes and Standards will hurt the construction industry and trades, and ultimately consumers.
- Fully committed to providing the best possible energy efficiency programs and services to our customers.
- Unique economic conditions make goal setting/goal attainment a real challenge.
- Customers (especially C&I) are very sensitive to bill impacts.
- Challenging economic conditions which have not turned around. The original 3 Year Plan was built on the premise that the economy would bounce back at the end of the third year.

Liberty Utilities

Local Economic Climate

- Historically, Fall River consistently has had among the highest unemployment rate in the Commonwealth.
- Textile based workforce, even though the jobs in this sector are no longer in large demand.
- Motivated and eager blue collar workforce with limited opportunities.
- Fall River Median Family Household Income is $33,211 vs. Massachusetts $66,866 (2009-2013 Census data)

Liberty Utilities

Unemployment Continues in the Service Territory

Potential Study Background

In addition to assisting the small PAs in quantifying remaining potential within their service territories, this effort was conducted in accordance with the Massachusetts Department of Public Utilities' January 31, 2013 Order D.P.U. 12-100 through D.P.U. 12-111 (sections IV.B.2.a & 4.a – pages 18, 19 & 40) and subsequent DOER Consultant feedback. Specifically, Section IV.B.2.a states:

> "The Program Administrators with an aggregate three-year savings goal of greater than 20 percent below the statewide three-year aggregate goal will conduct a study, either jointly or individually, during the upcoming three-year term to document the penetration of energy efficiency within its service territory and the remaining cost-effective energy efficiency opportunities available.."

Potential Study Results

- The Likely Achievable potential across Liberty's service territory is estimated to be 0.49% of 2016 annual sales (0.48% by 2018)
  - This is much lower than Liberty's current three-year(2013-2015) territory-wide target of 0.84%
- The sector with greatest potential for savings as a % of sector sales remains with Liberty's small commercial customers (0.51% of 2016 sales, 0.60% by 2018)
- Slightly less potential remains within Liberty's residential and largest commercial customer sectors (0.48% & 0.50% respectively by 2018)

Summary Likely Achievable Scenario	2016	2017	2018
Residential			
Annual Therm Savings	185,340	185,629	187,331
Forecast Sales	38,098,740	38,506,920	38,777,850
Savings as % of sales	**0.49%**	**0.48%**	**0.48%**
PA Cost to Achieve	$ 2,429,332	$ 2,423,384	$ 2,436,638
Total Cost to Achieve	$ 3,759,344	$ 3,755,204	$ 3,782,864
Small and Med C&I			
Annual Therm Savings	75,978	83,250	90,700
Forecast Sales	14,939,619	15,141,739	15,229,403
Savings as % of sales	**0.51%**	**0.55%**	**0.60%**
PA Cost to Achieve	$ 281,690	$ 297,149	$ 315,376
Total Cost to Achieve	$ 571,173	$ 602,550	$ 639,010
Largest Customers C&I			
Annual Therm Savings	51,009	51,009	51,009
Forecast Sales	11,299,971	11,479,211	11,368,657
Savings as % of sales	**0.45%**	**0.44%**	**0.45%**
PA Cost to Achieve	$ 134,644	$ 134,644	$ 134,644
Total Cost to Achieve	$ 256,662	$ 256,662	$ 256,662
TOTAL			
Annual Therm Savings	312,326	319,887	329,040
Forecast Sales	64,338,330	65,127,870	65,375,910
Savings as % of sales	**0.49%**	**0.49%**	**0.50%**
PA Cost to Achieve	$ 2,845,665	$ 2,855,177	$ 2,886,657
Total Cost to Achieve	$ 4,587,179	$ 4,614,415	$ 4,678,536

3-Year Energy Efficiency Plan (2016 – 2018)

Setting Aggressive, Sustainable Goals for the Next 3 Years

October 2015

Unitil

Basic Principles of Planning

Unitil

- In preparing our plan, we have sought to balance the need for aggressive savings goals with the need to consider:
  - rate and bill impacts
  - the challenges of continued program acceleration
  - the need for sustainable, cost-effective programs
  - service territory specific considerations
  - recent actual results
  - Unitil-specific potential studies
  - Evaluation driven impacts to savings and program design
  - Detailed knowledge of our customers and substantial experience planning and delivering programs in our service area.

