2016-2018

Massachusetts
Joint Statewide Three-Year
Electric and Gas Energy Efficiency Plan

October 30, 2015

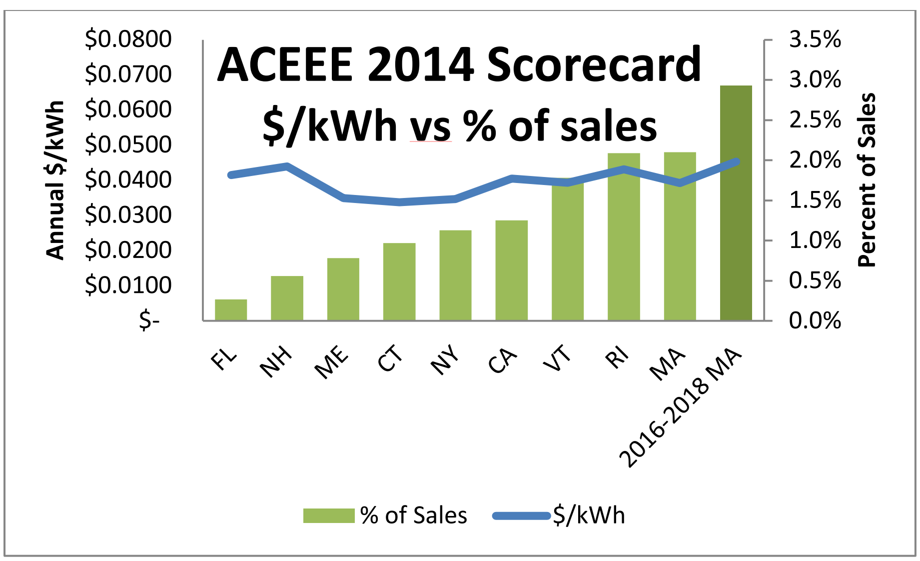
2016-2018 MASSACHUSETTS JOINT STATEWIDE THREE-YEAR ELECTRIC & GAS ENERGY EFFICIENCY PLAN

I. EXECUTIVE SUMMARY

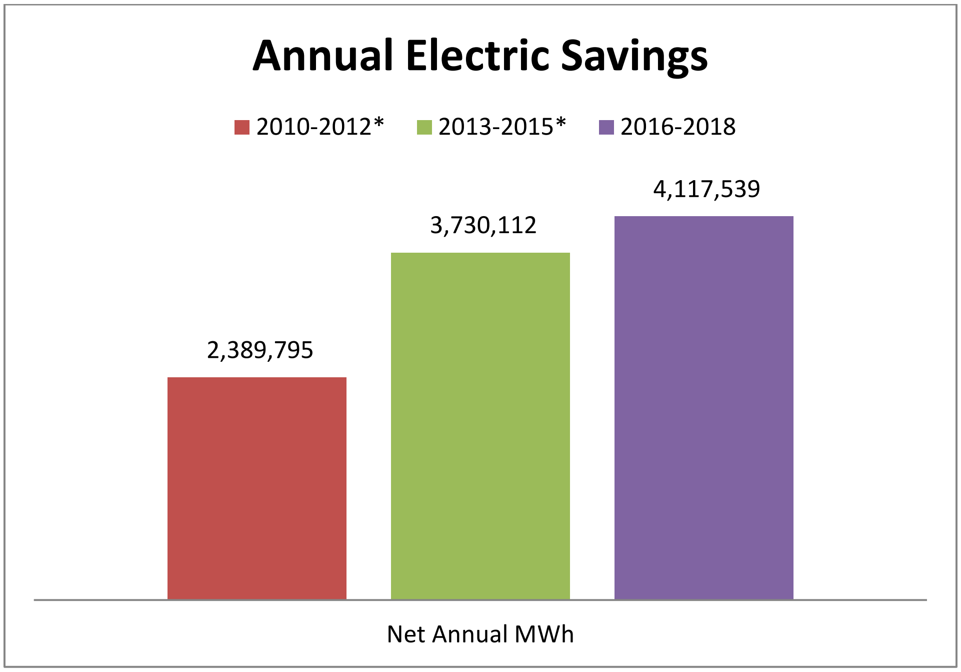
A. Context for the Program Administrators' Energy Efficiency Efforts Under the GCA

The Program Administrators' energy efficiency efforts under the Green Communities Act reflect an unprecedented collaborative undertaking with long-lasting multi-billion dollar benefits for Massachusetts. The magnitude of the success and accomplishments of the Program Administrators in implementing energy efficiency programs and services, with the support and aid of the Energy Efficiency Advisory Council and stakeholders, can be hard to conceptualize. Energy efficiency benefits are not always visible to the naked eye, taking the form of insulation in walls, deferred construction of generating facilities, reduced greenhouse gas emissions and improved comfort or industry profitability. The energy savings and benefits of energy efficiency programs, however, are real and measurable. With rigorously quantified total dollar benefits of over $12.5 billion since 2008 (many times greater than costs), energy efficiency under the Green Communities Act is truly a historic achievement, making Massachusetts a model of energy efficiency success for the rest of the nation.

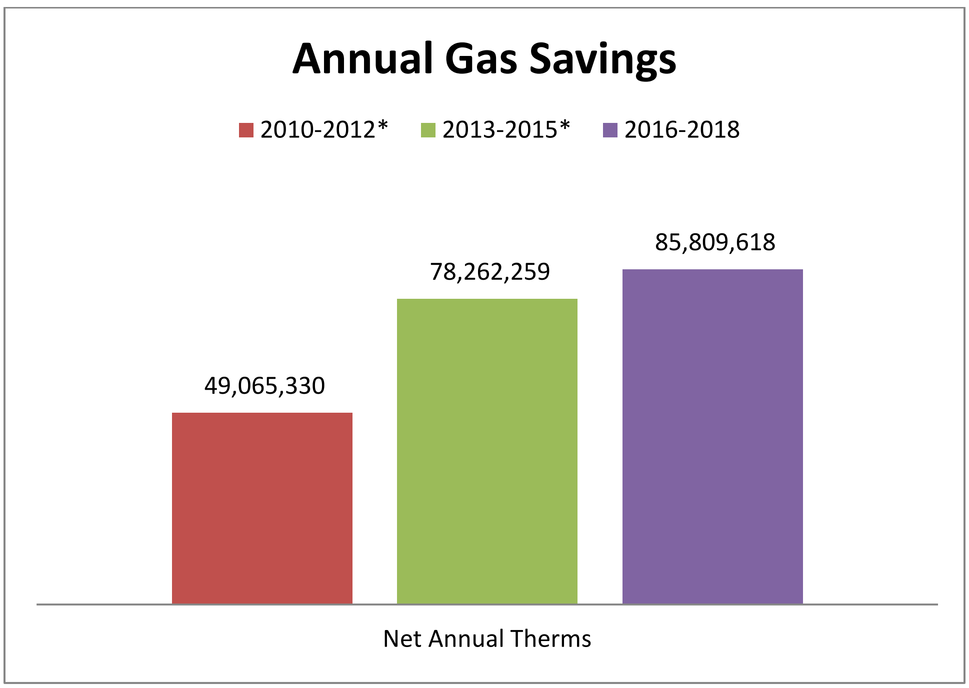
The Program Administrators have increased their savings achievements significantly since the 2008 passage of the Green Communities Act, with electric savings almost tripling between 2008 and 2014. These achievements have resulted in Massachusetts continuing to be the Number 1 ranked state in the nation for energy efficiency by the American Council for an Energy Efficiency Economy ("ACEEE"). Additionally, Massachusetts attained a perfect score on the ACEEE 2015 State Energy Efficiency Scorecard for its program administrator-operated energy efficiency programs and its policies to support the development of combined heat and power ("CHP") facilities.[1] In the 2016-2018 Plan, the PAs are proposing aggressive savings goals at levels even higher than the 2013-2015 Plan, despite increased challenges.



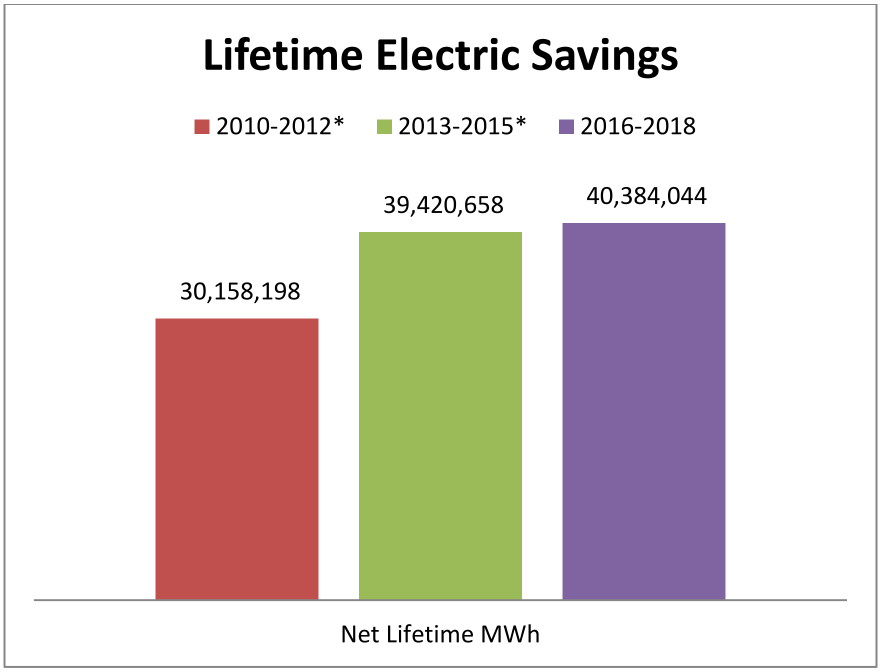
[1] ACEEE, "The 2015 State Energy Efficiency Scorecard," October 2015, Report Number U1509.

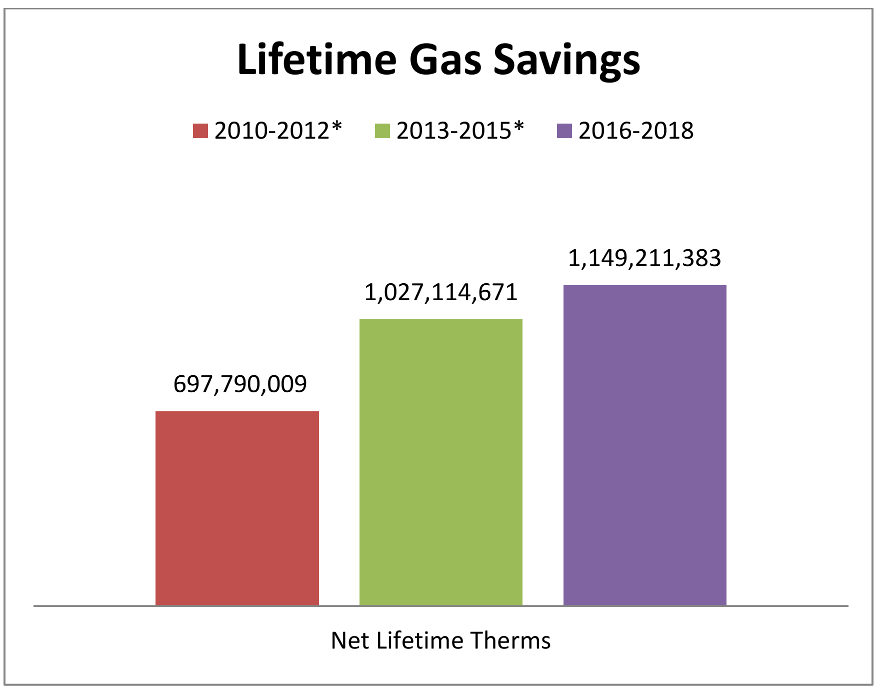


* 2010 - 2014 represent actual savings; 2015 - 2018 represent planned.

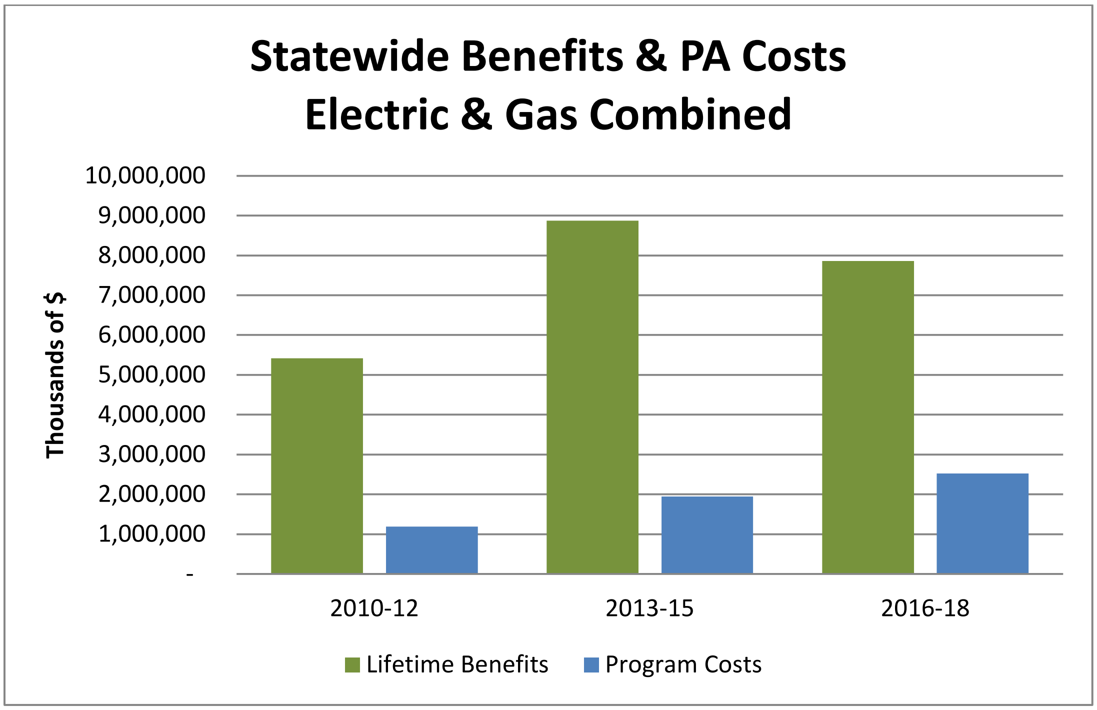


* 2010 - 2014 represent actual savings; 2015 - 2018 represent planned.



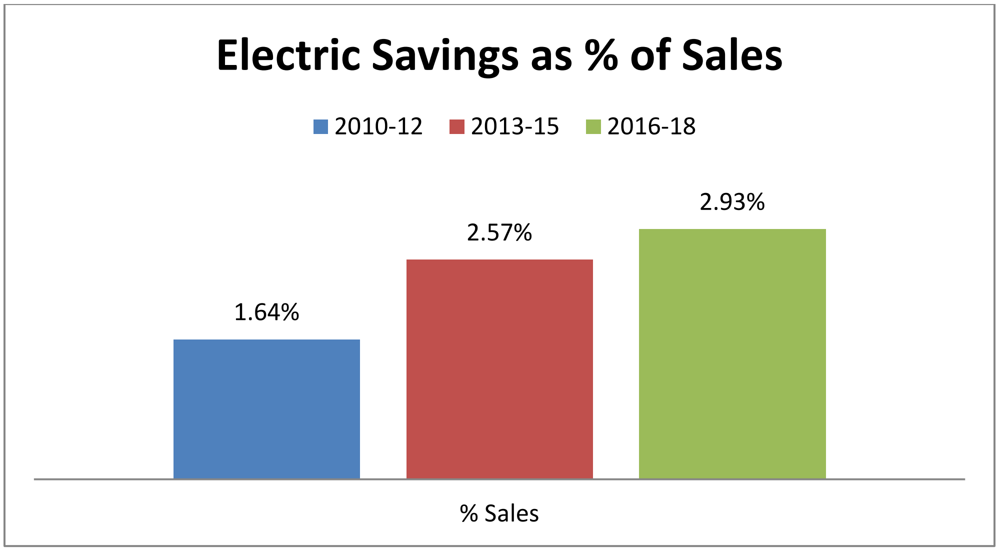


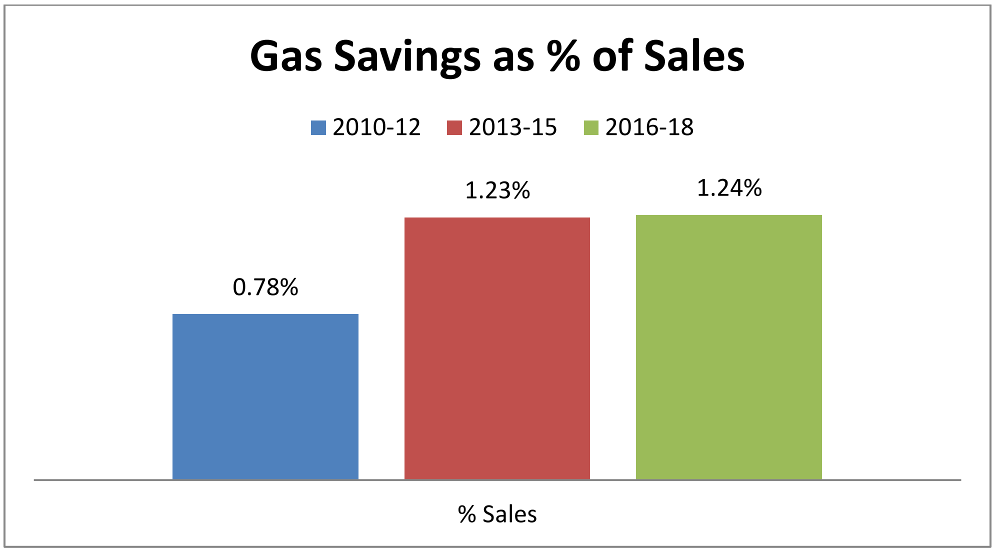
While delivering these unprecedented savings, the Program Administrators have carefully managed expenditures to keep costs as low as possible. The PAs strive to maximize the value of each dollar spent. The majority of energy efficiency expenditures are delivered to customers in the form of incentives that are intended to overcome the financial barrier to investment. For example, in the 2016-2018 Plan, approximately 74 percent of the electric budget and approximately 71 percent of the gas budget are dedicated to **participant incentives**, the biggest driver of savings. The next largest category of expenditures, approximately 15-18 percent, will go to payments for contractors, installers and training. Approximately 3 percent of the statewide budget is dedicated to the rigorous Massachusetts Evaluation, Measurement and Verification process. Other administrative functions like Program Planning and Administration and Marketing and Advertising combined make up approximately 8-9 percent of the statewide budget. These percentages are in line with the budget allocations previously approved by the Department of Public Utilities, demonstrating that the Program Administrators have been able to provide direct benefits to customers and contractors and grow the energy efficiency portfolios while minimizing costs. Due to avoided costs declining, despite increasing savings, dollar benefits are lower in the 2016-2018 Plan then they were in 2013-2015 (but greenhouse gas reductions increase in the Plan).



The Plan being filed today fully reflects the provisions of the Term Sheet dated September 23, 2015 (supplemented on October 26, 2015) agreed upon by the Program Administrators, the Executive Office of Energy and Environmental Affairs, the Department of Energy Resources, and the Office of the Attorney General, which is included in Appendix D. The Term Sheet is the result of extensive collaboration among the agreeing parties following the PAs' submission of their April 30, 2015 draft Plan and the July 27, 2015 Resolution of the Energy Efficiency Advisory Council. Further, the Plan gathered the broad support of the Energy Efficiency Advisory Council which led to the October 26, 2015 Resolution. The October 26th Resolution was approved by an overwhelming 14 to 1 vote of the Energy Efficiency Advisory Council, which is attached as Appendix I. In this Resolution, after extensive review and collaboration the Council respectfully requested that "the Commissioners of the Department of Public Utilities . . . approve the 2016-2018 Massachusetts Joint Statewide Three-Year Electric and Gas Energy Efficiency Investment Plan and the Individual Plans of the [program administrators], to the degree that the Individual Plans are fully consistent with the Statewide Plan."

The Plan provides for the most aggressive savings goals ever in the Commonwealth, and to the PAs' knowledge, in the United States. The Plan provides for an annual savings goal of 2.93 percent of retail sales (electric) and of 1.24 percent of retail sales (gas) at costs-to-achieve that are materially lower than those set forth in the April 30th draft. Moreover, the Plan prioritizes: (1) new demand reduction/peak reduction efforts; (2) continued commitment to innovation and technology; and (3) the creation of a new residential contractor engagement effort. All tables and values in this Plan are consistent with the Term Sheet. The PAs express their appreciation for the extensive efforts and diligent work of the Executive Office of Energy and Environmental Affairs, the Department of Energy Resources, the Office of the Attorney General, the Energy Efficiency Advisory Council, its consultants, and other interested stakeholders.





B. Moving Forward and Sustaining Excellence in 2016-2018

This Plan represents the Program Administrators' collective efforts – informed by in-the-field Program Administrator experiences, Evaluation, Measurement and Verification results, and outstanding input from and collaboration with the Energy Efficiency Advisory Council and stakeholders – to build upon and sustain Massachusetts' historic effort. Going forward, a key challenge to navigate is the danger of "over-promising and under-delivering." Sustaining very high savings goals becomes increasingly difficult in each subsequent year as markets become saturated, "easy" savings no long exist, and rising baselines continue to reduce claimable savings. Over the next three years, the Program Administrators will need to find ways to mine savings from more difficult, costly, and challenging projects and market segments. Extensive details addressing these challenges are set forth in the multiple sections and tables contained in this Plan.

In order to meet this challenge, the PAs have developed a number of innovations for the 2016-2018 Plan:

Residential and Low-Income

- 2016 initial implementation of an innovative new **Renter-Specific Offer**, including a special renter visit, installation of *instant savings measures* such as light bulbs, power strips, gas/water saving aerators and showerheads, and collection of information to use in following up with landlords.
- **Multi-family Initiative Enhancements**, creating a *project-level lead* to ensure optimal customer experience, tracking and reporting of commercial and residential meter savings *separately*.
- Continued driving of the **LED Revolution**, with LED offerings adapting to the changing lighting market.
- 2016 initial implementation of a new **Moderate-Income Offer**, with the Program Administrators working on a new *61-80 percent of median income opt-in approach* for those with weatherization opportunities.
- Continuation of the Program Administrators' historic **Low-Income Services Partnership with the Low-Income Energy Affordability Network (LEAN)** to ensure that the Commonwealth's most economically vulnerable citizens participate in specially tailored programs; PAs acknowledge and thank LEAN for its collaboration with the PAs and commitment to low-income populations across the Commonwealth.

Commercial and Industrial

- Broadening the **Upstream Program Delivery Mechanism** to encompass additional, appropriate equipment types and end-uses for the purpose of advancing the ongoing market transformation effort; implementation of a new upstream approach targeting water heating technologies will begin in late 2015.
- **Segment-specific Outreach and Implementation Strategies** (marketing strategies and materials, partnerships, campaigns) to advance energy efficiency implementation and

customized to overcome unique participation barriers of each segment; this Plan provides more details on sector-specific areas of focus for each PA.

- Comprehensive review/analysis of the very successful **Small Business Initiative** to advance participation and comprehensiveness at all customer sizes and energy usage ranges.
- Deployment of an exciting new online incentive application portal, with a menu drive interface enabling the creation and submission of customer applications for incentives; this portal will materially enhance the overall customer experience, especially for mid-sized customers.

Evaluation, Measurement & Verification and Data

- A high level **Strategic Evaluation Planning** document is included with this Plan. The development of this document was guided by an Evaluation Planning Summit held in February 2015. The Summit provided a forum for the PAs, Council consultants, and evaluation contractor teams to identify emerging evaluation topics and activities.
- A wealth of quantitative data is now readily available to stakeholders and the public (www.masssavedata.com). The **Mass Save Data** website has been developed to improve the transparency of and access to reported energy efficiency data. Currently this website includes data regarding program participation, annual and lifetime savings, benefits, cost to deliver, expenditures, greenhouse gas emissions reductions that result from energy efficiency efforts, and forecasted sales for the years 2010 through 2015. The PAs are also planning to add geographic and measure level data to the website, and will strive to continue to improve the functionality of this database while minimizing its costs.
- The Customer Profile Studies will provide **Customer Based Analysis**, including detailed geographic analysis across fuels and service territories. This information will also be used to populate the Mass Save Data geographic tab, which is under development.
- There will be renewed emphasis on enhancing the value of evaluation by producing **Real Time Evaluation Results** to the extent possible, shortening the feedback loop between evaluation and implementation, and making recommendations more actionable.
- Undertaking, through the Council's highly successful independent EM&V process, a new study to verify more precisely the emissions reductions resulting from the PAs' energy efficiency efforts, and potentially also looking at impacts from other efforts that interrelate with the PAs' efforts.

Marketing

- Implementation of **Spanish and Portuguese versions of the comprehensive Mass Save® website**, helping to ensure even greater access for customers to energy efficiency programs.

Savings, Benefits and Infrastructure

- Continuation of the **Aggressive Savings Goals** (2.93 percent of sales for electric and 1.24 percent of sales for gas). Based upon ACEEE data, the Program Administrators believe that these are the most aggressive goals for an integrated gas and electric energy effort in the nation.[2]

- Consistent with the Term Sheet and in response to the Council's comments, electric savings goals have increased from the April 30th draft by approximately 17 percent (annual) and 21 percent (lifetime). Gas savings have increased by 15 percent (annual) and 14 percent (lifetime); while savings have increased, per unit costs-to-achieve have decreased.
- Total Benefits of approximately **$8 billion** for customers; Net Benefits of approximately **$4.4 billion**.
- Clear and strong commitment to the support of the robust Massachusetts **Energy Efficiency Delivery Infrastructure and Contractor Network**, with a stable level of investment of over $2.5 billion in energy efficiency in 2016-2018.
- Environmental benefits equivalent to removing 410,162 cars from the road through annual electric and gas savings in 2016-2018.

The PAs have also sought stakeholder input and insights in the preparation of this Plan. The PAs have received constructive input from Councilors, government officials, stakeholders, energy experts and consultants, and participants in the Council workshops. This 2016-2018 Plan has benefited from this extensive input. The PAs appreciate their team; every Program Administrator contributes, every Program Administrator leads, and every Program Administrator learns.

C. <u>Cost to Achieve</u>

In addition to the challenges of meeting higher savings goals, PAs face increasing challenges to minimize increases in the cost to achieve these savings. The PAs have materially reduced their projected cost-to-achieve savings from the projections in the April 30th draft, as reflected in the Plan, with a reduction in electric cost-to-achieve per kWh of approximately 13 percent and in gas cost-to-achieve per therm of approximately 7 percent.

Cost to achieve looks at the PAs' total costs per unit of net savings attributable to the programs. Market penetration, increasing costs for key measures, and decreasing levels of claimable savings due to changes in federal standards and the application of results from the impact evaluations are all significant factors that can drive up the cost per kWh or therm saved. Two areas that are particularly impacted by these factors in the 2016-2018 Plan are the Residential Lighting initiative and Low-Income programs.

- The Residential Lighting initiative is facing a number of concurrent challenges that are increasing the cost to achieve. Federal Energy Independence and Security Act ("EISA") standards are eliminating inefficient bulbs from the market, raising the baseline and decreasing the savings that Program Administrators can claim. At the same time, programs are increasingly incentivizing a greater number of LEDs than CFLs, and the cost per kWh for an LED is significantly higher than that of a CFL. Additionally, recent

[2] ACEEE, "The 2015 State Energy Efficiency Scorecard," October 2015, Report Number U1509.

evaluation results have increased the free ridership rate for LEDs, further reducing the net savings that Program Administrators can claim. All of these factors have led to increases in the cost to achieve of 10 to 20 percent for the residential lighting initiative compared to previous three-year plans.

- Historically, the Program Administrators have partnered with the federal Weatherization Assistance Program to deliver programs to income-eligible customers and have been able to leverage federal funding. Going forward, however, the availability of federal funding will be sharply reduced due to national program cuts, and the Program Administrators will need to fund a greater portion of each project. For gas energy efficiency programs, the lack of available federal funding results in a greater than 50 percent increase in the cost per therm saved in the low-income sector. In addition, the Program Administrators must dedicate at least 20 percent of their gas budgets to low-income programs, which substantially impacts the portfolio cost to achieve. These costs have increased so significantly that if 2016-2018 costs were applied to 2014 programs, the cost per therm in 2014 would have been 20 percent higher. While the Program Administrators remain committed to finding efficiencies in program design and delivery and controlling costs to the maximum extent possible, these types of funding shifts are not the result of actual cost increases, are beyond the control of the Program Administrators, and must be taken into account when comparing across program years.

Despite these challenges, the Program Administrators have set aggressive goals (indeed, they believe, the most aggressive goals for any integrated gas and electric energy efficiency plan in the country) that are realistic, achievable and deliver unprecedented benefits to all customers. Setting unrealistic goals can reduce the PAs' flexibility to adjust to a changing market, risking missed targets and loss of the broad-based public support for energy efficiency that is a crucial component of the success achieved to date in Massachusetts. This Plan will allow the Program Administrators to achieve all cost-effective energy savings and continue to enjoy the broad-based public support for energy efficiency that will allow for continued success in delivering energy efficiency in Massachusetts.

II. INTRODUCTION

Bay State Gas Company d/b/a Columbia Gas of Massachusetts ("CMA"), The Berkshire Gas Company ("Berkshire"), Blackstone Gas Company ("Blackstone"), Boston Gas Company, Colonial Gas Company, Massachusetts Electric Company and Nantucket Electric Company, each d/b/a National Grid ("National Grid"), Fitchburg Gas and Electric Light Company d/b/a Unitil ("Unitil"), Liberty Utilities (New England Natural Gas Company) Corp. d/b/a Liberty Utilities; ("Liberty"), Cape Light Compact ("Compact" or "CLC"),[3] and NSTAR Electric Company, NSTAR Gas Company and Western Massachusetts Electric Company, each d/b/a Eversource Energy ("Eversource") (collectively, "Program Administrators" or "PAs") developed and prepared this 2016-2018 Energy Efficiency Plan ("2016-2018 Plan" or "Plan") pursuant to the mandates of An Act Relative to Green Communities, Acts of 2008, c. 169, codified at G.L. c. 25 §§ 19, 21-22 ("Green Communities Act" or "GCA"). The Program Administrators take great pride in planning and administering energy efficiency programs pursuant to the GCA's statutory framework for energy efficiency, which has resulted in nation-leading, award-winning programs with savings goals and delivery that are unprecedented.

This Plan reflects an extensive collaborative effort among the PAs. The PAs express their appreciation for the work of all stakeholders and, in particular, the members of the Energy Efficiency Advisory Council ("Council" or "EEAC"), led by the Council chair, the Department of Energy Resources ("DOER"). This Plan has also benefitted from suggestions and discussions made during stakeholder workshops facilitated by Raab Associates, Ltd., on behalf of the Council in February, March and June of 2015. Since the filing of the initial draft plan on April 30, 2015 the PAs have engaged in positive and constructive dialogue with the Council on the 2016-2018 Plan, culminating with the Council passing a resolution in support of the Plan.

The GCA and Department of Public Utilities ("Department")[4] precedent require that three-year energy efficiency plans, such as this 2016-2018 Plan, provide for the acquisition of all cost-effective energy efficiency resources in a manner that is sustainable and with consideration of short term customer bill impacts. In this Plan, the Program Administrators set aggressive, sustainable goals that: (1) capture all available cost-effective energy efficiency; (2) maximize net economic benefits; (3) achieve energy, capacity, climate, and environmental goals; and (4) consider both short-term customer bill impacts and longer-term benefits expected from proposed efforts. This Plan includes comprehensive energy efficiency services, large-scale marketing, and education campaigns, and extensive Evaluation, Measurement, and Verification ("EM&V") efforts, all resulting in significant and proven energy savings to customers in the Commonwealth of Massachusetts (the "Commonwealth" or "Massachusetts").

---

3 The Cape Light Compact is the only publicly funded, municipal aggregator (as defined by G.L. c. 164, § 134) energy efficiency program administrator in Massachusetts. Since it is a public entity consisting of twenty-one towns and two counties, it does not participate in performance incentives or collect lost-based revenues. As such, any discussion of these topics contained in the Three-Year Plan does not pertain to the Compact and general references to Program Administrators in these topic narratives do not include the Compact.

4 The Department is a regulatory agency subject to G.L. c. 30A that is statutorily responsible for extensive oversight of the Program Administrators in Massachusetts.

The Program Administrators developed and refined the Plan in a collaborative, transparent, and year-long process with the Council, its consultants, the DOER, the Office of the Attorney General (the "Attorney General" or "AG"), the Low-Income Energy Affordability Network ("LEAN"), and other interested stakeholders. The Council guides the development and implementation of Three-Year Plans with monthly meetings of the full Council and its subcommittees.[5] The PAs are active participants in all of these meetings. In addition to its regular meetings noted above, in 2015, the Council conducted a number of sector-focused workshops to help inform the development of the 2016-2018 Plan. The PAs were partners in developing the workshop briefing materials.

In November 2015, after detailed review and input from the Council, the Department will begin an extensive review of the 2016-2018 Plan through a formal investigation that includes standards for filing, discovery, evidentiary hearings, briefing, and careful and extensive analysis informed by the Department's technical expertise. The level of review, collaboration, transparency, and accountability of the current statutory framework ensures that customers are receiving beneficial and cost-effective services. Notably, the data demonstrating the costs and benefits to customers of these services is now more easily accessible to the public in a user-friendly database that provides a single source of both statewide and individual PA information.

In addition to the advice of the Council, the 2016-2018 Plan builds upon the experience of the Program Administrators in developing and implementing two Three-Year Plans pursuant to the GCA, specifically, the 2010-2012 Plan and the 2013-2015 Plan. The Program Administrators routinely share best practices and identify new and innovative strategies through their many working groups and management committees, including the Residential Management Committee ("RMC"), the Commercial & Industrial Management Committee ("C&IMC"), the Evaluation Management Committee ("EMC"), the Low-Income Best Practices committee, the Massachusetts Technical Advisory Committee ("MTAC"), the Planning and Analysis Group ("PAG"), and the Contractor Best Practices Working Group. To track their performance against their Three-Year Plans, each Program Administrator publicly files data tables and benefit-cost screening models that show information at the measure level with each plan and report submitted to the Department. The PAs also submit statewide quarterly reports and monthly data dashboards to the Council, along with many other ad hoc data requests. In 2014, the PAs developed an internet-based database to facilitate public access to statewide energy efficiency data in a more user friendly manner. Extensive planned and reported energy efficiency data for 2010 through 2015 is available at www.MassSaveData.com.

Finally, in advancing the objectives of the Green Communities Act, the 2016-2018 Plan also supports the Commonwealth's broader policy objectives. In a series of legislation enacted in parallel with the GCA, the Commonwealth signaled its commitment to being a worldwide leader in developing a green economy through the Global Warming Solutions Act, St. 2008, c. 298 ("GWSA"), and the Green Jobs Act, St. 2008, c. 307. The GWSA calls for broad statewide

[5] The Council holds monthly, publicly-noticed open meetings of the full Council, with regular presentations from the Program Administrators and the Council's consultants, as well as public comment. The Council's Executive Committee, which is comprised of a smaller group of councilors, conducts monthly meetings to facilitate the business of the Council and management of its consultants.

reductions of greenhouse gas ("GHG") emissions in the Commonwealth, thus spurring innovation and promoting research and development in the area of clean energy. Enacted concurrently, the Green Jobs Act provides a robust funding source for the green technology industry, facilitating economic development and job growth in the clean energy sector. Taken together, these legislative enactments reflect the Commonwealth's commitment to climate protection and its leadership in promoting clean and renewable energy. Reductions in GHG emissions and job creation are important results of energy efficiency programs implemented pursuant to the GCA. Like past plans, the 2016-2018 Plan will continue to fulfill the requirements of the GCA and support the goals of the GWSA and Green Jobs Act, with a focus on minimizing the cost of energy efficiency program design and implementation for the benefit of customers.

A. Core Goals for 2016-2018

In the 2016-2018 Plan, the Program Administrators seek to build on the lessons learned from their two previous Three-Year Plans, including both their successes and challenges, take advantage of new technologies and market opportunities, and continue to foster a sustainable energy efficiency infrastructure in the Commonwealth. The Program Administrators will pursue all available cost-effective energy efficiency, subject to reasonable short-term customer bill impacts, as mandated by the GCA, and will seek to maximize benefits to the Commonwealth and its citizens.

Statewide Electric Summary

	Units	2016	2016-2017	2016-2018
Forecasted Annual Retail Energy Sales	*MWh*	46,908,188	93,745,319	140,331,922
Average Annual Savings Over Three Years	*% of sales*	2.93%		
Cumulative Annual Savings Goals	*MWh*	1,371,584	2,744,075	4,117,539
Cumulative Lifetime Savings Goals	*MWh*	12,812,171	26,205,273	40,384,043
Cumulative Budget: Program Costs	*millions of $*	$ 598.8	$ 1,220.0	$ 1,857.6
Cost per Annual kWh Saved	*$/kWh*	$0.451		
Summer Demand Savings	*MW*	203	404	598
Winter Demand Savings	*MW*	222	440	649
Benefits	*millions of $*	$ 2,041.2	$ 4,105.9	$ 6,214.6

B. Statutory Context

1. Overview

Each PA is subject to the jurisdiction of the Department and individually bears responsibility for meeting the statutory mandate under the GCA to acquire all available cost-effective energy efficiency. The PAs are responsible for administering energy efficiency programs pursuant to the GCA. G.L. c. 25, § 19(a-b). The GCA also makes them *ex officio* members of the Council. G.L. c. 25, § 22(a).[6] This statutory construct appropriately recognizes that each PA is a distinct entity with a unique service territory, is owned by shareholders and/or governed by a municipal board of directors and has a deep knowledge of its businesses and customers and many years of experience implementing energy efficiency programs.

The GCA requires the PAs to jointly prepare, in coordination with the Council, an energy efficiency plan every three years. G.L. c. 25, § 21(b)(1). This plan "shall provide for the acquisition of all available energy efficiency and demand reduction resources that are cost effective or less expensive than supply and shall be prepared in coordination with the [Council]." G.L. c. 25, § 21(b)(1). As discussed in more detail in subsequent sections, a Three-Year Plan must include the elements set out in detail in the GCA. G.L. c. 25, § 21(b)(2). Every three years, the PAs must submit this plan to the Council for "approval and comment" and "review" on or before April 30. G.L. c. 25, § 21(c). The PAs "may make any changes or revisions to reflect the input of the [Council]." G.L. c. 25, § 21(c). The PAs must submit their plans, "together with the [Council]'s approval or comments and a statement of any unresolved issues, to the [Department] on or before October 31." G.L. c. 25, § 21(d)(1). This statutory context is discussed in more detail below. For a detailed overview of energy efficiency's regulatory background and Department history, please refer to the materials in Appendix B.

6 The dictionary defines "ex officio" as meaning "by virtue of one's position or status." The Oxford English Dictionary (2013). Ex-officio members have exactly the same rights and privileges as do all other members, except as otherwise specified by statute. See http://www.robertsrules.com/faq.html#2.

2. The Green Communities Act

As noted above, energy efficiency in Massachusetts is governed by the statutory framework set out in the GCA. The GCA transformed and institutionalized past practice to achieving energy efficiency savings in Massachusetts. Energy efficiency programs have been offered in Massachusetts since the 1980s and stakeholder working groups and a consensus approach have been the foundation for achieving savings.[7] The enactment of the GCA expanded energy efficiency mandates by requiring the PAs to develop three-year energy efficiency plans that will "provide for the acquisition of all available energy efficiency and demand reduction resources that are cost effective or less expensive than supply." G.L. c. 25, §§ 19(a), 21(a), 21(b)(1), 21(b)(2). It also institutionalized the collaborative, consensus approach to energy efficiency by creating a statewide stakeholder advisory body (the Council) to coordinate with the PAs and the Department on the development and implementation of three-year energy efficiency plans. G.L. c. 25, §§ 21-22.

In view of the GCA's collaborative paradigm, it is important to understand how the Department, Council, and PAs each contribute to ensuring the acquisition of all cost-effective energy efficiency in Massachusetts. Under the GCA, the Department is responsible for approving individual PA Three-Year Plans and determining individual PA plan-related performance. The Department also appoints and convenes the Council. The Council is an advisory body that leverages the expertise of its diverse stakeholder membership and expert consultants to meet its statutory mandates "through a sustained and integrated statewide energy efficiency effort." G.L. c. 25, § 22(b). By design, the Council provides valuable statewide advice and recommendations to the PAs and the Department on the development and implementation of Three-Year Plans. Finally, under the GCA, the PAs must coordinate with each other and the Council to develop Three-Year Plans. As discussed earlier, the PAs are also responsible for implementing Three-Year Plans and are subject to the regulatory authority of the Department.

To date, the GCA's statewide collaborative approach has produced excellent results. The PAs and the Council have a proven track record of reaching consensus on numerous topics. This is a signature success of the efforts of multiple stakeholders in Massachusetts. The roles of the Department, Council and PAs are discussed in more detail below.

3. Department of Public Utilities

The Department is a quasi-judicial regulatory agency with extensive statutory authority over the Program Administrators.[8] The Department is responsible for ensuring that the electric

---

[7] Energy efficiency programs have been offered by the electric and natural gas utilities since the 1980s and by the Compact since 2001. Prior to the GCA, the PAs each developed plans with limited budgets and relied on stakeholder working groups and a consensus approach to developing energy efficiency implementation.

[8] The Department's authority extends beyond energy efficiency to all aspects of the operations of electric and gas distribution companies including, but not limited to, rate setting, service quality, customer care, and the operation of a safe and reliable utility. See G.L. c. 164, § 76. Since its establishment by the Legislature in 1919, the Department has comprehensively regulated the operations of electric and gas utility companies

and gas utilities provide safe, reliable, and least-cost service to Massachusetts customers.[9] Under the GCA, the Department is responsible for ensuring that electric and natural gas resource needs are first met through all cost-effective energy efficiency resources as a means to reduce energy costs for all customers. G.L. c. 25, § 21(a).

In expanding energy efficiency and requiring the PAs to coordinate with the Council, the GCA subjects both the Council and the PAs to the Department's jurisdiction with respect to final plan approval, cost-effectiveness, rates, and cost recovery. G.L. c. 25, §§ 19, 21-22. The GCA requires the Department to convene and appoint the members of the Council and to conduct the final review and approval of each Three-Year Plan.[10] The GCA also requires the Department to ensure that each PA acquires all cost-effective energy efficiency resources, delivers energy efficiency programs while minimizing administrative costs, and complies with the other requirements of the GCA.[11] If a PA has not reasonably complied with its Three-Year Plan, the Department may open an investigation into the PA's performance. G.L. c. 25, § 21(e).

In sum, pursuant to G.L. c. 164, and the GCA, the Department has oversight authority over the PAs and the Council and is responsible for final administrative review of energy efficiency determinations. G.L. c. 25, §§ 19, 21-22. The GCA's grant of authority to the Department is consistent with the Department's enabling and comprehensive statutory regulation of utility companies and municipal aggregators under c. 164 and particularly its regulatory supervisory authority over the electric and natural gas distribution companies pursuant to G.L. c. 164 § 76. Having the resources, technical expertise, and the statutory obligation to regulate in the public interest, the Department is uniquely structured to ensure that energy efficiency funds are spent cost-effectively, that customers are receiving energy efficiency services, and that energy savings are being achieved. The Department conducts its review of Three-Year Plans and PA performance through individual adjudicatory proceedings consistent

---

in Massachusetts pursuant to General Laws Chapter 164 to ensure that electric and gas services are provided pursuant to just and reasonable rates.

9 In exercising its authority, the Department does not micromanage utility decisions or substitute its judgment for that of utility management. See New England Telephone and Telegraph Company v. Department of Public Utilities, 327 Mass. 81, 90 (1950) ("a public regulatory board cannot assume the management of the company and cannot under the guise of rate making interfere in matters of business detail with the judgment of its officers reached in good faith and within the limits of a reasonable discretion"). Instead, the Department reviews company management under well-established administrative principles applicable to cost and rate recovery.

10 The GCA sets outs the requirements of the Department's review process. After the PAs file a proposed Three-Year Plan, the Department must conduct a public hearing and, within 90 days, "issue a decision on the plan which ensures that the [PAs] have identified and shall capture all energy efficiency and demand reduction resources that are cost effective or less expensive than supply." G.L. c. 25, § 21(d). The Department "shall approve, modify and approve, or reject and require the resubmission of the plan accordingly." G.L. c. 25, § 21(d).

11 The GCA states that, in authorizing energy efficiency programs, the Department "shall ensure that they are delivered in a cost effective manner capturing all available efficiency opportunities, minimizing administrative costs to the fullest extent practicable and utilizing competitive procurement processes to the fullest extent practicable." G.L. c. 25, § 19(a, b). In order to mitigate capacity and energy costs for all customers, the GCA also requires the Department to ensure that electric and natural gas resources are first met "through all available energy efficiency and demand reduction resources that are cost effective or less expensive than supply." G.L. c. 25, § 21(a).

with the Massachusetts Administrative Procedure Act, G.L. c. 30A, which requires the Department to maintain standards of fair procedure such as notice, an opportunity to be heard, and the ability to appeal decisions.[12]

4. Energy Efficiency Advisory Council

The Department appoints and convenes the Council, which consists of 15 voting members of diverse backgrounds and expertise. G.L. c. 25, § 22(a). The Council's membership is comprised of governmental and non-governmental members, including representatives of DOER, the Department of Environmental Protection ("DEP"), the Attorney General, the environmental community, and residential, low-income and commercial and industrial customers. G.L. c. 25, § 22(a). The Council also includes one "non voting, ex-officio member" from each of the twelve Program Administrators (comprised of Massachusetts electric and natural gas distribution companies and municipal aggregators). G.L. c. 25, § 22(a). There is also one non-voting member from the heating oil industry, energy efficiency businesses, and Independent System Operator - New England ("ISO-NE"). G.L. c. 25, § 22(a).

Each Three-Year Plan must be prepared in coordination with the PAs and the Council. G.L. c. 25, § 21(b)(1). As part of the Department plan approval process, the Council is required in its advisory role to "seek to maximize net economic benefits through energy efficiency and load management resources and to achieve energy, capacity, climate and environmental goals through a sustained and integrated statewide energy efficiency effort." G.L. c. 25, § 22(b). In this role, the Council "shall review and approve demand resource program plans and budgets, work with program administrators in preparing energy resource assessments, determine the economic, system reliability, climate and air quality benefits of efficiency and load management resources, conduct and recommend relevant research, and recommend long term efficiency and load management goals to maximize economic savings and achieve environmental goals." G.L. c. 25, § 22(b). As part of its review of Three-Year Plans, the Council must approve "efficiency and demand resource plans and budgets" with a two-thirds majority vote. G.L. c. 25, § 22(b). In addition, the Council must "examine opportunities to offer joint programs providing similar efficiency measures that save more than one fuel resource or to coordinate programs targeted at saving more than one fuel resource," with costs for joint programs being allocated equitably. G.L. c. 25, § 22(b). After receipt of the April 30th draft plan, the Council has three months to review it and submit "approval or comments" to the PAs. G.L. c. 25, § 21(c).

The Council may retain energy efficiency experts provided they have no contractual relationship with the PAs or an affiliate. G.L. c. 25, § 22(c). The Department approves (and may modify) the level of funding required for the retention of experts and reasonable administrative costs. G.L. c. 25, § 22(c). The Council may ask the PAs for information as part of the development of the Three-Year Plan, and must provide an annual report to the Department

[12] See G.L. c. 30A, §§ 5, 10-12, 14 (outlining adjudicatory proceedings and availability of judicial review). Additionally, to comply with c. 30A, the Department must maintain a record of its adjudicatory proceedings, afford parties the opportunity to present evidence and argument and issue decisions in writing or on the record with a statement of reasons. G.L. c. 30A, §§ 10-11. Finally, Department decisions are subject to appeal to the Supreme Judicial Court on the record formed during the c. 30A adjudicatory proceeding. G.L. c. 30A, § 5.

and the Legislature regarding the implementation of the PAs' statewide Three-Year Plan. G.L. c. 25, § 21(c). The Council must also periodically review program cost-effectiveness. G.L. c. 25, § 21(b)(3). To conduct its business, the Council holds meetings, which are subject to the open meeting law, typically on a monthly basis with the full Council and with its Executive Committee.

In sum, the Council is designed to engage the expertise of its diverse membership and consultants to provide strategic, objective advice to the PAs and the Department. The Council is uniquely positioned to coordinate energy efficiency information on a statewide basis. It provides a forum for coordinating a statewide view from different PAs and for similarly coordinating stakeholder feedback on a statewide basis.

C. **Reporting of Energy Efficiency Data**

The Program Administrators provide extensive energy efficiency data sets in numerous public reports to the Department and the Council. This data is reported in a consistent and timely manner on a monthly, quarterly and annual basis. The D.P.U. 08-50 tables are one of the most comprehensive sources of reported PA data, providing quantitative data elements on numerous topics.[13] These tables were collaboratively developed by a diverse group of stakeholders.[14] In developing the table templates, the stakeholder working group sought "to serve the compatible but, not identical, requirements of both the Council and the Department." Energy Efficiency Guidelines, D.P.U. 08-50-B at 10 (2009). Each PA files detailed data tables as part of a

---

[13] The D.P.U. 08-50 tables address the following topic areas (with some gas/electric variations):

> (1) funding sources (summary, funding comparison between each Program Administrator's planned funding and the statewide total, SBC funds, FCM proceeds, RGGI proceeds, other funding if available, prior year carryover, energy efficiency surcharge funds); (2) budgets (summary, budget comparison between each Program Administrator's planned budget and the statewide total, budget comparison between the three-year plan's budget and previous year's budgets); (3) cost-effectiveness (summary, costs summary, costs comparison between each Program Administrator's planned costs and the statewide total, cost comparison between the three-year plan's costs and previous year's costs, benefits summary, benefits comparison between each Program Administrator's planned benefits and the statewide total, benefits comparison between the three-year plan's benefits and previous year's benefits, savings summary, savings comparison between the three-year plan's savings and previous year's savings, avoided cost factors summary, distribution and transmission avoided costs factors comparison between each Program Administrator's planned factors, distribution and transmission avoided costs factors comparison between the three-year plan's factors and previous year's factors); (4) monitoring and evaluation; (5) performance incentive; (6) cost recovery (LBR and energy efficiency surcharge); (7) low-income customer budget allocation; (8) outsourced services (summary, outsourced services comparison between each Program Administrator's planned outsourced services and the statewide total, outsourced services comparison between the Three-Year Plan's outsourced services and previous year's outsourced services); and (9) master summary. Energy Efficiency Guidelines, D.P.U. 08-50-B at 11-12 (2009).

[14] These tables were collaboratively developed in five months over 11 stakeholder meetings and were approved by the Department. D.P.U. 08-50-B at 10. Representatives from several entities actively participated in these meetings, including: Attorney General, DOER, the Council, Associated Industries of Massachusetts, Environment Northeast (n/k/a Acadia Center), Conservation Law Foundation, The Energy Consortium, LEAN, PAs, and Department staff. Id. at 9 & n.5.

Three-Year Plan, and annual and term performance reports.[15] The PAs have updated and enhanced the D.P.U. 08-50 tables for the 2016-2018 Plan and refer to them as the Energy Efficiency Data Tables (see Appendix C).

Program Administrators must provide quarterly reports to the Council on the implementation of their plans. G.L. c. 25, § 22(d). To be responsive to Council requests for additional data, the PAs voluntarily provide monthly data dashboards in months where no quarterly report is due to provide even greater transparency on their implementation efforts. The PAs developed the Council reporting formats in collaboration with the Council consultants. The PAs have been providing quarterly and annual reports since 2010 and monthly data dashboards since 2011. As part of this data reporting, the PAs provide preliminary numeric data on savings, costs, and participants to the Council on a monthly and quarterly basis. Since 2010, the PAs and the Council's consultants have together worked to expand and improve these reports in response to Council interests. PAs also provide large amounts of data with contextual analysis through the EM&V process, with all studies and executive summaries available on the Council's website after finalization, as well as filed with the Department as part of annual plan-year ("Plan-Year") and three-year term ("Term") Reports.

Final data is reported to the Department and Council in Plan-Year Reports and Term Reports. In order to provide final data, the PAs undertake an extensive process to ensure that the data is verified and reliable. Rigorous quality assurance/quality control ("QA/QC") of cost and savings information occurs throughout the year, and additional QA/QC of both cost and savings data is performed specifically for the final reports. PAs review invoices and take steps to quality check and correct any errors in PA tracking systems and review any outliers. They assess items such as participation, vendor savings, and measure categorization; review labor and vendor costs; and review competitively procured services. PAs prepare a report-version of the Technical Reference Manual for Estimating Savings from Energy Efficiency Measures ("TRM") and apply updated evaluation impacts to the data. Following this process, the PAs populate benefit-cost screening models to assess measure, program, sector, and portfolio cost-effectiveness as well as data tables for filing with the Department. This rigorous review process ensures that the data provided by the PAs and relied upon by the Department, Council, and other stakeholders, including ISO-NE, is accurate and of high quality.

Historically, reports to the Department and Council were made in writing, with the quarterly reports being provided in narrative and Excel formats. In order to increase accessibility, in 2014, the PAs developed a database to make energy efficiency data reported to the Department and the Council available in a user-friendly and accessible web-based platform. The public can access this information at www.MassSaveData.com and export data to PDF or Excel formats. The data is available by individual PA and can also be aggregated statewide or for specified PAs. The information available on www.MassSaveData.com replicates the data

15 Prior to 2013, the PAs would file D.P.U. 08-50 tables with mid-term modification filings. On January 30, 2013, the Department issued revised Energy Efficiency Guidelines as part of its streamlining docket in D.P.U. 11-120, which was focused on reducing regulatory burdens where possible. In finding that energy efficiency plans should be treated as true three-year plans and not three annual plans, the Department minimized the need for mid-term changes to the 08-50 tables. Energy Efficiency Guidelines, D.P.U. 11-120-A, Phase II (2013).

available in the Energy Efficiency Data Tables, except for those limited data points that do not lend themselves to quantitative roll-ups. The website currently replicates the data provided to the Council on a quarterly basis. The PAs recently released a monthly data tab that replicates the monthly data dashboard provided to the Council. The website also includes additional information, such as Home Energy Services ("HES") closure rates, cost to deliver and greenhouse gas emission reductions stemming from energy efficiency. Because the data available on www.MassSaveData.com is aggregated, it appropriately protects customer privacy and reduces the need for expensive data security measures, which are core database concerns of the PAs, Department, and stakeholders.[16]

In 2014, the PAs also began developing an electronic version of their specific inputs to the TRM, which documents impact factors and input assumptions used to calculate savings, with sources and references. This electronic version, known as the Technical Resource Library ("TRL"), reflects the effort of the PAs to align common measure naming across all PAs and will allow the public to access information from a central website. The TRL is currently in development, and is anticipated to be complete in 2016. The PAs provide a paper TRM in Appendix V of this 2016-2018 Plan and expect to supplement that document with the TRL when it is available.

D. Overview of Green Communities Act Compliance

1. The Sustained Acquisition of All Cost-Effective Resources

a. Reasonable Pace for Sustained Acquisition

The GCA requires the PAs to acquire all cost-effective energy efficiency resources in their Three-Year Plans. The Department has determined that the acquisition of these resources, however, must be achieved through a sustained effort. 2013-2015 Energy Efficiency Plans, D.P.U. 12-100 through D.P.U. 12-111, at 37 (2013) ("2013-2015 Order"); 2010-2012 Gas Order, D.P.U. 09-121 through D.P.U. 09-128 ("2010-2012 Gas Order"), at 71 citing G.L. c. 25, § 22(b); 2010-2012 Electric Order, D.P.U. 09-116 through D.P.U. 09-120 ("2010-2012 Electric Order"), at 85. To determine the rate at which PAs must acquire these resources, the GCA requires the PAs, Council, and Department to consider a number of factors.

> Determining a reasonable pace for a sustained acquisition requires the Program Administrators and the Council (in developing the Three-Year Plans) and the

[16] In Massachusetts, the PAs strictly control access to sensitive customer-specific account information like customer names, account numbers, rate class, location, usage, and demand data. The PAs have each adopted strict corporate privacy policies and safeguards to protect customer information. These corporate privacy policies explicitly state that customers' personal information will be safeguarded and only disclosed for a regulated PA business purpose. Each of the PAs maintains physical, electronic, and procedural safeguards to protect such sensitive data. Customer consent is necessary to permit third-party access to sensitive customer-specific account information outside the conduct of regulated PA business. Disclosure of customer information to a third-party without customer authorization would violate corporate privacy policies and expose a PA to liability under the Massachusetts Right to Privacy Act, M.G.L. c. 214, § 1B or Chapter 93A, Department precedent and directives to maintain customer confidentiality, and potentially other statutes.

> Department (in reviewing the Three-Year Plans) to strike an appropriate balance between several factors, including: (1) identifying the potential level of cost-effective resource currently available; (2) exploring ways in which this level can be increased; (3) assessing the capability of the energy efficiency vendor and contractor industry to support increased program activity; and (4) assessing the capacity of the Program Administrators to administer increases in program activity efficiently and effectively. The Department must take into consideration an additional factor: the rate and bill impacts that result from increased program activity.

2010-2012 Gas Order, at 71-72 and 2010-2012 Electric Order at 85-86. Consistent with the Department's directives, the 2016-2018 Plan provides a strategy for acquiring all cost-effective energy efficiency resources at a reasonable pace during this three-year term.

b. Statewide Strategic Plan

Like its predecessors, the 2016-2018 Plan includes multiple parts that taken together as an integrated whole describe the PAs' strategy for acquiring all cost-effective energy efficiency resources through a sustained effort. The provisions of the entire Plan must be considered as a whole in order to fully appreciate and understand both the PAs' energy efficiency programs and their strategy for satisfying the mandates of the GCA over the next three years.

While detailed, a Three-Year Plan is a strategic plan, not an implementation guide. This strategic plan approach provides the PAs with the flexibility necessary to make implementation changes to meet changing circumstances in order to deliver on their Plan goals and satisfy the GCA. Each PA retains the flexibility during the implementation of a Three-Year Plan to make modifications without Department or Council approval. A PA may adjust spending, add or subtract program measures, and make ongoing revisions and enhancements after the adoption of the Three-Year Plan in order to reflect in-the-field conditions, technological advances, financing opportunities, and state-of-the-art new technologies. PAs will seek Department and Council review and approval for modifications requiring such approval as set forth in the Department's Guidelines, as revised in Energy Efficiency Guidelines, D.P.U. 11-120-A, Phase II (2013) ("Guidelines").

2. Energy Efficiency Advisory Council

a. Introduction

For each three-year term the Program Administrators are required to submit to the Council a statewide energy efficiency plan on or before April 30th of the year prior to implementation. The GCA specifies the contents of the plan and requires that the plan be prepared by the Program Administrators in coordination with the Council. G.L. c. 25, § 21(b)(1)-(2). As part of the plan approval process, the GCA requires the Council to maximize benefits and achieve its goals through "a sustained and integrated statewide energy efficiency effort." G.L. c. 25, § 22(b).

To meet these statutory requirements for the 2016-2018 Plan term, the Program Administrators worked collaboratively to prepare an integrated statewide Plan that represents the collective efforts and objectives of the Program Administrators. The PAs also coordinated with the Council, participating in the processes developed by the Council for providing input on the 2016-2018 Plan. On April 30, 2015, the Program Administrators submitted the initial draft 2016-2018 Plan for the Council's comment and approval. After receipt of the April 30thdraft Plan, the Council had three months to review it and submit "approval or comments" to the PAs. G.L. c. 25, § 21(c). The Council approved a resolution on the April 30th draft Plan on July 21, 2015.

The PAs have been active and engaged participants in the Council process since its inception in 2009. Between 2009 and 2012, the PAs participated in at least 79 meetings of the full Council and/or its Executive Committee. From 2013 to the time of this Plan, the PAs have participated in at least 116 meetings of the full Council, its Executive Committee, its database subcommittee/working group, and/or planning workshops. In 2012, the Council membership was expanded, adding both voting and non-voting members. In 2015, membership in the Council's Executive Committee was also expanded by adding a Commercial and Industrial ("C&I") seat, replacing a low-income seat with a consolidated residential and low-income seat, and by formalizing a seat for the PAs. While these expansions have broadened the input on plan development and implementation, they have also increased the complexity of the Council dynamics and the time and effort the PAs must invest in responding to Council and individual councilor inquiries.

b. Council Priorities

In its January 13, 2015 Draft Priorities for 2015, the Council articulated a priority related to the 2016-2018 Plan, stating that the Council should "relay clear Council priorities and recommendations to the Program Administrators for inclusion in the 2016-2018 Three-Year Plans." The PAs worked with the Council on the 2016-2018 Plan and achieving all available cost-effective energy efficiency by maximizing net economic benefits through a sustained and integrated statewide energy efficiency effort, setting aggressive and achievable goals and addressing barriers to energy efficiency, while staying focused on bill impacts, cost efficiency and integrated program delivery.

c. Council Workshops

In February and March 2015, the Council conducted a number of sector-related workshops, facilitated by Raab Associates, Ltd., to assist in the development of the 2016-2018 Plan. The PAs were active and engaged partners in the development of meeting materials and in the workshops. There were three C&I workshops, three residential workshops, and one multi-family/low-income workshop. These workshops assisted the Council in developing recommendations for its Resolution dated March 31, 2015.

After the filing of the April 30th draft Plan, the Council held two follow-up workshops in June 2015 to allow for further stakeholder engagement and discussion of program designs. There was one residential/low-income workshop and one C&I workshop. The PAs provided insights and answered questions at these workshops. These workshops assisted the Council in developing recommendations for its Resolution dated July 21, 2015.

d. Council Resolution of March 31, 2015

On March 31, 2015, the Council adopted a "Resolution Concerning Its Priorities for the Development, Implementation, and Evaluation of the 2016-2018 Three-Year Energy Efficiency Plans." See Appendix E. This Resolution articulates the Council's priorities for the 2016-2018 Plan and makes 150 specific recommendations based upon the Council workshops. The PAs closely reviewed these recommendations and incorporated many of the themes and comments into the program design for the April 30th draft Plan.[17] Many of the topics in the recommendations were discussed at the June Council workshops. While the PAs did not adopt each and every recommendation in the April 30th draft Plan, the recommendations were valuable to the PAs in developing program designs that they believe will keep Massachusetts at the forefront of energy efficiency design in the nation. Working with DOER and Raab Associates, the PAs developed a matrix that gives feedback on each of the Council's 150 specific recommendations. See Appendix F (matrix dated May 25, 2015).

e. Council Resolution of July 21, 2015

In accordance with the GCA, "the [C]ouncil shall review the plan and any additional information and shall submit its approval or comments to the electric and natural gas distribution companies and municipal aggregators not later than 3 months after submission of the plan." G.L. c. 25, § 21(c). On July 21, 2015, the Council adopted a resolution entitled "Comments regarding the April 30th draft 2016-2018 Energy Efficiency Plan." See Appendix G. This Resolution articulates the Council's priorities for the 2016-2018 Plan and makes over 100 specific recommendations and other comments based upon the comments from councilors, stakeholders, legislators, and Council consultants provided during various Council meetings, including two public comments sessions of the Council and nine Council workshops. Like the previous Council recommendations, the PAs have carefully reviewed the Council's July 21st recommendations and incorporated many but not all of the themes and comments into the September draft plan.[18] The PAs appreciate the Council's thoughtful feedback on the April plan and believe that, together with the Council's input, they have developed comprehensive and innovative program designs that will continue to set the standard for the rest of the nation. For ease of reference, the PAs developed a matrix that provides feedback on each of the over 100 specific recommendations in the Council's resolution. See Appendix H (matrix dated September 23, 2015). The PAs look forward to continuing to discuss the Council's

---

[17] As expressly stated in this Resolution, the Council developed "recommendations," consistent with the Council's advisory role under the GCA, but they were not a consensus view of the Council. See Minutes of March 31, 2015 Council Meeting.

[18] As expressly stated in this Resolution, the Council made "recommendations," consistent with the Council's advisory role under the GCA. In addition the Resolution makes clear that the recommendations are not a consensus view of the Council, stating that they "may not represent the opinion or position of every Councilor on certain issues, but on the whole, the Council has determined that the recommendations should be considered and addressed in the Revised Plan." July 21, 2015 Resolution at 5; see also Minutes of July 21, 2015 Council Meeting.

recommendations in a collaborative and productive manner consistent with both the mandate of the GCA and the rich history of stakeholder discussions that are the hallmark of energy efficiency in Massachusetts.

f. Term Sheet

Following the July 21st Resolution of the Council, the PAs collaborated with the Council's consultants, along with the Executive Office of Energy and Environmental Affairs, DOER, and the Office of the Attorney General, to further discuss goals, budgets, and key priorities. As a result of these discussions, the PAs, DOER, and the Attorney General were able to agree upon the Term Sheet. See Appendix D (Term Sheet). The Term Sheet sets forth fundamental core goals for 2016-2018 that have served as a guide for the PAs in developing this Plan.

g. Council Resolution of October 26, 2015

In September and October 2015, the Programs Administrators continued to work collaboratively with the Council consultants and individual councilors to incorporate key priorities, and the goals and budgets reflected in the Term Sheet into the Plan. On October 26, 2015, the Council adopted, by a 14 to 1 super-majority vote, a Resolution commending the PAs, strongly supporting the 2016-2018 Plan, and respectfully requesting that the Department of Public Utilities approve the Plan. See Appendix I. The Program Administrators express their appreciation for the efforts of each councilor and the Council consultants. The ability to achieve such an overwhelming consensus on a Plan as complex and with as many moving parts as this one, reflects a signature achievement for the Commonwealth.

3. Department of Public Utilities

a. Introduction

In accordance with the GCA, the Program Administrators submit their 2016-2018 Plan "together with the [C]ouncil's approval or comments and a statement of any unresolved issues, to the [D]epartment," for approval no later than January 31, 2016. Since the Department reviews each PA's Three-Year Plan individually, these filings also include company-specific information. Additionally, for the 2016-2018 Plan the Department has requested that the PAs respond to certain questions set forth in the Department's Revised Additional Filing Requirements dated October 2, 2015. Responses to these questions are set forth in each PA's pre-filed testimony and in Appendix X.

b. All Cost-Effective or Less Expensive than Supply

In approving a Three-Year Plan, the Department is seeking to mitigate capacity and energy costs for all customers "through all available energy efficiency and demand reduction resources that are cost effective or less expensive than supply." G.L. c. 25, § 21(a). The Department is charged with ensuring that the PAs "have identified and shall capture all energy efficiency and demand reduction resources that are cost effective or less expensive than supply." G. L. c. 25, § 21(d)(2). To comply with the GCA, a Three-Year Plan must provide for the acquisition of these resources "with the lowest reasonable customer contribution." G.L. c. 25, § 21(b)(1).

In developing their 2016-2018 Plan, the PAs considered what an optimal pace is for acquiring all cost-effective energy efficiency resources for the period from 2016 to 2018, in order to ensure long-term sustainability for their energy efficiency program offerings. In developing savings goals for 2016-2018, the PAs took into consideration the four factors set forth in Section II.D.1.a, above, as well as rate and bill impacts on their customers. The PAs provide detailed information on the development of their goals in Section III, as well as their individual benefit/cost ratio ("BCR") models, demonstrating that they are seeking to acquire all cost-effective energy efficiency resources for the 2016-2018 term.

c. Program Cost-Effectiveness

The GCA specifically requires cost-effectiveness screening for energy efficiency programs. G.L. c. 25, §§ 19(c), 21(b)(3).[19] The Department has determined that a Total Resource Cost ("TRC") test that weighs the impact of societal benefits and costs associated with each program satisfies this requirement D.P.U. 08-50-A at 14; Guidelines § 3.4.3. The TRC test operates by weighing all program costs and benefits. Benefits calculations include the cost of energy supply that is avoided when energy efficiency efforts are utilized and therefore the TRC test satisfies the GCA's requirement that energy efficiency programs be less expensive than supply. D.P.U. 08-50-A at 14-15.

For the 2016-2018 Plan, the PAs applied the results of the regional Avoided Energy Supply Costs in New England: 2015 Report ("2015 AESC"), which was completed on March 27, 2015 and revised on April 3, 2015, and is attached hereto at Appendix J.

d. Program Authorization and Delivery

In authorizing energy efficiency programs, the Department must ensure that the PAs are: "[1] deliver[ing] programs in a cost-effective manner capturing all available efficiency opportunities [2] minimizing administrative costs to the fullest extent practicable and [3] utilizing competitive procurement processes to the fullest extent practicable." G.L. c. 25, § 19(a, b). The PAs have addressed each one of these issues throughout the Plan, and specifically in Sections V.A, V.D, and V.E, below.

e. Program Funding

i. <u>Funding Sources</u>

The PAs seek to leverage available funding sources and financing initiatives in order to increase the benefits of Three-Year Plans and minimize customer bill impacts. For electric PAs,

---

[19] The GCA requires energy efficiency programs included in PAs' Three-Year Plans to "be screened through cost effectiveness testing which compares the [economic] value of program benefits to the program costs to ensure that the program is designed to obtain energy savings and system benefits with value greater than the costs of the program." G.L. c. 25, 21(b)(3).

the GCA identifies four specific funding sources for energy efficiency programs: (1) revenues collected from ratepayers through the System Benefit Charge ("SBC"); (2) proceeds from the PAs' participation in the Forward Capacity Market ("FCM"); (3) proceeds from cap and trade pollution control programs, including but not limited to the Regional Greenhouse Gas Initiative ("RGGI"); and (4) other funding as approved by the Department, including revenues to be recovered from ratepayers through a fully reconciling funding mechanism (*i.e.*, an energy efficiency surcharge ("EES")). G.L. c. 25, §§ 19(a); 21(b)(2)(vii). For gas PAs, the GCA does not identify multiple funding sources for energy efficiency programs and instead requires the gas PAs to include a fully reconciling funding mechanism to collect energy efficiency program costs from customers (*i.e.*, EES). G.L. c. 25, § 21(b)(2)(vii); see also G.L. c. 25, § 21(d)(2). For a detailed discussion of the funding sources and financing initiatives that are currently available to the PAs, please refer to Section VI, below.

ii. Funding Allocation

Consistent with the Department's Guidelines, the Program Administrators allocate SBC, FCM, and RGGI revenues to each customer sector in proportion to the kWh consumption of each class. The low-income sector is allocated at least ten percent of the funds for electric energy efficiency programs and 20 percent of the funds for gas energy efficiency programs pursuant to G.L. c. 25, § 19(c).

iii. Funding Mechanism

The EES is a fully reconciling funding mechanism that the Department approves for funding the Three-Year Plans. G.L. c. 25, § 21(d)(2). Electric Program Administrators collect the EES through Energy Efficiency Reconciliation Factor ("EERF") or Energy Efficiency Program Cost Adjustment ("EEPCA") tariffs. Guidelines §§ 2(9), 3.2.1.6. For gas Program Administrators, the EES is collected through the local distribution adjustment clause ("LDAC") tariff in accordance with established Department practice. Guidelines §§ 2(9), 3.2.2. The EERF/EEPCA and LDAC filings of the PAs are separate proceedings from the Three-Year Plan proceeding and are implemented on schedules that vary among the PAs.

III. STATEWIDE PROGRAMS

A. Strategic Overview of Residential, Low-Income, and C&I Programs

The Commonwealth of Massachusetts has achieved national recognition for its leadership in energy efficiency policy and programming, ranked as the top state in the nation by American Council for an Energy-Efficient Economy ("ACEEE") for the past five years running. The Program Administrators' comprehensively designed and implemented energy efficiency programs operate day to day to deliver energy efficiency savings and benefits for Massachusetts businesses and consumers.

The PAs provide programs to three core sectors: Residential, Low-Income, and C&I. Within the residential sector, the PAs offer two programs: Whole House and Products, comprised of a total of seven core initiatives. PAs support the Low-Income sector with Whole House programming, delivered through two core initiatives targeting single family (1-4 unit) and multi-family buildings. The C&I sector is served by two programs, Retrofit and New Construction, with six tailored core initiatives within the programs. The Residential and C&I programs coordinate closely and are served by the Statewide Marketing and the Evaluation Management Committees. The Low-Income sector coordinates closely with LEAN.

The first Three-Year Plan (2010-2012) built upon a strong foundation of the efficiency programs that had been offered for years in the Commonwealth, but which revolutionized the scale and pace of efficiency programming. Lessons from that first Three-Year Plan led to significant expansion, including program re-design with multiple enhancements and additions. Those programming updates succeeded in broadening participation across sectors, increasing savings, and delivering unprecedented benefits for participants. In the second Three-Year Plan (2013-2015), the PAs continued to build on successful programs and strategies and make improvements to reach additional customers and seek deeper and broader energy efficiency opportunities. Over both terms, the PAs have consistently achieved record-setting levels of savings and participation, and in 2014 achieved greater than 100 percent of plan savings and benefits goals across gas and electric programs.

In reviewing the 2016-2018 Plan, it is critical that the energy efficiency community considers and celebrates the historic achievements of the PAs' energy efficiency programs, and the contributions of multiple stakeholders, including the Council, the DOER, the Department, the Attorney General, and LEAN, to these achievements. At the same time, it is necessary to acknowledge that many market factors, including more stringent codes and standards, the saturation of certain markets, and lower avoided costs, will naturally lead to a leveling off of savings and higher costs to secure additional kilowatt hour and therm savings. Recognizing these pressures on costs, PAs remain ever-conscious of the trust invested in PAs to deliver solid efficiency investments without creating undue bill impacts. PAs also remain committed to maintaining the stability of the robust efficiency infrastructure that has been built; most critically the network of energy efficiency vendors, contractors, installers, distributors, and manufacturers which form the backbone of the PA program delivery.

To address these pressures and commitments, the PAs have focused this Three-Year Plan on optimizing program potential by balancing investments to maximize benefits against a consistent, reasonably and moderately increased, funding scenario. This approach will require continued adaptation through market segmentation, effective targeting, streamlining, and improving access and program processes, along with ongoing review and inclusion of new efficiency technologies. PAs remain committed to continuously broadening and growing a competitive delivery workforce of participating vendors and contractors, and investigating and exploring program modifications through field tests and evaluations of novel approaches.

The 2016-2018 Plan also seeks to maintain the PAs' commitment to ensuring the highest quality customer experience. Ultimately, this customer experience is the cornerstone on which the programs must be built to ensure continued enthusiasm and support for securing energy efficiency as the Commonwealth's first and lowest cost fuel.

B. Sustainable Infrastructure

The Massachusetts model of Program Administrator delivery of energy efficiency programming has proven highly successful in building a robust energy efficiency industry. According to the 2014 Massachusetts Clean Energy Industry report[20] there are 65,000 workers and more than 4,000 firms working in the Massachusetts energy efficiency industry, representing a 35.6 percent growth in the number of firms conducting energy efficiency work since 2013. Energy efficiency employment makes up half (50.9 percent) of jobs at startups working on pre-commercialized technologies. The PA programs have broadened the ability of market actors to participate in energy efficiency programming. Partners have been able to grow businesses and continue to invest in growth based on the confidence that they, and their customers, have in the energy efficiency regime. The continued strength and growth of this energy efficiency industry is reliant on consistency in programming and a stable budget; this Plan provides the necessary predictability and stability, consistent with multiple comments and suggestions from contractors, including those offered at the Council's January and May stakeholder input meetings. The PAs remain committed to supporting the Massachusetts energy efficiency infrastructure with continued rigorous program design, evaluation, and delivery, while avoiding large shifts in direction or budget. The PAs will continue to optimize systems and expand offerings while recognizing the key role that PA partners play.

C. Mechanisms for Program Collaboration, Continuous Improvement, and Sharing and Incorporation of Best Practices Information

1. The Residential and C&I Management Committees

A central theme running through each generation of Three-Year Plans has been the ongoing PA commitment to work collaboratively on a daily basis to ensure that: (a) all eligible customers in Massachusetts experience seamless programs, with common application procedures, incentives, and supportive educational and technical services; and (b) those programs are subject to continuous improvement in order to retain their status as among the best in North America.

[20] Available at: http://www.masscec.com/content/2014-clean-energy-industry-report.

Before the first Three-Year Plan was submitted, the PAs developed informal working groups that brought together the respective residential and commercial program managers from every gas and electric company and energy efficiency service provider in the Commonwealth. Tasked with transitioning to an integrated statewide program portfolio, these working groups focused on producing the initial uniform administrative procedures, developing supporting materials for seamless program delivery across fuels and across service territories, and maintaining consistent messaging to customers, trade allies, manufacturers, market actors, and market channels.

However, managing and delivering a statewide portfolio of programs is an ongoing and dynamic exercise. Programs must evolve and respond in real-time to a myriad of forces, such as changing consumer dynamics and expectations, the appearance of new efficiency technologies in the market, price and baseline changes to existing technologies, as well as the impact of the general economy, which strongly influences the nature and degree of program participation. In order to facilitate efficient and timely program decision-making the successful informal structures of the working groups were formalized into a Residential Management Committee ("RMC") and a C&I Management Committee ("C&IMC"). Each committee developed a formal written charter to ensure that the roles and responsibilities of the committee and its members were understood by all PAs. To ensure efficient resolution of issues that come before them, each PA has delegated decision-making authority to their committee representative. Each committee has a chair or lead, who speaks for the PAs collectively on program matters, and a coordinator to assist in organizing committee activities and performing administrative tasks, such as memorializing the record of committee decisions and ensuring that decisions that impact program delivery are disseminated to every PA.

The management committees may delegate some tasks to various expert technology teams, individual experts, the Massachusetts Technical Assessment Committee ("MTAC"), or any other ad-hoc or permanent subgroups they may establish. The committees may also use contractors to facilitate specific elements of their work where internal capacity or expertise is insufficient or where an independent view is valued.

Each management committee works to ensure that: (a) all PAs remain abreast of the key activities of other PAs; (b) implementation activities and efforts by all PAs are integrated and coordinated to the optimal extent; (c) statewide marketing and media campaigns are developed with easy-to-understand communications that serve eligible customers; (d) evaluation and market assessment studies are reviewed and program modifications are executed accordingly; (e) program policy and implementation issues are resolved collectively, and decisions are communicated to each PA's staff to ensure uniform application; and (f) program best practices, technology innovations, and integration/coordination efforts in other jurisdictions are reviewed and incorporated as appropriate.

In addition to enhancements to existing programs and initiatives, new programs and initiatives are designed by the management committees, with input from the appropriate working groups, internal subject matter experts, and a variety of "best practices" resources.[21]

With respect to low-income efforts, LEAN has convened the highly effective Low-Income Best Practices Group to coordinate practices across all PAs and agencies. The Low-Income Best Practices group continues to offer opportunities for various stakeholders to discuss program implementation, new measures, innovative strategies, and other matters related to the PAs' low-income programs.

2. The Massachusetts Technology Assessment Committee

MTAC reviews new technologies that have the potential to cost-effectively save energy. MTAC is both a proactive and a reactive body, and consists of key technical staff from among the PAs. The committee addresses both residential and commercial/industrial technologies, drawing on the subject matter experts from the committee, PA staff, or outside expertise as necessary. It establishes and publishes threshold technical requirements that must be met to qualify products or processes as eligible for program incentives. It documents its findings in a standardized manner and disseminates them to the PA program managers, technical staff, account managers, and outside parties such as vendors, customers, and other interested parties, as appropriate.

The MTAC is the authority for consistent program interpretation of technical matters and provides information, documented technical interpretations, and technology assessments to the PAs. The committee has developed a set of protocols for the content of their review and procedures for documenting and disseminating their conclusions and technical interpretations. These protocols are publicly available on MassSave.com.[22] The MTAC meets as needed, either as a whole committee or in ad hoc technology or issue-specific subgroups, and more regularly during the annual program review and planning period.

In accordance with the October 26th Resolution, the Program Administrators commit to providing semi-annual updates to the Council on the PAs' progress reviewing and implementing new technologies into programs.

3. Ongoing Commitment to Innovation and Technology

The Program Administrators have been national leaders in their commitment to innovation, and the development and deployment of cutting-edge new technologies. As part of the Term Sheet, the PAs, EEA, DOER, and the Attorney General have prioritized the importance of this commitment as follows:

> The Council and the PAs agree on the importance of implementation of new technologies and program approaches. The PAs are committed to increasingly

---

21 Examples include the recent Retro-commissioning best practices study conducted in conjunction with the Council consultants, and a review of emerging program and technology trends conducted by E Source for both the C&IMC and the RMC.

22 MTAC materials can be found here: http://www.masssave.com/professionals/business-opportunities/assessment-of-new-efficiency-technologies.

develop and deploy new technologies, delivery models and business strategies with performance-based results that are appropriate for the customers and that are proven to be cost-effective. The Plan will reflect a continuous commitment by the PAs to exploring and adopting cost-effective innovations and new technologies in the residential, low-income and C&I sectors. In addition to specific efforts identified in the Plan, the PAs commit to continuous collaboration on innovation, including appropriate program updates and evaluation efforts with the Council.

D. Engaging Third Party Stakeholders

The PAs are constantly engaged with a myriad of stakeholders. Every day the PAs hear from and respond to residential and commercial customers, program participants, contractors, service providers, equipment manufacturers and distributors, trade and professional associations, legislators and regulators, environmental and community advocates, civic leaders, business owners and organizations, and other interested parties. Every citizen and every business has an interest and a stake in the effectiveness of the portfolio of Massachusetts energy efficiency programs because energy costs touch and affect every person and business in the Commonwealth.

The energy efficiency programs are designed and administered by the public utilities and energy efficiency service providers, which are open to input from members of the public. Massachusetts citizens and other interested parties are able to voice their views through existing and established public oversight processes. The Council, which represents a broad spectrum of stakeholder interests, has facilitated additional organized venues for individual and organizational input specific to the content of the Three-Year Plan through a series of topic area-specific public workshops and a number of general public hearings. The DOER has also invited and received comment and plan suggestions from all the cities and towns in the Commonwealth. All of the comment and input collected from these various forums has been reviewed closely by the PAs, and much of it has been reflected in this plan document. An additional opportunity for stakeholder input exists after the plan has been reviewed by the Council and forwarded to the Department. The Department’s regulatory processes are open to any interested parties.

On a continuing basis, there are a variety of other structured or semi-structured events, venues, or processes through which stakeholder input is encouraged. For example:

- **Annual open houses for trade allies/vendors.** Every year the PAs host several large statewide events for the express purpose of presenting and explaining program changes and updates to the business partners the PAs depend on to deliver their various programs to customers. Attendees have ample opportunity to network with each other and PA staff, and to engage in a dialog about program design and operations.
- **Best Practices Working Group.** This group is constituted of a subset of the HES contractors elected annually by their peers, as well as the PAs, and the Lead Vendors. The members meet monthly to provide continuous feedback for the improvement of the program across the state. Topics discussed have ranged from refining the QA/QC process, and adopting new measures such as spray foam to pricing and training.

- **The Proposal process.** The PAs provide a structured process by which any third-party organization can propose a program concept or proposal to supplement or enhance the PAs approved programs to the management committees. The criteria and two-step process for considering a proposal is clearly articulated. This process, while open, is rigorous and applicants must demonstrate that their concept can demonstrate and produce cost-effective and incremental savings beyond the approved program designs.[23]

- **The Massachusetts Technology Assessment Committee Process.** The clearly-articulated and open process by which MTAC reviews submitted technologies provides a level playing field. Any manufacturer or vendor of an emerging or newly-commercialized efficiency technology can make a science-based case for acceptance of their product into the PA incentive offerings.

- **Informal PA speakers' bureau.** PA representatives are regularly called upon to represent and explain the programs to trade and civic associations. Industry associations, like the Massachusetts Restaurant Association and the Massachusetts Lodging Association, seek knowledgeable speakers to explain how the programs can work for their members and provide relevant case study examples from their industry.

- **Proactively solicit input from customer and industry experts.** The PAs routinely seek input from key constituencies when they are considering program design changes or considering new product innovations. For example, Eversource recently completed a field trial of a new commercial laundry product in partnership with the product manufacturer and a customer – in this case, a hotel. The PA needed to establish that the product met the customer's priority need (*e.g.*, clean, white guest sheets and towels) before promoting the energy and water saving attributes.

- **Input and advice from peer programs.** The delivery of energy efficiency programs throughout the country is largely a collaborative and congenial business. PA program managers have come to know their peers in other leading jurisdictions around the country, and consider each other stakeholders in a shared mission of improving the efficiency of homes and businesses in the United States and reducing our collective carbon footprint. This means that emerging program ideas and best practices are freely shared. Massachusetts program managers test program concepts and share evaluation results and technical information with their counterparts, and receive feedback which is built into new program designs or improvements to existing ones.

- **Provide collateral materials for customer events.** Individual PAs routinely offer stakeholders significant volumes of program collateral for distribution at local community and trade association meetings.

---

[23] The documents related to the proposal process are available at http://www.masssave.com/professionals/business-opportunities/process-for-managing-unsolicited-proposals.

E. **Residential Programs**

1. Overview of Residential Programs – Whole House & Products

Massachusetts Program Administrators deliver the most comprehensive programs in the nation, with program and product offerings for every type of residential customer and every type of residential energy efficiency opportunity. The PAs' residential programs are designed to provide cost-effective energy efficiency savings opportunities to Massachusetts residential electric and gas customers. The programs address a range of building types, including both the traditional free-standing single-family home and the wide variety of multi-unit residential structures, from the iconic "triple decker" to mixed-use high rises to townhouse developments. The residential programs serve new construction and retrofit markets, and are responsible for ensuring that services are available to all residential sectors, including low-income.[24] The PAs have been offering residential programs for over 20 years.

Whole House Program Core Initiatives	Products Program Core Initiatives
New Construction	Heating & Cooling Equipment
Home Energy Services	Consumer Products
Multi-Family Retrofit	Lighting
Behavior/Feedback	

Low Income Whole House Program
Single Family
Multi-Family

There are two programs, Residential Whole House and Residential Products. The Whole House program targets residential single-family and multi-family dwellings, comprehensively addressing energy efficiency opportunities in the entire home or facility. Multiple core initiatives (New Construction, Home Energy Services, Multi-Family Retrofit, and Behavioral/Feedback) fall under the Whole House program. These initiatives allow for variations in program delivery and marketing that address specific moments in building life cycle, customer type, or market demand. Together these initiatives ensure that the Whole House Program is available to all customers and building types with targeted yet comprehensive energy efficiency services.

The Products program complements the Whole House program by focusing on optimizing the efficiency of lighting, heating and cooling equipment, and energy-consuming products that are introduced to the residential consumer market, whether they are sold by contractors or sold directly to consumers through big box stores, hardware stores, wholesale clubs, discount chains, and other retailers. The high visibility of the Products program across all sales channels provides tremendous marketing value and ensures that customers who do not take advantage of in-home services are able to easily participate in Mass Save® energy savings opportunities. PAs work with retailers, manufacturers, distributors, and trade allies within each

---

[24] The Green Communities Act requires that low-income residential demand side management and education programs be implemented through LEAN.

of the Products program's core initiatives (Lighting, Consumer Products, and Heating and Cooling Equipment) to ensure the highest-quality energy-efficient products are introduced and promoted to the residential consumer market. The Whole House and Products programs are tightly coordinated to ensure that innovations in technology and market dynamics are shared and leveraged. The PAs also work to provide consistent messaging and easy access for customers through coordinated marketing and the Mass Save® website.

2. Residential Highlights

The residential programs have historically met or exceeded their targets for participation, savings, and benefits statewide. The Whole House program has deployed highly effective participation paths, particularly in the HES core initiative. The HES core initiative generates greater participation rates than any other whole-house program nationwide, while maintaining high savings-realization rates. The Products program provides a broad opportunity to serve all customers, touching any customer who has purchased an efficient bulb or appliance. The Products program successfully leverages a complex array of delivery channels and partners to encourage Massachusetts consumers to install high efficiency technologies, including lighting, consumer products, heating, cooling, and water heating.

Much of the success of the last three years is due to the strong partnerships the PAs have developed with their network of vendors, contractors, manufacturers, distributors, and stakeholders. This network works alongside PA program staff to help PAs better understand their markets, identify new ideas, and support innovation in technologies and delivery systems.

The Council structure has offered a rich forum for exploring ideas. Several key successes noted as highlights below stemmed from a shared commitment by PAs and the Council to expanding and deepening participation by all customer segments, growing the qualified energy efficiency workforce, and securing cost effective energy efficiency for Massachusetts energy consumers. These successes will be key building blocks on which the shared priorities of the PAs and Council can be realized while maintaining Massachusetts' leadership in bringing cutting edge technologies into program design, ensuring customer acceptance and maintaining cost effectiveness.

The deployment of the online assessment tool and the incredible success of the Mass Save® Facebook page (which currently has more likes than ENERGY STAR®) speaks to the on-going commitment of PAs to reach out broadly and provide effective and creative entry points for customers. The on-line assessment effectively provides customers with a no–cost home energy score card, tied directly to customer-specific actionable Mass Save® energy efficiency opportunities specific to the resident's circumstances, all from the comfort of their keyboard and at their leisure. The existing online assessment tool and resulting scorecard provides a cost-effective, customer-centric approach, and addresses the Council's interest in ensuring that customers have access to actionable home energy scorecards.

Residential Highlights — 2013-2015

Customer Focus	Technology	Program Design
✓ Increased customer awareness of programs ✓ Social media outreach: over 110,000 Facebook fans (More than ENERGY STAR) and nearly 15,000 Twitter followers ✓ Mass Save® Online Assessment with digital path to HES ✓ Increased use of Multi-Family Market Integrator ✓ Expansion of HEAT loan program	✓ LED testing ✓ LED promotion through award winning marketing ✓ LED bulbs installed per household realized through bulk procurement ✓ Wireless-enabled thermostats ✓ Behavioral programs	✓ HES redesign ✓ Early boiler, furnace, and air-conditioning rebates ✓ Low cost pre-weatherization ✓ Deeper-energy savings incentives ✓ Contractor Best Practices working group ✓ Evaluation of Efficient Neighborhoods+ ® and review of Renew Boston ✓ Builder education on efficient building practices ✓ Multi-Family High Rise path in new construction

a. *Customer Focus*

- Increased customer awareness of programs, with 77 percent of customers agreeing that Mass Save® communicates how to lower energy bills, and 83 percent finding the Mass Save® campaign messaging clear and relevant. A majority of residential customers report awareness of the Mass Save® website, and 30 percent report using the website more than once in the past year.
- Built a strong social media presence over the 2013-2015 term, with over 110,000 Facebook fans (https://www.facebook.com/MassSavers) and nearly 15,000 Twitter followers (https://twitter.com/masssave).
- Jointly procured an industry-leading online assessment solution and configured it to meet the unique needs of Massachusetts consumers. This included a first-in-the-nation approach to displaying appropriate PA-specific information while maintaining the Mass Save® branding and enabling effective data sharing across PAs.
- Implemented the online assessment to introduce a digital path to participation in the HES program, while identifying opportunities for customers who may not be best served via HES. This easy-to-use tool gives customers a better sense of whether their home can benefit from the initiative, provides a high-level estimate of the potential savings that can be achieved, and identifies other opportunities they can pursue, all from the comfort of their home (or connected device) in under ten minutes.

- Increased access and use of the central point of contact, Multi-Family Market Integrator ("MMI") for customers of the Multi-Family Retrofit offerings. In 2012, there were 1,570 incoming calls to the MMI. In 2014, this number grew to 8,360. This increase in volume tracks the increased marketing with trade associations and coordination with account executives and other initiatives.
- Partnered with the local lending community to grow the Mass Save® HEAT loan initiative, the most successful initiative of its kind in the nation, growing from 532 loans in 2006 to over 11,000 loans in 2014 (annual). Since its inception, the Mass Save® HEAT loan has made over $200,000,000 available to thousands of homeowners implementing home energy efficiency improvements.

b. Technology

- Maintained leadership in testing and promoting LED technology in residential applications. Since 2008, several PAs have worked with the Department of Energy to test high quality LEDs in homes in the Commonwealth. Learning from its experience in the early promotion of compact-fluorescent lamps ("CFLs"), the PAs focused on LED lumen output, color, and dimming, among other desirable qualities for residential applications.
- Maintained leadership in a lighting program that has exponentially increased the number of LED sales and the breadth of LED types offered.
- Increased penetration of LED lighting technology through award-winning marketing campaigns promoting aggressive markdowns and buy-downs in retail outlets.
- Released a request for proposals ("RFP") to procure high-quality lighting through bulk purchase for Whole House initiatives. The effort dramatically reduced costs for the PAs while allowing them to install LEDs at a much more rapid pace than was originally planned.
- Offered rebates for wireless-enabled thermostats. The PAs completed a successful evaluation of the emerging wireless-enabled thermostats, becoming the first-in-the-nation energy-efficiency program to add a savings value to the TRM based on rigorous evaluated field results. Some PAs have begun to offer direct installation of wireless-enabled thermostats in the Whole House program; other PAs are exploring similar offers.
- Implemented one of the earliest and most comprehensive residential-behavioral programs in the country. Building off multiple early experimental designs, several PAs have been able to go to scale on behavioral program deployment, allowing for significant annual savings.

c. Program Design

- Implemented the redesigned HES program, expanding contractor participation in the program and supporting employment growth, contractor quality, and consumer value.

- Deployed early boiler, furnace, and air-conditioning rebates, demonstrating the ability to seamlessly integrate gas and electric initiatives.
- Offered special incentives to help customers overcome low-cost pre-weatherization barriers.
- Created the deeper-energy-measures offer to support customers seeking to super-insulate exterior walls, floors over a garage, or cathedral ceilings in retrofit applications.
- Convened the Contractor Best Practices working group forum to support regular communication between PAs, HES lead vendors, Independent Installation Contractors ("IICs"), and Home Performance Contractors ("HPCs"), resulting in several innovations and improvements, including a formal pricing-review process, support for training and marketing, and development of performance standards.
- Began evaluation of Efficient Neighborhoods +® and review of Renew Boston field trial to better understand how to increase access and secure savings for moderate-income residential customers and renters.
- Supported education of the builder market and promotion of efficient building practices, resulting in the average tier three (highest incentivized level) new construction homes achieving 50 percent savings, with some builders going all the way to net zero.
- Led the efficiency industry with deployment of the Multi-Family High Rise path in new construction, integrating Commercial and Industrial program expertise and Residential program expertise on the Joint Management Committee.