Unitil Service Area… Is Unique

- **6 Communities –38,925 Residential & 5,393 C&I Customers**
  - 26 Industrial customers represent 36% of electric sales
  - 30 Industrial customers represent 41% of gas sales
    - 3 special contract customers account for 22% of sales and cannot participate in EE programs.
- **Lower economic well-being than Commonwealth as a whole**
  - High poverty rate – Lower Median household income ($45,363)
  - One of the highest proportions of households with public assistance income
  - Consistently higher unemployment and underemployment rate
- **Significant hard-to-reach / serve population**
  - High penetration of renters, 38% overall, 54% in Fitchburg
  - ~25% of households have at least one person age 65 or older in the household
  - 4.2% of households have no one >14yrs of age who speaks English a their primary language
- **Building Characteristics**
  - 90% of all buildings are "occupied" (residential housing)
  - Smaller and much older stock -median age is 65+ years
  - 55% of housing stock is 1 unit –27% is 2-4 units
  - High penetration of heating oil leads to high non-electric benefits/lower electric savings

Challenging Factors… Influence Performance

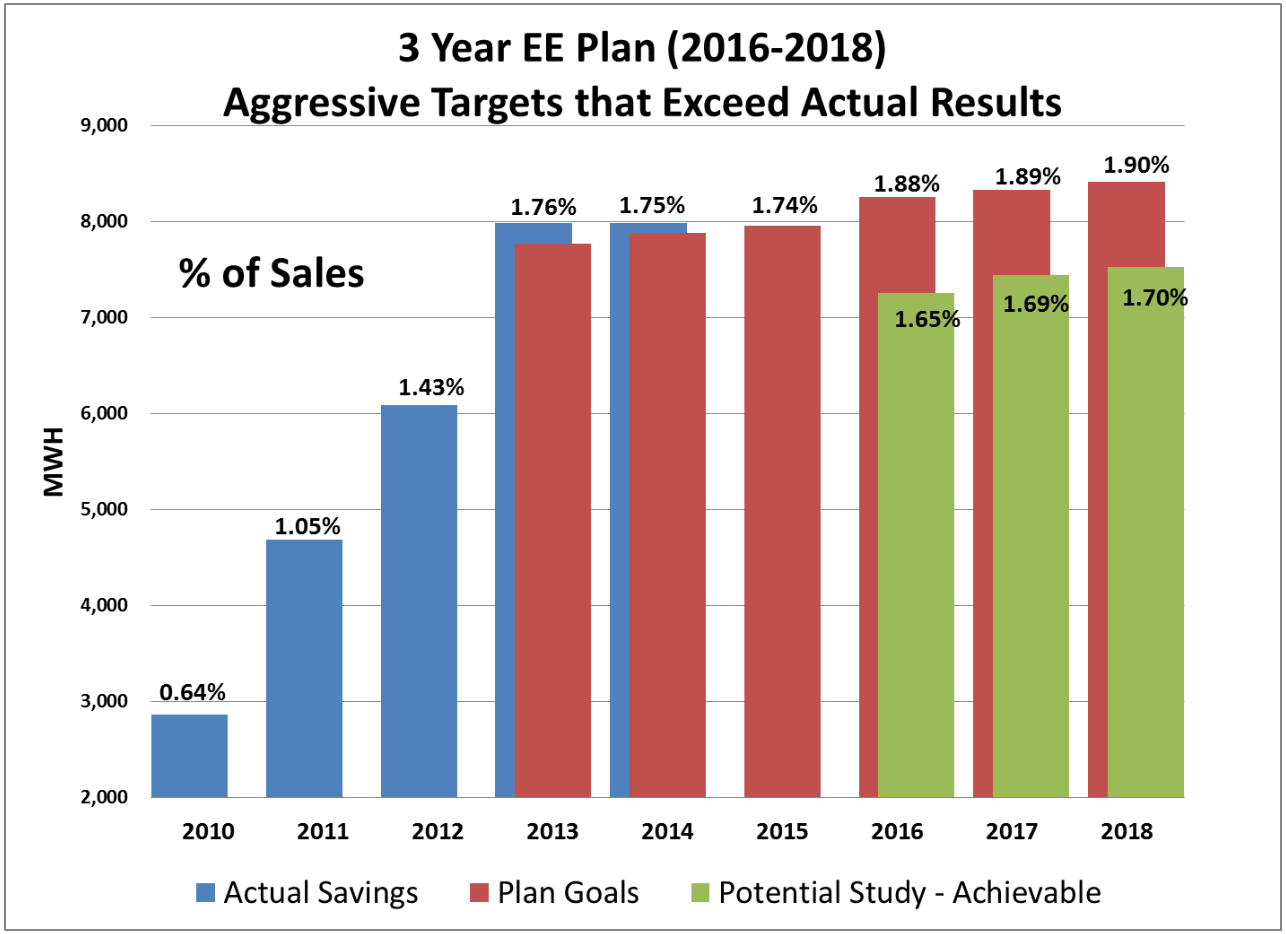
Unitil