3. New and Innovative in 2016-2018

The focus for the residential programs in this next Three-Year Plan is to capitalize on growth and enhancements made in 2013-2015 through targeted optimization efforts for program delivery, marketing, and new technology deployments. The PAs are using the following six high-level principles to prioritize and deploy program innovations in the 2016-2018 Plan:

- Streamline the customer experience where possible.
- Maximize integration and cross-promotion between programs and among initiatives.
- Increase the use of technology and information tools to put customers in charge of their energy use.
- Adjust rebates and incentives to support energy savings, cost efficiency, and cost effectiveness goals.
- Increase customer awareness to continue increasing customer participation.
- Leverage and protect the robust energy-efficiency workforce built over the past two plan periods, while taking steps to grow the existing workforce via training/outreach.

Each program core initiative is described in detail below. For each core initiative "New Enhancements" are outlined in detail.

Carefully considering the wealth of interesting ideas brought forward—whether from internal PA processes, from EM&V studies, from the Council Workshops and the resulting recommendations, or from other stakeholders and partners—has resulted in a rich set of program enhancements.

New in 2016-2018

- **Renter visit**
- **Moderate income offer**
- **New construction path to zero**
- **Performance path for high rise multi-family new construction**
- **Home automation field trials**
- **Multi-family project point of contact**

Enhancements in 2016-2018

- Deep review of the customer experience, investigation of online/digital options
- Broaden adoption of wireless enabled thermostats
- Increase adoption of LEDs for phase out of CFLs
- Exploration of behavioral initiatives leveraging near-real-time electric consumption feedback
- Continued focus on market segmentation
- Continued offer of training subsidies for HPCs and IICs
- Continued review of upstream delivery models

This dialog during the planning year, combined with rigorous application of the six principles above, has spurred planning for the introduction of a possible breakthrough—**a renter-specific visit**. The PAs will offer a program enhancement that provides effective screening and direction of renters to a specially designed home visit that is tailored to renter opportunities and constraints. The PAs see the potential for a well-designed renter visit to increase participation of both renters and landlords in HES offerings. The renter visit will focus on installation of instant savings measures such as LED bulbs, advanced power strips, and water saving devices, and inform the customer of other appropriate opportunities for renters. In addition, the renter visit will allow for the collection of key information to help PAs follow up with landlords. The renter visit is detailed under the HES initiative description. The PAs will launch the effort in Q1 2016 and closely monitor, review and refine over the Plan term to ensure it succeeds in securing additional savings. The PAs believe the renter visit shows real promise and can present another opportunity for Massachusetts to be at the forefront of national efficiency program design.

The renter visit is by no means the only enhancement to respond to the Council's and PAs' shared commitment to ensuring all customers are supported in realizing energy-savings opportunities. The Council workshops and resolutions helped to crystalize the need for continuity with the Low-Income programs and the need for a streamlined channel of entry and delivery for customers, regardless of income. PAs want to minimize customer confusion and avoid adding complicated layers and channels for program participation. The PAs are committed to optimizing the customer experience and connection points through the existing market rate HES initiative and the Low-Income program.

The PAs will offer a program enhancement to ensure that moderate income customers, from 61-80 percent of state median income, whose homes have weatherization opportunities, can be better supported. PAs are exploring an opt-in solution for an enhanced incentive for income qualified moderate income customers. This approach would ensure that customers remain in control of the process while targeting additional financial support to enable them to realize energy-efficiency opportunities. PAs will work closely with LEAN and our Low-Income vendors to ensure that customers falling into this income band are served effectively. Customers who seek Low-Income services but are determined by the Low-Income program to be fall above the qualification limit will be able to use the documentation to qualify for the moderate income incentive.

The continued evolution and optimization of the Multi-Family Initiative is another example of a significant program enhancement envisioned for the 2016-2018 Plan where PA and Council priorities closely align. PAs share the Council's objective to improve the customer experience and specifically to provide customers with a single point of contact. For 2016-2018, the PAs are planning to assign a single project-level lead contact. Under the enhanced program design, customers will have a project point of contact ("PPC"). The PPC will be the designated agent or lead vendor identified by the PA responsible for efficiency measures for the primary heating fuel. The PPC will support customers through the full program delivery path, coordinating efficient delivery of applicable measures.

The PAs are also moving forward with the Council recommendation to track and report Multi-Family commercial and residential meter savings separately. The PAs look forward to seeing how this information may illuminate new understanding and opportunities for further program enhancements.

The PAs will continue to coordinate on the best tactical approaches for implementing these new enhancements. Much of the planning for these enhancements has been completed. The renter visit and the moderate income offer are set to be available to customers in Q1 2016. The addition of a clear project point of contact in the Multi-Family Retrofit core initiative will be integrated within the first half of 2016. Fully realizing the promise of these strategic enhancements will entail work that continues well into the future, in a cycle of continuous review and refinement.

Additional enhancement highlights include:

- Conduct a deep review of the customer experience to identify opportunities for increased streamlining, improved timing and simplified content of customer information to more effectively influence customers to take action. This will include investigating digital and online options for customers and exploring enhanced follow-up strategies to track and reach out to customers at key moments, helping them pursue deeper and/or additional measures.
- Explore the inclusion of home-automation technologies across residential programs. Deploy new construction field trials in the 2016-2018 Plan. Depending on results, integrate home-automation technologies into the residential new-construction program design.
- Evaluate PA opportunities to leverage home-automation technologies, including eligible wireless enabled thermostats and their associated communication tools, as well as other custom engagement tools for behavioral messaging. Continued review of opportunities to incorporate behavioral-science-based messaging into existing program marketing and customer-engagement efforts.

- Expand efforts to increase adoption of LED bulbs and fixtures into the marketplace and phase out CFL bulbs. PAs will also explore lighting controls as a possible initiative-expansion measure.
- Explore offering behavior initiatives that have the potential to provide near-real-time electric consumption feedback via a mobile-based application (in addition to traditional web-based or paper reporting). Some PAs may research what potential exists to tie in home automation and smart appliances and other controls where applicable.
- Promote value of net-zero and renewable-ready measures to builders through marketing, education, and training.
- Explore creation of a "Path to Zero" option for the top tiers of the Residential New Construction performance path.
- Shift to a performance path for the Residential New Construction high rise multifamily initiative.
- Continue to improve the multi-family customer's single-point-of-contact experience, leveraging and expanding from the success of the MMI model to further support customers with project-level single-point coordination through a designated project point of contact ("PPC").
- Continue to seek to understand and delineate moderate-income and renter markets and explore solutions for clearly defined segments.
- Offer a renter specific visit to HES customers beginning in Q1 2016. A Whole Building Incentive will be offered in parallel to encourage landlords to participate in building enrollment.
- Offer moderate income HES customers the opportunity to qualify for an increased incentive(s) when income is a barrier to proceeding with identified weatherization opportunities.
- Support the continued development of highly qualified HPCs and IICs by continuing to offer training subsidies for workforce-development needs such as technical skills, business skills, and sales trainings. PAs will also continue active dialogue with HPCs and IICs through the Contractor Best Practices working group to support program quality and growth.
- Continue to review and monitor opportunities for upstream program models. The PAs will continue to coordinate with C&I team and work with manufacturers and distributors to identify potential approaches.

4. <u>Contractor Engagement</u>

The PAs are committed to working effectively with contractors, and to ensuring that contractors perform in accordance with rigorous quality and safety standards for the benefit of customers and deliver savings effectively. In accordance with the Term Sheet, the PAs will be active participants in a new contractor engagement effort. This effort is described in the Term Sheet as follows:

The Council and the PAs recognize that the successful implementation of the Three-Year Plan requires an engaged contractor community. The PAs and the Council will collaborate to identify opportunities to continue to maximize the impact of the contractor community in order to maintain high quality, cost-effective/efficient, high impact programs and increase penetration and success in new sectors. As part of this effort, the PAs will participate in a new Residential Contractor engagement effort to be convened by the DOER. PAs will participate in residential program related topics as appropriate, which may include how residential program contractors can be most effectively engaged in the programs, quality assurance/quality control related topics, appropriate data collection and analysis, and suggestions from the contractor community and the PAs for enhancements and improvements. This DOER effort is not in replacement of the ongoing contractor Best Practices group and does not constitute the formation of a new regulatory or adjudicatory body. The PAs will continue to have the right and responsibility to require contractor engagement and contract terms that protect customers consistent with their corporate/institutional quality and safety standards.

5. Residential Program and Core Initiative Descriptions

a. Residential Whole House: Residential New Construction

RESIDENTIAL WHOLE HOUSE	**CORE INITIATIVE** **RESIDENTIAL NEW CONSTRUCTION**
Overview & Key Objectives	The Residential New Construction core initiative strives to increase the construction of energy efficient homes that exceed the Massachusetts User Defined Reference Home ("UDRH"), a baseline determined by assessing the efficiency of homes across the state. Through support for builder and market acceptance of high efficiency design, the initiative has increased market penetration of high performance homes and residential technologies in the market. **Target Market:** All residential new construction projects in the Commonwealth are encouraged to participate in the initiative. The initiative has a Low Rise path targeting single and multi-family projects under three stories and a High Rise path designed for residential buildings of four stories and above.
	New Enhancements: • Explore the addition of home automation technologies in new construction. Deploy field trials in the 2016-2018 Plan.

RESIDENTIAL WHOLE HOUSE	**<u>CORE INITIATIVE</u> RESIDENTIAL NEW CONSTRUCTION**
	Depending on results, integrate home automation technologies into the residential new construction program design. • Transition the High Rise path to a performance path in 2016. • Explore a "Path to Zero" option for the top tiers of the performance path. • Increase promotion of the value of net zero and renewable ready measures to builders through marketing, education and training. • Continue to examine "pay for savings" models as a strategy to promote builders pursuit of deeper incremental energy savings levels, beyond the current tiered performance path cut-offs.
Core Initiative Design	**Measures Promoted:** Builders are encouraged to improve a building's energy efficiency through enhanced envelope measures, energy efficient space and water heating, appropriately sized cooling equipment, wireless enabled programmable thermostats, ENERGY STAR® qualified appliances, WaterSense® plumbing fixtures, efficient lighting and controls, and proper mechanical ventilation. Builders are also encouraged to properly orient homes to take advantage of passive heating and cooling. The Low Rise option offers a prescriptive path with two bundles and a performance path with incentives tied to tiered savings levels. The prescriptive path for Low Rise supports savings achievements over the UDRH. The High Rise option has offered a prescriptive in-unit package, a whole building prescriptive package and a whole building custom option (performance path). PAs will transition the High Rise option to a performance path in 2016. All homes participating in the initiative are required to install efficient lighting products in appropriate hard wired sockets and pass a final verification inspection. **Implementation Strategy:** The Residential New Construction core initiative's primary objectives are to provide builders and other allied professions with training, targeted incentives, and associated technical assistance to increase adoption of high efficiency technologies and construction practices in the residential market. PAs further support the adoption of efficient technologies and construction practices by broadly marketing the value

RESIDENTIAL WHOLE HOUSE	**<u>CORE INITIATIVE</u> RESIDENTIAL NEW CONSTRUCTION**
	of high efficiency homes to consumers and other key decision makers and influencers in the residential new construction market. A recent program impact evaluation has confirmed the strength of the program's approach, and identified the initiative as a market-leading program, which is defining best practices for the nation. The current core design elements have been demonstrated to be highly effective in gaining program participation and savings as well as more broadly driving efficient building practices. The evaluation also documented substantial spillover effects based on the initiative's success in driving market adoption of efficient building practices in new residential construction beyond direct participants seeking program incentives. Massachusetts PAs are amongst the earliest to offer a comprehensive Residential New Construction initiative and recognized early the challenges in serving the larger multi-family and mixed-use new construction sector. The successful deployment and continued refinement of this pioneering path for high rise and mixed-use residential new construction was a highlight of the 2013-2015 Plan accomplishments. The initiative is recognized for leading the program design nationally for this sub-sector. The US Environmental Protection Agency, the Department of Energy Better Buildings Program, and multiple other state efficiency programs are currently engaged in efforts to promote or emulate this model. The PAs will transition to a performance only path for the High Rise buildings. This will include common statewide modeling software, outreach and training on the new path, and evaluation to provide a smooth transition in 2016. The PAs will explore a "Path to Zero" option for the top tiers of the performance paths. The enhancement is envisioned to recognize new construction homebuilders for achieving both a high energy efficiency standard as well as the potential incorporation of renewable energy building features. The PAs plan to continue to deliver in-depth trainings to builders, architects, and others engaged in new construction to support high efficiency new construction. Historically, trainings have included technical topics such as the fundamentals of building science, energy codes, and the latest emerging technologies. PAs also support workforce development efforts to help ensure a robust and well-trained community of partners. The combination of builder training, targeted incentives, associated

RESIDENTIAL WHOLE HOUSE	**<u>CORE INITIATIVE</u> RESIDENTIAL NEW CONSTRUCTION**
	technical assistance, and targeted outreach all support enrollment in program offerings. Home Energy Rating System ("HERS") raters play a critical role in recruiting builders to enroll projects in the Low Rise path. HERS raters have the ability to directly enroll projects into the program via an online intake tool. Account managers, from the lead vendor work directly with larger developers and builders to enroll them in the High Rise path. The PAs will strive to retain existing participating builders and recruit additional developers, homebuilders, and contractors. The PAs will continue to provide targeted trainings on critical technical topics and techniques for achieving high energy savings in quality durable housing. For the Low Rise path, the PAs will continue working with the HERS infrastructure. In the High Rise path, the Joint Management Committee ("JMC"), including residential and commercial new construction technical experts from PA staff and the lead vendor, will continue to assist in defining performance targets, including setting performance path tiers, establishing incentive structures, recruiting developers, completing energy analysis, and providing technical guidance on energy efficiency construction practices.
Delivery Mechanism	PAs administer the initiative through a joint, competitively bid, statewide implementation vendor. The PAs have a residential working group of residential sector experts from each PA to oversee the implementation strategy with the lead vendor. The JMC, comprised of PA staff from both the residential teams and the commercial and industrial teams, oversees the implementation of the High Rise path. The lead vendor provides the direct field implementation. The vendor is principally responsible for development and deployment of training, education, and outreach efforts as well as tracking and reporting program activity to each PA. The lead vendor also has principal responsibility for recruiting and enrolling projects. In addition, many PAs maintain additional account representative and field personnel that support project recruitment and maintain relationships with the target market and allies. HERS raters, as noted above, play a key role in the Low Rise path for recruiting and enrolling projects. Incentives are directly tied to a home's modeled energy performance or installed prescriptive measures,

RESIDENTIAL WHOLE HOUSE	CORE INITIATIVE RESIDENTIAL NEW CONSTRUCTION
	and all participating homes must pass a final verification inspection. The PAs will continue to work with the market-based network of trained contractors who offer energy efficiency and rating services to homebuilders.
Marketing Overview	The initiative markets to a wide variety of partners engaged in the residential new construction process. The primary target of outreach is to the homebuilders, developers, and contractors who directly participate in program offerings. PAs also provide outreach to the associated market actors that interact with program participants, such as architects, designers, and trade allies. A third critical focus on initiative marketing is directed at key decision makers and influencers in the residential real estate market including homebuyers, realtors, code officials, appraisers, and mortgage bankers. This multi-pronged strategy guarantees that at each touch point in the new home construction and delivery process, PAs build awareness and demand for high efficiency homes and provide potential participants clear and easy access the residential new construction offerings. The new construction market is continuously evolving. The PAs are therefore continuously monitoring the market for key opportunities to engage market actors and promote efficient building practices. PAs have utilized multiple routes to engage key market actors including trade shows, builder trainings, lumber yard outreach, and strategic partnerships with targeted regional and national associations including the Home Builder Associations, Massachusetts Chapter of the US Green Building Council, The Boston Society of Architects, Youth Build and Northeast Sustainable Energy Association. The HERS rater community also continues to be a strong partner in helping to engage and educate builders about the programs. Recent work with the City of Boston and through the PAs' codes and standards efforts has offered additional opportunities to explore partnering with local building departments and other municipal programs to market offerings at critical moments when new construction is in a planning or permitting stage. Although not a requirement for participation, the initiative promotes participation in the national ENERGY STAR® Homes program and as a partner benefits from the regional, as well as national, advertising efforts that ENERGY STAR® Homes implements.

RESIDENTIAL WHOLE HOUSE	**CORE INITIATIVE** **RESIDENTIAL NEW CONSTRUCTION**
Three-Year Deployment Strategy/Roadmap	For the 2016-2018 term, the program will concentrate on continuous improvement to processes and exploration of targeted additions. The Residential New Construction initiative will continue to pursue efforts that aim to achieve both deeper savings and gain broader market penetration. A critical focus will be on ensuring the breadth and depth of the initiative's reach into the developer and builder communities with high quality trainings and an optimized experience for builders and home owners participating in program offerings. In 2013-2015, the program continued to see increased participation in the Low Rise tiered performance path and a corresponding decrease in participants utilizing the prescriptive path. In addition, it was noted, participants in the performance path kept closely to the tiered savings markers. Although the tiered approach is successful, the PAs continue to explore whether a "pay for savings" initiative might capture additional savings. PAs have begun evaluation of modeling software to allow full transition of the High Rise path to a tiered performance path and anticipate a smooth transition in 2016. Another success of the performance path has been that multiple builders in the highest performance tier are including renewable ready elements along with super-efficient designs and construction resulting in homes that achieve net zero or net zero ready status. The PAs have already begun to share these success stories and promote the approaches used in training and education offerings and through marketing. PAs will review these successes as they explore offering a "Path to Zero". The Residential New Construction core initiative plans, as early as possible, to include advances in high efficiency home measures determined to be cost effective. Field trials for home automation technologies will be a focus of exploration, with an eye toward potential inclusion of proven measures. The Residential New Construction core initiative will continue to review the participant experience and identify mechanisms for increasing the ease and fluidity of the system. The program is continuing to explore how to leverage information technology to increase ease of access to technical information and support for partners and customers.

b. Residential Whole House: Residential Multi-Family Retrofit

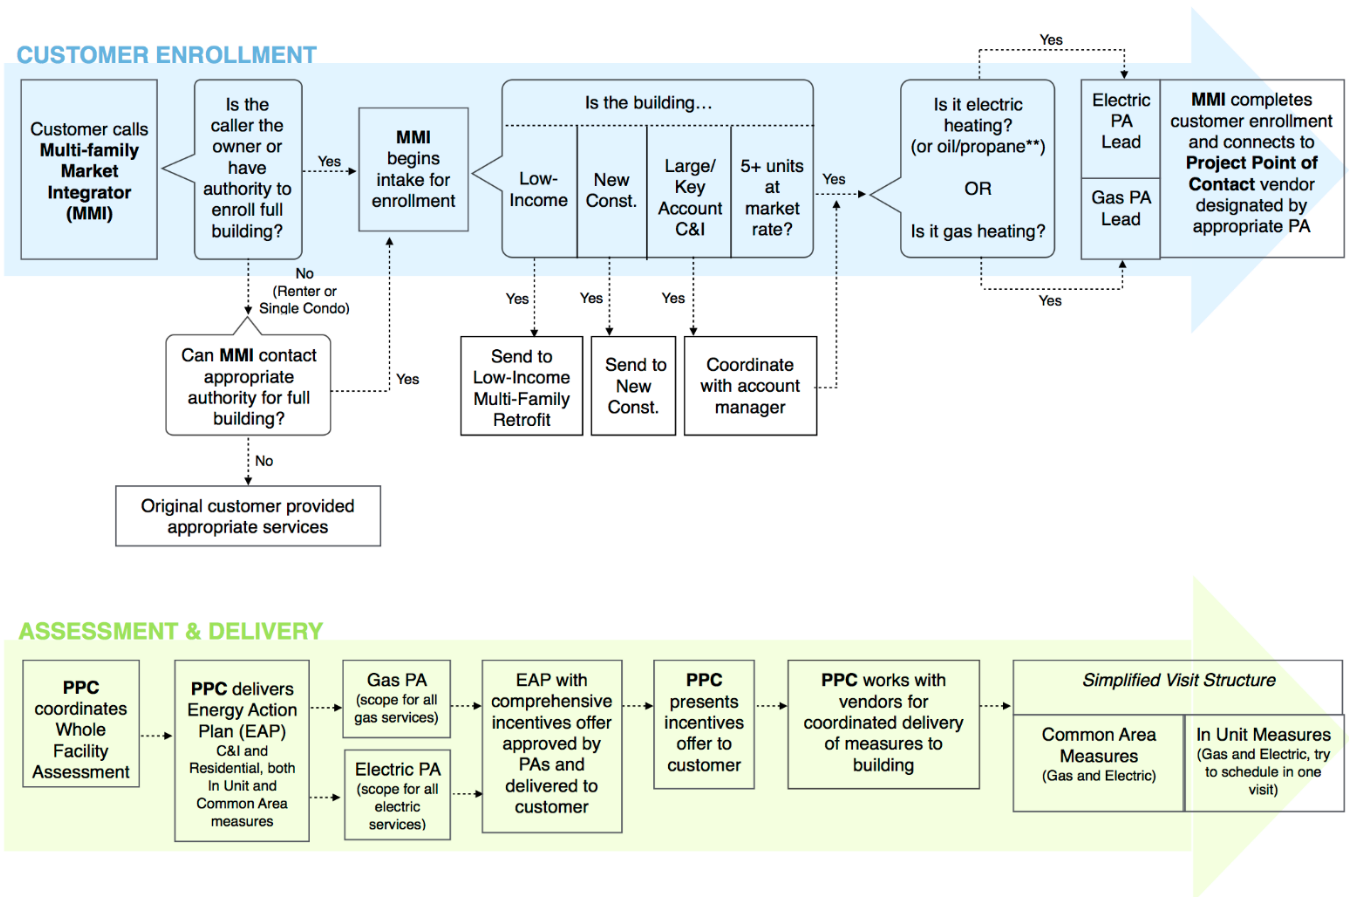
RESIDENTIAL WHOLE HOUSE	**CORE INITIATIVE** **RESIDENTIAL MULTI-FAMILY RETROFIT**
Overview and Key Objectives	The Multi-Family Retrofit core initiative provides comprehensive energy efficiency services to market rate* properties with five or more dwelling units. The initiative offers energy assessments that identify energy savings opportunities throughout the facility. An Energy Action Plan ("EAP") is developed for each facility, identifying all energy efficiency opportunities regardless of fuel source. Historically, this initiative has provided incentives for cost effective gas and electric measures. The PAs anticipate the addition of oil measures and other deliverable fuels, pending issuance of updated RCS regulations. Incentives include (but are not limited to) lighting, shell improvements, heating, cooling, and water heating equipment and controls. The Multi-Family Retrofit core initiative is part of an emerging set of relatively new efficiency program designs across the nation working to serve this unique building sector. The Massachusetts program is a leading national model that meets a majority of the best practices outlined by ACEEE. The PAs plan to continue to refine the initiative through significant new enhancements in the 2016-2018 term. A program impact evaluation is currently in progress, which will influence PAs ultimate program enhancement and design adjustments. **Target Market:** The target market for this initiative is market rate residential multi-family facilities with five or more dwelling units on a property. The Multi-Family Retrofit core initiative can address unique circumstances associated with mixed-use buildings. The low-income multi-family market is served through the Low-Income Multi-Family Retrofit core initiative. *(*i.e.*, 50 percent or more of units are market rate)
	New Enhancements: Massachusetts has pioneered a dedicated approach to the multi-family sector and has engaged in continuous improvements over the past two three-year planning cycles. During the 2010-2012 term, the PAs established the Multi-Family working group, integrated gas and electric measures, and introduced the MMI, a vendor supported call center which supports customer enrollment in connection to PA multi-family offerings. During the 2013-2015 term, the PAs added C&I representation to the Multi-Family working group, expanded HEAT

RESIDENTIAL WHOLE HOUSE	**<u>CORE INITIATIVE</u> RESIDENTIAL MULTI-FAMILY RETROFIT**
	Loan availability to residentially metered condominium owners, and successfully added in-unit direct install measures. The PAs rolled out the Multi-Family EAP in January 2014, further integrating all efficiency opportunities into a comprehensive customer-facing document. For the 2016-2018 cycle, the PAs will continue to focus on enhancing measure offerings and streamlining customer experience. Strategies to achieve deeper savings include: • Provide a single point of contact for measure delivery. The designated PPC will aid in streamlining the customers experience on the delivery side of the process, building off the success of the MMI model. In most cases, the PPC will be the designated agent or lead vendor identified by the PA responsible for the efficiency measures for the primary heating fuel.* • Incorporate additional emerging technologies. Ongoing throughout program years 2016-2018. • Continue to improve multi-family target marketing and education through groups such as landlords, building management, building operator trade associations, landlord associations, condominium associations, and other organizations and professionals involved in regular interaction with this unique hybrid market. Ongoing throughout program years 2016-2018. • Continue to focus on coordinating the residential multi-family and commercial initiatives through the joint participation on the Multi-Family working group of Residential and C&I program management staff and vendors, working together to streamline delivery of packaged, comprehensive energy efficiency services to the multi-family sector. *(For very large multifamily buildings PAs may continue to utilize Account Executives as the PPC.)
Core Initiative Design	**Measures Promoted:** The measures available to each property vary based on unique building characteristics/constraints but may include: • Insulation for attic, wall, basement, pipe, rim joist (in-unit, common areas)

RESIDENTIAL WHOLE HOUSE	CORE INITIATIVE RESIDENTIAL MULTI-FAMILY RETROFIT

	• Air sealing
	• Domestic hot water equipment (in-unit)
	• Heating equipment (in-unit)
	• Light fixtures (common area/exterior)
	• Instant savings measures (in-unit) typically include:
	  o Energy efficient light bulbs and nightlights
	  o Light fixtures
	  o Programmable and wireless enabled thermostats
	  o Faucet aerators
	  o Low-flow showerheads
	  o Smart strips
	Because multi-family buildings may contain residential and/or commercial metering, and include building level systems more traditionally found in commercial facilities, there are a number of measures more commonly found in the C&I Retrofit program. These C&I measures may include:
	• HVAC high efficiency equipment upgrades and controls
	• Variable speed drives, motors
	• Chillers
	• Air compressors
	• Water heating equipment
	• Energy management systems
	• Custom measures
	The Multi-Family Retrofit core initiative offers the residential 0% HEAT Loan to residentially metered condominium owners residing in facilities with five or more dwelling units on the property.
	Implementation Strategy:
	The PAs strive to deliver a comprehensive energy efficiency offering to participants, regardless of fuel type, service territory, or rate class. An integral part of the initiative's design involves the services of the MMI, who provides a single point of contact at intake. The newly created role

RESIDENTIAL WHOLE HOUSE	CORE INITIATIVE RESIDENTIAL MULTI-FAMILY RETROFIT
	of PPC will be responsible for managing the program delivery path, coordinating efficient delivery of applicable measures, and clearly tracking all measures and incentives regardless of meter type. The goal is to provide a seamless customer experience, mitigate potential customer confusion, and minimize or eliminate lost opportunities.



**conditional on approval of RCS regulations.

RESIDENTIAL WHOLE HOUSE	**CORE INITIATIVE** **RESIDENTIAL MULTI-FAMILY RETROFIT**
Core Initiative Design, cont.	Enrollment: The diversity of facility types, ownership, and management structures within the multi-family market, and the variety of actors involved, requires multiple points of entry for intake into the initiative. Participants may enroll via telephone or their request for services may be initiated by other market actors, such as a PA's Account Executive, or a referral from another PA initiative, contractor, consultant, or engineer. Regardless of point of entry, all participants will only need to contact one party to avail themselves of comprehensive services. Once the MMI is made aware of a project (either via telephone or lead from another market actor), he or she reviews the information provided, makes the initial contact with the customer, and collects further information, as needed, to complete screening and enrollment. Participant Screening: The MMI uses a screening process to obtain key information to identify projects and optimally dispatch resources to support customer participation in the initiative. During the initial discussion with the potential participant, the MMI will gain a better understanding of the end uses available for treatment and the motivations that drove the potential participant to solicit energy efficiency services. The MMI will explain the initiative's offer of an assessment to identify all energy saving opportunities and the value of the resulting EAP. Once the MMI has ascertained that the potential participant fits the parameters to enroll in the initiative, the MMI will record the heating source type (electric, gas, or pending RCS regulation approval, oil or propane) and connect the participant with the PPC assigned by the appropriate lead vendor. Whole Facility Assessment The assigned PPC will proceed to coordinate the Whole Facility Assessment. Based on the outcome of the enrollment and screening process, the appropriate technical resources will be assigned by the PPC to conduct a whole facility, fuel blind assessment. The MMI will attempt, through the screening process, to identify all resources required for the assessment. In the majority of cases the PPC will be able to deliver all assessment activities. However, there may be instances where additional expertise is required and additional custom technical

RESIDENTIAL WHOLE HOUSE	CORE INITIATIVE RESIDENTIAL MULTI-FAMILY RETROFIT
	assessments, benchmarking, and engineering studies will be coordinated. Proposal for Energy Efficiency Services Using the findings from the site-specific assessment, the PPC will draft an EAP, including all applicable energy efficiency opportunities, both residential and commercial (in-unit and common area measures). The EAP can provide participants with a road map to implement energy efficiency upgrades. The PPC will present the comprehensive offer to the customer, outlining all measures and services eligible and approved by both the gas and electric PAs for incentives, and assist the customer in fully understanding the opportunities. The customer then selects which measures they wish to implement. Delivery of Measures and Services The PPC will coordinate the delivery of the measures and services requested and agreed to by the customer. To the extent possible, all dwelling unit measures will be installed in a single visit to minimize disruption for the tenants; however, multiple visits may be required for the installation. The Multi-Family Retrofit core initiative will continue to integrate with the C&I initiatives for applicable measures and services for seamless delivery to the customer. Quality Assurance PAs contract with a third-party Quality Assurance/Quality Control (“QA/QC”) vendor to perform inspections on a select percentage of projects. The QA/QC vendor provides valuable information and feedback on successes and identifies areas of possible program improvement. These inspections are complementary to the final inspections performed by the implementation vendors of their subcontractors. Additional Core Initiative Design Elements A link to the current EPA Benchmarking tool (Portfolio Manager) is included on the website page(s) associated with the Multi-Family Retrofit core initiative. This supports building owners/managers in assessing the energy efficiency of their buildings against comparable facilities. EPA Portfolio Manager is a publicly available and free tool accessible to all property owners. PAs have supported data upload

RESIDENTIAL WHOLE HOUSE	**<u>CORE INITIATIVE</u> RESIDENTIAL MULTI-FAMILY RETROFIT**
	through the green button initiative and have extensively coordinated with disclosure efforts such as the Boston Energy Reporting and Disclosure Ordinance to support customers' ease of access to benchmarking and compliance with reporting requirements. The PAs recognize that proper training for building operators and maintenance staff is a key factor in ensuring that expected savings are realized initially and persist over time. The PAs' C&I offerings include building-operator training to support customers in maintaining their efficiency gains through proper operations and maintenance. The PAs plan to explore expanding training events and opportunities as appropriate
Delivery Mechanism	The initiative will be administered cooperatively by the gas and electric PAs. Each PA is represented in the Multi-Family working group, which will continue to be responsible for oversight of the initiative and promote continuous improvement/best practices with regard to the multi-family market. The MMI, jointly contracted by all PAs, remains the key to the delivery of this fully integrated statewide Multi-Family Retrofit core initiative. The MMI, as described above under program implementation, is responsible for ensuring all customers are properly enrolled and directed to the appropriate program resources, including connection to the designated PPC. PPCs will be designated by each gas and electric PA. Individual PAs have contracts with lead vendors for services to multi-family facilities, contracts with additional specialty vendors and access to a variety of supplemental engineering and other services. The MMI helps ensure smooth coordination to optimize the services for each participating facility. PAs have revised their BCR models and internal tracking to provide distinct gas and electric Residential and C&I Multi-family measure lines.
Marketing Overview	**Strategy:** • Target market and industry actors. Messages may focus on, but are not limited to: lower energy and maintenance costs, more durable and comfortable building, enhanced property value, generous financial incentives, tenant retention, and

RESIDENTIAL WHOLE HOUSE	**CORE INITIATIVE** **RESIDENTIAL MULTI-FAMILY RETROFIT**
	environmental benefits for the community. • Continue to promote case studies for print and online media to help educate and market to facility owners. • Target landlord, building management, building operator trade associations, design professionals, and other organizations and professionals involved in regular interaction with multi-family facilities. • Continue to enhance the online user experience. • Continue to build on the MMI relationship with larger property managers to enroll complete portfolios of eligible sites. • Explore opportunities in industry newsletters to educate market actors such as engineers, realtors, landlord associations, architects, and/or property managers. Participate, as appropriate, in trade ally shows, such as realtor and multi-family property manager conferences.
Three-Year Deployment Strategy/Roadmap	The Multi-Family working group will continue to coordinate efforts through the MMI and incorporate the PPC, to ensure consistent implementation across the Commonwealth for the next three years. The Multi-Family working group will continually review and evaluate new applicable measures and technologies. PAs have already identified and broken out for tracking measures both by meter type (Commercial/Residential) and fuel type (Gas/Electric) in preparation for the coordination efforts to be led by the PPCs. The integration of PPC services into the Multi-Family Retrofit core initiative is set to roll out in the first half of 2016. The Multi-Family working group will continue to coordinate with the Residential and C&I Management Committees and the Low-Income Best Practices working group, while working across the residential and commercial sectors, to ensure consistency and support for an integrated initiative. Results of the current Multi-Family evaluation will also influence the program evolution in the coming plan years. PAs welcome continued dialogue with Massachusetts affordable housing stakeholders to evaluate opportunities to maximize the opportunity for capturing energy efficiency savings at the time of financing and refinancing of affordable housing properties. PAs have committed to engaging with these stakeholders to jointly explore and scope these opportunities via planning meetings. The PAs are excited

RESIDENTIAL WHOLE HOUSE	**<u>CORE INITIATIVE</u>** **RESIDENTIAL MULTI-FAMILY RETROFIT**
	to learn from the experts within the Massachusetts Housing community about the timing, scope and processes of affordable housing finance and refinance, to share the PAs' technical resources and understanding on efficiency programming, and to work together to identify critical moments of potential opportunity in the finance and refinance process to secure additional savings. The PAs look forward to receiving additional and more specific information from the Massachusetts affordable housing stakeholders so that the PAs can explore opportunities to incorporate program design and implementation refinements that result from these dialogues within the 2016-2018 Plan term. In accordance with the Resolution, the PAs will continue to work with the Commonwealth's housing financing agencies and LEAN (with mutual expectations and deliverables) to develop and implement enhanced approaches to leverage multi-family refinancing events to maximize retrofit potential. The parties will specifically consider performance-based retrofit products. The PAs will present the results of these efforts and specific proposals derived from them by the close of Q1 2016.
Special Notes	

c. *Residential Whole House: Home Energy Services- Measures; Home Energy Services- RCS*

RESIDENTIAL WHOLE HOUSE	**<u>CORE INITIATIVE</u>** **RESIDENTIAL HOME ENERGY SERVICES – MEASURES** **RESIDENTIAL HOME ENERGY SERVICES – RCS**
Overview and Key Objectives	The Home Energy Services ("HES") core initiative provides residential customers, living in single family (1-4 unit) homes, energy efficiency recommendations and incentives that enable customers to identify and implement cost effective energy efficiency improvements. The initiative uses incentives, financing, outreach and education to make it easy, clear and compelling for customers to participate in residential energy efficiency programs. HES is a flagship initiative for the residential programs, and exemplifies a systems approach where all components work together to support customers in achieving deeper

RESIDENTIAL WHOLE HOUSE	<u>CORE INITIATIVE</u> RESIDENTIAL HOME ENERGY SERVICES – MEASURES RESIDENTIAL HOME ENERGY SERVICES – RCS
	energy savings. HES is fuel blind. Massachusetts's HES is a mature program with over 20 years of program delivery experience, including many refinements and expansions. The core initiative consistently delivers strong fuel blind energy savings while maintaining broad participation. The Massachusetts HES core initiative has the greatest reach of any whole home program in the nation, serving over 80,000 participants statewide in 2014 and continuing to grow. **Target Market:** HES targets all residents (home owners and renters) in single family and two to four unit buildings on a single property. HES is a market rate program serving non-low income residential customers. Low income customers (those under 60 percent SMI) are referred to appropriate low income programs.
	New Enhancements: The 2013-2015 Plan rolled out multiple new elements gradually over the three-year plan term, many of which are currently under evaluation. In the 2016-2018 Plan, PAs are focused on refining and expanding the successful elements begun in the 2013-2015 Plan, while avoiding elements or program redesigns that add complexity for customers and contractors. PAs plan to: • Conduct a deep review of the customer experience to identify opportunities for increased streamlining, simplifying and better targeting time and content of customer information to maximize the opportunity to influence customers taking action. This will include investigating digital and online options that improve the customer experience, and exploration of enhanced customer follow-up strategies that continue to track and reach out to customers at key moments, helping them pursue deeper measures and stay on track with open recommendations from their Home Energy Assessment ("HEA"). This is an ongoing effort. • Continue to seek to understand and delineate moderate income and renter markets and explore solutions for clearly defined segments. Beginning in Q1 2016, the PAs will trial a renter

RESIDENTIAL WHOLE HOUSE	**<u>CORE INITIATIVE</u>** **RESIDENTIAL HOME ENERGY SERVICES – MEASURES** **RESIDENTIAL HOME ENERGY SERVICES – RCS**
	visit and a moderate income offer enhancement, detailed below. • Support renter participation with a renter-specific visit beginning in Q1 2016. Customers will continue to be screened at intake, and an update is planned for the on-line audit tool to provide a clear path for renters. Customers for whom a full HEA may not be appropriate can schedule a renter visit. The renter visit will focus on installation of instant savings measures, high level screening for deeper measures, and follow up with landlords and other interested tenants. A Whole Building Incentive will be offered in parallel to encourage landlords to participate in building enrollment. • Offer moderate income HES customers the opportunity to be "qualified" for an increased incentive(s) when income is a barrier. The initial enhanced incentive is anticipated to apply to insulation, covering 90 percent of costs up to $3000. PAs will explore additional enhanced incentives, potentially including targeted appliance rebates and pre-weatherization barrier remediation, appropriate for qualifying customers. Each PA will monitor spending, customer interest, and savings from this trial offer in 2016, and adjust implementation accordingly for 2017-2018. • Investigate incorporation of additional cost effective new technologies and measures, including sealing and insulation for ducts, early clothes-washer turn-in rebates, and broader implementation of Wi-Fi thermostat installations. PAs will work with the evaluation team to review mechanisms to reduce the time between technology review and deployment. • Support the continued development of highly qualified HPCs and IICs by continuing to offer training subsidies for workforce development needs such as technical skills, business skills, and sales trainings. PAs will also continue active dialogue with HPCs and IICs through the Contractor Best Practices working group to support program quality and growth. • Explore improvements in tracking across programs for measure implementation originating from an HEA.

RESIDENTIAL WHOLE HOUSE	**<u>CORE INITIATIVE</u> RESIDENTIAL HOME ENERGY SERVICES – MEASURES RESIDENTIAL HOME ENERGY SERVICES – RCS**
Core Initiative Design	**Measures Promoted:** Customers receive a ***Home Energy Assessment ("HEA")***, an in-home visit. During the HEA, the Energy Specialist will: • Install instant energy saving measures at no cost to the customer, which may include ***LED bulbs, compact fluorescent light bulbs, faucet aerators and showerheads, programmable thermostats, and advanced power strips.*** • Provide recommendations on ***weatherization, including air sealing and insulation***, qualifying customers for instant incentives for these measures delivered by HPCs or IICs. • Provide recommendations and connections to ***heating, cooling, water heating equipment, and other qualified efficient product rebates***). • Provide connections to the HEAT Loan offers zero percent interest financing of loans from $500-$25,000 with terms from 2 to 7 years to approved customers for qualified measures PAs will work with the MTAC to include new measures or technologies as appropriate. For the renter-specific visit, the PAs plan to provide: • Installation of instant energy savings measures at no cost to the customer, identical to instant savings measures offered through an HEA. • Refrigerator screening, high-level visual inspection of possible weatherization opportunities, and review the heating system for potential rebates. • Information on deeper measures that could be installed with landlord approval. PAs plan to develop marketing materials specifically tailored to renters. **Implementation strategy:** <u>The HEA Visit:</u> The primary entry into HES is the HEA, an in-home visit that includes a variety of diagnostic testing and offers installation of instant energy savings measures. The HEA also provides education and direction on additional energy saving opportunities, rebates, and connection to

RESIDENTIAL WHOLE HOUSE	**<u>CORE INITIATIVE</u> RESIDENTIAL HOME ENERGY SERVICES – MEASURES RESIDENTIAL HOME ENERGY SERVICES – RCS**
	appropriate service providers. Customers schedule an HEA through a dedicated statewide toll free number. The Mass Save® marketing collateral and website, including the recent addition of the online energy assessment portal, supports customers accessing an HEA. The online assessment tool also helps any customers who may not benefit from an in-home visit to follow up with additional appropriate offerings. The HEA is a single comprehensive in home assessment. The HEA allows customization at the household level, ensuring the program delivers cost effective personalized energy saving recommendations on incentives while serving a broad market of customers in a variety of housing types. The HEA provides customers with specific energy efficiency education and identifies their unique opportunities for energy saving installations. With the customer's permission, efficient lighting is installed at no cost in all appropriate locations, as are the other instant savings measures (as needed and qualified). The instant energy savings from directly installed measures during the HEA are intended, on average, to exceed the expected average cost to deliver this visit. The HEA may include a variety of diagnostic techniques such as infrared scanning (temperature permitting) and combustion safety testing. A critical focus is to identify opportunities for thermal savings from air sealing and insulation. The HEA will include scoping of air-sealing and insulation work and support customers' to pursue implementation of measures. This support includes connection to appropriate contractors and information on the HEAT loan. At this stage of the HEA, customers with identified weatherization opportunities will be presented with information on the potential to qualify for an enhanced incentive if income is a barrier to completing weatherization savings measures. The Energy Specialist will provide direction to customers on how to verify that they meet moderate income criteria (61-80 percent SMI). Customers referred to the HES program from the Low-Income program, due to incomes above the low-income threshold, will be able to use the Low-Income program screening to document qualification for the moderate income enhanced incentive (to the extent that their screening documents income in the moderate income range) and not require further income verification. Two groups of participating contractors, HPCs and IICs provide installation of weatherization measures. A more detailed description of

RESIDENTIAL WHOLE HOUSE	**<u>CORE INITIATIVE</u>** **RESIDENTIAL HOME ENERGY SERVICES – MEASURES** **RESIDENTIAL HOME ENERGY SERVICES – RCS**
	the differing roles of each type of contractor is provided under Delivery Mechanism, below. Customers are always free to choose their preferred qualified participating contractor. Regardless of weatherization contractor type, full installation of targeted cost-effective air sealing is provided at no cost to the customer. Insulation work is similarly provided with an instant incentive; however, there is a customer co-pay and incentive cap. The enhanced moderate income incentive increases the amount of the incentive, reduces the co-pay, and increases the incentive cap for qualifying customers When the customer elects the fully subsidized air sealing offer or insulation installation, a blower door test and combustion safety test will be performed pre and post installation to measure air leakage reduction and ensure combustion safety standards. If specific energy efficient improvements require professional contractors, the Energy Specialist explains the contractor services required to install recommended measures. If the improvements require a customer contribution, the Energy Specialist provides information on available incentives and rebates. <u>Special Visits:</u> A special home visit may be scheduled for those customers interested in screening to determine incentive eligibility, a targeted visit such as a boiler screening, or in response to a specific request/concern. An Energy Specialist will perform an assessment of the home addressing the specific concern and/or screening a specific measure (*e.g.*, boiler) and install instant savings measures (where appropriate). A customer may be scheduled for a special home visit as determined during the initial intake process. <u>The Renter Visit:</u> The PAs will trial a renter visit, which is a modified HEA, offering a level of service better tailored to renters. Many renters are not in a position to participate in or influence adoption of weatherization measures for their units. The renter visit will focus on installation of instant savings measures and provide information on rebate opportunities appropriate for renters. The renter visit will be shortened by exclusion of the many diagnostic tests and inspection elements of the

RESIDENTIAL WHOLE HOUSE	**<u>CORE INITIATIVE</u>** **RESIDENTIAL HOME ENERGY SERVICES – MEASURES** **RESIDENTIAL HOME ENERGY SERVICES – RCS**
	full HEA. The renter visits allows a more streamlined delivery system to provide instant savings measures to renters. PAs see the potential for a well-designed renter visit to increase both renter and landlord participation in HES offerings. The renter visit will allow collection of key information for follow up with landlords, including a refrigerator screening, a high level visual inspection of possible weatherization opportunities and review of the heating systems for potential rebates. Energy specialists delivering the renter visit will also seek to collect landlord and other interested tenant information (if not already provided through intake or the online audit tool). PAs hope that renters with positive experiences can help secure the participation of their landlord and fellow tenants. The site specific information on potential opportunities provided by the high level visual screening for weatherization and heating system opportunities will help tailor messages for landlord enrollment in HES offerings. PAs are also planning to add a Whole Building Incentive for additional support for 2-4 unit building owners to move forward with full weatherization of the entire property. Deployment of a renter visit may also help to increase cost effective program delivery by providing the right level of service at a reduced delivery time and cost. Triaging customers in this way may also help vendors providing HEAs to effectively concentrate on customers who can convert to deeper measures.

RESIDENTIAL WHOLE HOUSE	<u>CORE INITIATIVE</u> RESIDENTIAL HOME ENERGY SERVICES – MEASURES RESIDENTIAL HOME ENERGY SERVICES – RCS

The Program Administrators plan to offer the following (as appropriate).