- Our plan does not benefit from "averaging" across diverse communities:
  - ~68% of customers are in a *single community*, which is significantly different from statewide averages in all key demographic and economic factors including; income level, employment and building stock
  - Lack of diversity and size results in higher variances relative to the mean – budgets and savings are more variable and harder to predict year to year
- Variances in key parameters strongly affect relative performance:
  - HES kWh savings were 10% of total HES program savings compared to the statewide average of 35% - but Unitil's non-electric savings were 90% of the total, compared to the statewide average of 65%.
  - Much higher non-electric savings (i.e. oil, propane, etc.) for Unitil distorts the comparisons. Overall B/C ratios are consistent with Statewide ratios.

Aggressive and Sustainable Goals - Electric

Unitil

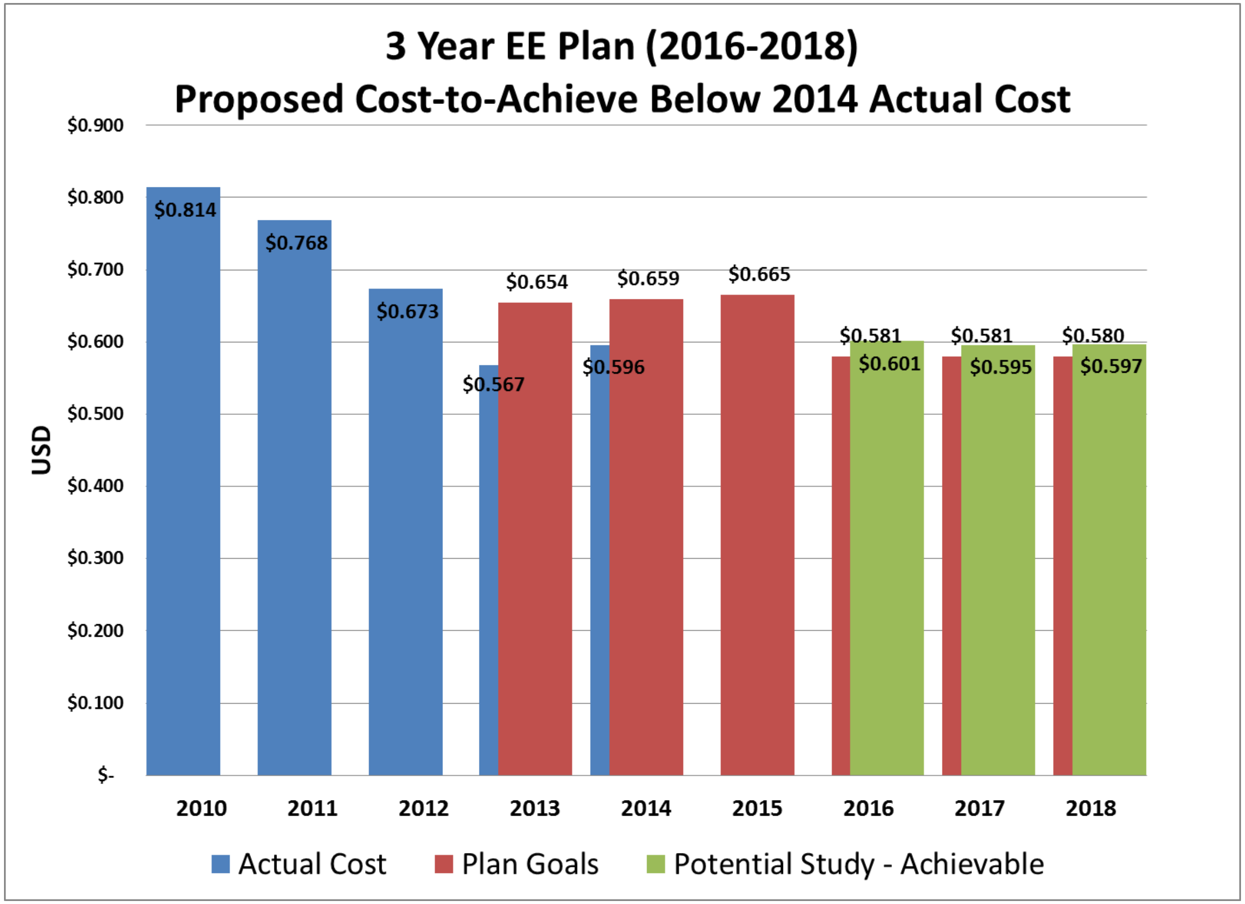
- Planned annual kWh savings exceed actual results as well as Potential Study targets
- Acceptable annual costs for participants
- Benefits per unit of spending better reflects impact than % of sales
  - Oil savings are better reflected in benefits
  - Non-energy impacts (NEIs) are more comprehensive
  - Smoothing effect for service area characteristics