	Renter Visit	HEA Visit
Instant Savings Measures	• LEDs • Low flow showerheads • Faucet aerators • Smart strips • Programmable thermostats	• LEDs • Low flow showerheads • Faucet aerators • Smart strips • Programmable thermostats
Assessment	• Refrigerator screening • High-level visual inspection for weatherization opportunities • Quick review of heating system	• Infrared scanning • Combustion safety testing • Identify weatherization opportunities (air sealing and insulation) • Recommendations for heating, cooling, water heating equipment
Collateral	• Renter specific rebates • Tailored collateral	• Rebates • HEAT Loan information • Standard collateral

<u>Quality Assurance Visits:</u>

A quality assurance visit allows weatherization work to be inspected to ensure the work is completed to the core initiative's standards. This may be done through a combination of methods, including a phone survey, postcard, email, or actual site visit by the lead vendor and/or a third party PA-approved vendor. Quality inspections are performed to ensure that contractor installed measures are accurate, professional, and safely and properly installed based on statewide material and installation initiative standards, as well as to ensure savings. On site

RESIDENTIAL WHOLE HOUSE	**<u>CORE INITIATIVE</u> RESIDENTIAL HOME ENERGY SERVICES – MEASURES RESIDENTIAL HOME ENERGY SERVICES – RCS**
	quality inspections are crucial to sustaining the impressive saving realization rates Massachusetts has experienced. The quality inspection visits provide valuable peace of mind for participants, as well as create the objective feedback loops that allow participating contractors to provide their employees with the training that assures continued high quality service delivery for Massachusetts rate consumers.
Delivery Mechanism	The program is delivered by PA-specific lead vendors selected through a competitive procurement process. Lead vendors are available, and required by contract, to provide services to any eligible customer. This ensures that all eligible Massachusetts customers, regardless of PA territory will have access to HES services. Lead vendors are also responsible for a multitude of program delivery elements including managing and training participating contractors such as the participating IICs and HPCs. Additional lead vendor responsibilities include intake via the statewide toll free number, customer eligibility screening, customer education, recruitment and follow-up, customer satisfaction and achievement of aggressive savings, administration of the HEAT loan, development and deployment of consistent statewide training, data invoicing, tracking and reporting, licensing approved energy modeling software at no cost to participating HPCs, developing and enforcing quality control standards for all participating contractors, scheduling requirements, maintenance of and reporting on health and safety information, technical assistance to customers, participating contractors and other market actors, management of multiple contractual relationships with IICs and HPCs, assistance in evaluation studies, management of performance rating systems for IICs and HPCs, and participation and collaboration in the Best Practices working group. In the original HES model, the lead vendor provided the HEA and coordinated comprehensive delivery of weatherization measures through direct sub-contractors. The new model requires lead vendors to enter into participation agreements with any qualified IIC and distribute weatherization projects via a merit based allocation system. HPCs were phased into the program in the 2013-2015 three-year plan. The promise of including the HPC track which can independently recruit customers, provide HEAs, and implement weatherization measures, was to open the market to additional providers who could drive more and different customers into the program. In order to receive incentives or rebates, customers are required to have

RESIDENTIAL WHOLE HOUSE	**<u>CORE INITIATIVE</u>** **RESIDENTIAL HOME ENERGY SERVICES – MEASURES** **RESIDENTIAL HOME ENERGY SERVICES – RCS**
	an HEA through either the PAs' lead vendor or via a participating HPC to identify and prioritize all cost effective energy efficiency upgrades. The initiative continues to implement "set" pricing, developed in conjunction with the Council and the Council consultants. The set pricing model provides certainty regarding *cost effective* energy efficiency upgrades for customers, contractors, and PAs alike. This prevents claims of price gouging by customers, provides ease of participation (*e.g.*, no requirement of the customer to solicit multiple bids) and helps generate and support further business within the market. Set pricing also allows contractors and PAs to plan more efficiently and ensure the total resource costs remains cost effective. Without set pricing the HEA could not result in the production of an executable weatherization contract for the customer, which is a very unique and valuable program design within the Massachusetts HES core initiative. All participating contractors must meet program eligibility requirements. HPCs independently recruit customers of their choice, provide the HEA, and implement weatherization measures. HPCs also have the opportunity to engage the customers they serve in additional turnkey energy efficiency services offered by their respective company (*e.g.*, heating upgrades, etc.) as ancillary services. IICs provide installation of weatherization measures for those customers who received an HEA from the lead vendor. IICs also have the opportunity to independently recruit customers who have identified weatherization opportunities and refer them to the lead vendor for the HEA. If an Energy Specialist from the HES lead vendor performs the HEA, the customer will be directed to a participating qualified IIC to complete the work. If a program IIC refers the customer to the HEA, the program will assign that IIC to complete the weatherization measures. Customers are always free to choose their preferred qualified participating HPC or IIC. Insulation work, whether performed by an HPC or IIC, may be selected to have a quality control inspection performed by the lead vendor or third party vendor when the work is complete. IICs are provided with merit-based allocation of work determined through several factors including documented work quality. This ensures that high quality is maintained and installations meet the Mass Save® Materials and Installation Standards. Through a competitive bidding process, the PAs contract with a third-party Quality Control ("QC") vendor to perform QC inspections of program implementation vendors, including PA lead

RESIDENTIAL WHOLE HOUSE	**<u>CORE INITIATIVE</u>** **RESIDENTIAL HOME ENERGY SERVICES – MEASURES** **RESIDENTIAL HOME ENERGY SERVICES – RCS**
	vendors and participating contractors. The QC vendor provides valuable information and feedback to the PAs on successes and identifies areas of possible improvement. The PAs are working together toward a best practices approach to provide more coordinated statewide training to reinforce quality installation techniques in HES. Recent evaluation results have found differences in realization rates when comparing lead vendor completed work versus HPC work. PAs will continue to review this third party research and explore if program changes are warranted to ensure whole house treatment is consistently implemented and customers are receiving the highest level of savings. It is expected that training requirements will increase over time in order for contractors to retain their status as an HES participating contractor. Additionally, contractors must maintain a high level of customer satisfaction to continue participating in the initiative. Most PAs have adopted a rating system to help contractors understand their performance in a holistic manner. These systems award work and/or financial bonuses based on performance. The PAs strive to maximize energy savings realized by promoting and supporting contractor training and education in an effort to establish a broader workforce knowledgeable and skilled in proper installation techniques. The goal is to have a sustainable and experienced workforce focused on achieving maximum energy savings and ready and able to meet customer demand. The contractors' ability to deliver high quality work that results in high realization rates is critical to delivering energy savings.
Marketing Overview	The HES initiative is marketed to all non-low income residential customers living in single-family houses or one-to-four unit buildings that are not part of a larger site where an association exists (such as a condominium association with multiple four unit buildings). Marketing efforts are designed to meet the objectives of reaching more customers (going broader into the customer base) and maximizing energy savings opportunities (going deeper into each home to find ways to save energy). The successful inclusion of a common online assessment tool that funnels interested customers to the HEA provides a model for

RESIDENTIAL WHOLE HOUSE	**<u>CORE INITIATIVE</u>** **RESIDENTIAL HOME ENERGY SERVICES – MEASURES** **RESIDENTIAL HOME ENERGY SERVICES – RCS**
	identifying low cost/high touch digital enhancements that streamline and improve customer experience. The PAs will continue market segmentation work to identify and strategically target customers with the most opportunity to increase the rate of audits that result in energy efficiency measure recommendations. The PAs will work closely with IICs and HPCs as a means to increase participation, satisfaction and energy savings. Further, the PAs will continue to seek new ways to identify, educate and reach segments such as landlords, renters and moderate income home owners. Efforts may include targeted marketing based on identified key demographics to overcome identified awareness and access barriers for specific customers. Different PAs are planning to explore partnerships and opportunities that respond to their service territories and will share learning as successful models emerge. The initiative will build off of the Mass Save® multi-media outreach campaign that focuses on partnerships with local media outlets or affiliates such as radio, print advertising, web-based marketing through various social media sites, and through www.Masssave.com. Current forms of multi-media outreach include the Mass Save® website, bill inserts, radio, print, and visual media advertising, digital media advertising (advanced online options), and targeted outreach through strategic partnerships with community organizations, municipalities, and other allies. PAs use timed marketing techniques to help support customers entry and deeper participation in program offerings. PAs will continue and explore enhancing the use of limited time "spiffs" during slower participation seasons as well as engage in follow up campaigns to participants known to have remaining opportunities. Individual PAs conduct additional marketing, such as behavior feedback mechanisms, and may ramp their marketing up or down as needed to meet participation and budget goals. This marketing targets specific measures/customer segments and is conducted strategically to meet initiative savings goals.
Three-Year Deployment Strategy/Roadmap	The goal of new enhancements in the 2016-2018 term is to refine and optimize the initiative, minimizing radical shifts in program design or delivery. PA efforts will focus on streamlining and enhancing the

RESIDENTIAL WHOLE HOUSE	**<u>CORE INITIATIVE</u>** **RESIDENTIAL HOME ENERGY SERVICES – MEASURES** **RESIDENTIAL HOME ENERGY SERVICES – RCS**
	customer experience while supporting a sustainable and robust delivery infrastructure. This focus will ensure the network of energy efficiency vendors and contractors meet the highest standards, and support delivery of highly cost effective deep savings. The PAs have worked over the Plan development year (2015) to be able to roll out, in accordance with the Resolution: • A renter-specific initiative to be rolled out in Q1 2016, including semi-annual PA reports to the Council that will include timely rental visit metrics including participation levels and conversion rates by renters and their landlords by PA, and qualitative information on any barriers encountered and plans to address them; • A moderate income initiative beginning in Q1 2016, including semi-annual PA reports to the Council on participation rates by PA. The PAs anticipate learning from the trials and adjusting and refining these new enhancements over the three-year plan term. The PAs are planning for increased installation of LEDs and expanded access to wireless enabled thermostats. PAs are also planning to explore sealing and insulation for ducts and offering a rebate for early clothes-washer turn-in. The PAs anticipate exploring similar technology advancements, particularly in home automation and control technologies, within the next three year cycle and aim to incorporate new technologies in HES as they are demonstrated to be cost effective and meet consumer performance expectations and acceptance. The key to new enhancements and field trials will be to research and test theories, program design changes, and new measures before broad application. PAs are also keenly attuned to balancing introduction of new enhancements with maintaining and responsibly growing opportunities for their delivery partners. Avoiding cycles of boom or bust are critical to maintaining a skilled and capable workforce and ensuring high customer satisfaction.

d. Residential Whole House: Behavioral/Feedback Initiatives

RESIDENTIAL WHOLE HOUSE	**CORE INITIATIVE** **RESIDENTIAL BEHAVIORAL/FEEDBACK INITIATIVES**
Overview and Key Objectives	The primary goal of the Behavioral core initiative is to encourage customer level behavioral change to conserve energy. Behavioral initiatives seek to identify the motivational factors that cause residential customers to actively employ personal energy saving actions and/or participate in energy efficiency programs. The PAs are continuously exploring opportunities to leverage behavioral science in the service of securing energy efficiency. Several PAs introduced and evaluated behavior based initiatives within their respective territories in previous plan periods. These initiatives varied in size and scope and include different implementation mechanisms along with a mix of vendors. One program, the Home Energy Report ("HER"), has moved from trial to full implementation by the largest PAs and is described more fully under implementation. **Target Market:** All residential customers
	New Enhancements: • Continued review of opportunities in the marketplace, new vendor offers, and opportunities to incorporate behavioral science based messaging into existing program marketing and customer engagement efforts. • Some PAs may explore offering behavior initiatives that have the ability to provide near real time electric consumption feedback, and have that ability to offer a mobile based application in addition to traditional web based or paper reporting. Some PAs may also look to see what potential exists to tie in home automation and smart appliances and other controls where applicable. Some electric PAs may leverage funding from their Grid Modernization Plan in areas where energy efficiency and grid modernization cross over. • Continue to evaluate and explore PA opportunities to leverage home automation technologies including eligible wireless enabled thermostats and their associated communication tools as well as other custom engagement tools for behavioral messaging.

<table>
<tr><th>RESIDENTIAL WHOLE HOUSE</th><th><u>CORE INITIATIVE</u>
RESIDENTIAL BEHAVIORAL/FEEDBACK INITIATIVES</th></tr>
<tr><td>Core Initiative Design</td><td>Measures Promoted:

Behavioral initiatives focus on motivating energy-conserving actions that residents can control, such as programming thermostats, monitoring and adjusting home temperatures via wireless-enabled thermostats or turning off or down power using equipment and electronics. Behavioral initiatives also cross-promote participation in other initiatives with specific measures including HES, lighting, and products offerings.

Implementation Strategy:

The most prevalent behavioral initiative currently deployed by multiple PAs is the HER program. PAs assign participants to the program and participants are offered an opt-out option.

The HER program assigns qualifying customers to treatment and control groups. The treatment groups receive mailer-based reports on an ongoing basis and have access to an online portal. Control groups are retained for the purposes of evaluation. Customers are treated as a group indefinitely, or until the PAs decide to stop treating customers.

The HER program prompts energy savings through two primary paths:
Educational reports;
Educational reports and customer interaction with their online platform.
The HER details and benchmarks customers’ energy usage against their past usage and against similar homes in the area. Customers also have the option of opting-in to an online platform to gain greater feedback on their energy usage.</td></tr>
<tr><td>Delivery Mechanism</td><td>The HER model is individually contracted by each participating PA with a single vendor. The vendor works with each participating PA individually to define the treatment group within the PAs customer group, the treatment periodicity, engagement mechanisms (generally mail, email and web portal) and content from a limited number of vendor designed options.</td></tr>
</table>

RESIDENTIAL WHOLE HOUSE	**CORE INITIATIVE** **RESIDENTIAL BEHAVIORAL/FEEDBACK INITIATIVES**
Marketing Overview	The current initiative uses an opt-out model, therefore does not employ additional marketing beyond direct offerings to selected customers.
Three-Year Deployment Strategy/Roadmap	PAs actively deploying HER initiatives intend to continue. PAs intend to continue to monitor opportunities for amendments to the current HER model and new behavioral initiative opportunities. The field of behavioral energy efficiency is evolving, with new product offers from vendors as well as new opportunities created by technology and engagement tools. The behavioral arena is ripe for experimentation. A benefit of the Massachusetts efficiency program regime is having multiple creative Program Administrators with varied territories where a variety of approaches can be explored and tested in the field. The Cape Light Compact already deploys an alternate behavioral approach and pioneered early learning in the field. In the 2016-2018 term many PAs will be exploring how the emergence of home automation and smart appliances and other controls may be tied into behavioral efforts. Some PAs may explore offering behavioral initiatives that have the ability to provide near real time electric consumption feedback, and/ or have the ability to offer a mobile based application in addition to traditional web based or paper reporting.
Special Notes	

e. Residential Products: Heating and Cooling (electric)

RESIDENTIAL PRODUCTS	**CORE INITIATIVE** **RESIDENTIAL HEATING AND COOLING - Electric**
Overview and Key Objectives	The primary objective of the Residential Heating and Cooling core initiative is to encourage consumers to purchase the most efficient heating, ventilation and air condition ("HVAC") and heat pump water heating technologies available when replacing older, less efficient equipment, and when considering equipment in new construction. The initiative also seeks to encourage contractors who service and install residential central air conditioning ("CAC") equipment and air source heat pumps to follow installation best practices. The PAs began offering rebates for residential CACs and heat pumps in

RESIDENTIAL PRODUCTS	**<u>CORE INITIATIVE</u>** **RESIDENTIAL HEATING AND COOLING - Electric**
	2004. Originally called the ENERGY STAR® HVAC Program, COOL SMART® was re-branded and designed to increase consumer awareness and the market share of ENERGY STAR certified CAC units, air-source heat pumps, and ductless mini-splits, and to promote quality cooling installations by HVAC technicians and contractors. With over ten years of implementation experience the program is considered mature. **Target Market:** Residential electric customers.
	New Enhancements: The PAs will explore the following proposed enhancements: • Explore emerging technologies, ongoing effort. • Continue to review and monitor opportunities for upstream program models. The PAs will continue to coordinate with C&I team and work with manufacturers and distributors to identify potential approaches. • Explore offering an online training for contractors in order to expand their participation in the program while reducing costs. • Explore protocols for installation and best practices for ductless mini-split heat pumps.
Core Initiative Design	**Measures Promoted:** High efficiency CAC, ducted air source heat pumps, ductless mini-split heat pumps (for heating and cooling), heat pump water heaters, ECM furnace fans, ECM circulator pumps. There are incentives provided to appropriate contractors for following installation best practices. COOL SMART® trained contractors earn an incentive for performing the proper testing to check and adjust system air flow and refrigerant charge using third-party verification. Other incentivized measures include duct testing and sealing and downsizing of replacement equipment. Additionally, customers may utilize the 0% HEAT loan to finance

RESIDENTIAL PRODUCTS	**<u>CORE INITIATIVE</u>** **RESIDENTIAL HEATING AND COOLING - Electric**
	eligible HVAC equipment purchases. **Implementation Strategy:** This core initiative provides rebates for the installation of qualified HVAC equipment, provides installation best practices training to residential heating and cooling contractors who install rebate eligible equipment, and provides upstream incentives on ECM circulator pumps. PAs use a third-party verification process for their quality installation verification offerings for all residential HVAC installations and tune-ups, including existing systems, retrofit, and new installations. The Residential Heating and Cooling - Electric core initiative will continue to work with the Residential Heating and Cooling – Natural Gas core initiative (GasNetworks®) on joint offerings; marketing, contractor training, and trade ally outreach including circuit rider. By collaborating, the PAs offer a near seamless integration of the gas and electric energy efficiency programs. The PAs will continue their work with HVAC distributors, and where possible, develop upstream opportunities. In addition, the PAs will continue to work with industry partners to promote best installation practices, awareness, education, and training for HVAC contractors, such as: • ENERGY STAR® HVAC Quality Installation program (EPA) • Consortium for Energy Efficiency • Air Conditioning Contractors of America The Residential Heating and Cooling - Electric core initiative will continue to promote the North American Technician Excellence (“NATE”) in HVAC contractor and customer educational materials. This strategy is designed to promote the value of NATE certification in the HVAC community and support installation best practices, education, and training for HVAC technicians and contractors
Delivery Mechanism	The Residential Heating and Cooling - Electric core initiative will be administered by the electric PAs in each service territory. Delivery is

RESIDENTIAL PRODUCTS	**<u>CORE INITIATIVE</u>** **RESIDENTIAL HEATING AND COOLING - Electric**
	through a common vendor selected through a competitive RFP. Whenever possible, there is coordination with the Residential Heating and Cooling – Natural Gas core initiative. These initiatives will continue to use a single, joint circuit rider in the field. The Residential Heating and Cooling - Electric initiative coordinates with Residential Whole House Program initiatives (Residential New Construction, HES, and Multi-Family Retrofit) to support comprehensive customer and contractor access to program offerings. The initiatives ensure participating residential new construction builders and their HVAC contractors are made aware of the Residential Heating and Cooling training. Whenever appropriate, these trainings are provided jointly with the Residential Heating and Cooling – Natural Gas core initiative. HES and qualifying Multi-Family Retrofit participants are also provided appropriate information and referral to ensure they can access appropriate rebates. Quality control/follow-up inspections are performed by independent inspectors on up to 10 percent of installations to verify equipment installation. The initiative continues to use equipment distributors to sell high-efficiency equipment and quality installation related technology, and to provide indoor training labs for HVAC contractors.
Marketing Overview	The Residential Heating and Cooling - Electric core initiative is designed to promote the purchase and proper installation of energy efficient residential central air conditioning and air source heat pump systems at multiple levels and therefore must design marketing and outreach to reach each of these levels. The marketing activities aim to reach several target markets: • New systems in existing and new homes (new systems) • Replacement systems in existing homes (new equipment/old systems), including the early retirement of existing equipment • Improvements in operational systems in existing homes (new equipment/old systems) Marketing strategies are developed for educating and promoting efficient choices to residential customers directly as well as working with other key decision makers such as new construction builder, renovation contractors, distributors, and retailers to ensure key

RESIDENTIAL PRODUCTS	<u>CORE INITIATIVE</u> RESIDENTIAL HEATING AND COOLING - Electric
	decisions makers and influencers are all aligned to promote efficient equipment adoption. In addition, the initiative marketing increasingly emphasizes the importance of proper installation and sizing practices as well as the promotion of duct sealing and enhanced air distribution system efficiency. The Residential Heating and Cooling – Electric core initiative will continue to collaborate with the Residential Heating and Cooling – Natural Gas core initiative to develop and implement joint marketing activities whenever feasible. The initiative also leverages relationships with HVAC professionals allowing them to market the advantages of supported products directly to their customers, thereby increasing the opportunity to sell energy efficient units while helping the PAs to achieve their energy saving goals. Marketing activities will continue to emphasize outreach to HVAC professionals (contractors and distributors, including gas contractors). The PAs will continue to build an integrated marketing and branding approach incorporating key elements such as contractor and distributor outreach and training, the Mass Save® website, collateral updates, email blasts, bill inserts, as well as other activities. In 2016-2018 the marketing strategy will utilize effective contractor and customer education messaging to meet the initiative goals and provide essential opportunities for HVAC professionals in coordination with all Residential Whole House core initiatives. A joint circuit rider will continue to provide outreach services, education, and support in the field through visits and calls to HVAC distributors, supply houses, and contractors. The circuit rider also participates in training, trade shows, and related industry events. The initiative tracks and provides targeted outreach to large HVAC contractors previously inactive in the program. The PAs plan to continue use of contractor competitions and awards programs, including an annual recognition celebration for contractors to maintain and improve program participation from existing HVAC partners and to recruit more contractors. The PAs will also work with the ENERGY STAR® HVAC Quality Installation program team, the CEE HVAC Committee, and other industry partners to promote best installation practices, awareness, education, and training for HVAC contractors.

RESIDENTIAL PRODUCTS	**<u>CORE INITIATIVE</u>** **RESIDENTIAL HEATING AND COOLING - Electric**
	The PAs plan to review cooperative (upstream) promotions with the HVAC industry, in coordination with C&I where feasible. The PAs will use print and media advertising targeting consumers, contractors, and distributors (including information on the website, participation at trade shows, articles in trade publications, and mailings to distributors, contractor, and non-participants). The PAs will collect and use consumer testimonials affirming the benefits of program measures. These efforts will be in conjunction with the Residential Heating and Cooling – Natural Gas core initiative, where possible. The PAs will continue to leverage manufacturer/distributor level marketing and training infrastructure as a platform to educate contractors and wholesalers at a regional level. These will be in conjunction with the Residential Heating and Cooling - Natural Gas core initiative, where possible. PAs will market and leverage all available federal tax credits where applicable as well as all supplemental consumer incentives (*e.g.*, equipment manufacturers) as a means to increase consumer purchases of high efficiency central air conditioning and heat pump systems.
Three-Year Deployment Strategy/Roadmap	A mini-split evaluation currently underway and due in the summer of 2016 will influence incentive deployment in the 2016-2018 plan term. Consumer interest in cold climate heat pump technology and its application in Massachusetts is also likely to lead to additional PA exploration and testing of different heat pump technologies and applications.
Special Notes	

f. Residential Products: Heating and Cooling (gas)

RESIDENTIAL PRODUCTS	**<u>CORE INITIATIVE</u>** **RESIDENTIAL HEATING & COOLING - Natural Gas**
Overview and Key Objectives	The primary objective of the Residential Heating and Cooling - Natural Gas core initiative is to overcome market barriers and increase market awareness and penetration of high efficiency gas heating (hot water boilers and warm air furnaces), water heating equipment, and associated

RESIDENTIAL PRODUCTS	**CORE INITIATIVE** **RESIDENTIAL HEATING & COOLING - Natural Gas**
	controls including wireless programmable thermostats and outdoor reset controls. This initiative is administered by the Gas PAs. Heating and water heating systems fueled with oil, propane, or solar (in the case of CLC) have been supported through the HES core initiative by electric PAs. A major focus of program activity is to provide support to plumbing and heating contractors and the full supply chain (manufacturers, distributors and suppliers) to ensure availability, promotion, and quality installation of the highest efficiency equipment. Program rebates are provided to customers to help offset the higher cost of their investments in high-efficiency heating and water heating equipment. Massachusetts PAs were amongst the earliest sponsors of gas efficiency programs, offering gas high efficiency heating and water heating rebates for over 15 years. While the core program design is considered mature, the PAs continue to innovate and lead the nation in program refinement. The PAs' concentration of incentives on the highest efficiency models and concurrent reduction or elimination of incentives on lower efficiency models has had a demonstrable effect in increasing the availability, promotion, and acceptance of the highest efficiency equipment by Massachusetts residential gas customers. **Target Market:** All residential gas customers.
	New Enhancements: The PAs anticipate the following initiative enhancements for the three year planning term of 2016-2018: • Continue to expand trade ally awareness and strengthen existing partnerships, including deploying use of the redesigned website for contractors, implementing seasonal or year-round contractor incentive promotions, and new technology training initiatives. These efforts will be ongoing throughout the Three-Year Plan. • Continue to focus on streamlining customer and contractor transactions with tools such as online rebate fulfillment and increased leveraging of data from the GasNetworks® website to design additional targeted marketing as well as increase use of digital marketing.

RESIDENTIAL PRODUCTS	**<u>CORE INITIATIVE</u>** **RESIDENTIAL HEATING & COOLING - Natural Gas**
Core Initiative Design	**Measures Promoted:** The Residential Heating and Cooling – Natural Gas core initiative promotes high efficiency products and installation best practices for hot water boilers, warm air furnaces (with electronically Commutated Motor or equivalent advanced furnace fan systems), select heating system controls including after-market boiler rest controls, programmable and wireless enabled thermostats, gas water heating equipment, and heat recovery ventilator equipment (“HRV”). **Implementation Strategy:** The Residential Heating and Cooling – Natural Gas core initiative is designed to overcome market barriers and increase awareness among consumers, plumbing/heating contractors, and home builders/developers. The initiative utilizes a combination of marketing and customer rebates to help build demand and acceptance of high efficiency natural gas equipment. The purchase and installation of heating and water heating equipment is heavily influenced by the installing contractors and the supply chain behind them. For this reason, a major focus of this initiative is the market actors who strongly influence the purchase and placement of efficient options. These include : • Plumbing and HVAC contractors and technicians • Manufacturers, distributors, and suppliers of high efficiency heating and water heating equipment and related parts/accessories • New home builders and remodeling contractors • Home designers, architects, and engineers. • Building Inspectors and industry affiliate organizations including the Massachusetts Building Inspectors, *i.e.*, Southeastern Massachusetts Building Officials Association (“SEMBOA”), Plumbing, Heating and Cooling Contractors of MA (“PHCC of MA”), International Association of Plumbing and Mechanical Officials (“IAPMO”) • Residential home owners and multi-family property owners (residentially metered) with natural gas heating and water heating equipment or in the market to purchase equipment.

RESIDENTIAL PRODUCTS	**CORE INITIATIVE** **RESIDENTIAL HEATING & COOLING - Natural Gas**
	The initiative maintains a contractor facing GasNetworks® website that was recently completely refreshed. The site is tied to the Mass Save® website but allows for more in depth and targeted information for the target market actors. The initiative keeps current on emerging trends and technologies, works closely with manufacturers and distributors, as well as coordinates with supply houses to ensure awareness of the highest efficiency equipment availability and benefits. Equipment stocking must be done well in advance of the season and has significant impact on what contractors will offer and promote. The initiative includes regular visits with supply houses and big box stores to educate partners and to support optimal stocking practices. These regular visits can also leverage the relationships for training and promotions targeted at the installation contractors. The initiative depends significantly on high quality training opportunities as a mechanism to connect with installation contractors and influence installation practices. GasNetworks® has run numerous training events as well as a highly effective annual conference for over 15 years. The initiative also works with vocational school faculty to reach emerging professionals. The initiative offers customer rebates to offset the higher cost of purchasing qualifying gas heating, water heating equipment, and controls in the new construction and replacement market. In collaboration with the Residential Heating and Cooling - Electric core initiative, the Residential Heating and Cooling – Natural Gas core initiative also offers a dual electric/natural gas rebate incentive for high-efficiency furnaces equipped with Electronically Commutated Motor ("ECM") or equivalent advanced furnace fan systems. The initiative offers customer incentives for energy efficient water heating equipment. In addition to heating and water heating equipment, customer incentives are also offered for select heating system controls, such as programmable and Wi-Fi thermostats, boiler reset controls, and heat recovery ventilator units. The initiative will continue to support the early replacement boiler/furnace promotion, integrated with the HES core initiative, which provides an incentive to replace old, inefficient, but still operating, heating equipment with new high efficiency equipment. Gas PAs consistently monitor this initiative and evaluate free-ridership

RESIDENTIAL PRODUCTS	**CORE INITIATIVE** **RESIDENTIAL HEATING & COOLING - Natural Gas**
	in order to drive customers to go deeper and achieve the highest level of efficiency available.
Delivery Mechanism	The initiative is administered by gas PAs. Given the complex nature and critical importance of the supply chain and installation contractors in reaching end customers the residential Heating and Cooling – Natural Gas core initiative uses three complimentary delivery support vendors. PAs jointly contract with a competitively bid primary delivery vendor. This vendor is responsible for direct communication and education of all key trade allies, in particular manufacturers, distributors, supply houses, heating and water heating contractors, and vocational school faculty members. This vendor monitors the website interface, helps connect PA partners to the website and offers suggestions for content. The vendor maintains primary circuit riding responsibilities to supply houses. PAs have also leveraged the circuit rider secured by the Residential Lighting and Products core initiatives to provide field visits and sales training through the distribution of point-of-purchase rebate materials to big box stores and other applicable retail outlets. PAs jointly contract with a rebate processing vendor. This vendor is secured to review, process, and deliver valid rebate claims to customers. This vendor is also responsible for tracking and reporting program activity to gas and electric PAs as well as providing verification of a percentage of installed qualified equipment across PAs. PAs own the GasNetworks® website. PAs jointly contracted with the vendor who had supported the Massave.com site for a complete site refresh. This vendor is continuing to provide support to PAs for website interface and functionality related updates to the website and to support digital marketing opportunities.
Marketing Overview	The initiative will be promoted through a variety of marketing and educational campaigns including, but not limited to: upstream outreach, direct mail, bill inserts, sponsorships and trade ally circuit-rider visits, and other training events. The GasNetworks® annual conference is a signature event with over 400 attendees annually and a key opportunity to connect with installation contractors, manufactures and distributors of high efficiency technologies. The initiative has been particularly successful utilizing a direct vendor outreach marketing approach to gas equipment suppliers and installation contractors. The

RESIDENTIAL PRODUCTS	**<u>CORE INITIATIVE</u>** **RESIDENTIAL HEATING & COOLING - Natural Gas**
	PAs will continue to implement this approach in 2016-2018. PAs have also built strong relationships with building inspectors and industry affiliate organizations including the Massachusetts Building Inspectors, *i.e.*, SEMBOA, PHCC of MA, IAPMO and will continue to promote initiative offerings through these strategic relationships. The PAs will continue to enhance their outreach to customers in collaboration with the other PA working groups. PAs will also enhance awareness through successful targeted techniques involving website and email. In addition to direct rebate offers to customers, PAs offer strategic seasonal or year-round contractor incentives to further encourage the installation of high efficiency heating equipment. PAs also market and leverage all available federal tax credits where applicable and other consumer incentives as a means to increase consumer sales of high efficiency heating and water heating equipment.
Three-Year Deployment Strategy/Roadmap	PAs will continue to explore cost-effective offerings, such as seasonal incentives to contractors or special promotion resources to trade allies and other market actors, which assist with the stocking, sales, and installation of high efficiency heating and water heating equipment. The March 2015 High Efficiency Heating Equipment Impact Evaluation has raised some concerns over the installation of condensing boilers. The high efficiency of condensing boilers relies on a low boiler return water temperature, which means that differences in installation practices that impact return water temperature have a large impact on savings. PAs remain enthusiastic about the savings potential of this technology and will focus on additional study and experimentation to overcome these issues in installation practice. PAs will continue to leverage the GasNetworks® website. The refreshed website offers new analytics on who and what partners are searching for and allows new opportunities for increased targeting and digital marketing. The PAs will continue to enhance integration and cross-promotion efforts with the Residential Heating & Cooling – Electric and HES core initiatives. In addition, PAs will review emerging technologies for cost-effectiveness and will continue to explore an upstream program model.

RESIDENTIAL PRODUCTS	**CORE INITIATIVE** **RESIDENTIAL HEATING & COOLING - Natural Gas**
Special Notes	Increasing product standards and significant volatility of the avoided cost of natural gas are putting increased pressure on this program to deliver cost effective savings.

g. Residential Products: Residential Consumer Products

RESIDENTIAL PRODUCTS	**CORE INITIATIVE** **RESIDENTIAL CONSUMER PRODUCTS**
Overview and Key Objectives	The objective of the Residential Consumer Products core initiative is to increase consumer awareness of the importance and benefits of purchasing or ENERGY STAR® certified appliances and electronic products. It also seeks to expand the availability, consumer acceptance, and use of high-quality energy-efficient technologies. This initiative also promotes the recycling of certain older, less efficient appliances. The initiative utilizes upstream incentives, mail-in rebates, and an on-line catalog to deliver lower product costs to customers and drive increased customer acceptance and sales. Increasing product standards combined with the success and maturity of Program Administrator programs have limited the savings opportunities in several appliance product categories. PAs continue to explore emerging technologies and innovative program design to drive market penetration of the most efficient products. This is accomplished through increasing the balance of upstream and midstream incentive placement and alternative or bundled incentive/rebate structures and placement. The Products initiative has successfully leveraged creative marketing, including significant social media, affinity marketing, retail partnerships and point of purchase promotions. **Target Market:** All residential electric customers
	New Enhancements: PAs are exploring various methods to streamline incentive delivery

RESIDENTIAL PRODUCTS	**<u>CORE INITIATIVE</u>** **RESIDENTIAL CONSUMER PRODUCTS**
	methods to the consumer (*e.g.*, midstream/upstream) and to address the rapidly changing appliance and electronics marketplace. This is an ongoing effort.
Core Initiative Design	**Measures Promoted:** Incentives are provided for qualifying consumer products. The list is continuously updated and frequently changes. It has included certain refrigerators, freezers, air cleaners, clothes dryers, advanced power strips, televisions, desktop computers, pool pumps, dehumidifiers, water saving products and refrigerator/freezer recycling.
	Implementation Strategy: The Residential Consumer Products core initiative educates consumers about the benefits of ENERGY STAR® certified products to increase consumer acceptance of products and to encourage them to look for and purchase ENERGY STAR® certified models when they shop. The initiative promotes select ENERGY STAR® certified consumer products at the point of sale by providing promotional literature and displays to retailers, working with sales staffs to ensure they understand and can accurately market the benefits of these products, and providing labels to identify models that meet ENERGY STAR® standards. The initiative actively participates in national ENERGY STAR® awareness campaigns and in efforts to keep ENERGY STAR® specifications up to date and relevant. The Residential Consumer Products core initiative primarily focuses on customer rebates, which can be completed on line or mailed in. The initiative is tightly interwoven with the Lighting initiative and leverages many of the same access points as the Lighting program including: • Upstream incentives/negotiated promotions which can provide instant price discount to the consumer for qualified products. Along with the price reductions provided by rebates, incentives and promotions makes products more attractive to the customers, which in turn increases the number of retail outlets willing to carry these products. • Partnerships with local and national retailers with joint

RESIDENTIAL PRODUCTS	**<u>CORE INITIATIVE</u>** **RESIDENTIAL CONSUMER PRODUCTS**
	promotions and coordinated point of purchase promotional materials and support. Retailers are also provided training and additional support to ensure they can be one-on-one consumer educators and effective champions for the energy efficient appliances and electronics. • Social media outlets, like Facebook and Twitter, offer the ability to launch creative campaigns promoting energy efficient products and package with lighting offers. • "Pop-up" retail allows the PAs to offer smaller products such as advanced power strips ("APS"), a product that's benefits typically need to be explained to consumers, along with lighting in temporary retail locations, such as mall kiosks, corporate, and public events. This brings the technology and education about the technology directly to the consumer.
Delivery Mechanism	PAs jointly contract with a ***manufacturer/retailer outreach contractor***, often called a "circuit rider". This contractor recruits and train retailers (including discount retail outlets) to participate in the incentive program, places point of purchase materials in participating retail stores, and acts as a liaison for PAs, manufacturers, and retailers. This vendor is also responsible for supporting and tracking midstream incentive efforts. The Residential Consumer Products core initiative utilizes the same competitively bid ***rebate fulfillment contractor*** used in the Residential Lighting initiative to process both mail in and online rebates. This vendor also collects data and payment requests from consumers, manufacturers, and retailers. In addition, they will process reimbursement requests from customers and NCP partners. The contractor provides documentation to the PAs for program tracking and evaluation purposes. The Consumer Products initiative is also able to share the ***internet/mail-order sales channel contractor*** used in the Residential Lighting Initiative. This vendor maintains stock of products offered through the catalog and the Mass Save® website, staffs a toll-free line for customers, and processes catalog and website purchases. The temporary "pop-up" retail kiosks described under implementation, done in conjunction with the Residential Lighting initiative, create an opportunity to promote a small number of consumer products, currently the APS and Shower Start products. To the extent that smaller

RESIDENTIAL PRODUCTS	**CORE INITIATIVE** **RESIDENTIAL CONSUMER PRODUCTS**
	electronics or other efficiency technologies appropriate to a retail kiosk are added to the program they may be deployed in this way. This involves an additional specialized vendor jointly contracted by the PAs for this offering.
Marketing Overview	The Consumer Products initiative provides significant opportunity to market the Mass Save® brand, by placing the brand and efficient products firmly in the consumer market place. The value of end cap displays in major retail outlets with direct access to Massachusetts customers brings efficiency into the daily lives of many who may otherwise never encounter the efficiency messages. Relationships with product manufacturers also offer unique opportunities for “prizes” and special promotions like the Super Bowl efficient TV sweepstakes that can broaden PA reach and tap new market segments with efficiency messages. Even as the Consumer Products category becomes more challenging as a sector for savings, its value to overall efficiency marketing and Mass Save® brand should not be underestimated. In the appliance and electronics category, marketing initiatives will be designed to leverage new product specifications being rolled out in several product categories and the emergence of new high efficiency technologies. Key marketing strategies will aim to build awareness and demand for new, high efficiency products, as well as consumer education to help customers take advantage of these technologies. Consumer education tactics will continue to employ retail point of purchase materials, sales promotions, consumer engagement events, social media, email, and other best practice marketing tactics to drive sales of qualified energy efficient appliances and electronics. Efforts will continue to monitor the market for energy efficient "smart" technologies in appliances and consumer electronics to inform future program planning and marketing opportunities. Go-to-market strategies will be explored to introduce new connected smart appliances and plug load controlling electronics into the marketplace as the PAs better understand their value in securing energy efficiency benefits for their customers. Tactics to support these efforts will include consumer education via social media channels, consumer events, and retail promotions and point of sale materials to educate and motivate consumers to use these new technologies.

RESIDENTIAL PRODUCTS	**CORE INITIATIVE** **RESIDENTIAL CONSUMER PRODUCTS**
	As in lighting, product marketing will continue to leverage the strong social media presence built over the 2013-2015 term.
Three-Year Deployment Strategy/Roadmap	For consumer products, efforts to broaden categories as well as allow consumers the opportunity to increase the savings in their homes with new technologies provide unique challenges for the PAs. Increasing standards and market saturation will continue to decrease electric savings for some energy efficient products, forcing the PAs to adapt and explore avenues of program deployment that are new and possibly untested. PAs will continue to explore expanding the products included in upstream efforts in an attempt to duplicate the successes with lighting. As standards became more stringent during the 2013-2015 term, the PAs successfully developed tools and techniques for promoting more efficient products to consumers, such as the higher CEE Tiers, and the newer higher tier of ENERGY STAR® "Most Efficient" categories. The PAs plan to continue to use these tools and techniques to continue to support the consumer awareness and adoption of highest efficiency appliances. The PAs will also explore tactics to support deeper savings through education, promotion, and possibly higher incentive offerings, if appropriate.
Special Notes	

h. Residential Products: Residential Lighting (electric)

RESIDENTIAL PRODUCTS	**CORE INITIATIVE** **RESIDENTIAL LIGHTING**
Overview and Key Objectives	The objective of the Residential Lighting core initiative is to increase consumer awareness of the importance and benefits of purchasing ENERGY STAR® qualified lighting products and expand the availability, consumer acceptance, and use of high quality energy efficient lighting technologies and controls. Residential lighting provides 54 percent of the annual electric savings for the residential and low income sectors. There are increasing pressures on these savings

RESIDENTIAL PRODUCTS	**<u>CORE INITIATIVE</u> RESIDENTIAL LIGHTING**
	from increased standards/baselines and higher prices for the newer energy efficient technologies. However, lighting remains a critical driver of residential savings. The initiative utilizes a combination of upstream incentives at the manufacturer and retail level, and an online catalog channel to deliver lower product costs to customers and drive increased customer acceptance and sales. The Lighting initiative has successfully leveraged creative marketing, including significant social media, affinity marketing, retail partnerships and point of purchase promotions. Lighting technology has evolved rapidly from the basic compact fluorescent spirals to multiple specialty bulbs, fixtures, and light emitting diodes ("LEDs") applications. PAs saw rapid expansion of the LED market in 2013-present through aggressive upstream incentives enabling more affordable pricing by manufacturers and retailers. **Target Market:** All residential electric customers.
	New Enhancements: PAs will continue to explore approaches that support additional savings. This is an ongoing effort. • PAs plan further expansion and focus on introducing LED bulbs and fixtures into the marketplace and phasing out CFL bulbs. • PAs will explore lighting controls as a possible initiative expansion measure. PAs will coordinate with other research and development efforts.
Core Initiative Design	**Measures Promoted:** The Residential Lighting core initiative promotes ENERGY STAR certified light bulbs and fixtures. Current offerings include CFL and LED bulbs, with a continuing emphasis on expanding LEDs while phasing out CFL bulbs. **Implementation Strategy:**

RESIDENTIAL PRODUCTS	**<u>CORE INITIATIVE</u>** **RESIDENTIAL LIGHTING**
	The Residential Lighting program strategy depends on a fluid mixture of: • Advanced market knowledge and data of efficient lighting technology and products • Sophisticated incentive structure that includes incentive placement at the manufacturer (upstream) and at retail purchase points (midstream) • Cutting edge marketing and educational strategies to support customer adoption of the most efficient technologies To achieve this complex mixture, PAs invest strongly in staying up to date on overall residential lighting market conditions, product availability, market share, and pricing. This allows PAs to adapt initiative offerings, as needed, to introduce new cost effective savings technologies, target incentives, and marketing to build customer acceptance and adoption. This ultimately increases the market share of energy efficient lighting products. The Residential Lighting core initiative includes several components and entry points designed to educate consumers about the benefits of ENERGY STAR® qualified lighting products and to make these products more affordable and easily available: • Upstream incentives/negotiated promotions provide instant price discounts to the consumer for qualified products. The price reductions provided by incentives and promotions makes lighting products more attractive and affordable to the customers, which in turn increases the number of retail outlets willing to carry these products. • Partnerships with local and national retailers with joint promotions and coordinated point of purchase promotional materials and support. Retailers are provided training and additional support to ensure they can be one-on-one consumer educators and effective champions for the energy efficient lighting technologies. The initiative partners with retailers for end cap space for display and with point of purchase marketing putting high efficiency lighting prominently in consumer’s path. The initiative’s field service vendor will also set up educational tables to promote the program at various times throughout the year. • Special attention and increased incentives to retail outlets

RESIDENTIAL PRODUCTS	**CORE INITIATIVE** **RESIDENTIAL LIGHTING**
	designated to serve hard to reach customers, to ensure equal access to affordable efficient lighting for all customers. • An internet/mail-order sales channel offers education, rebates, and introductions to new products that may not be available at most retailers, as well as access to a variety of hard to find replacement bulbs. PAs are working on improvements to the internet/mail-order website, increasing its functionality as an educational tool for consumers. PAs have enhanced the products pages of the Mass Save® website helping guide customers to the online store and to local retailers with promotional activity. • Social media outlets, like Facebook and Twitter, offer the ability to launch creative campaigns promoting energy efficient lighting as well as other products. Social media campaigns and contests provide an exciting way to leverage PA customers as brand ambassadors and greatly expand the initiative's reach. • Affinity marketing has been added to the mix of promotional strategies. Similar to social marketing, affinity marketing allows a reach into a broader consumer demographic while continuing to build brand awareness. It offers additional community benefits through the significant charity donation raised. PAs are continuing to explore additional affinity marketing opportunities. • "Pop-up" retail allows the PAs to offer efficient lighting products to consumers in temporary retail locations, such as mall kiosks, corporate, and public events. This brings the technology and education directly to the consumer. • Some PAs provide a school fundraising offer which allows PAs the opportunity to educate students on the benefits of energy efficiency, while helping schools to raise funds through the sale of lighting products.
Delivery Mechanism	With the multiple points of entry for customers and the multilayered incentive and marketing strategy, the Lighting and Products programs have a complex set of delivery vendor partners. PAs engage vendors to support manufacturer and retail recruitment, on-going partnership training and promotion activity, as a marketing vendor partner, and a rebate and on-line store vendor. To ensure a consistent and smooth customer experience as well as greater ease for manufacturers and retailers to engage with the program, PAs have worked effectively to coordinate and jointly contract services with common vendors.

RESIDENTIAL PRODUCTS	CORE INITIATIVE RESIDENTIAL LIGHTING
	PAs jointly contract with a ***manufacturer/retailer outreach contractor***, often called a circuit rider. This contractor recruits and train retailers (including discount retail outlets) to participate in the incentive program, places point of purchase materials in participating retail stores, oversee the Negotiated Cooperative Promotions ("NCP") process, attends in-store events on behalf of the PAs to further promote the programs, and acts as a liaison for PAs, manufacturers, and retailers. A ***rebate fulfillment contractor*** collects data and payment requests from manufacturers, retailers, and consumers. In addition, they will process reimbursement requests from NCP partners and provide documentation to the PAs for program tracking and evaluation purposes. The ***internet/mail-order sales channel contractor*** will purchase and stock products offered through the catalog and the Mass Save® website, staff a toll-free line for customers, and process catalog and website purchases. PAs employ temporary "pop-up" retail kiosks at key events and locations as described under implementation. This involves an additional specialized vendor jointly contracted by the PAs for this offering.
Marketing Overview	**Strategy:** As lighting technology rapidly expands with new LED replacement bulbs and fixtures, and we explore lighting control options increasingly introduced into the market, marketing initiatives may include support for consumer trial through the use of discounted products and special manufacturer/retailer promotions. A key to growing market share for LEDs will be to shift consumer perception of lighting from a commodity product to a more considered purchase. It remains critical for marketing to support customers understanding of each lighting product's application and benefits. This will be accomplished through strategic use of educational advertising, in-store displays, social media outreach, and other point of sale communications. It is critical to roll out products that have proven performance and clearly communicate to customers the appropriate application to ensure their optimal experience with the new technologies. PAs remain ever cautious of the potential for customer rejection of new technology

RESIDENTIAL PRODUCTS	**CORE INITIATIVE** **RESIDENTIAL LIGHTING**
	classes due to the experience of continued customer perception of CFL applications from early sub optimal customer product experience. PAs remain vigilant in managing introduction of technologies at optimal product evolution stage and doing so with strong communication about best applications. The marketing team has designed highly effective campaigns that help focus consumers on appropriate end uses or applications for specific lighting technology, *e.g.*, LED BR 30. For example, few customers have any idea what a LED BR 30 is and its shape is somewhat unfamiliar as it is meant for use in recessed can fixtures rather than traditional lamp application. To take the mystery out of a specialty bulb like BR30s marketing works to offer promotions and marketing that help consumers connect the lighting to a specific room or use, like a "kitchen 3 pack" in the case of BR30s. The Residential Lighting initiative has seen tremendous success and intends to expand its affinity marketing activity. In the 2013-2015 term, the Residential Lighting initiative launched a promotion with our manufacturers and retailers supporting the Ellie Fund, described more fully under the implementation section above. The PAs will explore other affinity marketing opportunities to expand the reach to new market segments while offering the added benefit of supporting our community beyond energy efficiency.
Three-Year Deployment Strategy/Roadmap	The Residential Lighting core initiative continues to face challenges in the upcoming three-year term. The per unit annual savings for CFLs and LEDs will continue to decline to account for the anticipated multi-year phase out of incandescent bulbs due to EISA standards. In addition, both the per unit lifetime savings and the per unit measure lives have been reduced in this plan to estimate the post 2020 EISA code change may have on savings for both CFLs and LEDs. PAs plan to continue to increase penetration of LEDs and roll out new LED bulb types and fixtures based on estimates of future product availability and price. While LED technology is evolving very rapidly and becoming more cost competitive, the bulb price is still markedly higher than for equivalent energy saving CFLs. Even when longer life is included in savings, the shift to an increasing mix of LEDs will impact the cost of savings. PAs will be balancing the phase in of LEDs to maximize provision of high performance lighting that offers customers a positive experience and builds continued acceptance with a focus on responsible investment of efficiency dollars to continue to achieve savings targets

RESIDENTIAL PRODUCTS	**<u>CORE INITIATIVE</u> RESIDENTIAL LIGHTING**
	within responsible budgets. For the three-year deployment, the PAs will focus on: • Expanding the mix of energy efficient lighting products available in retail • Increased focus on LED products to reach “deeper” savings for each customer with more options for each socket • Continuous offerings over longer horizon periods at retail to ensure year-round product availability to consumers • Innovative approaches to community and corporate events including areas with high percentages of renters or moderate income households. • Phasing in of qualified products for new technologies that require new entrants and implementation strategies.
Special Notes	Specialty CFL bulb incentives will phase out in 2016.

F. **<u>Low-Income Programs</u>**

1. <u>Low-Income Program Descriptions</u>

a. Low-Income: Single Family

LOW-INCOME	**<u>CORE INITIATIVE</u> SINGLE FAMILY**
Overview and Key Objectives	The Low-Income Single Family core initiative implements cost-effective, energy efficiency products and services directly for residential customers living in one to four unit dwellings in which at least 50 percent of the occupants are at or below 60 percent of the state median income level. The initiative is implemented by local Community Action Program (“CAP”) Agencies and integrated with the Department of Housing and Community Development (“DHCD”) Weatherization Assistance Program (“WAP”). All applicable revenue streams from each program are leveraged and offered jointly to income eligible residents. This approach provides a seamless, integrated experience for the participants with deeper efficiency penetration consistent with a whole house approach generally with no co-payment

LOW-INCOME	**CORE INITIATIVE** **SINGLE FAMILY**
	required from participating customers. **Target Market:** Residential customers living in one to four unit dwellings who are at or below 60 percent of the state median income level or who are qualified to receive fuel assistance and/or utility discount rates. For two to four unit dwellings, 50 percent of the occupants must qualify as low-income in order to be served by the Low-Income Single Family core initiative. Any changes to eligibility criteria will be addressed collectively between the PAs, LEAN, DHCD, lead vendor (where applicable) and CAP agencies.
	New Enhancements: • The PAs will continue to work with the Low-Income Best Practices working group to identify new cost-effective energy efficiency services, measures and technologies that are appropriate to offer to low-income customers. In 2014, the PAs collectively went out to bid for the fulfillment distributor of High Efficiency Lighting Products for all residential and low-income, direct install programs. Through this process, the PAs have realized significant cost savings and are in the process of transitioning the bulb offer to allow for more installations of LED bulbs within low-income customer homes. As new LED technology continues to emerge and pricing continues to decline, the PAs will look to transition to LED technology over the next three years exclusively as applicable and dependent upon PA budgets. • PAs will work with LEAN, state organizations such as the DHCD, lead vendor, and CAP agencies to increase qualified contractor participation in the initiative through training and workforce development. The PAs also plan to continue to support contractor and auditor training as needed, throughout the 2016-2018 program years.
Core Initiative Design	**Measures Promoted:** Measures are provided at no cost to the customer with established caps, where applicable. The measures available to each low-income single family property include:

LOW-INCOME	<u>**CORE INITIATIVE**</u> **SINGLE FAMILY**
	• Insulation (attic, wall, pipe, and duct) • Air sealing • Heating system repair and replacement • Programmable thermostats • Domestic water heating, including low-flow showerheads, faucet aerators, pipe wrap, heat pump water heater (electric) • Lighting, including LEDs, CFLs, lighting fixtures, and torchieres • Appliances, including refrigerator and freezer replacement, second refrigerator removal, advanced power strips, window air conditioner replacement • Weatherization repairs (electrical, roofs, etc.) • Health and safety In coordination with LEAN, the PAs will work with the MTAC to include new measures or technologies as appropriate **Implementation Strategy:** Once customers are deemed eligible, they will receive an in-home energy assessment from their local CAP agency. The assessment evaluates the building shell, efficiency, and (for electric PAs only), the appliance conditions. All assessments include an evaluation of home health and safety. The lead vendor/CAP agency will then arrange for all applicable measures and services to be installed by a qualified contractor. The initiative piggybacks on the current DHCD WAP. All applicable revenue streams available are leveraged to enhance services consistent with a whole-house approach. PA funding will primarily be used to address more items on the cost-effective priority list, including approved weatherization-related repairs. Federal money will primarily be used to address health and safety issues, as well as repairs, to allow for cost-effective energy efficient measures to be installed. As mandated by DHCD for all projects that receive Department of Energy ("DOE") funding, the CAP agencies perform 100 percent post-installation quality assurance inspection of projects to ensure that all work is performed to the program guidelines. The CAP agencies also perform a minimum of 50 percent in-process inspection of projects.

LOW-INCOME	**CORE INITIATIVE** **SINGLE FAMILY**
	Because the PA initiative piggybacks on the DHCD program, many jobs are multi-funded; therefore, quality control is completed for both DOE and PA-funded projects at the same time. DHCD performs another level of visual inspection for 20 percent of all DOE-funded projects. During these inspections, DHCD reviews both DOE and PA-funded work. Additionally, the PAs have an independent third-party vendor perform quality assurance inspections for an additional level of quality control. PAs require 5 percent of all jobs that are exclusively funded by the PAs to be inspected by a third party quality control vendor. Energy efficiency education and information is provided to all participating customers. The primary form of energy education is verbal communication between the auditor and the client along with leave-behind materials. In 2013, the PAs collaborated with the Low-Income Best Practices working group and developed common, statewide educational materials. Educational materials will continue to be updated and provided to customers as applicable. The PAs will work in collaboration with the Low-Income Best Practices working group, including LEAN, DHCD, lead vendors (where applicable), and CAP agencies to coordinate statewide on all aspects of the Low-Income Single Family core initiative, including but not limited to planning, delivery, implementation, education, marketing, training, cost-effectiveness, evaluation, and quality assurance.
Delivery Mechanism	PAs, when appropriate, use lead vendors to administer the initiative. The PAs work closely with their lead vendors and/or respective CAP agencies on all aspects of the initiative design and implementation. The lead vendors/CAP agencies are responsible for providing coordination of energy efficiency services to the customer. The lead vendors/CAP agencies work with installation contractors to ensure that the proper initiative guidelines are enforced. These agencies are also responsible for ensuring that the customer meets the eligibility requirements for initiative participation and providing the lead vendors and/or PA with the required documentation of all work performed. Quality assurance is completed by the lead vendor/CAP agencies, DHCD, as well as by a PA-funded independent third party vendor.
Marketing Overview	**Strategy:** Marketing outreach designed to reach more income-eligible customers

LOW-INCOME	**CORE INITIATIVE** **SINGLE FAMILY**
	and maximize energy savings opportunities will continue to expand through the 2016-2018 Low-Income Single Family core initiative (where applicable). PAs, in collaboration with lead vendors (where applicable) and CAP agencies, will continue to engage in targeted, localized outreach efforts to notify customers of the availability and value of energy efficiency services. Marketing consists of contacting qualified income-eligible customers subscribing to the discount rate who have not received prior energy efficiency services. Telemarketing, direct mail, bill inserts, and literature distributed through social services agencies, government offices, and other networks when appropriate are also used to market the initiative. In addition, PAs are participating in statewide marketing efforts to encourage all customers to participate in energy efficiency initiatives. Those efforts will assist in driving income-eligible customers to take advantage of not only energy efficiency programs but also discount rates, fuel assistance, and other social programs. Awareness of the initiative is also gained through participation in local community events such as job fairs, senior centers, and employee presentations, which may include case studies. Outreach and marketing efforts, as well as PA collaboration, will be expanded as needed. Approaches may include building relationships with unemployment centers, medical service providers, and other venues that could reach potential income-eligible customers. PAs will continue to examine other potential service providers and venues that could reach income-eligible customers.
Three-Year Deployment Strategy/Roadmap	The PAs will coordinate efforts through the existing low-income weatherization and fuel assistance program via LEAN to ensure consistent implementation throughout the state and retain the advantages of the existing infrastructure of central coordination while avoiding the creation of a new or central entity. Training and workforce development will be accomplished by the PAs working with LEAN, DHCD, lead vendors, and CAP agencies to increase the number of qualified contractors, energy auditors, and administrative staff. The PAs in conjunction with LEAN, the lead vendors and the CAP agencies will continually review and evaluate new measures and technologies. All applicable revenue streams available will be leveraged to enhance services. Through marketing and outreach efforts, the PAs will attempt to broaden initiative participation. PAs will attempt to deepen efficiency penetration consistent with a comprehensive, whole house approach.

b. Low-Income: Multi-Family

LOW-INCOME	**<u>CORE INITIATIVE</u>** **MULTI-FAMILY**
Overview and Key Objectives	The Low-Income Multi-Family Retrofit core initiative provides cost-effective, residential energy efficiency improvements that benefit income-eligible occupants and owners of multi-family buildings. Energy efficiency products and services are implemented within the common areas as well as directly in the dwellings of residential, income eligible customers living in multi-family facilities (with 5 or more attached units), in which at least 50 percent of the occupants are at or below 60 percent of the state median income level. The Program Administrators will provide up to 100 percent of the funding for cost-effective projects with established caps based on projected savings. **Target Market:** Low-Income Multi-Family properties owned by public housing authorities, non-profit organizations as well as for-profit organizations are eligible to participate. The initiative targets residential customers on the discount rate and/or customers living in multi-family facilities with five or more dwelling units in which at least 50 percent of the occupants are at or below 60 percent of the state median income level in addition to the landlords and property managers of these buildings. Any changes to eligibility criteria will be addressed collectively between the PAs, LEAN, lead agencies and CAP agencies.
	New Enhancements: • In 2012, the funding of the Low-Income Multi-Family core initiative and Low-Income Single Family core initiative was proposed to be combined. The PAs continue to combine funding for the Low-Income Multi-Family and Single Family core initiatives in 2016-2018 to offer more flexibility in servicing the greatest potential number of income-eligible customers if demand for one initiative surpasses the other. Additionally, the PAs and LEAN will explore ways to address the disproportionate electric and gas Multi-Family budgets. Ongoing throughout program years 2016-2018. • The PAs will continue to work with the Best Practices working group to identify new cost-effective energy efficiency services, measures, and technologies that are appropriate to offer to income-eligible customers. Common area lighting controls

LOW-INCOME	<u>**CORE INITIATIVE**</u> **MULTI-FAMILY**
	provide an excellent opportunity to reduce wasted lighting energy in common-area applications such as stairwells and hallways when the area is unoccupied. In 2014, the PAs collectively went out to bid for the fulfillment distributor of High Efficiency Lighting Products for all residential and low-income, direct install programs. Through this process, the PAs have realized significant cost savings and are in the process of transitioning the bulb offer to allow for more installations of LED bulbs within income eligible customer homes. As new LED technology continues to emerge and pricing continues to decline, the PAs will look to transition to LED technology over the next three years exclusively as applicable and dependent upon PA budgets. • As a new initiative in 2010, the Low-Income Multi-Family core initiative focused on multi-family properties that were non-institutional dwellings owned or operated by non-profit entities or public housing authorities. In 2012, based upon available funding, some PAs also served for-profit properties under the same guidelines in which at least 50 percent of the occupants were at or below 60 percent of the state median income level. The Low-Income Multi-Family core initiative will continue to serve all three types of properties. Currently each type of property represents approximately one third of properties served, and PAs will continue to balance by type of property and by geography. Ongoing throughout the program years 2016-2018 • PAs will work with LEAN, the Low-Income Multi-Family Advisory Committee, state organizations such as the DHCD, and CAP agencies to increase qualified contractor participation in the initiative through training and workforce development. The PAs also plan to continue to support contractor and auditor training as needed. Ongoing throughout program years 2016-2018. • Currently, the Low-Income Multi-Family core initiative serves properties that are heated by gas and electricity. Historically, this initiative has provided incentives for cost effective gas and electric measures. PAs anticipate the addition of oil measures and potentially other deliverable fuels, if allowed by RCS regulations.

LOW-INCOME	**<u>CORE INITIATIVE</u>** **MULTI-FAMILY**
Core Initiative Design	**Measures Promoted:** PAs will pay up to 100 percent of the project cost with established dollar caps where applicable. Larger capital investment projects will be screened for cost-effectiveness (with the Low-Income Multi-Family Advisory Group). The measures available to each low-income multi-family property include: • Insulation (attic, wall, pipe, and duct) • Air sealing • Heating system repair and replacement • Programmable thermostats • Domestic water heating, including low-flow showerheads, faucet aerators, pipe wrap, water heating equipment, heat pump water heater (electric) • Lighting, including LEDs, CFLs, lighting fixtures, common area (interior and exterior) lighting upgrades and controls, torchieres • Appliances, including refrigerator and freezer replacement, ENERGY STAR® clothes washer replacement, power smart strips, window air conditioner replacement • HVAC/mechanical systems, including Energy Management System (“EMS”), motors and drives, chillers, air compressors, ventilation system repair adjustment or replacement, heat recovery ventilation/energy recovery ventilation, redistribution systems, temperature building controls • Weatherization repairs (electrical, repairs, roofs, etc.) • Health and safety The PAs will work with the MTAC to include new measures or technologies, as appropriate, and in coordination with LEAN’s other efforts.
	Implementation Strategy: The Low-Income Multi-Family core initiative services properties that have five or more units in which at least 50 percent of the occupants are at or below 60 percent of the state median income level, owned by public housing authorities, non-profit organizations as well as for-profit

LOW-INCOME	**<u>CORE INITIATIVE</u>** **MULTI-FAMILY**
	organizations. Eligibility for the initiative measures and services will be based on the established cost-effectiveness test, which includes agreed upon non-energy benefits, and will not be restricted, to the greatest extent possible, by rate class associated with the meter(s) for the facility. Eligible projects involve efficiency upgrades for buildings with currently high energy consumption and require that applicants participate in benchmarking their building's energy usage post-improvements. The Low-Income Multi-Family building inventory has been an innovative component of this initiative to both help identify potential participants and help determine usage patterns in this sector. The PAs will work in collaboration with the Low-Income Best Practices working group including LEAN, the Low-Income Multi-Family Advisory Committee, DHCD, lead vendors, and CAP agencies to collaborate and coordinate statewide on all aspects of the Low-Income Multi-Family core initiative, including but not limited to planning, delivery, implementation, education, marketing, training, cost-effectiveness, evaluation, and quality assurance. When topics to be discussed apply to both market-rate customers and low-income customers, PAs will further coordinate between initiatives as needed. The initiative will be structured to ensure that participants are provided with a whole building, fully integrated offering that targets both gas and electric end users. Once a property is deemed eligible, it will receive an energy assessment through a lead vendor or local CAP agency. The assessment evaluates the building shell, efficiency, and (for electric PAs only), the appliance conditions. All assessments include an evaluation of home health and safety. The CAP agency will then arrange for all applicable measures and services to be installed by a qualified contractor. Savings will be deepened by installing additional efficiency measures; to the extent the overall project remains cost-effective. The initiative piggybacks on the current DHCD low-income energy efficiency programs and all other eligible funding sources (*i.e.*, federal and state) to enhance services consistent with a whole-building approach. PAs will use a lead vendor or local CAP agency to administer the initiative. Sub-contracting will be appropriate due to the complexity of the work required. Low-income customer inquiries will be referred to the lead vendor/CAP agency, the Low-Income Multi-Family Advisory Committee, or PA by the MMI, as defined in the Multi-Family Retrofit Core Initiative. Low-income customers may also apply directly to the initiative via the Low Income Multi Family Energy Retrofits website, their PA and/or local CAP agency. An essential

LOW-INCOME	**<u>CORE INITIATIVE</u>** **MULTI-FAMILY**
	element of this initiative is that interested customers also have the option, at their discretion; of electing to participate in the Multi-Family Retrofit core initiative. This approach helps ensure that there are multiple paths to participation in energy efficiency initiatives in this unique market sector that has also been served over many years by skilled contractors and engineering firms. These firms will continue to be eligible to provide services in this sector, both through the Multi-Family Retrofit core initiative (and its terms and conditions) and, where qualified, as providers for the Low-Income Multi-Family core initiative under the terms and conditions of this initiative. <u>Customer Education</u> Energy efficiency education and information are included in all PAs energy efficiency initiatives. The primary forms of energy education are benchmarking building inventories, verbal communication between the auditor and the participants, as well as leave-behind materials. In 2013, the PAs collaborated with the Low-Income Best Practices working group and developed common, statewide educational materials. Educational materials will continue to be updated and provided to customers as applicable. The Low-Income Multi-Family core initiative plans to develop/improve education materials that will include education for landlords, property managers, building occupants, and property management personnel as well as development of case studies as applicable.
Delivery Mechanism	The initiative will be administered cooperatively by the gas and the electric PAs in conjunction with interested stakeholders. <u>Enrollment</u> Participants for this initiative may enroll through a local CAP agency, statewide website, the multi-family statewide toll free number, PA(s), the Low-Income Multi-Family website or other venue (use of the low-income multi-family website is required in most cases). <u>Participant Screening</u> Currently, the Low-Income Multi-Family Advisory Committee composed of LEAN, Community Development Corporations (“CDCs”), other non-profit owners of low-income non-institutional multi-family housing, and Public Housing Authorities (“PHAs”) are tasked with prioritizing low-income multi-family projects for each PA.

LOW-INCOME	**CORE INITIATIVE** **MULTI-FAMILY**
	The advisory committee integrates flexibility into their planning to handle unique needs of PAs and their customers or potential participants. The Low-Income Multi-Family Advisory Committee may include representatives of other sectors. Due to the nature of this market segment, most leads will be generated through the Low-Income Multi-Family Advisory Committee. However, leads coming in via other venues will be screened by the MMI and forwarded to the Low-Income Multi-Family Advisory Committee for eligibility confirmation. Upon confirmation of a project, the lead vendor or CAP agency is responsible for coordinating the appropriate parties to address the project needs based on protocols agreed to by the specific PA(s) and in consultation with the specific PA(s) to move the project forward. Whole Building Assessment Based on the outcome of the screening process, the appropriate technical resources will be assigned to conduct a whole building (fuel blind) assessment. The lead vendor or local CAP agency will attempt, through the screening process, to identify all resources required for the assessment. However, there may be instances where additional expertise is required and therefore more than one site visit is necessary. Technical assessments and engineering studies will be conducted as needed. At the time of the assessment, education will be provided to participants and instant saving measures will be installed, as appropriate. Integrated Proposal for Energy Efficiency Services Using the findings from the site-specific assessment, the appropriate parties will draft a project proposal that will include gas and electric cost-effective measure opportunities and other available services where applicable. Where appropriate, the project proposal will be forwarded to the appropriate PA(s) for approval. Once the comprehensive offer has received PA approval (if necessary), it will be presented to the participant by the parties required to help the customer fully understand the offering. Delivery of Measures and Services The lead vendor or CAP agency will coordinate the delivery of the measures and services. The installation contractors will strive to have

LOW-INCOME	**<u>CORE INITIATIVE</u>** **MULTI-FAMILY**
	all dwelling unit measures installed in a single visit to minimize disruption for the tenants; however, multiple visits may be required for the installation of common area measures. All installations are coordinated with the owners, property managers and the tenants. <u>Quality Assurance/Quality Control</u> Quality assurance will be performed in support of this initiative. Quality assurance is completed by the CAP agencies, as well as by a PA-funded independent third party vendor. The delivery mechanism serves to minimize lost opportunities and encourage deeper savings in the following ways: • The increased incentive amounts may allow for achieving energy savings that would not be possible if this customer sector had to provide a significant co-payment. • Having the PHAs and CDCs and other owners of non-institutional low-income multi-family housing involved in the process helps facilitate access to the tenant spaces, which has been traditionally cited as a potential barrier in the multi-family market.
Marketing Overview	Demand for the Low-Income Multi-Family core initiative will be managed jointly by the PAs and the Multi-Family Advisory Committee. The PAs will engage in outreach efforts to notify customers of the availability and value of energy efficiency services to stimulate interest in the initiative and operate within budgets. Marketing will consist of contacting landlords or property managers of income-eligible tenants as needed. Direct mail, bill inserts, case studies and literature distributed through social service agencies, housing funders, government offices, community outreach, and other networks can also be used to market the initiative. PAs will use their relationship with PHAs, CDCs, community based outreach and other income-eligible property managers to market the benefits of the initiative. In addition, PAs are participating in statewide marketing efforts to encourage all customers to participate in energy efficiency initiatives. Those efforts will assist in driving income-eligible customers to take advantage of not only energy efficiency programs but also discount rates, fuel assistance, and other social programs when appropriate.

LOW-INCOME	**<u>CORE INITIATIVE</u>** **MULTI-FAMILY**
Three-Year Deployment Strategy/Roadmap	The PAs will coordinate efforts via LEAN to ensure consistent implementation throughout the state and retain the advantages of the existing infrastructure of central coordination while avoiding the creation of a new or central entity. Participants may enroll through a CAP agency, statewide website, low-income multi-family website, multi-family statewide toll free number, PAs or other venue. Many leads will be generated through the Low-Income Multi-Family Advisory Committee; however, leads coming in via other venues will be screened by the MMI and/or the PAs and forwarded to the lead vendor/CAP agency for eligibility confirmation. Once eligibility has been confirmed, the Low-Income Multi-Family Advisory Committee prioritizes the low-income multi-family projects for each PA as needed. Training and workforce development will be accomplished by the PAs working with LEAN, DHCD, and CAP agencies to increase the number of qualified contractors, energy auditors, and administrative staff. The PAs in conjunction with LEAN and the CAP agencies will continually review and evaluate new measures and technologies. Through marketing and outreach efforts, the PAs will attempt to broaden participation. PAs will attempt to deepen efficiency penetration consistent with a comprehensive, whole building approach. PAs welcome continued dialogue with Massachusetts affordable housing stakeholders to evaluate opportunities to maximize the opportunity for capturing energy efficiency savings at the time of financing and refinancing of affordable housing properties. PAs have committed to engaging with these stakeholders to jointly explore and scope these opportunities via planning meetings. The PAs are excited to learn from the experts within the Massachusetts Housing community about the timing, scope and processes of affordable housing finance and refinance, to share the PAs technical resources and understanding on efficiency programming, and to work together to identify critical moments of potential opportunity in the finance and refinance process to secure additional savings. The PAs look forward to receiving additional and more specific information from the MA affordable housing stakeholders so that the PAs can explore opportunities to incorporate program design and implementation refinements that result from these dialogues within the 2016-2018 Plan term. In accordance with the Resolution, the PAs will continue to work with the Commonwealth's housing financing agencies and LEAN (with mutual expectations and deliverables) to develop and implement enhanced approaches to leverage multi-family refinancing events to maximize retrofit potential. The parties will specifically consider

LOW-INCOME	**CORE INITIATIVE** **MULTI-FAMILY**
	performance-based retrofit products. The PAs will present the results of these efforts and specific proposals derived from them by the close of Q1 2016.
Special Notes	

G. Commercial & Industrial Programs

1. Overview of C&I Programs – New Construction & Retrofit

As discussed in greater detail below, the Program Administrators organize their programs, and the outreach and marketing that support them, according to the way the non-residential marketplace is organized – *i.e.*, there is the built environment and the environment being built or renovated. The built environment encompasses existing buildings and the market actors that own, service and occupy them and includes property owners and managers, facility managers, the manufacturers and vendors of products and services that address building or occupant needs, and the occupants and tenants who work in the space. In the environment being built or renovated the key actors include developers (for both owner occupancy and tenancy), architects, engineers, equipment specifiers, equipment suppliers, and many others who serve specialized niches.

The two umbrella programs that serve these markets, Retrofit and New Construction, are mature and well developed. Their lineage extends as far back as the mid-1980s. They were among the first utility-based energy efficiency programs in the country. The design, organization, and delivery structure of the Massachusetts programs have served as models for most of the other non-residential energy efficiency programs developed throughout North America today.

While these programs have been, and continue to be, highly successful, the PAs continually seek ways to improve delivery of the services they offer, to enhance program reach into relatively under-served markets, and to engage customers they have served in the past with new offerings and technologies to further increase the efficiency and performance of their buildings. Examples of sources for program improvement concepts are described below.

2. Sharing Innovations in Program Design, Marketing, and Delivery

The C&I Management Committee ("C&IMC") serves as the ongoing venue for sharing individual PA innovations in program design, marketing, and delivery. The C&IMC regularly reviews its processes and operations in order to continuously optimize the balance between innovation and consistency and will continue these efforts throughout 2016-2018.

Consistency in offerings, eligibility and incentives is fundamental to all PA program design and delivery. Consistency assures customers that they will receive uniform services no matter where their facilities are located in the Commonwealth and ensures that the benefits of ratepayer funded programs are distributed both widely and equitably. That said, it is important to recognize that innovation by individual PAs in program design and delivery is equally important. The flexibility of individual innovation allows PAs to respond to the variations of local markets and market conditions, but more importantly it is through this experimentation – be it in program design, product promotion, or a unique focus on distinct market segments of local importance – that concepts that might have statewide applicability can be tested and evaluated in a limited low-risk/low-cost environment, with the results then shared and scaled up statewide as appropriate and practicable.

- *Independent Evaluations of our own Programs:* For many years, third-party evaluations, both process and impact, have been conducted on many of the key components of the Massachusetts C&I programs. The results and recommendations from these evaluations are reviewed and, when appropriate, incorporated into PA programs going forward.
- *Evaluations of Programs in Other Jurisdictions:* Due to the fact that efficiency program designs in other leading jurisdictions (such as California, Oregon, New York) are so similar to Massachusetts programs, PA staff often review evaluations from programs in these states to glean improvement concepts that could be applied locally.
- *Review of Industry Best Practices and Other Studies and Conferenced Proceedings:* Organizations like the ACEEE produce a wealth of useful studies and industry best practice reviews, and also publish and archive professional papers and presentations from their numerous conferences and study sessions. Similar studies are available from the Department of Energy's network of national research laboratories, regional efficiency organizations, such as the Northwest Energy Efficiency Alliance, and industry collaborations like the Consortium for Energy Efficiency. Additional sources of thought leadership and information include the Rocky Mountain Institute, the Institute for Market Transformation, the New Buildings Institute, and E Source.
- *Peer Networks:* Energy efficiency programs do not compete with each other; therefore, there is a culture of collaboration among the staff and managers of these programs across the country. PA staff members know many of their counterparts, and there is a regular exchange of information and advice among peers for the mutual benefit of the industry.
- *The EEAC and Other Stakeholder Input:* The PAs are active and engaged participants in Council proceedings and in various Council-facilitated public participation processes. PA staff has participated in over 100 Council-related public meetings since 2013. Further, PA staff have invited Councilors, as individuals and small groups, to participate informally in C&IMC meetings and other internal team meetings in order for them to develop a fuller understanding of how the PAs work together to administer and advance the programs.

The PAs have benefitted from both the formal Council and stakeholder input processes and the informal exchange of ideas and concepts that comes from this form of continuing close engagement. Many of the concepts advanced in these venues and exchanges are reflected in the detailed program designs that follow.

Going forward, the PAs are fully committed to continuing this dialogue and communication regarding program developments and progress towards goals throughout the entire Three-Year Plan term, including, in accordance with the Resolution, regular and specific updates to the Council on C&I program progress and penetration (including segment specific approaches - especially for challenging subsectors such as small and mid-size commercial, small hospitals, non-profits, and multifamily - measures such as street lighting and LED costs and conversion, and innovations such as strategic energy management) through semi-annual presentations to the Council. The PAs will collaborate with DOER by the end of 2015 to consider how best to present this information (*e.g.*, potential use of roundtables, webinars, etc.) and to develop a schedule for updates on specific topics. Also, in accordance with the Resolution, the PAs will demonstrate a clear commitment to Combined Heat and Power ("CHP") installations, and tracking CHP project savings and expenditures (subject to customer confidentiality requirements) against PA's CHP Plan projections in semi-annual presentations to the Council and in data sets provided on Mass Save Data. The PAs are also committed to providing, in accordance with the Resolution, more detail about the PA's Massachusetts Technology Assessment Committee, and semi-annual updates to the Council on progress reviewing and implementing new technologies into programs.

The PAs believe this thoughtful, prioritized, and systematic approach will ultimately result in a greater visibility into the programs and their progress and at the same time will be respectful of the valuable time resources of all parties and provide the Council with considerably greater appreciation and understanding of the major program developments and drivers.

Over the course of the development of this plan, PA staff accessed, or re-accessed, many of these sources of program innovation. In addition, the PAs contracted with a highly-respected independent consultancy, E Source, to conduct targeted research on best practices and emerging trends and technologies in areas of particular importance to the Council and the PAs. E Source also provided independent verifications that the PAs internal research and conclusions did, indeed, reflect the most current assessments of industry best practice.

Lastly, it is important to recognize that the process of program improvement and adjustment of delivery to incorporate new technologies, new delivery modes, and changing market and economic conditions is continuous and ongoing. In that context, a Three-Year Plan is, by necessity and practicality, a strategic document. In discussing our commercial and industrial programs, the PAs attempt to outline a reasoned and balanced path forward into the future in an industry where technologies and programs are evolving at an exponential pace. In areas where there exists reasonable certainty about the precise nature and timing of the program enhancements being proposed, the plan sets forth that detail. In other areas, the necessity or desirability for program changes are identified and discussed along with a proposed path forward, but the exact details and schedule, of necessity, require more investigation and planning. The PAs take the position that a well-conceived strategic plan is one that captures future program details and schedules when those can be confidently stated, and lays out the scope of the issue and the plan of attack when they cannot. For example, the last three-year plan had no discussion of "big data" because no one in 2012 – PAs or stakeholders – could have imagined its 2015 implications regarding program design and delivery, market segmentation, evaluation, behavior tracking, etc. Undoubtedly, three years from now the drafters of the 2019-2021 Three-Year Plan will be discussing in some detail program concepts and technologies that are unknown to us today.

3. Accomplishments During 2013-2015 Plan Term

The program plans for 2016-2018 rest on the solid foundation constructed during the previous three-year planning cycles. At the macro level, key C&I accomplishments during the 2013-2015 Plan Term (through the end of 2014) include the following:

- *Energy Savings*
  - 9.5 Million therms per year – equivalent to the usage of roughly 10,000 residential homes
  - 720 Thousand MWh per year – equivalent to the usage of roughly 100,000 residential homes
- *Benefits*
  - 40 percent increase in gas benefits to $200 Million
  - 16 percent increase in electric benefits to over $1.4 Billion
- *Participation*
  - 88 percent increase in gas participation – equivalent to roughly 4,500 additional businesses
  - 27 percent increase in electric participation – equivalent to roughly 3,800 additional businesses
  - 25-30,000 total C&I customers participating annually
- *Green House Gases*
  - Reduction in CO_2 emissions equivalent to the removal of nearly 115,000 automobiles from Massachusetts roads

In addition, the PAs have successfully evolved their C&I programs and produced many notable achievements including:

- Economy and weather adjusted statewide C&I electricity sales have declined and are projected to continue declining over the three consecutive years of this plan, for the first time ever;[25]
- Conducted 20 code compliance training sessions, attended by almost 700 code officials, architects, and contractors;

[25] US Energy Information Agency and ISO-New England.

- Completed a redesign and rewriting of the C&I section of Mass Save® website, improving organization, navigation, and customer-oriented language;
- Grew C&I customer awareness of Mass Save® precipitously to its highest point ever (66 percent); and likewise grew C&I customer use of the Mass Save® website nearly tripling traffic over the last two years (from 13 percent to 34 percent).[26] Brand awareness among C&I customers even outpaced that of residential customers (66 percent to 54 percent);[27]
- Drove explosive growth of the LED lighting market – broadening and deepening penetration in virtually every end use principally as a result of the upstream approach to lighting initially launched in 2012. The PAs success has been documented in the recent LED market effects evaluation[28] which found that as of 2014, 63 percent of Massachusetts commercial customers reported having installed at least one type of LED lighting in their facilities versus just 46 percent in California. Similarly, 42 percent of Massachusetts commercial customers reported installing screw-based LEDs versus only 12 percent of their counterparts in California;
- Developed a new delivery mechanism – the Upstream Approach – that reaches and engages significantly more customers and influences manufacturers to produce more of their premium efficiency products and distributors to stock and promote them;
- Achieved substantial growth in the number of CHP participants, driven by rapid uptake of smaller customers identified and prescreened by the PAs as good candidates for the technology. In addition, positive realization rates and comparatively low rates of free-ridership have both fostered a favorable environment for CHP expansion and proven that the programs are meeting customers' needs and achieving desired results;
- Expanded the Upstream portfolio to include additional lighting products and technologies, as well as HVAC and water heating equipment – with a tremendous increase in participation and savings;
- Completed a significant body of best practices research – in Commercial Real Estate, Retro-commissioning, etc. – some successfully conducted in collaboration with EEAC Consultants and others including involvement from various PAs, third party subject matter experts, and external stakeholders;
- Consolidated Residential & C&I MTAC into a single entity and the addition of Connecticut representation to increase efficiencies, improve coordination, and expand reach;
- Added many cutting-edge measures/technologies to the portfolio of offerings – including ductless fume hoods, green cooling towers, drain water heat recovery, pump coatings, window glaze, diaphragm pump control, polymer bead laundry, etc.;
- Statewide implementation of a standardized approach to serving Municipal customers;

---

[26] *2014 Massachusetts Statewide Marketing Campaign, Post-Campaign Report*, Opinion Dynamics February, 2015, at 2.

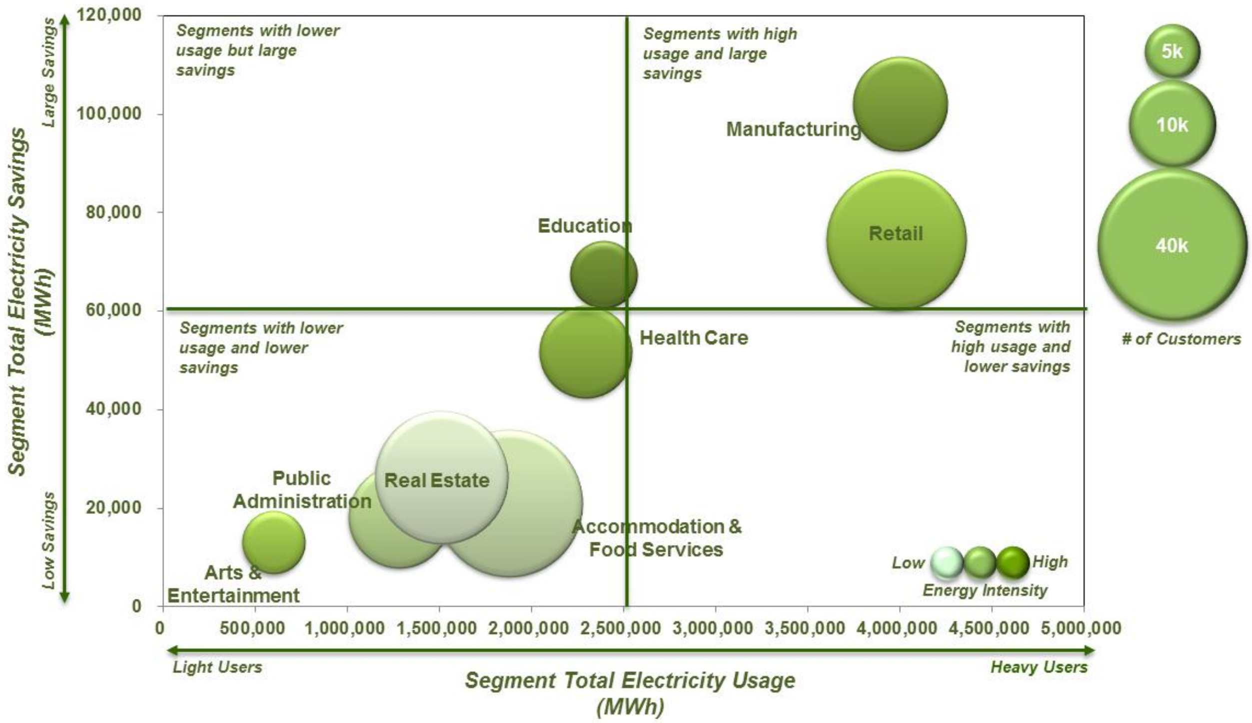
[27] Id. at 16.

[28] *Final Draft Report of Massachusetts LED Market Effects: Baseline Characterization*, DNV GL, March 1, 2015.

- Delivered specialized best practices in EE sales training through a nationally-recognized firm to improve the level of commercial excellence both among PA sales staff and trade allies including manufacturers, distributors, and contractors;
- Launch of the Sustainable Office Design initiative to capture greater market share in leased office space;
- Developed a number of segment-specific approaches to serving customers – grocers, municipalities, offices, etc.;
- Collaborated with DCAMM to dramatically increase penetration of high efficiency equipment in state owned/operated buildings.

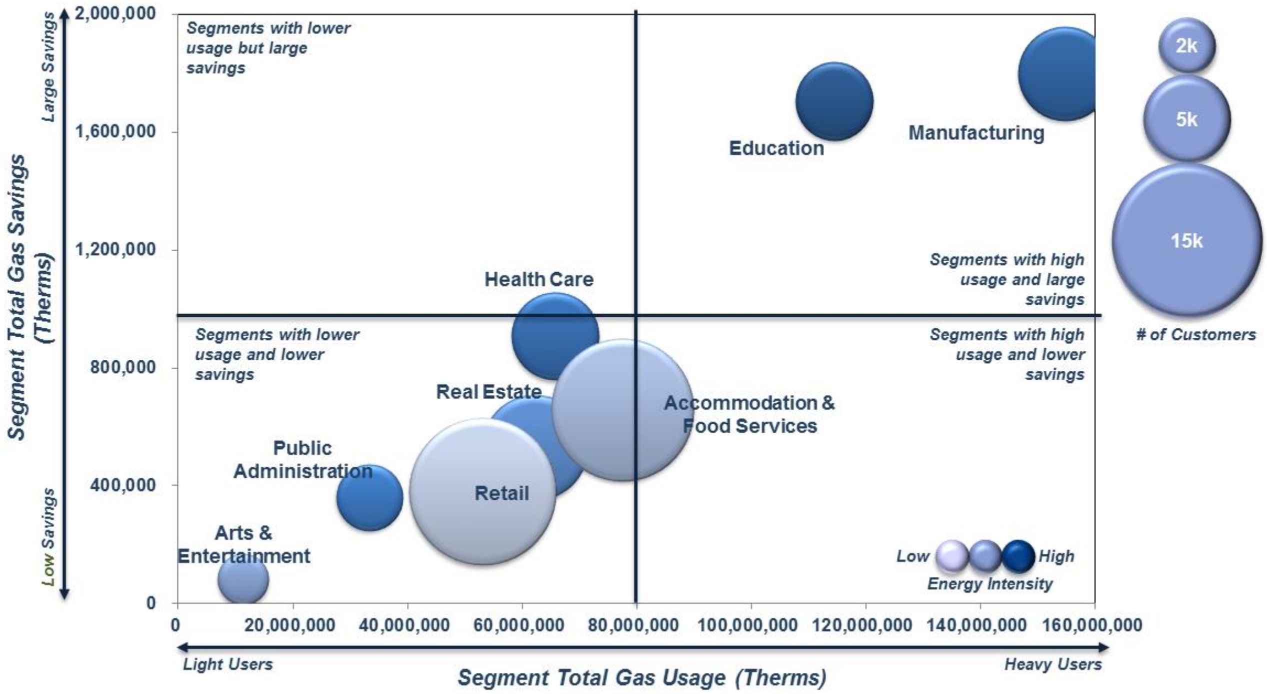
For reference purposes, the following exhibits provide a high level snapshot of the composition of the statewide C&I customer base including the size of each customer segment in terms of customer counts and usage as well as the gas and electric savings generated from each segment historically.

a. C&I Electric Savings & Usage by Segment: Historical Overview



Source: ***2013 Commercial & Industrial Customer Profile Report, DNV GL, March 27, 2015***

b. C&I Gas Savings & Usage by Segment: Historical Overview



Source: ***2013 Commercial & Industrial Customer Profile Report, DNV GL, March 27, 2015***

4. <u>Highlights of 2016-2018 Enhancements</u>

The sections below provide descriptions of a number of new initiatives or improvements the PAs plan to implement over the next three years. The level of detail varies as some elements are more conceptual in nature at this juncture and are planned for introduction in the out years of the Plan. In those cases further study and/or evaluations of field testing (either in Massachusetts or in another jurisdiction) may be warranted before the enhancement is introduced as a full program element.

The following is a representative listing of some of the proposed program or administrative enhancements discussed in further detail in the sections following, or elsewhere in the plan:

- An online incentive application portal with a menu driven interface enabling the creation and submission of customer applications for incentives. This will reduce application errors, accelerate the review process, and greatly enhance the overall customer experience. The PAs expect that this added functionality will be particularly helpful for mid-sized customers, as studies often conclude they lack the technical expertise to fill out the current application forms. This menu based, all-in-one system will make it easy for anyone to fill out and submit an application for incentives.
- A thorough analysis of the current Small Business program model. This long-standing program is regularly cited as a best-in-class model and is now widely copied by other program administrators around the country. Here in Massachusetts, it continues to be highly successful in reaching small business customers, and evaluations repeatedly show that these

customers are very satisfied with the services they receive. However, the PAs recognize that in order to continue with this success they will need to anticipate the ever-changing needs of small commercial customers and assure that new technologies and new delivery options are available to address these needs.

- Expansion of the portfolio of upstream offerings where appropriate – including water heating technologies, beginning in fall of 2015.
- Staged revisions to retro-commissioning services based on the findings of the joint PA/EEAC consultant best practices study.
- Encouragement of Net Zero Buildings as the premium option in the Whole Building path in the New Construction Program.
- Improved comprehensiveness in mid-sized new construction buildings through the use of Advanced Buildings and other tools. Broader application of Sustainable Office Design as a means of delivering integrated and comprehensive technical solutions to the leased commercial office market.
- Increased focus on gathering early intelligence on the efficacy and cost-effectiveness of emergent energy efficient technologies – both as they enter the market and earlier when they are in the market readiness testing mode.
- Evolving formal and informal cooperation within the region and beyond through joint R&D and cooperative exchange of information regarding emerging technologies.
- Expanded segment-based delivery approaches to broaden participation, increase comprehensiveness and depth of savings, and enhance the customer experience.
- A broader menu of training offerings for customers, trade allies, vendors, and PA staff and contractors that provides services to the PAs, as well as the use of new modalities for delivering trainings.
- A reorganized and refreshed Mass Save® website that better directs customers to information specific to their needs in their business segment. The new design will focus less on technologies and programs and more on customers and their end uses. It will also feature new materials directed to specific segments and their needs.

5. Mechanisms for Program Collaboration, Continuous Improvement, Incorporating Emerging Technologies, and Sharing and Incorporating Best Practices Information

a. Introduction

The vital feedstock for PA program advancement is a continuing stream of new energy-efficient technologies that can produce demonstrable, repeatable, verifiable, and cost-effective savings. A robust process to identify and screen candidate technologies is not only critical to meeting savings goals, it also facilitates innovation, provides a platform for technological development, and addresses customer expectations that the PAs will rigorously and impartially vet manufacturer and vendor savings claims on their behalf. And, over time, it transforms the market.

The PAs identify prospective new technologies through multiple sources and streams of information including the following.

b. In-house R&D

Many of the PAs provide efficiency services in several states, each of which has a similar need for a pipeline of new efficiency measures. These PAs have in-house staff of technical and engineering professionals with expertise in such areas as energy codes and standards, building energy simulation tools, lighting technology and controls, assessment of energy efficiency products, and product development who are dedicated to new technology research and, in collaboration with their evaluation colleagues, savings verification. Examples of products in various stages of vetting by individual PA technical staff include the following:

- Air source and water source gas engine driven heat pumps;
- Several proprietary gas fired heat pumps with variable refrigerant flows;
- Removable jackets for valves, fittings and specialty piping in boiler rooms and other mechanical spaces;
- Advanced rooftop unit controllers that may have application in big box stores;
- A pipe, valve and tank insulation tool that can be used to calculate savings for insulating steam or hot water piping, valves and tanks for customers with usage of less than 50,000 therms per year;
- Distributed refrigeration that can reduce the pounds of refrigerant used and increase usable floor space in supermarket applications;
- Electrically commutated ,motors for pumping applications;
- Drain water heat recovery;
- Heat pump dryers;
- Automatic temperature control which provides thermostat optimization, load shifting and demand response control as well as communication and bill estimation capabilities;
- Thermal storage optimization control strategies to shift hot water load;
- A boiler QI tool which optimizes the heating system performance and boiler sizing;
- Smart communicating appliances which allow communication and utility control of appliances;
- Advanced buildings net energy optimizer (NEO) building energy modeling;
- Analytics to assess post construction zero energy building performance;
- Existing building HVAC retrofit controls;
- Emerging HVAC technologies;
- Automated window shades;

- Exterior performance lighting;
- Existing space performance lighting;
- LED integrated control logic;
- Smart grid controlled street lighting;
- A variety of emerging lighting technologies
- Window glazing;
- Highly efficiency filtered fume hoods;
- Smart plugs;
- Ozone laundry;
- Air operated double diaphragm (AODD) pump control;
- Washing with polymer beads;
- Hand dryers;
- Building insulation;
- Energy recovery filters.

The companies also cross-pollinate information gathered from research and field testing between the states they serve. For example, National Grid in Rhode Island is engaged in piloting several commercial sector behavior initiatives the results of which will be made available for review and consideration in Massachusetts. The synergies generated by this multi-jurisdictional sharing of information reduce R&D costs for the Commonwealth, and for the other states.

c. Partnerships with MOU customers

In 2013, as a byproduct of its confidential MOU relationship with Proctor & Gamble ("P&G"), Eversource learned that P&G was in the process of developing a new cold water washing product for commercial applications that had potential for significant gas and water savings for customers with large laundry operations, such as hotels, institutions, assisted living, etc. In 2014, Eversource partnered with P&G to test the product in a controlled setting with an Eversource lodging customer, using both gas and water metering equipment. When the product's savings were proven and quantified, the PAs could add the product as an approved measure, and P&G could promote nationally that the savings value of its new product, the Tide® Professional Coldwater System, had been verified by a highly-credible independent authority on efficiency – Eversource. In another case, National Grid and Eversource are helping EMC Corporation (a joint MOU customer) develop an RFP to select a monitoring-based commissioning ("MBCx") contractor to implement MBCx across its entire U.S. real estate portfolio. EMC Corporation will apply the lessons from its Massachusetts experience in their North Carolina and California facilities.

d. Cooperative relationships with similar technical bodies at other program administrators or regional efforts

The PAs have established formal and informal working relationships with such organizations as the Consortium for Energy Efficiency ("CEE"), the Northwest Energy Efficiency Alliance ("NEEA"), the California Emerging Technologies Coordinating Council ("ETCC"), the Northwest Regional Technical Forum ("RTF"), NYSERDA's Emerging Technologies Accelerated Commercialization initiative, Southern California Edison's Lighting Research Program, the Fraunhofer Center for Sustainable Energy Systems, the Food Service Technology Center, several of the Department of Energy's National Research Laboratories, etc. These relationships can involve a continuum of activities from simple information exchange to participation in jointly funded and managed research, technology assessments, or field tests.

For example, the development of the Sustainable Office Design ("SOD") initiative started as a joint project to develop technical specifications for energy-consuming office spaces initiated by Eversource, National Grid, and Southern California Edison, and ultimately involved several other West Coast utilities. Also, the PA-sponsored training delivered to the Massachusetts Water and Wastewater facility operators by faculty from the University of Wisconsin ("UW") originated in training developed by UW for the Wisconsin program administrators. Additionally, Eversource and National Grid co-sponsored new insulation research at the Fraunhofer Center for Sustainable Energy Systems with the goal of reducing barriers to insulating older building types in the Northeast.

As a forward-looking example, in 2016 the PAs will convene a meeting between peer leading energy efficiency program administrators, both regionally and nationally, and a select group of lighting industry experts for the purposes of: (1) identifying LED technologies that are market ready (*i.e.*, reliable and cost-effective) or will be in the near term; and (2) exploring potential common approaches to integrating these technologies into efficiency programs in a manner that simultaneously aligns with policy objectives and serves the best interests of customers. In addition to the obvious value of sharing implementation experience between jurisdictions, the PAs believe there is potential benefit in developing common messaging about program expectations to the lighting industry.

Many PA engineers are also involved as technical experts on regional and national committees (*e.g.*, establishing national standards for commercial kitchen equipment, designing an Advanced Roof Top Unit Controllers program, etc.). National Grid staff in New York collaborate with NYSERDA staff in the latter's emerging technologies program, and the two have collaborated in a sustainability and efficiency program for hospitals, the lessons from which will be shared with Massachusetts. Eversource recently participated in CEE's Connected Committee to develop a coordinated national response to the new ENERGY STAR® Program Requirements for Connected Thermostat Products specification.

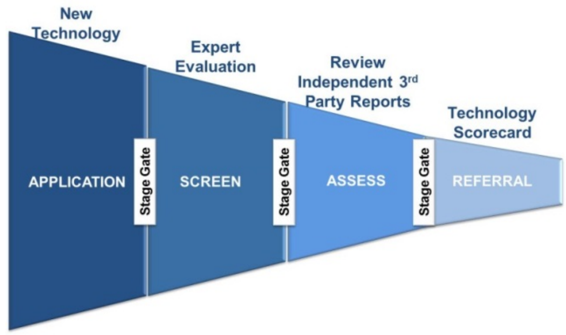
e. Supplier and manufacturer product submissions

Manufacturers and distributors of energy-consuming equipment regularly submit product information, and accompanying savings claims, to the PAs and petition to qualify them for program eligibility and incentives. All such requests are referred to the MTAC, as described below.

6. The Massachusetts Technology Assessment Committee

MTAC consists of key technical and evaluation staff from each of the PAs. A Project Manager designated by the PAs coordinates the work of the Committee. Also, the chair of the Connecticut Joint Utility RD&D Program attends monthly MTAC meetings for the purpose of sharing information about ongoing technology research, tests, and results from that state.[29]

The Committee addresses both residential and commercial/industrial technologies, drawing on the subject matter experts on the Committee, other subject matter experts at the various PAs, and outside expertise as necessary. MTAC meets monthly while a variety of ad hoc technology or issue-specific subgroups meet as required.



MTAC is both a proactive and a reactive body. It proactively identifies emerging technologies that may have proven savings, are reliable, and generally available and market ready to include in the programs. It does so by keeping abreast of industry literature and by coordinating and networking with groups around North America who have missions similar to that of MTAC. It also manages inbound requests for consideration of a new or unfamiliar technology that come from manufacturers, vendors or customers. These requests are generally made to an individual PA and then forwarded to the Committee, or are received through a process accessible via the Mass Save® website.

MTAC establishes and publishes threshold eligibility requirements that must be met to qualify products or processes as program-eligible. MTAC documents its findings in a standardized manner and disseminates them to the PA program managers, technical staff, account managers, and outside parties such as vendors, customers, and other program administrators beyond Massachusetts, as appropriate. After MTAC qualifies a product or process, the appropriate PA subcommittee (lighting, non-lighting electric, or gas) then leads efforts to determine how to actually integrate it into the program (incentive levels, application requirements, quality control, etc.) offerings. Documentation of recently reviewed technologies is always posted on the Mass Save® website at:
http://www.masssave.com/en/professionals/business-opportunities/assessment-of-new-efficiency-technologies

29 The Connecticut Joint Utility RD&D Program reviews technologies submitted to the Connecticut Energy Efficiency Board for potential inclusion in programs in that state. The RD&D group meets monthly for application review with a Policy Working Group ("PWG") comprised of professionals from the energy efficiency, science and technology, economic development and legal communities.

MTAC provides quarterly status updates to internal stakeholders such as the C&I and Residential Management Committees as well as the Energy Efficiency Advisory Council along with semiannual updates to other external stakeholders.

MTAC has the following principal functions:

- It provides information, documented technical interpretations and technology assessments to the PAs and is the authority for consistent program interpretation of technical matters;
- The Committee reviews candidate technologies according to industry-standard protocols, documents its decisions in a consistent and unbiased manner and disseminates its conclusions and technical interpretations in a standard format;
- It determines whether a specific new technology is program-eligible, and then refers it to the appropriate PA subcommittee to develop implementation requirements;
- When appropriate and directed by the PAs, it develops common program implementation materials or procedures including: technical specifications, technical study/commissioning protocols, equipment baseline reference sheets, inspection forms, and other technical and administrative support materials, for use by PA staff and contractors;
- It coordinates its work with the EM&V staff at each PA in order to support the determination of program savings values;
- It responds to inquiries from third parties, primarily vendors and manufacturers, who wish to have their products considered as incentive-eligible through the Massachusetts programs.

Over the next three years the PAs will continue to build upon the technology identification and vetting systems and cooperative alliances discussed above. The PAs will seek opportunities to both expand collaboration with existing partner organizations where the sharing of expense and/or technical expertise has added value for Massachusetts ratepayers, as well as seek out new opportunities for collaboration with other program administrators, government and university research laboratories, and regional technology development organization.

7. C&I Program and Core Initiative Descriptions

a. C&I New Construction: New Buildings & Major Renovations; Initial Purchase & End of Useful Life

C&I NEW CONSTRUCTION	**CORE INITIATIVES** **NEW BUILDINGS & MAJOR RENOVATIONS** **INITIAL PURCHASE & END OF USEFUL LIFE**
Overview &	The New Construction Program has two core initiatives. The objective of the first – New Buildings & Major Renovations – is to offer developers

C&I NEW CONSTRUCTION	**CORE INITIATIVES** **NEW BUILDINGS & MAJOR RENOVATIONS** **INITIAL PURCHASE & END OF USEFUL LIFE**
Key Objectives	of new buildings, and the owners of existing buildings that are undegoing major renovations or additions, a menu of efficiency services and incentives that are tailored to complement their unique ownership objectives and investment criteria, and can add value no matter where their building is along the design and construction continuum and can do so without impacting the design/build schedule. The second – Initial Purchase & End of Useful Life – encourages customers purchasing new energy-consuming equipment, or replacing equipment that has reached end of useful life or failed, to opt for the most efficient choice within each product category. When new buildings are designed and constructed, and when existing ones are renovated or expanded, there is a window of time to increase the efficiency and reduce the demand profile of the project dramatically at relatively modest incremental cost. The greatest potential to achieve savings, and to add value to the customer, occurs when PA new construction representatives, and the team of pre-screened energy design experts at their disposal, can engage with designers and their projects in the initial conceptual phase. Here the project can be examined comprehensively, allowing for design assistance, scenario modeling, and whole building equipment specification. At this early stage measures that can commonly be considered include orientation and site considerations, envelope improvements (*e.g.*, insulation above code), motors and drives, HVAC equipment and system design, and lighting design and controls, including daylighting. These fundamental early design decisions can shape the energy and demand costs of a building for its entire life, which in New England can be a hundred years or more.[30] Similarly, initial equipment choices may establish energy consumption patterns for decades, until that equipment fails and must be replaced, or until a more costly retrofit project is proposed. If this narrow and fleeting window of opportunity to influence building design and equipment specification is missed, it is not hyperbole to say that it is lost for a lifetime. The services provided through the New Construction program help lower building operating and maintenance costs throughout its entire life cycle while increasing comfort, health, and productivity for building occupants. If the design process is well underway when program representatives engage, a more prescriptive approach to individual measures, or a custom approach to discrete building systems, can still

[30] Approximately 70% of the building stock in Massachusetts is more than thirty years old.

C&I NEW CONSTRUCTION	<u>CORE INITIATIVES</u> NEW BUILDINGS & MAJOR RENOVATIONS INITIAL PURCHASE & END OF USEFUL LIFE
	capture considerable efficiency, again at relatively modest expense. The objective of the New Construction program is to offer building owners and designers a menu of efficiency services and incentives that are tailored to complement each customer's ownership objectives and investment criteria, can add value no matter where their building is along the design and construction continuum, and can do so without impacting the design/build schedule. The PAs aggressively seek out and recruit owners and designers involved in the construction or major renovation of all non-residential buildings. This process requires multi-faceted strategies, because development is, by its nature, a competitive process that largely takes place out of the public eye, often until a construction trailer and fence appears on site. The challenge is to gain market intelligence – from a myriad of sources – so that program representatives can intersect with customers as early as possible in their process, preferably at the time when the fundamental design decisions that most impact future energy use are being made. PA services range from a package of expert design and engineering assistance and incentives at the level of the whole building (when the project is in early design), to similar assistance within discrete facility systems, components, or processes in cases where the project is more advanced, to prescriptive incentives for a large menu of pre-selected premium performance lighting, HVAC, and other mechanical measures – or a mix of all of these options. For many participants, the value of this program is not just in the incentives, but also for the opportunity to access the expert, impartial, unbiased technical assistance provided by PA staff and through the stable of technical experts with whom they collaborate. Thousands of similar, but smaller, time-dependent opportunities occur whenever energy-consuming equipment fails in existing buildings. Just as in new construction, there is a brief window of opportunity for the program to intervene to present a more efficient option when the customer is focused on purchasing replacement equipment quickly and returning their facility to full operation. In these cases, the PAs work with equipment vendors and suppliers – often using an upstream approach – to ensure that premium alternatives are available and promoted in that brief window.

C&I NEW CONSTRUCTION	**<u>CORE INITIATIVES</u>** **NEW BUILDINGS & MAJOR RENOVATIONS** **INITIAL PURCHASE & END OF USEFUL LIFE**
	Target Market Program staff aggressively attempt to identify and influence decisions affecting all non-residential new construction, renovation, and addition projects in the Commonwealth, as well as businesses replacing outmoded or failed equipment outside of a more comprehensive construction or upgrade project.
	New Enhancements The New Construction program is a mature and successful offering with broad market recognition, understanding, and acceptance. Nonetheless, the PAs constantly monitor peer programs in other jurisdictions (many of which are duplicates of the Massachusetts program model) in search of ideas for delivery or administrative improvements. Among the areas the PAs will consider for inclusion in their New Construction program during the coming plan term are the following: <u>Net Zero Buildings</u> Massachusetts, California, the Pacific Northwest, and New York are the leading jurisdictions advancing Net Zero – the vision that a building could have no energy impact on its environment; that is, a building can be designed to consume dramatically less energy than current practice, and then produce its reduced requirements on site using renewable sources. There are many challenges to achieving this vision, as set forth in the report of the Massachusetts Zero Net Energy Task Force.[31] Nevertheless, the path to a visionary goal almost always consists of numerous incremental steps – steps that change building design and technology, owner and developer investment approaches, government regulation and tax policy, etc. Because each of these steps towards Net Zero is likely to introduce technologies, concepts, and policies that carry the potential to make all new buildings (and renovations of existing ones) incrementally more efficient, even for the vast majority of owners who are not driven to achieve Net Zero, the PAs have an interest in staying closely engaged in the Net Zero movement. This engagement will take place on several fronts.

[31] *Getting to Zero Final Report of the Massachusetts Zero Net Energy Buildings Task Force*, March 11, 2009.

C&I NEW CONSTRUCTION	**<u>CORE INITIATIVES</u>** **NEW BUILDINGS & MAJOR RENOVATIONS** **INITIAL PURCHASE & END OF USEFUL LIFE**
	First, the PAs will continue to closely monitor developments in Massachusetts with the DCAMM/DOER ZNE Advisory Council and Working Group, as well as in other states, like New York, which have recently evaluated ZNE pilots and may sponsor further building science/NZE research and demonstration projects going forward. Second, the PAs will assess opportunities for joint NZE R&D efforts with other jurisdictions or program administrators, particularly where Massachusetts participation can be used to leverage additional resources from these entities, or in government research investments. Lastly, for the prospective owner or a developer who wishes to take up the Net Zero challenge, the PAs will continue to provide, as they have historically, technical and modeling assistance and incentives for all the efficiency measures towards Net Zero Ready that are cost-effective through the Whole Building Path of the New Construction Program. This path is explicitly designed for the purpose of promoting high performance buildings with lower energy use intensities ("EUIs") and ongoing operational costs than code compliant buildings. Indeed, the PAs view a Net Zero Ready ("NZR") Building as the ultimate expression of this path – driving the energy use intensity of the building to the lowest practical and cost-effective level before considering renewables. This concept of "rightsizing" the building is very similar to the efficiency services proved by the PAs for facilities considering CHP, because energy efficiency measures will always cost the customer less than another increment of generation capacity. The PAs will also help customers with the necessary coordination with the Clean Energy Center in order to qualify for renewables incentives and inform them of the interconnection process to move the final step to Net Zero. It is important to consider NZE efforts within the perspective of overall efforts of the PAs to reduce energy consumption and greenhouse gas emissions. The actual number of market-based and cost-effective non-residential Net Zero buildings constructed in the Commonwealth over the coming three years is likely to be exceedingly small, and those that are undertaken are likely to be quite modest in size, if historic patterns persist.[32] However a larger cohort may be interested in pursuing

[32] A recent national survey of Net Zero buildings by the New Buildings Institute found a total of 39 Net Zero buildings have been verified since 2000; 14 of these are in temperate climate zones in California. Thirty-two are less than 25,000 square feet. It appears that only 6 are private sector buildings; the

C&I NEW CONSTRUCTION	**<u>CORE INITIATIVES</u>** **NEW BUILDINGS & MAJOR RENOVATIONS** **INITIAL PURCHASE & END OF USEFUL LIFE**
	Near Net Zero, or highly efficient, status. The overall goal of the PAs in this arena is to establish a basis of technical knowledge and expertise, and develop a framework for program support, for projects that wish to aspire to a ranking anywhere along the NZE continuum. <u>Expanding Upstream Offerings</u> The upstream delivery model leverages existing distributor and manufacturer networks and infrastructure to influence the thousands of equipment purchasing decisions that customers and contractors make every day. To date, the PAs have offered an upstream approach for select lighting and HVAC products, with considerable success. As described in greater detail below, the PAs are researching other products that might fit the special set of unique circumstances that are required for an upstream approach to succeed. The PAs plan to add a variety of products to their overall upstream portfolio such as water heating equipment as well as a number of other equipment categories including boilers, furnaces, circulator pumps, some component motors in HVAC systems, and some commercial kitchen equipment. <u>Improved Comprehensiveness in Small/Midsized Buildings</u> All of the PAs have developed streamlined approaches to encourage comprehensiveness in smaller (<100,000 square feet) buildings where: (a) full-scale scenario modeling is often cost-prohibitive, and/or (b) where building systems are often less complex. It is important for the PAs to focus efforts on comprehensiveness on this segment of new construction as 95 percent of the US non-residential building stock is less than 50,000 square feet.[33] National Grid and Cape Light Compact use the Advanced Buildings ("AB") approach in this market. AB was designed by the New Building Institute ("NBI") as a comprehensive, prescriptive program for small commercial new construction in the 10,000–100,000 square foot range. Eversource has developed its own approach using engineering

remaining 33 are either public buildings or buildings in the non-profit/philanthropic/higher education sectors.

33 *Industry Research and Recommendations for Small Buildings and Small Portfolios*, Langner, et al, National Renewable Energy Laboratory and Huppert, et al, Preservation Green Lab, National Trust for Historic Preservation, December, 2013.

C&I NEW CONSTRUCTION	CORE INITIATIVES NEW BUILDINGS & MAJOR RENOVATIONS INITIAL PURCHASE & END OF USEFUL LIFE
	assumptions and an analysis approach that are very similar to those used by NBI. Under both models, the customer receives a set of recommendations that guides them to a more comprehensive approach to their building project without the necessity of a complex and often expensive modeling process. The gas PAs have adopted these models as well, which has reduced overall program administrative costs, due to the sharing of resources. In the future, the PAs plan to streamline these approaches and strive to adopt a single approach statewide. The PAs will increase their focus on the building types that are most amenable to this approach; specifically, small office, retail, public assembly, and school/preschool applications.[34] Sustainable Office Design National Grid and Eversource have introduced a new offering called Sustainable Office Design ("SOD") as a means of delivering integrated technical solutions to the leased commercial office market.[35] The goal is to capture the energy savings and demand reduction potential that becomes available in the period when office space is vacated by one tenant and refitted for occupancy by a new one (the tenant improvement, or TI, process) or when a new office building, constructed for tenant occupancy, is in the initial leasing phase (tenant fit-out). At least 20 percent of all energy used in commercial buildings is in office space and estimates show that the average commercial office building could reduce its energy use by 20 percent.[36] During the TI/fit-out process, the office space is typically vacant and decisions are made regarding lighting fixture selection and a design to fit the needs of the new occupants. This creates an opportunity to significantly influence energy and demand elements of a building, as well as enhance aesthetics of a space and increase the likelihood of higher levels of comfort and productivity for future occupants, in that unique

34 The economics of both approaches are based on buildings with central mechanical cooling systems.

35 The smaller PAs will consider adoption to the degree applicable once experience with the larger PA effort has produced results for consideration.

36 *Office Real Estate Value Proposition*, Northwest Energy Efficiency Alliance.

C&I NEW CONSTRUCTION	**CORE INITIATIVES** **NEW BUILDINGS & MAJOR RENOVATIONS** **INITIAL PURCHASE & END OF USEFUL LIFE**
	moment when both the tenant and owner are actively thinking about both the space and the financial considerations around it while the space is vacant and the parties already assume and accept some level of construction disruption in their planning. Owners typically have a set-aside for TI, which is negotiable based on market conditions, lease terms, or plans for general property improvements or market repositioning.[37] Tenants can contribute funding to the TI process as well, either in cash, increased rent, or longer lease terms, to ensure that the space is suitable for their needs. In other words, there is both a financial negotiation and space design process in play, which creates an opportunity to get deeper energy savings without the typical owner/tenant "split incentive issue" dominating the financial discussion and with minimal construction-related disruption to the occupants. The SOD offering provides enhanced services to building owners and prospective tenants, aligning on the market-based TI/initial fit-up opportunity. SOD provides both technical assistance and incentives designed to motivate the parties to think beyond simple lamp and ballast replacements to consider function-based integrated lighting and controls solutions, designed for the specific proposed occupancy activity. This approach offers a predictable incentive at $1.00 per square foot of leased space (net of common areas) for qualifying light fixtures and controls projects, with a guaranteed fast-track timeline for application review and approval. SOD combines aspects of the prescriptive and performance lighting options to promote thoughtful, innovative, and controls-rich lighting designs. The effective lighting power density ("LPD") of SOD qualifying projects will be significantly below code requirements, which can make important contributions toward obtaining critical LEED energy credits and Energy Star® certification. Key elements of SOD include: • Lighting solutions that emphasize efficiency and occupant comfort and productivity; • Low Lighting Power Density;

[37] According to a GSA survey, allowances can range from $2/SF for paint only to $50/SF for extensive TI.

C&I NEW CONSTRUCTION	**<u>CORE INITIATIVES</u>** **NEW BUILDINGS & MAJOR RENOVATIONS** **INITIAL PURCHASE & END OF USEFUL LIFE**
	• Exceptional lighting energy savings (>2 kWh/square foot, on average); • Thoughtful, integrated application of lighting controls (*i.e.*, programmable sweep, tuning, vacancy, etc.); and • Daylight harvesting, where possible.
Program Design	**Participation Options** The New Construction program has multiple participation options, depending both on where the building is in its construction or renovation schedule and the owner's investment criteria and goals for the project. Assistance can range from simple plan review and efficiency upgrade recommendations to complete technical assistance studies performed by leading energy engineering firms.  • *The Whole Building Approach* allows the customer, the design team, and program-supported experts to work together from the conceptual design stage of a new construction or substantial renovation project to consider holistic design and equipment options that will improve the overall efficiency of an entire building and its operating systems. This path is explicitly designed for the purpose of promoting high performance buildings with lower energy use intensities and ongoing operational costs than code compliant buildings. Under this path customers can elect to pursue cost-effective options that drive the energy use intensity of their building to the lowest practical level

C&I NEW CONSTRUCTION	<u>**CORE INITIATIVES**</u> **NEW BUILDINGS & MAJOR RENOVATIONS** **INITIAL PURCHASE & END OF USEFUL LIFE**
	possible – including going all the way to a NZR building. Eligible customers may take advantage of both program-sponsored technical assistance to help define and quantify cost efficiency options, as well as reimbursement to the customer's own design team for additional design work or analysis necessary to accommodate program recommendations. The customer's financial incentive is calculated to help offset increased design interaction and potential costs of construction and is awarded based on an analysis of the entire project design and the interrelationship between the various building energy-consuming systems. In order to encourage such a comprehensive approach, incentives are usually calculated at a significant percentage of incremental cost. The Whole Building Approach provides technical support and incentives which allow building owners and their design teams to aggressively pursue high efficiency options that fully integrate building envelope, lighting and mechanical systems to produce a building that is as efficient as current technology and design techniques allow. The combination of technical consultation and incentives provided by the program will cover a significant portion of the additional design, modeling, and equipment costs required to turn an average building into an exemplary one. • *The Systems Approach* focuses on one or two aspects of a building's energy systems during new construction, a remodel, or a change in space use. Program experts encourage customers to think broadly as systems are frequently interrelated and may be more economical to install when walls and ceilings are open or down, or large equipment is being installed. Customers who select the Systems Approach will receive Prescriptive incentives for each measure for which one exists, or Custom incentives for site or use-specific measures. • The *Custom* path is designed to facilitate creative and deeper energy savings in systems of a new construction or major renovation project. Custom projects rely on engineering calculations to estimate energy savings and evaluate whether or not a project is cost effective and, as a result, eligible for financial incentives. The custom path is designed to encourage non-standard energy efficiency measures and allows customers to request a technical assessment of measures of their own choosing that are not on the prescriptive list. This option allows for a

C&I NEW CONSTRUCTION	CORE INITIATIVES NEW BUILDINGS & MAJOR RENOVATIONS INITIAL PURCHASE & END OF USEFUL LIFE
	more comprehensive and creative consideration of projects that are more complex than the prescriptive option allows, but involve less than a whole building design. It also encourages and rewards customer initiative and creativity. Often the savings generated by these measures are site and end use-specific, and thus a detailed analysis is required to qualify them for incentives. Project viability, eligibility and incentives are assessed on a case-by-case basis, and are determined by a technical study, which details energy and demand savings, and project costs. The study is conducted according to program specified procedures and is subject to review and approval by PA technical staff. The baseline standard practice against which each proposal is judged is determined on a case-by-case basis, using such resources as: current baseline studies and other market research, program experience with similar projects, as well as utility or public program experience from other comparable jurisdictions. The measures eligible for the custom path include, but are not limited to, lighting and lighting systems, HVAC systems, water heating, motor systems, building envelope and refrigeration measures, and a variety of industrial process end uses. Incentives are related to a number of site or use-specific variables, total project costs, and associated savings. • The *Prescriptive* path is a standardized, streamlined approach for energy efficiency incentive delivery. It allows customers to choose equipment from a prequalified list of measures and receive an incentive that covers a significant percentage of incremental cost (adjusted for consideration of market barriers, baseline construction practices and market transformation objectives). This path is designed for customers who have projects that are beyond the design phase, and perhaps are in actual construction, and can include new construction, renovation, remodeling, and equipment replacement projects. Prescriptive measures are available for those technologies for which energy savings can be predicted with reasonable accuracy across all applications (as compared to counterpart technologies of lesser efficiency). These technologies include: lighting equipment and controls, unitary HVAC equipment, water heating equipment, chillers, motors, and variable speed drives, as well as food service equipment. This path often serves as the customer's initial exposure to the program and, following an initial experience, customers may choose the more sophisticated comprehensive or custom paths for subsequent projects.

C&I NEW CONSTRUCTION	CORE INITIATIVES NEW BUILDINGS & MAJOR RENOVATIONS INITIAL PURCHASE & END OF USEFUL LIFE
	Component and Ancillary Services Technical Assistance ("TA") Services Providing high-quality, independent technical advisory services to customers and their design teams in a timely manner is essential to achieving comprehensive savings in new construction as well as system-based savings in industrial or process-related projects or in discrete building systems such as HVAC or lighting. In this market, time is money, and any perception that program participation will cause delay is a deal-breaker. TA Services provides technical support, and a technical support services provider, that is matched to the specific requirements of each project and the needs of each design team. Service can range from comprehensive and detailed energy modeling of the performance of an entire proposed building, using various configurations of design and equipment, to targeted studies and recommendations for specific building components or systems, or specialized technical studies, such as proposed industrial process improvements and compressed air projects. In general, study proposals are referred to TA consultants who have been pre-screened by the PAs. TA consultants are assigned to a project based on an assessment of their expertise and experience with the technologies under consideration. It is vital to program credibility that the customer has confidence that the TA provider assigned to their project is truly an expert whose recommendations will add value (and, conversely, will not introduce risk and delay) to their project. Customers can also elect to use a TA provider of their own choosing, subject to the co-funding PA's approval of the firm's qualifications and cost estimate. Non-preferred vendors must comply with the same level of detail and quality in their TA studies as pre-screened vendors. In many instances, customers have both gas and electric equipment options that require analysis. In these cases the gas and electric PA will co-fund the TA studies, and gas and electric program staff will work as a team to implement the recommendations. Performance Lighting The PAs promote high performance lighting technologies and design

C&I NEW CONSTRUCTION	CORE INITIATIVES NEW BUILDINGS & MAJOR RENOVATIONS INITIAL PURCHASE & END OF USEFUL LIFE
	practices that are either more efficient than standard practice and/or the requirements of the Massachusetts Building Energy Code through incentives for better lighting design. The Performance Lighting option promotes the thoughtful combinations of energy efficient lighting fixtures and lighting controls in site-specific lighting designs that produce quality lighting using lower watts per square foot than the current code. By encouraging, and rewarding, the market to move away from simple prescriptive incentives that reward customers for simply substituting one piece of hardware for another the PAs hope to shift the focus to using more efficient equipment (with controls) within the context of a more thoughtful and efficient lighting design that actually utilizes the full potential of the technology to achieve lighting that reflects the functional requirements of occupants in their workspaces. Thus, Performance Lighting is both a resource acquisition and a market transformation initiative. Building Energy Codes and Appliance Standards Incorporating high levels of efficiency in buildings during design and construction is the least expensive and most practical and equitable way to achieve broad scale energy efficiency in the built environment. The PAs will continue to focus on both advancing adoption of progressive energy codes, including voluntary stretch codes, and improving levels of compliance with these codes in new construction and major rehabilitation, through training and technical assistance. Sound energy codes are practical and cost-effective because the additional time and expense to produce an efficient building design, and to specify efficient equipment for it, is negligible when compared to the cost and inconvenience of retrofitting an inefficient building once it is in place. Also, most of the fundamental design decisions that dictate a building's efficiency are irreversible, and the costs of a non-code compliant building can burden future owners throughout the life of the structure. Strong energy codes that are uniformly enforced are also equitable because they establish a high standard for all construction. In a competitive building market, particularly when space is designed for a speculative building for tenant occupancy, efficient design and specification of efficient equipment can take a back seat to first cost, and default to code minimum requirements. Value engineering can also squeeze out efficiency options that may reward over time, but have a

C&I NEW CONSTRUCTION	<u>CORE INITIATIVES</u> NEW BUILDINGS & MAJOR RENOVATIONS INITIAL PURCHASE & END OF USEFUL LIFE
	higher first cost. A progressive energy code ensures that at least the floor requirements for efficiency are high. It should be noted that PA programs also indirectly support code advancements. The programs serve to introduce new technologies into the marketplace and lower their cost through volume sales. The PAs also help introduce the building design community and specifiers to new technologies and, by endorsing and incentivizing them, instill confidence that they are reliable and actually save energy. Education and incentives bring about large-scale adoption and subsequently lower product incremental costs. When advanced technologies achieve broad market acceptance and become common practice, they can be codified and PA attention and incentives can be redirected to the next emerging technology. Massachusetts is considered a leading state for advanced energy codes, and a model for cooperation between PAs and government to improve code compliance in commercial and residential construction. However, recent baseline studies have shown that code compliance rates remain well below 100 percent in the Commonwealth. Efforts to improve compliance rates were increased in 2014 with the Energy Code Technical Support effort. The effort supports training for building code officials and for the building design and construction communities. It also offers circuit rider technical assistance to increase on-the-ground compliance to the code in actual underway building projects. The PAs organize and offer code training sessions throughout the state in partnership with the DOER and the Department of Public Safety, with the training directed to both design professionals and local code officials. In 2014, the program reached 174 percent of its target attendance goal and has received high marks with attendees in post-session evaluations. The PA supported circuit riders provide technical assistance to building design professionals on energy codes and energy efficient building design and best practices. They help interpret and explain code requirements and serve as liaisons between designers, builders, contractors and public code officials. By helping building industry professionals interpret and apply the code to the actual day to day projects they have in front of them, circuit riders help instill the understanding necessary to apply the requirements to the next project, when the circuit rider will not be there. Circuit riders cover the entire state and can provide on-call technical

C&I NEW CONSTRUCTION	<u>CORE INITIATIVES</u> NEW BUILDINGS & MAJOR RENOVATIONS INITIAL PURCHASE & END OF USEFUL LIFE
	assistance to project teams, as well as to local code officials. The PAs will continue to support DOER's efforts to encourage more Massachusetts cities and towns to adopt the stretch code, and provide education and training on compliance. In addition, the PAs plan to work with the DOER and other stakeholders to develop the technical and economic case for a variety of proposed state level appliance standards. In addition to progressive energy codes, well-targeted increased efficiency standards on widely used appliances represent a significant low-cost energy efficiency source for the Commonwealth, and for the citizens who occupy its buildings and use appliances sold in the state.
Delivery Mechanisms	The portfolio of program services and incentives to new building construction, renovation, and expansion market actors – owners, developers, architects, engineers, equipment specifiers – is marketed and delivered by PA staff and contractors. This includes account managers and, in the case of the larger PAs, dedicated new construction program professionals. Responsibilities include identifying and capturing construction leads, and then identifying and managing delivery of the mix of participation options and core and ancillary services that best fits the customer's business needs, project type, and development schedule. Products eligible for the upstream approach are marketed and delivered through a statewide network of equipment distributors, supply houses, and manufacturer's representatives. For the upstream delivery model to succeed, a special, and limited, set of special circumstances are required: (a) The premium equipment must be suited for either one-for-one replacement for a less efficient measure in a failed equipment scenario or in new construction; (b) the equipment purchase decision must be almost entirely driven by first cost, with no real amenity or reliability distinctions between the products; (c) the substitute premium equipment must be stocked and available at distributors at the time of the purchase decision; and (d) there must be no, or minimal, additional or unique installation requirements that distinguish it from the product for which it is substituted. That is, it must be "plug-and-play." The upstream model leverages existing distributor networks and infrastructure to influence the thousands of equipment purchasing decisions that customers and contractors make every day. Under the upstream model, the PAs provide incentives directly to distributors and

C&I NEW CONSTRUCTION	<u>CORE INITIATIVES</u> NEW BUILDINGS & MAJOR RENOVATIONS INITIAL PURCHASE & END OF USEFUL LIFE
	manufacturers rather than end users, with the end users benefiting from the significant reductions in retail product costs that this enables. The incentives are structured to entirely remove the price premium between conventional and premium products at the point of purchase, thereby placing premium product in direct competition with the conventional product on the basis of attributes of quality and efficiency alone – with the assumption that the purchaser will make the wise choice.
Marketing Overview	The target market for the New Construction program is all "time-dependent" gas and electric energy efficiency opportunities in the non-residential sector, which includes commercial, industrial, institutional, and governmental customers and their buildings. Time dependent opportunities exist when new buildings are being designed and constructed, and when existing ones are expanded, remodeled, or renovated. Time dependent opportunities are also available when existing equipment fails, and must be quickly replaced to restore the building to full functionality. In the new construction market key market actors include architects, engineers, equipment specifiers, manufacturers, distributors, suppliers, commissioning agents and the owners or developers of new buildings. In the replacement market key decision-makers include building owners or managers, facility staff, and equipment supply houses. The non-residential development process has a number of characteristics that make it difficult to influence from the outside. First and foremost, with the exception of government or institutional projects, or very large projects that require some form of planning body approval, most of the process occurs in an environment that is outside of public view. Decisions to develop particular buildings on particular sites, and subsequent agreements for financing, real estate purchase, design and construction services, and, ultimately, sale or rental are, after all, private business. The participants do not reveal that a development is even contemplated because they do not wish to alert potential competitors to their intentions or because there is simply no need or requirement to do so. Also, the process itself often does not proceed along a seamless continuum. Development can be an episodic process, with flurries of activity around securing permitting or financing for example, followed by periods of dormancy until the next hurdle is addressed. And with many hurdles, a significant number of projects never move from the conceptual

C&I NEW CONSTRUCTION	<u>CORE INITIATIVES</u> NEW BUILDINGS & MAJOR RENOVATIONS INITIAL PURCHASE & END OF USEFUL LIFE
	stage to actual completion, and from all the projects that are proposed, it is often difficult to determine which proposed projects will materialize, particularly at the earliest conceptual phase. Yet it is at the conceptual phase, when all plans are fluid that the greatest potential exists to influence the project in the direction of a comprehensive, holistic energy efficient design. When earth gets moved, the plans have long since been functionally complete and all attention is then and from that point forward on the projected completion and occupancy date. Millions of dollars have been borrowed and no revenue is generated to repay these loans until the tenants or owners move in. A change to incorporate efficiency, or any change for that matter, is perceived to mean delay, and delay costs money. Additionally, it is estimated that between 40 and 50 percent of small commercial buildings are built for tenant occupancy. This creates two very daunting barriers to the consideration of more efficient design or equipment. First, the typical lease model (the so-called “triple net” lease) flows all operating costs, including utility bills, through to the tenant. Sometimes this is accomplished through direct metering of the tenant premises as in a freestanding retail space. In other cases, there is a master meter with a pro-ration of costs to all tenants as in the case of a strip-mall or a small office building. In neither case does the tenant have the incentive to upgrade the landlord’s property except in the limited instances where the payback term is significantly less than the remaining life of the lease. Thus, lowest first cost often rules the day in the development process. If there is additional money to be spent on building systems, the developer and his design engineer will often invest it to oversize HVAC equipment and over-light spaces as a shield against future tenant complaints or litigation. A retrofit project typically involves a turn-key vendor selling a project specifically on efficiency attributes. By contrast, in the new construction market, products are specified in the design process, not sold. Among the market actors whose interests must be considered are: • Owner/occupants, who expect to be long term tenants in their own buildings, and therefore are more likely to be receptive to the concept of life-cycle costing and to longer payback measures, or to an “inspiring” design; • Larger architectural and engineering firms, who tend to design

C&I NEW CONSTRUCTION	**<u>CORE INITIATIVES</u>** **NEW BUILDINGS & MAJOR RENOVATIONS** **INITIAL PURCHASE & END OF USEFUL LIFE**
	from a library of "typical" building packages. Once their template design and equipment specifications are modified, they will be reapplied in numerous similar buildings in the future; • Leading design firms who tend to establish the new market standards that are then followed by more conventional firms; • Chain and franchise owners, who often use one design template, which can be varied according to site requirements, and who often use in-house architects and engineers; • Public sector owners, who often have regulatory requirements that include life-cycle costing and legislated goals for energy efficiency; • Environmentally conscious owners, who wish to promote their building as an extension of their corporate ethic; • Speculative developers to the extent they can be persuaded that a low-energy-cost building has a promotion value to attract tenants; • Equipment manufacturers and suppliers who need to be persuaded to stock energy efficient equipment so that it will be available to meet program-generated demand. Specific outreach strategies are designed for each of these groups, but for all, one-on-one communication is the primary approach that has produced results over time. Building relationships by partnering on an initial successful project and showing added value, leading-edge technical expertise and rapid response to the client's needs puts the program top-of-mind when the next project comes along. This direct marketing is facilitated and supplemented through other channels including brown bag educational seminars, formal training seminars and webinars particularly when they qualify for continuing education unit credits, case studies, open houses, etc. For time-dependent projects involving replacement of failed or end-of-life equipment, the PA's marketing efforts focus on customers and their facility managers and on equipment vendors, again using extensive one-on-one communications. This communication is supported by case studies and other promotional pieces, participation in a variety of trade shows and industry conferences, breakfast meetings, and other customer and vendor focused training seminars. The PAs continually engage with equipment distributors and installers to help them promote

C&I NEW CONSTRUCTION	**<u>CORE INITIATIVES</u>** **NEW BUILDINGS & MAJOR RENOVATIONS** **INITIAL PURCHASE & END OF USEFUL LIFE**
	energy-efficient equipment and systems to their customers and to explore innovative ways to work together to mutual advantage. With specific regard to the upstream delivery approaches, the existing distributor networks and infrastructure are leveraged to influence the thousands of equipment purchasing decisions that customers and contractors make every day. Under the upstream model, the PAs provide incentives directly to distributors and manufacturers rather than end users. The incentives are structured to entirely remove the price premium between conventional and premium products at the point of purchase, thereby placing premium product in direct competition with the conventional product on the basis of attributes of quality and efficiency alone, with the assumption that the purchaser will make the wise choice. Removing the price premium is critical because, without explicit direction to the contrary, equipment specifiers in new construction or renovation projects and building maintenance personnel when replacing failed equipment will usually select the lowest cost option that can fulfill code requirements. Similarly, the trades that compete on construction or equipment replacement work are under market pressure to offer the lowest cost bid. For lighting products, the target markets are: (a) electrical contractors ordering commercial lighting products or purchasing them over the counter; (b) facility managers ordering commercial lighting products or purchasing them over the counter; and (c) engineers and other specifiers who dictate commercial lighting product specifications in new construction. For HVAC products, delivery is primarily through the contractor network that replaces failed equipment in existing facilities and installs new equipment in construction projects.
Three-Year Deployment Strategy/Roadmap	For the 2016-2018 term, the program will concentrate on continuous improvement and refinement to core program elements and expansion of more customized services into relatively underserved markets such as the tenant fit-up/TI processes and deeper savings in small and medium building markets as described above. The PAs will examine market data to determine if additional segments can be identified that would benefit from discreet, targeted approaches such as the potential opportunity that

C&I NEW CONSTRUCTION	CORE INITIATIVES NEW BUILDINGS & MAJOR RENOVATIONS INITIAL PURCHASE & END OF USEFUL LIFE
	exists when hotels are either rebranded or "refreshed" to keep customer amenities current and competitive.[38] With the recession now largely behind us, forecasters are seeing tightening vacancy rates in the large commercial markets of Eastern Massachusetts. This means new construction starts, at least in the Eastern part of the state, will continue to accelerate, with a mix of both build-to-suit and speculative office space, as well as a growing laboratory/life sciences presence. [39] One recent respected study placed Metro Boston as the number nine (of 75) U.S. Markets to Watch for real estate development prospects.[40] The study advises investors to particularly focus on opportunities in the lodging, retail, and office markets, with an eye to the growing life sciences/laboratory market as well. National-level analysis ranks the strongest overall development prospects in warehousing and limited-service hotels. This forecast serves as a good guide to priorities for PA focus in the Commonwealth's largest commercial market area for the intermediate term. With regard to the upstream delivery model, the PAs have achieved considerable success with lighting and HVAC equipment. The PAs have, and will continue to, research additional products that might fit the special set of unique circumstances that are required for an upstream approach to succeed. In addition to water heating equipment, which will be offered during or before the start of this Plan term, potential candidates include: boilers, furnaces, circulator pumps, some component motors in HVAC systems, and some commercial kitchen equipment measures.

[38] National Grid in Rhode Island and Southern California Edison are engaged in a joint research project to better understand the hotel renovation/refreshment market dynamic, and the potential to present efficiency options to customers when they are about engage in a renovation/refreshment project.

b. C&I Retrofit: Existing Building Retrofit, Small Business, Multi-family Retrofit, Upstream Lighting

C&I RETROFIT	**<u>CORE INITIATIVES</u>** **EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING**
Overview & Key Objectives	The Retrofit Program consists of two sets of core initiatives. The first consists of Existing Building Retrofit, serving all non-residential customers, along with two additional specialized initiatives -- Small Business and Multi-family Retrofit – each of which serves specific subsets of non-residential customers. The second, Upstream Lighting, is primarily a marketing channel approach, but is presented here separately primarily for accounting purposes, as it has provided a large share of the commercial lighting savings in recent years, and is expected to continue doing so in the coming plan term. <u>Existing Building Retrofit</u> This broad core initiative promotes a menu of equipment incentives and technical services to encourage building owners to replace functioning, but outdated and inefficient equipment with premium efficiency counterparts. Because this program accounts for a significant share of C&I savings, the PAs continuously monitor its performance and refine delivery approaches, the product mix, and incentive levels to reflect changing market expectations and evolving technologies. As the program has matured and customers have become more aware of the variety of energy-saving investment opportunities available to them, the PAs have encouraged a transition away from episodic equipment-based retrofit events to engaging customers in a thoughtful series of building upgrades that move their property towards a "building renewal". Mature efficiency programs, those that have harvested the easiest and less expensive savings opportunities and have established trusted relationships with customers, are often characterized by a preponderance of more sophisticated custom projects and a lesser number of simpler prescriptive ones. The Massachusetts C&I Retrofit program fits this mature program profile. The program offers prescriptive incentives for widely-applicable electric and gas technologies, and a custom approach which focuses on unique opportunities that are customer, site, or process specific. Prescriptive incentives are offered for measures that provide predictable energy savings in virtually all applications where they replace a similar technology of lessor efficiency. These incentives are available for a long

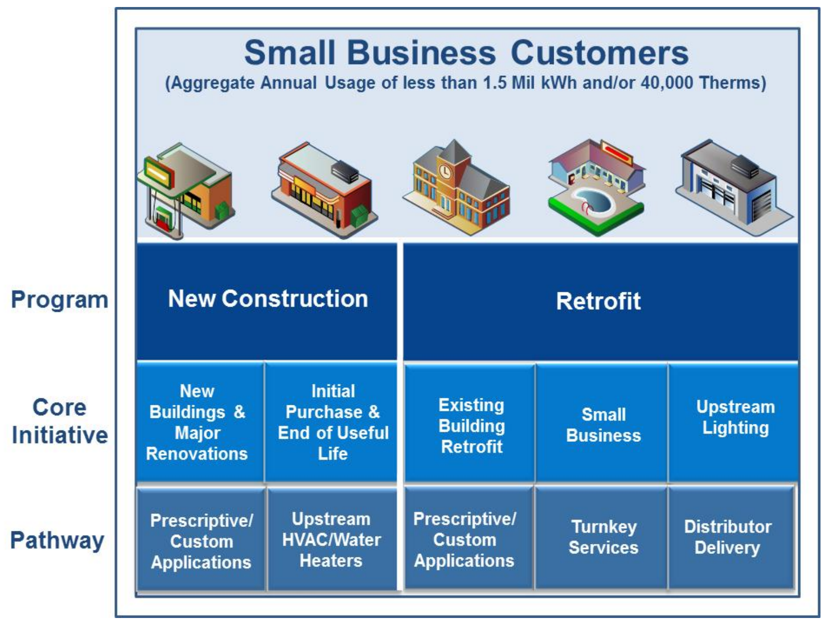
C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	list of electric and gas technologies such as lighting equipment and controls, HVAC controls, chillers, motors and drives, spray valves and steam traps, etc. This commodity-based path often serves as the customer's initial exposure to the program and may lead to more complex custom projects. To identify and quantify custom opportunities, the PAs provide customers with expert technical assistance, using both their own technical staff and subject matter experts drawn from a pool of prequalified expert private sector engineering consultants. To move customers to action once opportunities have been identified, the PAs offer financial incentives that are calibrated to match customer investment criteria. The overarching goal is to instill customer confidence in projections of project savings and the reliability of equipment performance, in order to make the financial investment attractive, and to provide a delivery process that makes the upgrade process as simple and seamless as possible. In addition to periodic equipment upgrades, the PAs offer a suite of ongoing services to business customers, including subsidized training for building operations and maintenance tasks and access to retro-commissioning ("RCx") services to ensure that energy-consuming equipment operates as designed, and that all low-cost/no-cost opportunities for energy and electrical demand savings are fully exploited. <u>Small Business</u> Small businesses[41] account for about 45 percent of the energy consumed in Massachusetts, but that potential for savings is scattered in small segments located in over 330,000 facilities scattered across every community in the Commonwealth. Moreover, small businesses have many well-documented barriers that impede their investment in efficiency: the landlord/tenant split incentive, lack of capital, short planning horizons, lack of awareness/expertise, perceived complexity of the technology and mistrust of savings claims, etc. Small Business customers can access any of the incentive and service options available to all C&I customers depending on their needs and

[41] The "Small Business" category also includes a majority of the non-profits and houses of worship in the Commonwealth. These entities can – and do – fully participate in all of the program offerings described under this heading.

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING

preferences. In addition, they have a unique ability to access the Small Business core initiative, which has features that are explicitly designed to address the unique barriers and limitations in this market.

Small business customers will continue to have full access to the custom and prescription offerings of both the New Construction program and Existing Building Retrofit Initiative. Small businesses also often access new technologies through the upstream channel for lighting, HVAC or water heating equipment. Thus, as the graphic below illustrates, the turnkey delivery model that underpins the Small Business core initiative should be seen as but one of the multiple means by which small business customers in the Commonwealth are supported by the PAs in their efforts to improve the efficiency and productivity of their buildings and businesses.



The Small Business core initiative was designed to specifically address each of the above mentioned barriers by offering a package of services – assessment, installation, incentives, financing, and repayment methods – that make it easy for a customer to say yes.[42] As noted elsewhere, this

[42] The Small Business core initiative is simply a subset of the Retrofit Program. In addition to this specialized service, Small business customers can also participate in the full range of other retrofit options, including custom electric and gas measures. In addition, small business customers can receive incentives to upgrade to the most efficient option when they replace furnaces, boilers, water heaters, kitchen equipment, etc.

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	Massachusetts delivery model has been widely imitated and is accepted as an industry best practice program delivery model for small business customers. Delivery to this market segment through this initiative will continue uninterrupted, with refinements identified through the program review process incorporated into delivery as soon as practical. There will be increased attention on streamlined services to micro-businesses and customized offerings to market sectors with unique business needs and measure opportunities. Multi-family Retrofit As described in greater detail in the Residential Section of this Plan, Section III.E, because multi-family buildings may contain residential and commercial metering and, as a result, technologies more associated with commercial buildings, services and incentives are also provided to this sector through the C&I Retrofit Program. However, as the beneficiaries of the Multi-Family Retrofit core initiative are primarily the residents of individual units, and the measures and services associated with this core initiative are primarily residential in nature, the PAs residential program managers have taken a leadership role in delivering the cross-sector Initiative. The MMI assures that cross-sector services are delivered seamlessly to customers, including services provided by commercial sector service providers. The commercial sector services are then attributed to commercial sector budgets and goals at each PA. These C&I measures may include: • HVAC high efficiency equipment upgrades and controls; • Variable speed drives, motors; • Chillers; • Air compressors; • Water heating equipment; • Energy management systems; • Building envelope measures; and • Custom measures.

C&I RETROFIT	<u>CORE INITIATIVES</u> EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	Target Market The potential market for the C&I Retrofit Program is the entire non-residential built market in the Commonwealth. In addition to typical commercial office buildings, this includes schools (K-12 and colleges and universities); public and institutional buildings and facilities (state and municipal buildings, water and wastewater facilities, hospitals, and a variety of not-for-profit enterprises); and industrial facilities (including factories, warehousing, agriculture, storage and processing, etc.), as well as common area spaces in multi-family buildings. For submarkets of special interest, beyond small business and multi-family, there are added participation services or features in addition to the core program offering.
	New Enhancements <u>Further Market Segmented Delivery</u> Market segmentation is the process of defining and subdividing the class of C&I customers into identifiable segments that have similar needs, wants, or usage and demand characteristics, who are likely to respond to similar program approaches and marketing or outreach messaging. The process is a means to an end for the PAs: to inform design and delivery of a mix of program offerings, with appropriately tailored outreach and delivery that will resonate with and match the expectations of customers in the targeted segment, and will motivate them to action. PA markets can be defined by business type (*e.g.*, health care, education, government, agriculture, industrial, hospitality, etc.), building type (*e.g.*, hospital, university, retail, hotel, factory, etc.), by geography, size (of energy use or demand), by ownership type, or any of a number of ways. The PAs segment their customers according to the unique mix of customers of each PA service territory. For example, National Grid has a large number of industrial customers, so the company has developed the organizational and technical capacity to serve industrial needs and investment horizons. It further subdivides manufacturing into process, fabrication, food and heavy industry in order to better target its services to the different needs of each of these sub-segments. Eversource has a heavier concentration of commercial real estate, and organizes its delivery to effectively serve that market. Likewise, Cape Light Compact has a large number of hospitality customers and thus is targeting segment-specific services to them.

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	The PAs continue to evolve customized approaches for these and other markets, making use of local EM&V studies, the experience of peer programs around the country, and data reported in studies and program evaluations from other jurisdictions. For example, the "Mid-Size Customer Needs Assessment"[43] which looked at a snapshot of customers in the 300-750 kW range in a single year found that these customers require more complex solutions than are customarily available through the Small Business core initiative alone, and yet may require different financial incentives and application requirements than they experience in the C&I Retrofit Program as a whole. That study was followed by the *2013 C&I Customer Profile Report* which looked at customer trends longitudinally. The study revealed that on average these customers comprised about 23 percent of both statewide electricity usage and statewide savings in 2012 and 2013. The PAs will continue to develop a more detailed understanding of the various sub-sectors contained within this mid-sized sector in order to develop marketing and delivery strategies that will resonate with customers who have similar energy use, business requirements, and investment criteria. This will also involve reviewing the definition of mid-sized customers across all PAs and develop more contractors who are trained in providing comprehensive solutions to this midmarket, including providing more comprehensive leads to the current pool of preferred trade ally contractors. An example of a specific submarket sector analysis is the profile of small and medium sized food stores conducted in 2014.[44] This study reported the results of interviews with key decision-makers in this market with the goal of providing more and better information about this customer segment to inform PA program design and delivery. The PAs plan to incorporate recommendations from this study during the 2016-18 Plan term. The chart below is illustrative of the energy using characteristics as well as the motivations and barriers with regard to efficiency investments experienced by key PA customer segments:

The above drivers, barriers and metrics are all taken into consideration, in conjunction with information about purchasing behavior and procurement practices, supply chain dynamics and past efficiency investment patterns when developing a customized strategic approach to serving these, or any other, segment of C&I customers. These factors underpin the PAs choices regarding a wide range of design and implementation elements such as product/technology offerings, incentive levels and structure, marketing and messaging mix, channel selection and engagement, staffing, etc.

Using this thoughtful, strategic, holistic approach to serving C&I customers can lead to considerable improvements in participation rates, comprehensiveness and depth of savings, and improved customer experience and associated satisfaction. The PAs, individually and/or

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	collectively have actively pursued, or are developing plans to pursue, such strategies targeted to a number of C&I customer segments including grocery, hotel, restaurant, local and state government, houses of worship, industrial, lodging, offices, tenants, and medium commercial customers in general. The chart below is illustrative of the market segmented approaches that have been and will continue to be deployed by the PAs or are in active development for deployment in the 2016-2018 Plan term.

Program Administrator	Segment	Why this Segment	New, Existing, Expansion of Existing, Extension of Existing?	Market Test or Full Deployme nt
Cape Light Compact	Grocery	Common measures, business model and barriers, can benefit from provision of industry expert technical assistance. Also, potential for economies of scale in marketing and delivery.	Expansion of existing test	Full

During the course of the Plan term, the PAs will continue to identify additional segments that may best lend themselves to these more targeted approaches.

Expand Strategic Energy Management

The concept of Strategic Energy Management ("SEM") is fluid and evolving, and can encompass a number of interconnected and mutually reinforcing activities. A common definition of SEM is that it is "a comprehensive set of business practices that establish energy management as a standard operating procedure."[45] While there are different variations in SEM programs, they all focus on business practice change - shifting how organizations get things done, improving their capacity to reduce energy waste, and reducing energy intensity throughout the entire organization.

Within the Massachusetts programs, activities that contribute to Strategic Energy Management include:

- Retro-commissioning;
- A variety of broadly-available and ongoing facility owner,

45 http://neea.org/docs/default-source/default-document-library/nw-industrial-sem-collaborative-overview.pdf?sfvrsn=2

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	manager, and operator training and education opportunities; and • Customized process and behavioral approaches within the broader context of a customer-specific MOU/Strategic Energy Management Plan ("SEMP") Over the 2016-2018 Plan term, the PAs plan to refine and expand these existing approaches, as well as examining methods to expand SEM to a broader market as the concept becomes a more familiar model in the business community. Additional areas to be explored to support and reinforce SEM activities include the use of benchmarking and the variety of proprietary tools known as remote or "virtual" or "no-touch" audits. Retro-commissioning ("RCx") The majority of buildings in Massachusetts are more than 30 years old, and many are much older.[46] Since being built, most have changed in occupancy and function. Also, over time, HVAC and electrical systems have become less efficient in operation, often because of outdated operational approaches, lack of maintenance, and changes to equipment that do not integrate well with existing systems. To address this inevitable process of degradation by building systems left unattended, the PAs offer an RCx service within the C&I Retrofit Program. RCx is defined as "the process of applying a rigorous testing, verification, and upgrade protocol to an existing building control system to identify and correct operational inefficiencies."[47] RCx can be coupled with a monitoring system which uses metering and software to provide ongoing energy performance feedback directly to building operators and/or the PAs. RCx that is facilitated by such a monitoring system is called monitoring based commissioning ("MBCx").[48] Generally, RCx consists of identifying (through an RCx study) a number of no-cost/low-cost maintenance or operational improvements that can, when systematically implemented in a facility, produce improved performance and energy savings without significant capital investment.[49]

46 National Grid's data indicates that almost a third of their building stock (31%) predates 1940.
47 *Retro-commissioning Best Practice Study*, Revised Draft for C&IMC Review, May 22, 2014.
48 Id.
49 As well as identifying promising capital measures that can be implemented through regular program channels.

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	Historically, delivery of RCx services in Massachusetts has been relatively expensive and persistence of savings has been low. For these reasons the PAs supported undertaking a best practice study to learn of improvements that could be made, based on the experiences of other program administrators. In 2013-2014, a joint team of PA technical staff and EEAC consultants conducted a "Retro-commissioning Best Practice Study." The study produced recommendations for consideration to revise the current structure of Massachusetts' programs. These recommendations were based on the design features and actual performance results of a number of industry leaders (primarily Pacific Gas and Electric, BC Hydro, and Commonwealth Edison). Based on the experience of the studied programs, the PAs expect that implementing many of the recommended modifications to current efforts will result in more savings through RCx in the Commonwealth and that savings persistence will increase. The final RCx report identified five "programs and elements that should be investigated for applicability in the Massachusetts existing building market." These were elements that were common to most of the leading RCx programs examined. The report also recognized that "(b)ecause there is an existing program being delivered, the process and timeline for program changes will need to be managed by the PAs to limit market disruptions." [50] The following summarizes the report recommendations around each of the five "elements", as rank ordered in the report, and planned PA actions in response: (1) "RCx provider gives on-going support through implementation and operation including: commissioning for measures implemented as a result of the RCx study; M&V; and building operator training." The PAs expect to implement these recommendations, commencing with new RCx projects. As noted in the Training discussion elsewhere in this section of the Plan, several programs in other regions have integrated the Building Operator Certification ("BOC") training into their retro-commissioning services offering, and the PAs will examine this

[50] Id. at 4.

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	experience to date for Massachusetts application. (2) "Savings estimates (are) developed by RCx providers using a consistent statewide set of approved tools; reviewed by program administrator and validated through M&V provided by RCx provider." The detailed recommendation in the Best Practices report was to explore adopting and/or adapting the suite of tools developed for the California Commissioning Collaborative, with the hope that using or revising these existing tools would be relatively less expensive than creating them anew for Massachusetts. However, this appears unlikely to be the case,[51] and the PAs will need to develop an alternative plan, which is expected to involve development of a proposal for a competitive procurement of services tailored to Massachusetts needs. (3) "Control costs of RCx study with an in-house budgeting tool and a joint scoping exercise with the customer, PA, RCx provider and controls contractor." The PAs exercise many of these controls now, but expect to implement all of those suggested in the Best Practices study. RCx contractors will work under contract to the PAs, so scope of work and budget will be directly manageable. The PAs will either develop an in-house budgeting tool or investigate the possibility of purchasing and adapting a proven existing tool from another program administrator. (4) "Aggressive screening of potential participants to reduce risk, combined with up front incentives covering study cost." The PAs are implementing the former already, and will test application of the latter before making a full implementation decision. (5) "Energy Management Information System ("EMIS")/interval meters directly funded by PA. Ongoing support to assure savings and measure persistence." The PAs recognize that maintaining the outcomes of the RCx process over time is critical to cost-effectiveness, customer confidence, and

51 The estimate provided to the PAs by the firm which maintains the California Commissioning Collaborative materials and website on behalf of the cooperating utilities was in the range of $250,000.

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	achieving verifiable savings throughout the projected measure lives for the actions taken. The PAs plan to develop a methodology for integrated delivery of RCx services and post-service follow-up and follow-through that addresses the issue of maintaining persistence of savings. In addition to the Best Practices study, the PAs reviewed a very similar study conducted by E Source during the same time period. The study was even more comprehensive, looking at a total of 15 RCx programs. E Source reached very similar conclusions and recommendations regarding best practices, to: "(1) offer generous study incentives; (2) get commitments from customers; (3) cultivate qualified commissioning providers; (4) keep program messaging simple; and (5) expand the participant universe."[52] Since both studies were issued, the PAs have engaged in RCx market tests that are consistent with their findings. For example, some of the PAs are now delivering a consistent experimental RCx approach to the hospital segment, applying many of the recommendations of the study. The enrollment eligibility period for this test was the first half of 2015. Any hospital of 100,000 square feet or greater using at least 2,000,000 kWh or 150,000 therms per year and equipped with a DDC Energy Management System was eligible, provided that the facility also: (a) had access to sufficient funding to implement agreed RCx measures within 12 months; and (b) had an internal "champion" who could ensure timely decision making and access to needed systems and data. These PAs provided no-cost engineering resources (capped at a value of $5,000 per site) from a PA selected and pre-approved Technical Assessment ("TA") vendor to perform scoping studies to identify and analyze potential energy savings from RCx measures. The PAs also agreed to pay incentives based on annual energy savings at the rate of $0.12 per kWh and $1.20 per therm with scoping studies required to be completed between January 1 and June 30, 2015. Uptake thus far has been relatively modest and the PAs are discussing possible modifications or alternatives to this approach. In addition, National Grid is testing three different turnkey RCx services provided by three different companies. One firm is targeting medium and large buildings using whole building and system level analytics that

52 *Retro-commissioning Programs, Five Tips for Boosting Participation*, E Source Focus Report, Merson, et al, December 9, 2013.

C&I RETROFIT	**<u>CORE INITIATIVES</u>** **EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING**
	enables targeting and implementation; one is targeting small and medium buildings using whole building level analytics and training building operators (this test has behavioral aspects); and one is targeting medium and large buildings using whole building level analytics and trade ally expertise. The Company is examining additional options with other firms, but will await initial results from the first three tests. The PAs are also testing an "RCx lite" concept, targeting smaller buildings and the firms that currently provide EMS services to these buildings. The objectives were to: (a) reach a smaller set of buildings with a streamlined set of high-value services that could be delivered cost-effectively; and (b) attempt to expose smaller, traditional EMS firms to a potential new line of service offerings – a potential market expansion/market transformation exercise. National Grid found many of these providers were reluctant to step out of their traditional business models, and that many of their systems had operational or functional limitations that inhibited their value for even limited RCx applications. <u>Education and Training for Customers, Trade Allies, and PA Staff and Contractors</u> *<u>Customer Education</u>* Every year the PAs sponsor and participate in hundreds of training or educational events around the Commonwealth to reach and influence all the parties who own, manage, or operate and staff buildings in Massachusetts. Some of these events provide customers with a broad exposure to a number of energy-savings technologies and service providers, such as the annual PA-sponsored Vendor Open Houses, while others are more focused and specialized, such as presentations to meetings of the local ASHRAE and IES chapters. The following are examples of local organizations with which the PAs have regularly partnered and collaborated in the past, and expect to continue to do so in the future, to deliver educational and training content that fits the unique energy concerns of their members and constituents: • Advanced Manufacturing Collaborative ("AMC") • American Society of Heating, Refrigerating, and Air-Conditioning Engineers ("ASHRAE")

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	• Association of Energy Engineers ("AEE") • BOMA – Boston, the Greater Boston Real Estate Board • Boston Green Ribbon Commission • Boston Green Tourism • Boston Society of Architects ("AIA") • Boston Redevelopment Authority • Illuminating Engineering Society ("IES"), Boston and Rhode Island Section • International Facility Management Association ("IFMA"), Boston Chapter • Massachusetts Clean Energy Center ("CEC") • Massachusetts Lodging Association • Massachusetts Restaurant Association • Municipal Solid-State Street Lighting Consortium ("MSSLC") • Northeast Sustainable Energy Association • U.S. Green Building Council ("USGBC"), Massachusetts Chapter At the local level, the PAs give countless program presentations – both general and specific to specialized audiences. For example, in a given year, Cape Light Compact: • Strives to make at least one general C&I program presentation each month, with the goal of reaching every town or regional chamber on Cape Cod each year; • Makes specialized segment-relevant presentations at both the Cape Code Chamber and at the Martha's Vineyard Chamber; • Makes one or two presentations at the Lower Cape Community Development Partnership as part of their Cape & Islands Green classes for Cape Cod businesses; • Presents periodically to town Energy Committees, as well as to Boards of Selectmen, and in particular when rolling out Three-Year Plans or other new initiatives;

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	• Presents at the annual Massachusetts Facilities Managers when it takes place on the Cape; and • Has a booth at Cape and Plymouth Business Connect trade show; and at many other regional events, trade shows and town meetings, where program staff have the opportunity to interact with local officials, business owners and employees, as well as residential ratepayers. The CLC listing is offered as an illustrative example -- a full composite list of all PA activity would be too voluminous for this document. However, just like CLC, each of the PAs is constantly on the lookout for opportunities to reach potential new business program participants, or remind past participants that there are always new options for participation, so each maintains a presentation or public speaking schedule that is similar to CLC's. *Vendor, Trade Ally, External Energy Professional and PA Staff Training* The PAs offer regular specialized training sessions for all their trade allies, other energy professionals who support or participate in the programs, and for their own program and technical staff as well. For example, over the course of the current Three-Year Plan, National Grid has held dozens of such sessions, with a total attendance of over 3,200 individuals. Common formats include webinars and live presentations at multiple sites around the service territory. Subjects have included: • Trade Ally & PA Staff Sales Training (by EEFG/Mark Jewell); • Changing technology and Energy Efficiency in Data Centers; • Laboratory safety and EE can work together to reduce cost; • Changing opportunities in exterior lighting as technology rapidly advances; • CHP opportunities and advances; • High Efficiency water heating solutions; • Impact of steam system O&M on energy expense and often overlooked EE opportunities; • Advances in lighting control technology; • New accelerated pre-inspection service;

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	• Energy Management Systems as a tool to improve building environment; • Hospitality industry efficiency day event; • Often overlooked opportunities to save energy in C&I heating systems; • Commercial leased space rapid project turnaround – advanced lighting system and technology incentives; • VFD opportunities on HVAC systems; • Introduction to scope of New Construction services; • Introduction to National Grid energy saving solutions and incentives; and • National Grid Customer & Partner Summit. Similarly, the gas PAs, using a contractor retained through GasNetworks®, conducted 79 training events, often technology-specific and co-hosted by a vendor/trade ally and located at their site. *End Use-Specific Training* In addition, the PAs offer very specialized training to the operators of commercial facilities and specialized industrial equipment. Like any complex machine, a commercial building, or wastewater plant, or a compressed air system, requires constant regular attention to run well and serve the needs of its owners and the occupants or users that rely on them every day. According to E Source, "providing trade allies and contractors with training and certifications can serve as a powerful marketing and outreach tool, and help ensure program standards are met."[53] Examples of specific PA-sponsored targeted training, each of which has been a long-standing component of the PA menu of service offerings, include those listed below. Each offering is regularly updated and refreshed by their sponsoring organizations to meet the needs of a changing workforce and updates to technology.

[53] *Best and Emerging Practices and Technologies in Energy Efficiency Program Delivery: Phase One Findings*, Memo to the Massachusetts Program Administrators, March 20, 2015.

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	• *Building Operator Certification* ("BOC") is a nationally recognized, competency-based training and certification program.[54] It is designed to give facility staff practical skills and knowledge that they can apply to make their buildings more comfortable, energy-efficient, and environmentally friendly. BOC credentials are recognized by employers across the country. BOC courses are delivered throughout New England using locally-based instructors approved by the parent organization.[55] Building operators earn certification by attending training classes on a variety of topics, including electrical lighting systems, HVAC, indoor air quality, sustainability, and energy efficiency. Classroom instruction is combined with required hands-on projects in the students' own facilities, making the experience more relevant and practical. There are two sequential certifications: BOC Level I and Level II. The Level I course series offers eight one-day classes and Level II offers seven one-day classes. In most cases, the sponsoring PA has one class day to brief participants on the features, requirements, and procedures of the energy efficiency programs and services specific to their area. Both series include classroom training and project assignments to be completed at the participant's facility. The PAs actively recruit BOC participants and some provide partial tuition reimbursement upon course completion and certification. In many instances PAs provide an additional incentive for submitting a proposed energy efficiency project within a year of certification. The PAs work with the national sponsoring organization, the Northwest Energy Efficiency Council ("NEEC"), to continually update BOC training and materials to ensure that they are relevant to local Massachusetts conditions and also incorporate the latest advancements in the industry. In addition, the national BOC administrator conducts an annual curriculum review to ensure that all materials reflect the latest technologies and practice innovations. In recent years NEEC has made significant updates to the Level I and II. In 2013, almost 40 percent of the content was updated or replaced. The new content focuses on low-cost opportunities to

54 http://www.theboc.info/index.html

55 http://www.theboc.info/

C&I RETROFIT	**CORE INITIATIVES** **EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING**
	improve energy performance, building scoping and tune up, retro-commissioning, high performance HVAC systems, energy diagnostics using data loggers and BAS, selling efficiency projects, occupant engagement, and water conservation.[56] Additional new products include: • A six-part continuing education webinar series to help BOC operators maintain their certification. Maintenance of certification (MOC) increases persistence of BOC savings based on third party impact evaluations; • One day MOC events provided in partnership with sponsoring utilities for BOC certified operators in their service areas; and • A blended, online Level I course offering a mix of classroom and online training to earn the BOC Level I credential. NEEC has also developed sector-focused BOC collateral which targets commercial offices and is preparing collateral targeting the Healthcare sector. Several utility sponsors in other regions have fully integrated BOC with core programs such as retro-commissioning and SEM, and the PAs will examine those options as well. BOC was the subject of a very recent evaluation in Massachusetts.[57] The evaluation suggests that the PAs can best promote BOC enrollment and increase the savings attributable to BOC by: • Employing multiple channels to promote BOC - e-blasts to eligible customers, direct outreach by account executives promotion of BOC at trade events, etc. • Working with NEEC to ensure that the program collateral, website, and registration systems serving the Northeast are clear to prospective Massachusetts participants. • Crafting messaging that conveys the value proposition of

56 Detailed curriculum outlines are at: http://www.theboc.info/h-course-descriptions.html.

57 *Comprehensive Review of Non-Residential Training and Education Programs, with a Focus on Building Operator Certification*, Prepared for the Massachusetts Program Administrators and the Energy Efficiency Advisory Council, Navigant Consulting, June 19, 2015.

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	certification and maintenance of certification to high-level managers, who must authorize staff training. The value proposition should include that energy savings will offset the training cost and that additional benefits accrue as well, such as reduced emergency failures and more effective use of maintenance contractors, and these benefits are documented in BOC evaluations, • Promoting and explaining to participants the benefits of all the other energy efficiency programs offered by the PAs.[58] The findings also suggest that the level of effort put into promoting BOC affects training uptake.[59] Some PA sponsors currently provide tuition reimbursement upon course completion and certification. In other instances the PAs provide an additional incentive for submitting a proposed energy efficiency project within a year of certification. The PAs will be guided by the above findings and recommendations when sponsoring BOC or its derivative options over the next three years. • *Compressed Air Challenge* training has also been offered by the PAs for a number of years. The Compressed Air Challenge is a voluntary collaboration of industrial users, manufacturers, distributors and their associations, consultants, state research and development agencies, energy efficiency organizations, and utilities.[60] Training is led by subject matter experts who provide facility managers with strategies for proper configuration of a compressed air system, system operation, maintenance requirements, and user accountability. Instructors also help participants develop a compressed air system management action plan for the unique processes in their home plant. CAC regularly updates its Best Practices for Compressed Air Systems manual, and its Level 2 Revision Working Group is finalizing a next phase of revisions to the Advanced Management of Compressed Air Systems training. Also, its New Training Working Group continues work on a new one-day "strategies"

58 Sponsoring PAs currently use one class day to brief participants on the features, requirements, and procedures of the energy efficiency programs and services specific to their area.

C&I RETROFIT	**<u>CORE INITIATIVES</u>** **EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING**
	course. Two Massachusetts PAs, Eversource and National Grid, sit on the CAC Board of Directors, so Massachusetts experience with the program, and expectations for the future, are integrated into this planning. • *Water/Wastewater Plant Operator Training:* Every year since 2010 the PAs have partnered with the nationally-known experts in water and wastewater at the University of Wisconsin – Madison to deliver annually-updated best practices training for water and wastewater plant operators, tailored to the needs and conditions of the Commonwealth. The course combines engineering principles, best practices, case studies, and current technologies to help plant personnel manage their energy budget and improve energy efficiencies in water and wastewater treatment plants and pumping systems. The curriculum for this training is tailored to Massachusetts self-identified needs, as reflected in past participant evaluations and through direct communications between the PAs and the UW faculty. In turn, UW brings its expertise to the table, suggesting content revisions to reflect the latest technologies and techniques they encounter in their research and practice. • *Building Owners and Managers Association High-Performance Sustainable Building Principles:* BOMA has recently launched this new course, which provides a comprehensive treatment of high-performance sustainable buildings and exposes learners to the critical components of sustainability – "where building systems and the ecosystem intersect."[61] The course is taught both on-line and in a classroom setting and covers such issues as identifying and overcoming the hurdles to achieving true high-performance, attaining full organizational buy-in for sustainable building initiatives, resource management concepts, benchmarking value and standards for design review, integrated systems and commissioning concepts (HVAC, lighting, and electrical), water and wastewater system considerations, renovation and tenant improvement guidelines, sustainable contracting and vendor management principles (maintenance and purchasing), finance/portfolio considerations, etc. The course has not yet been offered in the Northeast, and the PAs have contacted

[61] http://www.bomi.org/Courses/High-Performance-Sustainable-Building-Principles

C&I RETROFIT	**CORE INITIATIVES** **EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING**
	BOMA to explore development of a partnership to do so in 2016 and beyond. • *California Advanced Lighting Controls Training Program* ("CALCTP"): was developed by Southern California Edison and has now been adopted by all the California utilities, as well as program administrators in other jurisdictions. CALCTP provides electrical contractors and electricians with training and a certification in Advanced Lighting Controls (ALC). The curriculum covers the proper programming, testing, installation, commissioning and maintenance of advanced lighting control systems, including dimmers, occupancy sensors, photo-sensors, relay modules and communication-based control devices. CALCTP graduates receive certification that permits them to work on ALC projects, which are then eligible for incentive programs. • *Site-Based Facility Management Initiative:* The PAs are exploring development of an on-site facility tune-up and operator training concept. The idea would be to work with a facility's on site staff and existing equipment and maintenance support contractors to identify opportunities for low-cost/no-cost system improvements, undertake those improvements, and then follow up at intervals to ensure that enhancements do not degrade and that facility staff continue to implement identified operational improvement procedures. *Memoranda of Understanding/Strategic Energy Management Planning - Based Training* Some PAs offer MOUs or SEMPs, which contain behavioral and process improvement components, with incentives awarded for verifiable reductions in energy use that can be attributed to each action. Each agreement is customer-specific and structured through an exchange of ideas between the PA and customer staff. It is dependent on the nature of each of the customer's facilities and the demographics of their users/occupants. For example, the operational improvement opportunities and the customer tolerance for deviation from the current operational norms are very different between a university and a critical care hospital. Similarly, the "customers" of these buildings – students and faculty in the former and medical staff and patients in the latter – will likely respond differently to the behavioral strategies and prompts. Submetering will

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	always be incorporated into these agreements when, in the judgment of the principals, it will help identify and prioritize opportunities at the outset of the relationship and it will lead to customer action. Submetering will also be offered to other customers when, in the judgment of the PA, it can be cost-justified because it will help identify and prioritize opportunities and it will lead to customer action. In addition, submetering is integral to the EM&V process, particularly when attribution and verification of behavior-based savings must be established. When considering expanding SEM efforts, much as with retro-commissioning, it will be critical for the success of recruitment efforts to understand what individual customer characteristics or categories of customers can be identified that will identify them as those who are most likely to see a value proposition in SEM. As the PAs consider SEM expansion opportunities (both in number and in kind) they will integrate the growing body of knowledge from their own local MOU/SEMP experiences and engage with SEM early adopter jurisdictions and their allies (such as the Pacific Northwest and the Northwest Industrial Strategic Energy Management Collaborative[62]), and incorporate the results of their research activities and field experience.[63] *Increased Use of Interactive and Web-Based Learning* Training in the energy efficiency domain, as in society at large, has moved more and more into the mode of distance learning. The advantages for participants are obvious: convenience and flexibility as well as avoided travel and time away from the facility. For the PA's distance learning can more effectively reach busy facility operators and allows for creation of niche-specific training modules that would be too expensive to deliver to a limited audience in the conventional classroom /instructor model. During the last Plan term the PAs moved aggressively into multiple new modes of education and training. During the 2016-2018 Plan term the PAs will investigate and implement even more distance learning training techniques – from scheduled webinars to on-demand materials that can be archived and accessed online.

	As a part of the planned Mass Save® website upgrade, a calendar feature will be added that shows all scheduled trainings, and provides contact information to register or participate. Small Business Core Initiative The Small Business Core Initiative, often referred to as the direct install or turnkey program, is a long-standing PA offering, and one of the most successful in the nation, with very high rates of customer uptake and satisfaction.[64] In Massachusetts, each PA began offering some kind of specialized efficiency services for small business customers roughly 25 years ago. The turnkey model was first offered by National Grid in 1990 for customers 50 kW and smaller. It was subsequently adopted by all the PAs and, with experience, it has evolved, expanded, and improved over time, with the addition of gas measures specifically and more measures generally. The core initiative is regularly cited by independent industry organizations, such as ACEEE, as the most successful program directed to the small business sector in in the country[65], and it has served as the template for dozens of imitators in other states and provinces. In 2013, 4,646 customers statewide participated in this program, saving, on average, 17.3 percent of their prior electric consumption and 5 percent of gas consumption.[66] Since its initial introduction, over 50,000 small businesses in Massachusetts have taken advantage of the Small Business offerings.[67] Its success notwithstanding, the PAs have jointly embarked on a thorough review of every aspect of the program – administration and delivery, target markets, measures, marketing, etc. – with no preconceived notions or limits as to outcomes. Many of the options under consideration by the

64 87 percent of program participants are satisfied with program overall. *DI Process Evaluation: Final Report for the Massachusetts Program Administrators*, DMV.GL, February 2015, at 51.

65 Exemplary Program Award in the Small Business category: National Grid Small Business Services, *Leaders of the Pack ACEEE's Third National Review of Exemplary Energy Efficiency Programs*, York, et al, June 2013. The program also received Exemplary awards in the First and Second ACEEE national reviews of program.

66 Id. at 59.

67 As conservative estimate, as National Grid's participate count can only be traced back to 2003, and the predecessor companies – New England Electric and Massachusetts Electric – had offered the program since 1990.

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	PAs were also subsequently raised by the EEAC consultants in their briefing memo to the Council.[68] The recent process evaluation of the program pointed to some potential process and delivery improvements that will also be explored.[69] Examples of the options under consideration include: addition of more gas measures, including thermal measures; better and more referral follow-up services for measures not amenable to the direct install delivery model (such as thermal measures and heating systems, for example, so that deeper treatments can be undertaken); further segmentation to reach the smallest of the small customers through consideration of web portals, self-service delivery concepts, further development of the Main Streets or other geographically-focused delivery models, adaptation of successful residential delivery models such as HES, and more targeted marketing and measure mixes by business type. Examples of the tests currently underway and continuing into the next Plan term or targeted to begin in 2016 are: • Eversource will be working in the greater Boston area to test ways to increase tenant space improvements, particularly those tenants who are located in buildings that fall under the scope of the Boston Building Energy Reporting and Disclosure Ordinance (“BERDO”) and the Cambridge Building Energy Use Disclosure Ordinance (“BEUDO”). The test will involve local turnkey contractors, working in coordination with Eversource’s C&I teams to engage property management customers. For purposes of this test, the initial audit will be done by a firm that is independent of the turnkey contractor, who will focus on comprehensive recommendations, with particular focus on lighting controls. The post-audit will also be conducted by this independent firm or an Eversource internal auditor. Incentives are to be delivered through the usual turnkey process. • In a second test, focused on Cambridge and Framingham, Eversource will focus on getting more customers to adopt more controls-enabled retrofit kits and fixtures. Customer installation will include LED lighting retrofit kits or fixtures, enabled with controls (daylight, dimming, occupancy sensors, etc.). Installation will be performed by product vendors with standard program

68 *Effective Practices for the Small Business Sector*, February 11, 2015

69 Small Business Program Process Evaluation Final Report, DNV GL, March 23, 2015.

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	incentives. Post installation will be conducted by an independent firm or an Eversource internal auditor. • National Grid plans to experiment with the EnergySavvy[70] platform as an online portal to guide small and medium businesses to the program offerings applicable to their business. EnergySavvy walks customers through a five to ten minute online assessment whereby they learn what is available/applicable to them from the full C&I menu, and National Grid learns a bit about them and their needs. Theoretically, this should allow for more efficient and targeted deployment of resources. The experiment will move from improved customer experience in the lead intake phase, to a greater awareness of the range of options available, to conversion of this customer interest into additional tangible projects and savings. • To better serve the smallest customers and niche customers, National Grid will also continue to experiment with variations of the "Main Street" delivery model. • Cape Light Compact is launching a new effort for its smallest and most numerous C&I customers – those using less than 100,000 kWh annually. The new initiative will be modeled after the HES program and will include a BEA (Business Energy Audit) and a core offering of deemed savings measures, many of which can be installed in the first visit. Factors that must be balanced when considering the results of these or other tests in any redesign include: • *Cost of delivery:* The transaction costs of serving small customers are high relative to the savings potential contained in their facilities. Small Business has been successful because of the mix of incentives. Financing, on-bill repayment (where technically available), and turnkey delivery make it easy for customers to say yes, thereby creating the cost advantages of a high sales closure rate and commoditized delivery at scale. Some of the proposals to reach more and smaller customers, and achieve deeper savings, are likely to increase the cost of acquisition; • *Equity:* All business customers, including the smallest of

70 http://www.energysavvy.com/

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	businesses, contribute to the efficiency fund, and thus all should have easy access to measures and services that will lower their gas and electric bills, and improve comfort for them and their customers. In order to open the discussion to the widest range of ideas, the PAs are conducting an ongoing national best practices inquiry to identify any creative features in other small business programs, as well as additional gas or electric measures beyond those currently offered in Massachusetts. In addition to research elements, the PAs are also discussing operational and delivery insights with their peer program administrators around the country. This inquiry may produce recommendations for a series of incremental program improvements that can be incorporated serially into the existing delivery structure through amendments to existing contracts with delivery contractors. Any larger modifications would likely be incorporated in the contractor rebid process. Further Engage the Commercial Real Estate Sector In the last Plan, the PAs committed to engage in a stakeholder process with the goal of better identifying any unique barriers that could inhibit full participation by the Commercial Real Estate ("CRE") community in the Massachusetts programs. In 2013, a representative Commercial Real Estate Working Group was convened and conducted primary and secondary research throughout 2013 and 2014.[71] This research led to the development of several tentative strategy proposals to broaden and deepen CRE program participation, which were then vetted in late 2014 in a series of roundtable discussions involving representatives of owners of large buildings and their tenants, as well as later interviews with small building owners. The strategies explored included: turnkey service delivery to small and mid-size customers, pre-packaged prescriptive options that could be quickly implemented, "energy dashboards", and promotion of "Green Leases." The research and subsequent discussions revealed that in the most common lease structures energy costs are passed through to tenants, creating the classic split-incentive problem. Owners are generally the

[71] Secondary research included: C&I Customer Profiles & Market Sector Profiles, Mid-Size Customer Needs Assessments, A Better City Reports, NEEA - Existing Building Renewal/Commercial Real Estate Research.

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	primary decision-makers with regard to energy matters, and the majority do track their energy use and compare it to peer buildings. However, as with most non-core business issues they face, owners lack the time, knowledge, and resources to pursue strategies to increase the efficiency in their facilities comprehensively and effectively. To the extent that efficiency upgrades are considered, the best opportunity is when office space is fitted out for initial occupancy or when existing space is in transition from one tenant to another. These tenant fit-up/refit decisions occur rapidly, and the window of opportunity to consider energy efficiency improvement opportunities is very narrow. The research also found that CRE firms are open to more regular contact from the PAs, and some owners do have an interest in more complex solutions, and PA assistance in assessing and executing them. The PAs plan to pursue the following potential strategies due to the considerable interest received from industry representatives: • *Tenant build-out/refit offerings:* Clearly, the best time to install efficiency measures is during the build-out for new tenants or the refit when old tenants depart and the new ones have yet to arrive. The Sustainable Office Design ("SOD") initiative, discussed in a preceding section of this Plan, was launched by Eversource and National Grid to address just this market-driven opportunity. As the SOD initiative is further developed, and is adopted by other PAs, it could be augmented with additional enhancements recommended by the industry such as: o Packages of lighting, space conditioning, refrigeration and commercial cooking offerings. This could also include bonus incentives for installing multiple measures in the package, which was of interest to both owners and tenants. o Offerings could also be provided on a tiered – good, better, best – basis to cater to firms' varying interests, needs and budgets, and overall expectations for the building's aesthetics and operations. This approach was viewed favorably by both owners and tenants with tenants also suggesting the addition of plug load monitoring and controls. o Packages could also vary according to the space types,

C&I RETROFIT	<u>CORE INITIATIVES</u> EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	particularly in market sectors where CRE firms are more prominently represented, such as retail and hospitality.[72] • *Turnkey-delivery models for CRE customers*: With research showing that_much of the CRE property in Massachusetts is small – on average half the size of non-CRE property[73]-- and as a result having limited resources to identify potential improvements and keep track of available incentives, the turn-key approach would reduce cost and the time and resources required for CRE customers to benefit from energy efficiency. To be successful, however, the PAs need to train vendors, particularly their small business vendors, to better identify, understand, and capture CRE specific opportunities such as fast-moving fit-up opportunities.[74] • *Dashboards and building labeling*: Roundtable participants indicated that displaying energy usage at the tenant and building level through dashboards can contribute to energy efficiency and real-time tracking can improve occupants' awareness of energy use and behaviors. o There are a variety of tools in this area, more appearing on the market with regularity, and the PAs will experiment and compare the effectiveness of some of the most promising.[75] o Most feel that Boston's benchmarking requirement has been successful. It has allowed consumers to track the heretofore untrackable, provided enlightening comparisons between buildings. PA support of benchmarking will become increasingly important, particularly as a number of communities beyond Boston are adopting commercial building energy disclosure ordinances. At a minimum, it heightens awareness and sets the stage for action. o Presenting consumption in terms of end use intensity ("EUI") and usage per square foot (kWh/sf and/or

72 "Massachusetts Commercial Real Estate Survey Analysis-Final Report", DNV-GL, March 18th, 2015, p. 4.

73 <u>Id.</u> at 5.

74 The CRE Report suggested partnering with key trade associations, such as BOMA and NAIOP that are active in this marketplace.

75 http://www.linkcycle.com/review-of-top-energy-management-software/

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING

	KBTU/sf) metrics is most useful, as are peer level benchmarking comparisons.
	
	• *Additional program improvements*
	  o Process improvement – CRE customers would like reduced paperwork and streamlined application processes. The PAs will be implementing online incentive applications to address this need.
	  o Collaboration with building operators – in order to build awareness and expertise, the PAs will continue to support a variety of training offerings such as building operator certification ("BOC") and seek opportunities to expand and/or augment the array of trainings available.
	
	In general, the specific elements and approaches of a successful CRE strategy include:
	• Developing marketing strategies that resonate with the distinct submarkets within CRE;
	• Developing unique technical solution sets for each distinct building type in CRE, with accompanying financial incentives that are both sufficient and presented in a manner that make them attractive to subsector decision-makers;
	• Streamlining PA paperwork and decision making to meet the pace of decisions being made in the sector;
	• Delivering better CRE training for all channel partners, particularly Small Business contractors.
	
	Additional Planning Input
	
	The NEEA also released an assessment of the CRE Market this year.[76] The Northwest research plan also involved extensive interviews: 21 executives representing 18 CRE firms and 17 representatives from five CRE-related trade associations. This study reached substantially the same conclusions as the Massachusetts report, with the additional caveat that "The primary market motivations to invest in energy efficiency vary greatly based on the business structure of the firm. When it comes to the

76 "Commercial Real Estate (CRE) Market Test Assessment: Understanding Delivery, Partnership Strategies and Program Channels", New Buildings Institute for NEEA, March 16, 2015

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	promotion of energy efficiency we believe it to be beneficial to tailor strategies and approaches to the following three types of firms: (1) Larger Investor/Owners and Real Estate Investment Trusts ("REITs"); (2) Third-Party Property Managers; and (3) Smaller Independents." Perhaps most significant for the Massachusetts programs, our neighbors at NYSERDA in New York have recently announced that as a part of their Commission-ordered program redirection they will "(p)artner with large commercial portfolio owners and receptive tenants, service providers, industry trade and research associations, and governmental organizations to pilot standardized tenant energy efficiency packages."[77] In 2016-2018, NYSERDA will develop and conduct a set of replicable pilot studies of efficiency packages in key building types and market segments. The objective of these pilots will be to acquire building data for analysis and to conduct M&V studies to provide insights into the actual performance of these packages. Results will be used to produce case studies that will be shared with the efficiency industry. Also in 2016-2018, NYSERDA will partner with large portfolio owners in key building segments (CRE, medical centers, colleges/universities, etc.) and providers of various Real Time Energy Management ("RTEM") service providers to conduct a set of replicable pilots using a variety of these tools that monitor data and use analytics to identify where, when, and how energy is being used in a building. In addition to the direct technical and financial support to the participants, NYSERDA will acquire building data for analysis and will conduct M&V and persistence studies "to provide insights into the technical/operational underpinnings of RTEM and to develop credible models and case studies to support a clear value proposition for owners of similar buildings."[78] The PAs will discuss with NYSERDA management the potential for collaboration in these two test areas, and potentially others as well. These discussions will be led by National Grid, as the PA whose operations span both jurisdictions. At a minimum, the PAs own test designs can be informed by NYSERDA experience.

[77] NY PUC Case 14-M-0094, "Proceeding on Motion of the Commission to Consider a Clean Energy Fund, Clean Energy Fund Information Supplement", submitted by the New York State Energy Research and Development Authority, June 25, 2015, at 46.

C&I RETROFIT	<u>CORE INITIATIVES</u> **EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING**
	<u>Maintain/Improve Services for Financing Energy Efficiency Investment</u> The PAs have partnered with the Massachusetts Bankers Association to make available heavily subsidized financing for business, multi-family, and non-profit commercial customers who need capital beyond the value of the PA incentive to implement a project. Loans can range from $5,000 to $500,000, and can extend to 7 years. For the PAs, the ability to link customers to capital where that is the barrier to project execution is an invaluable sales tool. For participating lenders, the partnership opens up a new market to attract new customers, with the assurance of receiving a market rate interest payment from the PAs. Mass Save® Financing for Business has had a modest uptake, and is best viewed as a useful, but niche, tool in the energy efficiency sales toolkit. To many observers, the importance of making additional outside financing available for energy efficiency investments seems intuitive: even when investments in retrofits and new equipment pay off in future energy savings, the up-front expenditure is often substantial. It would seem that many building owners would welcome financing. However, larger sized businesses in the Commonwealth have indicated that access to outside capital financing is not a primary barrier to program participation.[79] As the 2012 “Massachusetts Large Commercial & Industrial Process Evaluation” concluded: “Lack of financing activity appears to be due mostly to very few organizations relying on outside financing in general.”[80] A PA review of recent studies of financing programs revealed two trends. First, the Massachusetts experience is consistent with the financing experience of most other program administrators.[81] Second, because of

79 In 2012, KEMA surveyed 354 companies or organizations who were recent program participants (2010 or 2011). 68% of respondents reported they “never” or “rarely” depend on outside financing. Only 2% said capital availability was a barrier, and only 6% said they always or most of the time rely on outside financing. 81 Borrowing to Save Energy: An Assessment of Energy-Efficiency Financing Programs, Karen Palmer, Margaret Walls, Todd Gerarden, Resources for the Future, April, 2012

> “In our experience examining efficiency programs across the country, lack of financing is seldom the primary reason that efficiency projects do not happen. Financing is only useful once the “product” has been sold to the customer, just as a car loan can only be appealing once you want a car (and then only if there are no better payment options

C&I RETROFIT	**CORE INITIATIVES** **EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING**
	this disappointing performance there is a new surge of interest in investigating alternative and creative financing vehicles, such as commercial PACE.[82] New financing options may have the potential to improve customer uptake of project financing and reach more customers who heretofore may not have participated in energy efficiency programs due to capital constraints. The PAs will continue to review new studies and proposed mechanisms as they emerge and participate in financing policy forums.[83] They will also closely watch financing pilots and initiatives being conducted in other jurisdictions to determine which emerging models, if any, show promise for replication in the Commonwealth.[84] More Tools for Customer Engagement Surveys indicate that consumers have tremendous expectations that they will have an abundance of choices in energy services in the future.[85] However, the surveys also indicate that consumers are also largely unaware that they will need to take a more active role in managing energy decisions for their expectations to become a reality.[86] In many cases, business consumers lack essential knowledge of how they use energy and what steps they can undertake to use it more efficiently to accomplish their same business objectives. The PAs fully understand the value of expanding the channels of information transfer to customers, and building and deploying communications tools that allow for a more interactive experience between customers and their suppliers of energy and energy efficiency services. While evaluations have indicated high levels of

available.", The Limits of Financing for Energy Efficiency, Borgeson, Zimring, and Goldman, Lawrence Berkeley National Laboratory, 2012 ACEEE Summer Study

82 A unique, and potentially attractive, feature of the PACE model is that allows for longer terms – potentially up to 20 years, which allows more opportunity for a positive cash flow on capital-intensive or long payback measures.

	satisfaction among Massachusetts businesses that have participated in Massachusetts programs,[87] and that customers view the PAs as trusted sources of information,[88] it is also clear that more customers need to be engaged. Customers that have participated on a project-by-project basis must be engaged on a more continuing and comprehensive basis in order to fully realize the efficiency capabilities in their properties. All of the PAs are examining ways to connect the power of data and data analysis with the increasingly interactive capabilities of their customer website portals. An illustrative example here is the Eversource Customer Engagement Platform that is being implemented in phases across all of its operating companies. This platform will provide tools that will enable Eversource to more efficiently identify, target, and reach all customer segments and provide each customer with customized energy efficiency recommendations. Eversource is implementing three customer-facing tools: Residential, for all residential customers; Commercial, for micro, small, and medium business customers; and Enterprise, for the largest customers. The project plan calls for a phased roll-out of these portals, with full functionality in place in the first year of the Plan, 2016. An example of the platform's capabilities is the online tool, *Energy Savings Plan*. *Energy Savings Plan* is an interactive tool within Eversource.com that enables residential and business customers to learn how they currently use energy, how they compare to other similar customers, and, most importantly, practical steps they can take to reduce their energy consumption and costs. *Energy Savings Plan* utilizes the customer's usage data, collects additional information through a series of easy-to-answer profile questions, and then makes customized, actionable energy efficiency recommendations. Features of the online tool include potential savings estimates, "learn more" case studies, and links to solution resources. In addition to the foregoing, the PAs will also be building an entirely new capability for customers, or their agents, to create and submit project

[87] 89 percent of participants gave the PAs a four or a five on five-point scale for overall satisfaction. "Massachusetts Large Commercial & Industrial Process Evaluation", KEMA, May 17, 2012.

[88] When asked about trust in a variety of different sources of information, from community and business organizations to the press and other media, 78 percent of Renew Boston Business program participants had the greatest level of trust in NSTAR/National Grid – second only to the City itself. "Massachusetts Special and Cross-Sector Studies Community-Based Partnerships 2011 Evaluation, Final Report", Opinion Dynamics Corporation, July 2012, at 56.

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	applications using an on-line or web-based incentive application portal. This portal will not only greatly enhance and simplify the user experience but will also increase the likelihood that more applications would be submitted while increasing the satisfaction of those that submit applications. Beyond the potential benefits to customers, and their contractors, the PAs expect the application portal will also result in considerable efficiencies in terms of reviewing, approving and performing data entry on the roughly 10,000 gas and electric applications that are processed each year. Combined Heat and Power During the 2016-2018 Plan term the PAs will aggressively explore more ways to increase CHP installations in Massachusetts while maintaining the high standards for project screening, qualification, and performance for which PA programs are known. The PAs will initiate this process by commissioning a best practices review of other programs nationally and a reassessment of the CHP market in Massachusetts in 2016.[89] Among the areas that the latter investigation must consider are the following: (a) are there barriers to doing more CHP projects with customers of each size; (b) are the barriers technical, policy, financial, legislative, or market issues; (c) can potential solutions to overcome the barriers be identified; and (d) is it feasible and cost-effective for the PAs to implement the solutions. The PAs have developed a network of over 50 vendors, developers, and installers who want to sell CHP in the Commonwealth. As a result, the issue-identification process can be initiated by the PAs in advance of contracting for studies, and this conversation will help shape the study directions. Initial areas for investigation include: (a) the challenges posed by natural gas availability and volatility in fuel prices for installing CHP systems and potential programmatic approaches to mitigating those risks; and (b) continued work to seek ways to safely install CHP in urban settings.[90] Lastly, the PAs will enhance the education campaign for CHP technology, including providing technical assistance on determining cost-effectiveness and navigating the DEP permitting process, when applicable. Customers will receive information on the efficiency of the

[89] The last assessment was conducted in 2009.

[90] CHP on spot networks has been resolved in NY, Chicago, and San Francisco., but remains a concern in New England. The Institute of Electrical and Electronics Engineers (IEEE) has had a standard under development, but it has not been finalized.

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	systems, carbon reduction, payback formulas, and incentives.
Program Design	The Retrofit Program targets customers who have functioning, but inefficient, equipment in their facility, or their older building's performance is not code compliant and can be upgraded to higher efficiency without undergoing major renovation. The program uses a variety of sales and delivery strategies to educate customers about the true cost of continuing to operate inefficient equipment, including the "cost" of reduced customer or employee satisfaction with the building environment they experience. The program provides customers with information on the cost saving and ancillary additional benefits of a more efficient building and/or equipment, and then provides an easy path to the upgrade, including streamlined incentives and direction to a skilled contractor who can perform the work. In some cases all of these services are provided through turnkey service providers working under contract to and supervision by the PAs, as with trade allies and Small Business delivery firms. In other cases, particularly with larger customers or property management firms, the outreach, sales, and service coordination is conducted by PA Account Managers. The core elements of the program are the Prescriptive and Custom path options. The Prescriptive path offers fixed incentives for purchase and installation of a broad menu of prescriptive measures. Prescriptive measures are those for which the energy savings can be predictably assumed in a wide variety of building types and business environments. Many are lighting and lighting control measures, but there are also prescriptive incentives available for variable speed drives ("VSDs"), HVAC controls, spray valves, steam traps, etc. Some of the richest sources of energy savings potential are found in equipment or processes that are unique to a customer's premises and/or operational requirements. These unique, or custom, opportunities require a site-specific engineering analysis to determine costs and benefits. Custom opportunities account for a large share of PA savings. When a promising efficiency opportunity has been identified, often by a PA Account Manager, an appropriate technical expert, drawn from a pool of pre-qualified engineering consultants selected as preferred vendors through a competitive procurement process and matched to the specific needs and capabilities of the customer, is assigned to further define and quantify the potential. These highly skilled, unbiased, and independent

C&I RETROFIT	<u>CORE INITIATIVES</u> EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	technical experts can conduct walk-through audits, perform detailed energy-efficiency studies of whole buildings systems or building components, or conduct specialized technical studies, such as studies of industrial or manufacturing processes. TA consultants are assigned based on their recognized expertise with the technology area under consideration. Customers can also elect to use their own TA consultant provided that the partnering PA approves of the firm's qualifications and cost estimate. Non-preferred vendors must comply with the same level of detail and quality as preferred vendors. Often customers will have both gas and electric savings opportunities. In these instances the relevant gas and electric PA will instruct the TA consultant to examine all savings potentials. The two PAs share the study costs and coordinate delivery of the recommended improvements.
Delivery Mechanism	The Retrofit program is largely delivered through a mature and growing network of trade allies. These include contractors providing retrofit services directly under contract to the PAs, such as the Small Business and preferred trade ally contractors, and the hundreds of independent lighting and HVAC contractors, supply houses, electric and gas equipment vendors, RCx service providers, etc., who service their customers' needs and, in the process, assure that those customers install the best possible equipment and facilitate program participation on their behalf.
Marketing Overview	Collectively, the PAs serve approximately 350,000 electric and 154,000 gas C&I customers. These run the gamut from the one-chair barbershop and corner bodega to massive manufacturing, health care, and educational facilities. Serving this diverse and large population of business customers effectively requires an understanding of their unique attributes. Based on that understanding, the PAs have designed and implemented a number of marketing strategies specifically targeted to various sub-segments of C&I customers. Examples of current strategies to serve the diversity of submarkets, and some proposed enhancements are detailed below. <u>Segments of Special Interest</u> <u>*Large Customers*</u> In Massachusetts, as in most states, a relatively small number of customers account for a disproportionately large share of the state's energy consumption. These customers – hospitals, universities, industrial

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	complexes, owners of building portfolios, etc. – often present more opportunity for efficiency, but usually these opportunities are found in more complex systems that require unique analysis and customized solutions. The conventional trade ally-driven approach of a mix of prescriptive and custom equipment-based incentives, designed for a volume-based mass market, does not adequately address the needs of these customers, nor is it equipped to systemically harvest the vast saving potential that exists in these facilities. From the PA perspective, large customers also have many beneficial attributes that make them ideal long-term partners. They generally have sophisticated in-house engineering and facility staff and sophisticated financial analysis capabilities. They also tend to have longer term planning and investment horizons. For the very small subset of customers with this combination of high savings potential and sophisticated in-house technical and financial resources, the investment of more program technical and financial resources can be warranted and, where there is owner or corporate commitment, the PAs will invest significant staff and consultant technical expertise, as well as financial incentives, to execute multi-year arrangements that meet the business needs of both parties. An MOU or SEMP partnership is the culmination of a process that begins with discussions between senior level decision makers from the customer and the PA. Over the course of these discussions PA management develops an understanding of the customer's intermediate and long-term business intentions, motivations, and limitations. The customer, in turn, comes to a better understanding of what technical and financial resources are potentially available to that match their objectives. When there are sufficient commonalities of interest and an accompanying willingness to dedicate staff and financial resources, both parties ultimately capture their commitments and objectives in an MOU. This document details with specificity the commitments and actions required of each party to achieve the agreed efficiency resource goals. The PAs will only move forward when there is a match between their acquisition requirements and a clear customer commitment to engage their resources as well. Early in the process a joint team of customer and PA subject matter experts is convened. This team must include a representative from the customer's organization who is both committed to the effort and has the appropriate stature to represent it to his/her upper management. The team may also include finance, sales, technical, implementation, procurement,

C&I RETROFIT	**CORE INITIATIVES** **EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING**
	corporate/public relations, or any other internal stakeholders deemed critical to ensure success. This joint team should be small enough to remain functional and be empowered to make decisions, including engaging third party expertise when necessary. The team is responsible for designing the details of the MOU/SEMP partnership, establishing the implementation framework, and managing progress towards established goals. Depending on the maturity of the customer/PA relationship, it may take from three to 12 months to establish the terms of an MOU agreement. From agreement forward, the implementation progress is tracked monthly at the project level. This frequent reporting encourages progress and momentum and flags roadblocks or loss of momentum quickly. These partnerships are significant undertakings and require very real ongoing commitment by both parties. However, the experience so far is that significant energy/cost savings can and will be achieved – often on the order of 20-30 percent – and achieved at a lower cost to both parties, as compared to traditional implementation methods. In addition, these partnerships often have intangible but valuable benefits to the customer, such as positive public visibility as an environmental steward. These intangibles help maintain lasting relationships between PAs and customers. By way of example, past MOUs/SEMPs have included such features as: • Customer access to utility equipment procurement processes to achieve volume pricing; • Turnkey installation services using PA contractors, pre-selected for price and competence; • Joint engineering reviews and installation inspections, eliminating duplication and costs; • Simplified incentives, such as $/kWh saved; • Tiered incentives for higher, deeper savings; • Expansion of eligible technologies/strategies beyond the common portfolio; • Support for staff behavioral efforts; • Facility staff and user training; • Joint application for outside federal and state funding/grants;

C&I RETROFIT	**CORE INITIATIVES** **EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING**
	• Sharing of company-specific expertise; and • Test bed for new technologies and promotions. Based on their respective organizational commitments and internal resources, PAs may incorporate other components to address customers' energy needs and interests, and broaden the scope of these partnerships beyond energy efficiency. For example, these components may include technical assistance for on-site renewables and alternative fuel vehicles, with the idea of bringing integrated energy solutions to customers, with energy efficiency as the foundation. *Cities, Towns and Special Purpose Districts* Local public bodies have unique challenges and opportunities with regard to efficiency investment. The needs, opportunities, and capabilities vary widely across the Commonwealth's 351 cities and towns, 400 hundred school districts, and 350 water/wastewater treatment plants. Very often they have staffing and capital limitations as well as statuary restrictions on how they can raise capital and contract for delivery of efficiency services. Historically, these restrictions had limited the ability of governmental units to participate in PA programs that were primarily vendor-driven and designed to meet the requirements and expectations of private sector decision-makers. Until recent years, this had resulted in lower public sector program participation, with the result that many public facilities had very antiquated building energy systems in place. In recognition of these special barriers, the PAs developed a tailored approach that includes a single point of contact within each PA's staff[91] funding for engineering assessments of opportunities, and financial assistance structured to meet their needs and constraints.[92] Services can be tailored to the needs of individual municipalities, and services are delivered through a group of installation contractors who are experienced in navigating state law regarding municipal procurement. The long-standing working partnership between the Program Administrators and DOER has been invaluable for the implementation of these services. PA and DOER's Green Communities Division staff meet

[91] The larger PAs, with many municipal accounts, coordinate these resources through a fully dedicated municipal account manager.

[92] Reporting data indicates that municipalities and other public entitles now receive at least their fair share of funding.

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	regularly to discuss issues of common concern and to leverage the unique resources of each partner on an ongoing basis. On an ongoing basis, DOER's resources can also be accessed through their team of Green Communities Regional Coordinators, who work in close coordination with their PA counterparts. In addition, the PAs maintain a regular routine outreach schedule with municipalities, schools, and water treatment facilities to keep PA efficiency services top of mind with municipal leaders and to develop and implement projects as local resources and priorities allow. A statutory change to the municipal procurement process contained in the Green Communities Act has greatly expedited the process of delivering efficiency services to government entities. Because the PAs select their contractors through a competitive procurement, cities and towns can avoid a redundant competitive process and sole-source efficiency projects to a PA or the PA's delivery contractors if the project is less than $100,000. By providing this upfront competitive bidding, enhanced financial incentives, and additional financing options, including on-bill payment in some cases, the PAs have been able to provide a turnkey service with incentives structured to create positive cash flow and encourage comprehensive municipal projects. Water and wastewater facilities are a unique public sector market segment because the energy savings potential exists in measures that are more industrial in nature – motors, drives, pumps, fans, etc. These plants are very energy-intensive. A wastewater treatment plant can spend as much as 30 percent of its operational budget on electricity. Since 2006, the PAs have collaborated on almost 350 distinct water/wastewater facility improvement projects in 120 towns, and with the MWRA on more than thirty projects. They have awarded nearly $10 million in incentives to save municipal ratepayers almost 37 million kWh, and $4 million in costs, annually. In this market, DEP is the PA's key public-sector ally. The PAs work with DEP to conduct equipment screening of facilities aeration and pumping system assets in order to identify potential energy-saving opportunities in high electric use areas. Facilities with opportunities are eligible for incentives and technical assistance, as well as preferential scoring when applying to the State Revolving Loan Fund to finance proposed energy efficiency project components, making efficiency-related proposals more competitive in the selection process.

C&I RETROFIT	<u>**CORE INITIATIVES**</u> **EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING**
	The PAs stay current in the water/wastewater area by monitoring other best practices programs nationally[93] and by routinely reviewing emerging technologies and refinements to existing technologies.[94] Also, PA staff who advise facility operators are expected to know both the state of the art and the state of the shelf. Eversource staff, for example, has received annual water/wastewater training updates every year since 2010. The PAs also provides best practices training to facility operators, using recognized industry experts, such as the University of Wisconsin School of Engineering. *<u>Industrial</u>* There are almost always a wide variety of cost effective energy efficiency investment opportunities present in industrial facilities, and industrial participation in PA programs is consistent and strong.[95] Industrial energy use is usually tied closely to the production process itself. As such, it is generally a significant cost and tied closely to profitability. Facility managers must always balance the potential cost savings advantages of equipment improvements against the risk, of disruption to the production process itself. To provide the highest level of confidence in their recommendations the PAs seek out skilled TA service providers who are recognized as subject matter experts, and thus trusted, by the industrial decision-makers in their service territories. The PAs engage these expert service providers to compressively examine all the savings opportunities in a facility and quantify the potential electric and/or gas savings streams in each. To support deeper savings with industrial processes, the PAs also help customers reduce operation and maintenance costs, improve productivity, equipment reliability, asset value, throughput, and profitability while managing their carbon footprint. When the potential savings warrant it, and there is customer commitment, a MOU/SEMP approach (as detailed

93 *E.g.*, Wisconsin Focus on Energy, Energy Trust of Oregon, NYSERDA.

94 *E.g.*, the PAs commissioned an E Source "Best Practices" review in 2013, and PA staff regularly review reports and activity from the Northwest Energy Efficiency Alliance (NEEA), EPA, the California utilities. A recent example is the "California "Water/Wastewater Market Characterization Study" (for PG&E and SCE), KEMA, January 2012.

95 "Manufacturing Savings are consistently high year-over-year….As in past years, Manufacturing contributed the largest proportion of participant savings in 2013." 2013 Commercial & Industrial Customer Profile Report, at 22 and 26.

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	above) may be appropriate. Typical industrial projects may incorporate lighting, compressed air, HVAC, and process heating or cooling, as well as industry specific measures, such as injection molding measures for plastic molding manufacturers. When they are present, non-gas/electric energy benefits are quantified and their costs and benefits estimated. Examples can include savings in raw material inputs, scrap economies, increased through-put efficiencies, and potential water and/or wastewater savings. As noted above, the PAs also offer a range of training programs specific to the needs of the industrial and manufacturing sectors. In addition, they collaborate with organizations focused on improving industrial efficiency and productivity, such as Massachusetts Energy Efficiency Partnership ("MAEEP"). The PAs also collaborate with their peer efficiency programs around the country, and incorporate the best practices experiences of others. In addition, National Grid, which has a large industrial sector, is testing a targeted effort for medium and large industrial customers (> 500 kW) to augment their core industrial efficiency services. The effort funds a team of "industrial energy advisors," available at no cost to the customers, to provide industrial subject matter expertise and help explore energy-savings as well as process improvement opportunities. This team then assists the customers in following through with the identified opportunities by offering a range of support activities such as technical support, assessments, basic project management support, or simply helping navigate through the programs. It also facilitates continuous strategic energy management as a tool to influence a culture change with regard to energy use in the customer's facility. Additionally, for customers where known energy projects are stalled due to lack of staffing resources, National Grid offers a co-pay to fund a staff position to oversee the implementation of such projects. The results of this effort will be shared with all PAs, and depending on an assessment of its effectiveness, it may be expanded statewide. *Commercial Non-Profits* Non-profit commercial customers are unique in that the barriers to being effectively served can be quite different than typical commercial customers. Lack of awareness, limited time and resources, insufficient in-house technical expertise, and limited access to capital are all barriers that must be addressed to successfully serve non-profits. Drawing on delivery models from other programs and initiatives such as

C&I RETROFIT	**<u>CORE INITIATIVES</u> EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING**
	multi-family and the residential home energy services effort, as well as experiences of other PAs around the country, National Grid is developing a prototype approach for serving a particular subset of non-profit commercial customers – houses of worship. That prototype will be developed and tested within National Grid's own service territory using a phased approach over a number of months. The results of that effort will be analyzed and shared, as are all such efforts, with the other PAs as an approach that could possibly be extended and adopted statewide. <u>Combined Heat and Power</u> During the 2013-2015 Three-Year Plan term, CHP continued to expand, both in number of participants and in realized savings. Massachusetts continues to have one of the most successful CHP offerings in the country. In each of the last five years, ACEEE has ranked Massachusetts as first in the nation for CHP policies and implementation success.[96] That success is largely attributable to a fair but rigorous screening process that gives customers the information necessary to make an informed decision regarding CHP and energy efficiency investments in their own individual and unique circumstances. The PA's CHP Guidebook provides clear and complete information that delineates the process to achieve a successful CHP project and qualify for an incentive. CHP projects can produce dramatic savings and can have a significant positive impact on overall PA goals and savings results, with a low cost per kWh. Thus, a good CHP installation is highly desirable. Despite the potential for significant savings and generally very favorable economics, CHP projects often do not move forward. Recent market research indicates that the majority of commercial customers will not move forward with CHP projects having a simple payback of three years or more, and, surprisingly, almost 40 percent of surveyed customers would not accept paybacks of just one year.[97] At the same time, CHP systems typically have a benefit cost ratio between 1.0 and 1.5, which means that it is critical that potential opportunities identified are impartially qualified and that installations are properly engineered. A number of key lessons have emerged from the

96 ACEEE, "The 2014 State Energy Efficiency Scorecard," October 2014, Report Number 01408.

97 Combined Heat and Power: Policy Analysis and 2011-2030 Market Assessment. ICF International. February 2012.

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	past six years of experience in implementing CHP projects. These include: • Good CHP candidates have a year-round thermal load requirement in excess of 5,000 hours annually to ensure cost-effectiveness. Good candidates include facilities with significant daily laundry requirements like hospitals, nursing homes and some hotels, as well as others with thermal process requirements like food processors and other manufacturers. • CHP projects require significant customer investments in time, engineering planning, and capital commitment. Thus they require greater customer attention and involvement than more common energy efficiency projects. PA account executives play a vital role in enabling CHP projects, as they can help guide informed customer choices and maintain customer momentum through the several stages of the CHP process, which are: (a) initial identification and quantification of the CHP opportunities; (b) advocacy for the appropriate CHP projects for the customers circumstance and needs; and (c) managing the customer through the process to successful conclusion, including interconnection. PA involvement has been designed to assist the customer throughout the process (see below). • Proper sizing of CHP systems is essential to cost-effectiveness; which requires that virtually all thermal output be used by the facility. Key to correct sizing and assuring that any significant opportunities to reduce load through energy efficiency is identified and pursued prior to final sizing of the CHP system. Absent this step, the customer may install an oversized system that produces excess heat, and thus will not be cost-effective. Accordingly, the PAs emphasize to the customers that prior to conducting a CHP engineering study, they should first implement electric and thermal energy efficiency measures as their first priority, as efficiency is by far the more cost-effective savings opportunity and will reduce the size and cost of the CHP system. Through this experience the CHP offering has evolved to ensure more successful targeting, quantification, and completion of CHP installations. The PAs survey customers for CHP potential and offer significant technical assistance where appropriate. The process begins with an initial scoping assessment of electric and thermal loads and where reasonable potential exists, the customer is offered a co-funded in-depth engineering

C&I RETROFIT	CORE INITIATIVES EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING
	analysis. The PAs' staffs provide continuous active assistance and are objective and unbiased partners to the customer throughout the process. LED Street Lighting During the last Plan term the PAs worked with a number of cities and towns to facilitate a transfer of ownership of the street lighting in their communities and convert it to LED technologies. For example, in 2014, the Cape Light Compact converted almost 16,000 municipally-owned street lights in 20 towns. Similarly, Eversource and National Grid worked with the Metropolitan Area Planning Council Conversion Program to convert 58,000 lamps in 21 municipalities. The PAs remain committed to providing their municipal customers with the most up-to-date street lighting technology options – including lighting and controls – as well as providing options for them to assume ownership and maintenance of lighting where it is cost-effective and they so desire. More than 75 of the Commonwealth's 351 cities and towns have purchased their streetlights from their local utility and others are in process. The PAs are also committed to working with any community wishing to explore the process of conversion to municipal ownership. Experience to date has indicated that the municipal process for consideration, analysis, decision-making, and actual conversion can be quite extended, and that the local conditions and priorities of the local governing body in each unique city or town will control the rate at which the conversion can be accomplished for the Commonwealth.[98] Conversion of utility-owned street lighting to LED is inherently a more complex topic than many realize. First and foremost, it requires a new tariff, approved by the regulators, to be in place that allows the utility to account for and recapture its existing capital investment. For the actual conversions themselves to take place, multiple utility departments – engineering, operations, billing, purchasing, and inventory/stocking – must establish procedures and coordinate so that the conversions take place in a manner that is safe, fiscally responsible, and seamless to a public that depends on adequate street lighting for safety and

98 The City of Boston's conversion has been underway for five years.

C&I RETROFIT	**CORE INITIATIVES** **EXISTING BUILDING RETROFIT, SMALL BUSINESS, MULTI-FAMILY RETROFIT, UPSTREAM LIGHTING**
	security. Further, all of the costs of the process must be tracked and accounted for in a manner that satisfies regulatory requirements. Both National Grid and Eversource will be proposing rate cases during the Plan term that will allow all these issues to be considered and addressed, and rate policies to be established by the Department that will facilitate and expedite the conversion process. The PAs have always given high priority to serving the needs of their municipal customers, have staff and/or account managers dedicated to cities and towns, and will continue to keep these customers advised of new developments such as the implementation of new street lighting tariffs that result in opportunities to convert streetlights to more efficient LED technologies. The PAs will also continue to collaborate with the field staff of DOER's Green Communities Division to support these efforts.
Three-Year Deployment Strategy/Roadmap	For the 2016-2018 Plan term, the program will concentrate on continuous improvement to our processes and exploration of targeted additions.

c. C&I Retrofit: Existing Building Retrofit

C&I RETROFIT	**CORE INITIATIVE** **EXISTING BUILDING RETROFIT**
Overview & Key Objectives	This broad core initiative promotes a menu of equipment incentives and technical services, along with associated financial incentives, to encourage building owners to replace functioning, but outdated and inefficient equipment with premium efficiency counterparts. Because it accounts for a significant share of C&I savings, the PAs continuously monitor its performance and refine delivery approaches, the product mix, and incentive levels to reflect changing market expectations and evolving technologies. As this core initiative has matured and customers have become more aware of the variety of energy-saving investment opportunities available to them, the PAs have encouraged a transition away from episodic equipment-based retrofit events to engaging customers in a thoughtful series of building upgrades that move their property towards a "building

C&I RETROFIT	**CORE INITIATIVE** **EXISTING BUILDING RETROFIT**
	renewal". Mature efficiency programs, those that have harvested the easiest and less expensive savings opportunities and have established trusted relationships with customers, are often characterized by a preponderance of more sophisticated custom projects and a lesser number of simpler prescriptive ones. The C&I Retrofit Program generally, and this Existing Building Retrofit core initiative specifically, fits this mature profile. This core initiative offers prescriptive incentives for widely-applicable electric and gas technologies, and a custom approach which focuses on unique opportunities that are customer, site, or process specific Prescriptive incentives are offered for measures that provide predictable energy savings in virtually all applications where they replace a similar technology of lesser efficiency. These incentives are available for a long list of electric and gas technologies such as lighting equipment and controls, HVAC controls, chillers, motors and drives, spray valves and steam traps, etc. This commodity-based path often serves as the customer's initial exposure to energy efficiency and may lead to more complex custom projects. To identify and quantify custom opportunities, the PAs provide customers with expert technical assistance, using both their own technical staff and subject matter experts drawn from a pool of prequalified expert private sector engineering consultants. To move customers to action once opportunities have been identified, the PAs offer financial incentives that are calibrated to match customer investment criteria. The overarching goal is to instill customer confidence in projections of project savings and the reliability of equipment performance, in order to make the financial investment attractive, and to provide a delivery process that makes the upgrade process as simple and seamless as possible. In addition to periodic equipment upgrades, the PAs offer a suite of ongoing services to business customers, including subsidized training for building operations and maintenance tasks and access to RCx services to ensure that energy-consuming equipment operates as designed, and that all low-cost/no-cost opportunities for energy and electrical demand savings are fully exploited.
Design and Delivery Mechanism	The Existing Building Retrofit core initiative targets customers who have functioning, but inefficient, equipment in their facility, or their older building's performance is not code compliant and can be upgraded to higher efficiency without undergoing major renovation. The core initiative uses a variety of sales and delivery strategies to educate

C&I RETROFIT	CORE INITIATIVE EXISTING BUILDING RETROFIT
	customers about the true cost of continuing to operate inefficient equipment, including the "cost" of reduced customer or employee satisfaction with the building environment they experience. It also provides customers with information on the cost saving and ancillary additional benefits of a more efficient building and/or equipment, and then provides an easy path to the upgrade, including streamlined incentives and direction to a skilled contractor who can perform the work. In some cases all of these services are provided through turnkey service providers working under contract to, and supervision by, the PAs. In other cases, particularly with larger customers or property management firms, the outreach, sales, and service coordination is conducted by PA Account Managers. The core elements of this core initiative are the Prescriptive and Custom path options. The Prescriptive path offers fixed incentives for purchase and installation of a broad menu of prescriptive measures. Prescriptive measures are those for which the energy savings can be predictably assumed in a wide variety of building types and business environments. Many are lighting and lighting control measures, but there are also prescriptive incentives available for VSDs, HVAC controls, spray valves, steam traps, etc. Some of the richest sources of energy savings potential are found in equipment or processes that are unique to a customer's premises and/or operational requirements. These unique, or custom, opportunities require a site-specific engineering analysis to determine costs and benefits. Custom opportunities account for a large share of PA savings. When a promising efficiency opportunity has been identified, often by a PA Account Manager, an appropriate technical expert, drawn from a pool of pre-qualified engineering consultants selected as preferred vendors through a competitive procurement process and matched to the specific needs and capabilities of the customer, is assigned to further define and quantify the potential. These highly-skilled, unbiased, and independent technical experts can conduct walk-through audits, perform detailed energy-efficiency studies of whole buildings systems or building components, or conduct specialized technical studies, such as studies of industrial or manufacturing processes. TA consultants are assigned based on their recognized expertise with the technology area under consideration. Customers can also elect to use their own TA consultant provided that the partnering PA approves of the firm's qualifications and cost-estimate. Non-preferred vendors must comply with the same level of detail and quality as preferred vendors.

C&I RETROFIT	**CORE INITIATIVE** **EXISTING BUILDING RETROFIT**
	Often customers will have both gas and electric savings opportunities. In these instances the relevant gas and electric PA will instruct the TA consultant to examine all savings potentials. The two companies share the study costs and coordinate delivery of the recommended improvements. The Existing Building Retrofit core initiative is largely delivered through a mature and growing network of trade allies. These include the contractors providing retrofit services directly under contract to the PAs as well as the hundreds of independent lighting and HVAC contractors, supply houses, electric and gas equipment vendors, RCx service providers, etc., who service their customers' needs and, in the process, assure that those customers install the best possible equipment and facilitate participation on their behalf.
Marketing Overview	Collectively, the PAs serve approximately 350,000 electric and 154,000 gas C&I customers. These run the gamut from the one-chair barbershop and corner bodega to massive manufacturing, health care, and educational facilities. Serving this diverse and large population of business customers effectively requires an understanding of their unique attributes. Based on that understanding, the PAs have designed and implemented a number of marketing strategies specifically targeted to various sub-segments of C&I customers. Examples of current strategies to serve the diversity of submarkets, and some proposed enhancements are detailed earlier in the Retrofit Program description.
Three-Year Strategy/Roadmap	For the 2016-2018 Plan term, the Existing Building Retrofit core initiative will concentrate on continuous improvement to our processes and exploration of targeted additions.

d. C&I Retrofit: Small Business

C&I RETROFIT	**CORE INITIATIVE** **SMALL BUSINESS**
Overview & Key Objectives	Many small businesses have low energy consumption and are tenant occupied. In rental situations there is little incentive for landlords to improve the energy efficiency of their buildings because the tenants pay utility costs. In instances when the small business is owner-occupied, there is little incentive for energy service companies or other vendors to target these businesses because individual building savings opportunities are small, potential customers have little discretionary capital, and transaction costs are high. As a consequence small business customers frequently

C&I RETROFIT	**CORE INITIATIVE** **SMALL BUSINESS**
	have outdated energy consuming systems and are effectively excluded from any market-based opportunity to correct the situation. However, from a Program Administrator perspective, while energy use in each of these businesses is modest, there are tens of thousands of these customers in Massachusetts, each pays into the energy efficiency fund, and in aggregate their savings potential is significant. The Small Business core initiative provides a simple, streamlined path for these customers to reduce their energy use, and for the Commonwealth to acquire the energy savings cost-effectively.[99]
Design and Delivery Mechanism	The core initiative is designed to provide seamless full service delivery for small business customers from opportunity identification (the "audit') to turnkey installation of measures, to financing of the customer's share of the project cost. Because of the low savings potential per transaction, the program model has been refined over the years to take full advantage of economies of scale. Installation costs are reduced by the competitive procurement of vendors who specialize in comprehensive service delivery to small customers. These vendors keep costs low by mastering the art of streamlined service delivery through repetitive installation of similar measures and the ability to purchase competitively priced equipment due to their high volume purchasing power. Assigned franchise sales territories and the ability to market large PA incentives (with attractive financing and, where available, on-bill repayment options for the customer portion) reduce marketing costs and produce high sales closure rates, further reducing overheads.
Marketing Overview	Vendors can choose marketing options that they find the most successful and are suited to their business model. These include direct mail, cold calling, and word-of-mouth referrals. The ability to identify themselves as agents of the Program Administrators elevates their credibility and provides customers assurance that the assessments of opportunities and estimates of project costs will be objective and fair, that the installations will be quality-controlled, and that there will be recourse if there are subsequent performance issues.
Three-Year Strategy/Roadmap	As described in greater detail above, the PAs have begun a thorough review of the Initiative. Many of the opportunities under consideration by the PAs include those identified in recent evaluations. In addition to basic

[99] Small business customers are fully eligible for all of the services and incentives available through the Retrofit Program in addition to the targeted services described here.

C&I RETROFIT	**<u>CORE INITIATIVE</u> SMALL BUSINESS**
	delivery improvements and economies, the PAs hope to identify additional gas measures and processes to encourage better identification of, and referral follow-up services for, measures not amenable to the direct install delivery model (such as thermal measures and heating systems, for example) so that deeper treatments can be undertaken. They will also conduct further segmentation to reach the smallest of the small customers through consideration of web portals, self-service delivery concepts, further development of the Main Streets or other geographically-focused delivery models, adaptation of successful residential delivery models such as HES, etc. and more targeted marketing and measure mixes by business type.

e. C&I Retrofit: C&I Multi-Family Retrofit

C&I RETROFIT	**<u>CORE INITIATIVE</u> C&I MULTI-FAMILY RETROFIT**
Overview & Key Objectives	As more fully described in the Residential section of this Plan, the Multi-Family Retrofit core initiative provides comprehensive energy efficiency services to market rate properties with five or more dwelling units, including the common area spaces of these properties. The core initiative offers energy assessments which identify energy savings opportunities throughout the facility. An EAP is developed for each facility, identifying all energy efficiency opportunities regardless of fuel source. Because multi-family buildings may contain both residential and commercial meters, residential services and incentives are supplemented by applicable commercial program services and incentives. However, because the primary beneficiaries of the services of this offering are the occupants of the units within the building, and both the measures and services are predominately residential, oversight and management is assigned to the residential program managers at each PA, with appropriate commercial services provided at the direction of a contracted MMI.
Design and Delivery Mechanism	The PAs strive to deliver a fully integrated offering to participants, regardless of fuel type, service territory, or rate class. An integral part of the core initiative's design involves the services of the MMI, who provides a single point of contact at intake, guides participants, and coordinates delivery of resources, including both residential and commercial-sector services, through the effort's phases. The goal is to provide a seamless customer experience, mitigate the potential for customer confusion, and minimize or eliminate lost opportunities. Commercial Retrofit measures may include:

C&I RETROFIT	**CORE INITIATIVE** **C&I MULTI-FAMILY RETROFIT**
	• HVAC high efficiency equipment upgrades and controls; • Variable speed drives, motors; • Chillers; • Air compressors; • Water heating equipment; • Energy management systems ("EMS"); • Building envelope measures; and • Custom measures. A commercial sector PA representative fully participates in the joint PA committee assigned to plan and oversee the delivery of the core initiative. This process is more fully described in the Residential section of this Plan.
Marketing Overview	Please refer to Residential Multi-Family Retrofit core initiative description.
Three-Year Strategy/Roadmap	Please refer to Residential Multi-Family Retrofit core initiative description.

f. C&I Retrofit: Upstream Lighting (electric)

C&I RETROFIT	**CORE INITIATIVE** **UPSTREAM LIGHTING (Electric Only)**
Overview & Key Objectives	As noted in the description of the Initial Purchase and End of Useful Life core initiative description earlier in this Plan, the upstream delivery approach was initially designed to influence the purchase decision for replacement of standard efficiency fluorescent bulbs. Monitoring of the progress of that Initiative indicates that the upstream approach not only impacted market-driven equipment purchases, but the favorable economics of the improved equipment efficiency, coupled with an incentive, drove substantial purchases for retrofit purposes (*e.g.*, replacement of functioning, but less efficient lamps) as well.
Design and Delivery Mechanism	A special, and limited, set of circumstances are required for an upstream lighting approach to succeed. That is: (a) the premium equipment must be suited for one-for-one replacement for the less efficient product; (b) the equipment purchase decision must be driven by first cost, with no real amenity or reliability distinctions between the products; (c) the substitute premium efficiency equipment must be stocked and available at distributors at the time of the purchase decision; and (d) there must be no additional or unique installation requirements that distinguish it from the

	product for which it is substituted. That is, it must be "plug-and-play."
Marketing Overview	The upstream lighting incentive model leverages existing distributor networks and infrastructure to influence the thousands of equipment purchasing decisions that customers and contractors make every day. Under the upstream model, the PAs provide incentives directly to distributors rather than end users. The incentives are structured to entirely remove the price premium between conventional and premium products at the point of purchase, thereby placing premium product in direct competition with the conventional product on the basis of attributes of quality and efficiency alone – with the assumption that the purchaser will make the wise choice. For lighting products in a retrofit scenario the target markets are facility or maintenance managers and operators.
Three-Year Strategy/Roadmap	To date, the PAs have offered an upstream approach for select lighting products including premium efficiency linear fluorescent lamps, LED screw-ins, and an assortment of LED fixtures and downlights. As the lighting market evolves, particularly as LEDs become more cost-competitive and available for a wider range of end uses, the list of eligible products will expand.

H. <u>Pilots, Hard-to-Measure Efforts, and Creative New Approaches</u>

1. <u>Pilots</u>

The Program Administrators are not proposing any new pilot programs or initiatives for the 2016-2018 Plan term. The PAs will continue to explore new efforts to determine if a pilot would be a useful tool for studying a new effort. A key goal of any pilot is to ensure that data is collected to help determine if the approach explored in the pilot should be implemented on a larger, statewide scale, as a full program, or an element of a program. While the PAs are not proposing to conduct formal "pilots," there is a strong focus on conducting demonstration projects. These demonstration projects are regularly deployed to assess new technologies and strategies, with PAs using the resulting findings to improve upon their existing program offerings. The current approach of focusing on broad "umbrella" programs creates the opportunity to refine efforts quickly based on the lessons learned during the demonstration project. Below is a sample list of technologies studied by National Grid and Eversource through demonstration projects. These reports are included in Appendix K.

Research & Development and Demonstration Studies	
Report 1	Evaluation of 2013–2014 Smart Thermostat Pilots: Home Energy Monitoring, Automatic Temperature Control, Demand Response
Report 2	Heat Pump Clothes Dryer Technical Demonstration
Report 3	Technical Assistance Study - Vacuum Steam Heating
Report 4	Wi-Fi Thermostat Assessment

2. Hard-to-Measure Efforts

- *Statewide Marketing (Residential, C&I)*

The budget in the Statewide Marketing hard-to-measure effort is used to support statewide marketing efforts, as described in in Section III below.

- *Statewide Database (Residential, Low-Income, C&I)*

The PAs have allocated a statewide total of approximately $1.5 million to support database and data review and sharing efforts in 2016-2018, as described in Section III. Database efforts will affect all sectors, with funds budgeted for each sector.

- *DOER Assessment (Residential, Low-Income, C&I)*

The DOER Assessment represents an annual budget for DOER that is assessed per G.L. 25A §11H.

- *Council Consultants (Residential, C&I)*

The Council Consultants budget is collected by DOER and used to support the retention of expert consultants by the Council and reasonable administrative costs, in accordance with G.L. c. 25, § 22(c). The Council must annually submit to the Department a proposed budget for the "retention of expert consultants and reasonable administrative costs." G.L. c. 25, § 22(c). The cost for Council consultants allocated to the electric PAs is taken directly out of RGGI revenue that would have been distributed to PAs by DOER. As a result, the electric PAs do not collect this expenditure through the energy efficiency surcharge. The gas PAs, however, do recover these costs through their energy efficiency surcharges.

- *Sponsorships & Subscriptions (Residential, Low-Income, C&I)*

The budget for Sponsorships & Subscriptions is PA-specific and is made up of administrative costs such as membership fees to key associations within the industry (*i.e.*, ACEEE and the Association of Energy Service Professionals) and sponsorships at industry events. These sponsorships and subscriptions support information sharing with others involved in energy efficiency, education, and training.

- *Residential HEAT Loan (Residential)*

HEAT Loans are available to help customers finance the purchase and installation of qualified energy efficiency measures. The Residential HEAT Loan budget includes costs to buy down the interest due on the loan and the cost to administer the loans. Any savings or costs associated with installing energy efficiency measures due to availability of the HEAT Loan are included in the core initiative under which the measure was installed, for example, in HES - Measures.

- *Workforce Development (Residential, C&I)*

The PAs continue to monitor and contribute to trainings in order to:

- Educate new or promoted employees in topics such as marketing, building science, energy efficient new construction, heating and cooling technologies and techniques;
- Contribute to building a qualified workforce that will meet the demand for energy efficiency; and
- Promote cross training across different areas of expertise.

The PAs plan to look for collaborative ways to improve the delivery of trainings to address the demands of the market. This effort is ongoing within the respective management groups and best practices group, as exemplified by the Low-Income Best Practices Working Group chaired by LEAN, and the Contractor Best Practices Working Group, as well as through ongoing communication with key trade allies.

- *R&D and Demonstration (Residential, C&I)*

In the continued efforts to explore new technologies and measures through the MTAC, as well as proactive research and development into areas of interest, the PAs propose a consolidated research and development ("R&D") effort to (a) support the work of the MTAC, and (b) pursue technologies of interest in order to remain at the top of the "innovation curve." For residential innovations/enhancements within a planned initiative, please refer to the initiative enhancement sections within each program.

- *Education (Residential)*

The budget in the Education hard-to-measure effort is used to support public education efforts, as described in in Section III.J below.

- *Low-Income Energy Affordability Network (Low-Income)*

LEAN works with the Program Administrators to comprehensively serve low-income households. LEAN delivers low-income energy programs and represents low-income PA customers in legislative discussions and regulatory proceedings. The LEAN budget is used to pay for administrative and personnel costs.

3. Creative New Approaches

a. Demand Savings

Achievement of demand savings in 2016-2018 is a key goal shared by the PAs and the Council. In its March 31, 2015 Resolution on priorities, the fifth articulated priority of the Council is to "realize electric demand savings to significantly mitigate peak demand costs to the electric sector." In that same Resolution, Council Cross Cutting Recommendation #2 recommends that the PAs "support products and practices that reduce winter and summer peak." Demand savings have been a point of particular emphasis at the Council for ISO-NE and in the stakeholder workshops.

Issues relating to demand savings can be complex, and it is important to design efforts that take into account unintended negative consequences, such as increased energy usage (which, for example, can be an unintended result of subsidizing ice storage plants that reduce demand).

The PAs have formed an *ad hoc* group that is discussing these matters informally with the Council's consulting team. These discussions are expected to continue into the 2016-2018 term. The Term Sheet set forth at Appendix D provides for the continuation and expansion of this ad hoc group as follows:

> The PAs and the Council recognize the growing economic importance of achieving demand reduction goals and mitigating winter and summer peaks. The Term Sheet does not include targets for potential new statewide summer and winter demand peak reduction initiatives, and does not reflect costs, benefits or incentives associated with such initiatives. Subject to open meeting law requirements, PA representatives will work with a small Demand Savings Group that includes the DOER, the Attorney General's Office, the Low-Income Energy Affordability Network, interested expert and qualified stakeholders and the Council's consultants to explore approaches to cost-effective new demand reduction/peak reduction electric and gas initiatives. This Demand Savings Group will be addressing challenging and important matters, and all parties are committed to the successful development and actual implementation in-the-field during the 2016-2018 Plan term of new demand/peak reduction initiatives. To ensure that this in-the-field implementation goal is reached, the PAs will provide a report to the Council setting forth the specific scope, tasks, and detailed timelines for this group by the end of Q1 2016. This report will also provide an anticipated, high-level in-the-field deployment schedule for 2016-2018 based upon the then most current information. Deployment in-the-field will be subject to approval by the Department of Public Utilities and confirmation of cost-effectiveness. The PAs will also provide a report to the Council on the ongoing "super peak" avoided cost study on or before December 31, 2015 (if that study is delayed, this PA deliverable date will be appropriately adjusted).[100]

Demand savings opportunities can be divided into four categories with different strategies/approaches. The four categories are described below.

1. **Demand Savings from Traditional Energy Efficiency**. Excellent progress and results have been achieved in this essential category. The PAs' traditional energy efficiency efforts, historically and as proposed for 2016-2018, result in substantial demand savings. The 2016-2018 Plan projects electric demand savings of 592,375 kW (summer) and 620,992 kW (winter). In 2010-2014, the PAs achieved over 650,000 kW of summer

[100] CLC reserves its right to raise issues at any time with either the Demand Savings Group or the Council generally regarding its unique role as a municipal aggregator that may affect its ability to fully participate in the development and implementation of demand/peak reduction initiatives.

capacity savings. These substantial demand savings are a core element of the success of energy efficiency in Massachusetts and will continue to be important in 2016-2018. The PAs will continue to promote and prioritize energy efficiency measures that contribute both energy savings and demand savings, as well as explore adding technologies that have the potential for additional demand savings such as dimmable/"daylight dimming" LED lighting technologies (that, when installed in large enough scale, can be used for demand response efforts as well), tailored behavioral programs with a focus on achieving demand savings, and Wi-Fi thermostats and home automation technologies.

2. **Demand Response**. The Green Communities Act calls for PAs to "provide for the acquisition of all available energy efficiency and demand reduction resources that are cost effective or less expensive than supply." G.L. c. 25, §§ 19(a), 21(a), 21(b)(1), 21(b)(2). Demand savings through demand response (peak shaving and load shifting efforts) can contribute benefits such as reducing prices and price volatility for consumers, avoiding or deferring future generation, transmission and distribution investments, and reducing environmental impacts from electric generation. Demand response is a flexible, low-carbon resource that can also be used to help integrate renewable resources as they come onto the electric grid. Viable demand response strategies, combined with planned aggressive energy efficiency efforts, will contribute to the Commonwealth's economic and environmental sustainability goals.

   Keeping in mind the goals and objectives described above, PAs are seeking ways to understand both the costs and benefits of demand response in a way that will inform full scale deployment where benefits are expected to exceed costs. In order to contribute to this goal, individual PAs have developed or are working on developing individual or joint demonstration projects to gain a better understanding of costs and benefits of demand response in the context of the energy efficiency portfolio of programs. PAs will share the results of demonstration projects in order to gain insight, develop best practices, and utilize demand response strategies where appropriate going forward. Following the implementation of demonstration projects and related evaluation, PAs will use the results, along with related research and analysis, to guide the deployment of larger scale demand response initiatives in the latter years of this Three-Year Plan and beyond.

   Current avoided costs are not designed to assess cost-effectiveness for demand response initiatives. The PAs are working regionally to expand the scope of work completed by the avoided cost study contractor in order to derive the value of demand reductions from demand response efforts. These avoided cost values will be focused on the "super peak" period of highest demand, rather than the broader summer and winter peak periods that are currently considered when assessing demand savings from energy efficiency efforts.

   For PA-specific descriptions of demand response efforts, please see PA-specific materials at Appendix L.

3. **Load Shifting**. Similar to demand response, the PAs are examining the possible role of load shifting initiatives. Some efforts designed to shift load, such as time-of-use rates, are outside the scope of energy efficiency plans under the GCA. However, PAs are

reviewing storage technologies as a potentially appropriate focus in the energy efficiency Plan. In addition, behavioral programs and messaging may be used to drive load shifting. The PAs are continuing to review these possible strategies.

4. **Geo-Targeting**. The PAs are exploring whether the strategic investment of energy efficiency in specific geographic locations can yield additional benefits to customers and the energy network, particularly in regions that are subject to gas constraints, or as a strategy to help defer the need for infrastructure investments. The PAs are actively reviewing geo-targeting strategies and will deploy some geo-targeting demonstration projects in 2016-2018 to develop information, test strategies and drive demand savings.

   The hypothesis for implementing geo-targeting is that, if locations with projected high congestion and/or future planned infrastructure investments are targeted with incentives and/or concentrated marketing tactics, the resulting increase of energy efficiency and other demand reduction efforts in those areas may be able to alleviate the congestion or defer the need for infrastructure investments. Such results may have cost savings associated with them that are incremental to those counted in the current set of avoided costs.

   While increased energy efficiency alone will not solve capacity issues, it can be part of an overall plan to address capacity and gas deliverability, save energy, and provide benefits to customers. Berkshire and CMA are reviewing these matters at this time given capacity constraints in areas of their systems.

   As set forth in more detail in Appendix L containing National Grid specific materials, an example of geo-targeting for an electric PA is National Grid's ongoing Nantucket based initiative. National Grid is actively engaged in geo-targeting on Nantucket as one component of a comprehensive "non-wires alternative" ("NWA") project aimed at deferring the long term need for a third undersea cable to serve the island's electric load. In 2015, implementation began on an initial plan, primarily comprised of energy efficiency, to reduce almost 5 MW of load on the island by the end of 2019. The project's overall load reduction targets are approximately 18 MW over 17 years. If successful, the efforts could defer construction of the third cable for at least five years. The NWA project will combine geo-targeted energy efficiency with other technologies, such as renewables, energy storage, demand response, and potentially time varying rates to achieve the necessary load reduction during peak hours.

The PAs look forward to continuing to review potential demand savings approaches for 2016-2018.

b. Integration of Renewable Technologies

In its March 31, 2015 and July 21, 2015 Resolutions the recommended that the PAs proactively promote renewable thermal technologies and identify appropriate incentives for renewable thermal technologies. Exploring and deploying renewable thermal technologies was also a theme that was developed and discussed in the stakeholder workshops facilitated by Raab Associates, Ltd. More broadly, a point of interest for the PAs is exploring ways to leverage the powerful energy efficiency delivery infrastructure that the PAs have developed (working with many stakeholders, including the DOER and the program delivery contractor network) in order to provide increased benefits to customers and the Commonwealth.

The PAs have not fully developed strategies for addressing renewable thermal savings in 2016-2018, but are reviewing these matters, and seeking to ensure that they are addressed in the most appropriate forum. Core question to be addressed is exactly what technologies are contemplated by Councilors, what is their applicability in a three-year energy efficiency plan under the GCA and is implementation of some of these efforts perhaps more appropriately handled in other contexts or proceedings, *e.g.*, grid modernization. More specifically, some essential elements and questions in the PAs' review are:

- Are there cost-effective measures/strategies that are appropriately delivered as energy efficiency measures, as opposed to renewable supply side measures?
- What funding sources are potentially available to fund the measures/strategies, *e.g.*, energy efficiency funds under the GCA, Massachusetts Clean Energy Center ("MassCEC") grants, tax credits, HEAT Loan expansion (funding sources could vary by measure)?
- What energy savings and other quantifiable benefits can be claimed for incentivizing these measures, and can they be quantified and claimed under the TRC test as required for energy efficiency efforts under the GCA?
- What, if any, are the most promising potential technologies and, if applicable, how should deployment of these technologies be prioritized?

As with demand savings, issues related to renewables are complex, and it is important that any design efforts are carefully cost-justified and that appropriate funding sources are used. The PAs and Council do not have these issues resolved at this time, but efforts are continuing and the PAs will remain engaged with the