… Cost & Rate Impact are Priority

Unitil

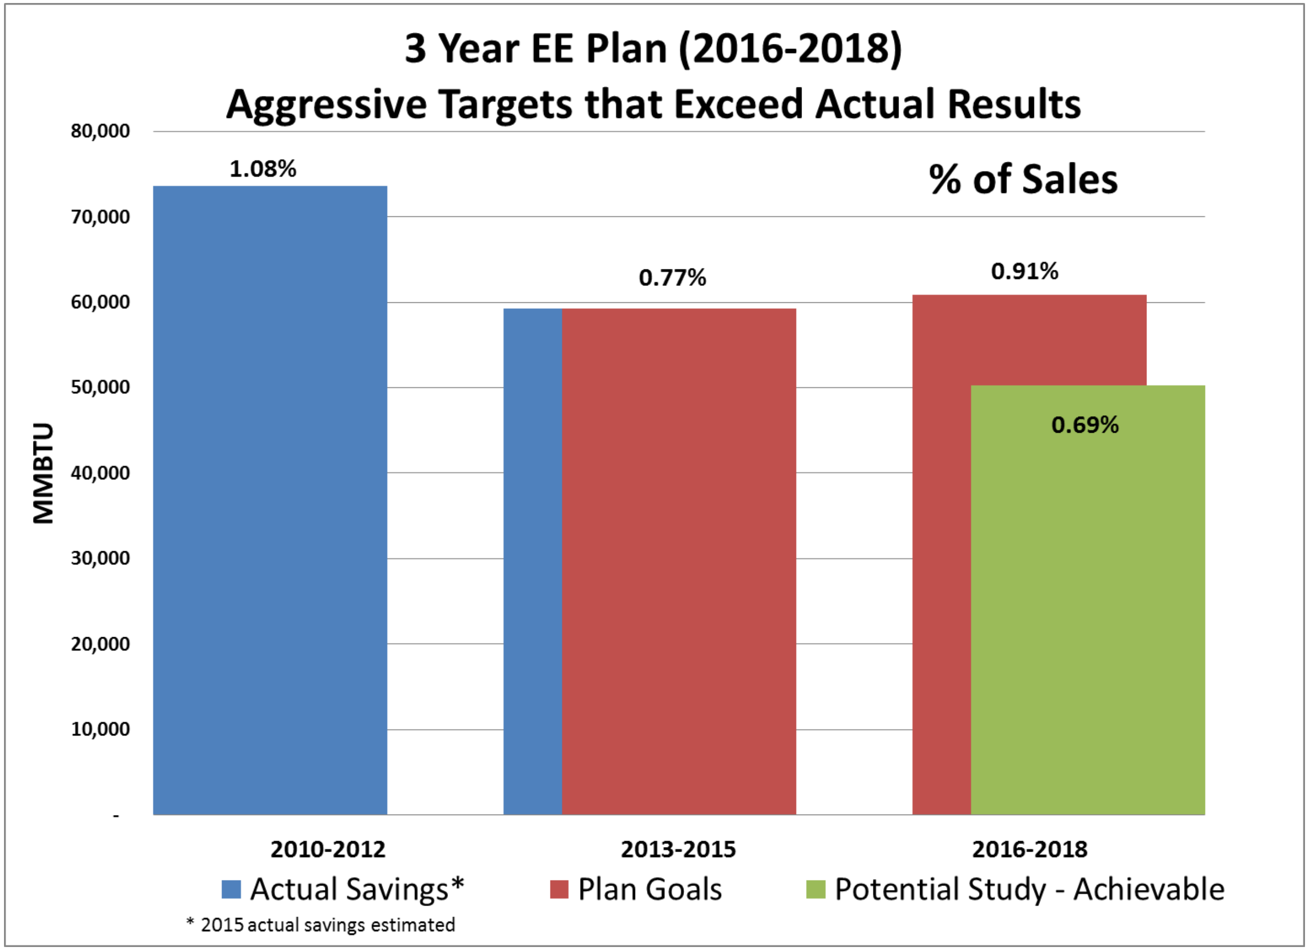
- Cost-to-Achieve kWh savings below 2014 actual costs/kWh
- 2016 proposed Cost / kWh is down 14% from 2012
- Attentive to Rate and Bill Impacts
    - Less than 1% for electric and less than 1%-3.1% for gas
    - Budgeting 2.9% of electric sales (if it were achievable) would cumulatively over 3 years increase electric bills by .1% to 5.1% depending upon rate class



Unitil

Aggressive and Sustainable Goals - Gas

- Planned MMBTU savings exceed achievable potential study estimates
- Lack of diversity & size results in greater variation in year over year results - 3 Year outlook is a better planning tool.
- Budgeting 1.24% of gas sales (if it were achievable) would increase gas bills in 2016 by 4.1% to 8.7% depending upon rate class



P. **Participant Definitions**

Participant Definitions for 2016-2018

PROGRAM/CORE INITIATIVE	PARTICIPANT DEFINITION
A - Residential	
1 - Residential Whole House	
A1a - Residential New Construction	Dwelling unit
A1b - Residential Multi-Family Retrofit	Dwelling unit with any measure installed
A1c - Residential Home Energy Services - Measures	Unique account number with at least one major measure installed
A1d - Residential Home Energy Services - RCS	[no participants; not a separate core initiative]
A1e - Residential Behavior/Feedback Program	Unique account number
2 - Residential Products	
A2a - Residential Heating & Cooling Equipment	Unique account number
A2b - Residential Consumer Products	Number of widgets; unique account number when available, assumption for upstream (2 measures per participant for Tier 1 smart strips, 1 measure per participant for all other measures).
A2c - Residential Lighting	Number of widgets, see chart below
3 - Residential Hard-to-Measure	
B - Low-Income	
4 - Low-Income Whole House	
B1a - Low-Income Single Family Retrofit	Unique account number
B1b - Low-Income Multi-Family Retrofit	Dwelling unit
5 - Low-Income Hard-to-Measure	
C - Commercial & Industrial	
6 - C&I New Construction	
C1a - C&I New Buildings & Major Renovations	Unique account number or equivalent
C1b - C&I Initial Purchase & End of Useful Life	Unique account number; for upstream, unique installation address
7 - C&I Retrofit	
C2a - C&I Existing Building Retrofit	Unique account number
C2b - C&I Small Business	Unique account number
C2c - C&I Multifamily Retrofit	Unique account number
C2d - C&I Upstream Lighting	Unique installation address
8 - C&I Hard-to-Measure	

Residential Lighting Assumptions

2016-2018 Residential Lighting	Widget per Participant
CFL Bulb	4
CFL Bulb (EISA Exempt)	2
CFL Bulb (Hard to Reach)	4
CFL Bulb (School Fundraiser)	4
Fixture	1
LED Fixture	1
LED Bulb	8
LED Bulb (EISA Exempt)	4
LED Bulb (Hard to Reach)	8
LED Bulb (School Fundraiser)	8
LED Reflectors	4

Q. **Vendor Cost Categories**

Program Administrator Vendor Cost Categories

Row Number	Cost Type	Elec/Gas/Both	Cost Category (to be applied 1/1/2016)	Additional Info/Comments
1	Statewide Database/Mass Save Data	B	Eval	Not in PP&A to enable cost tracking separately from DOER assessment
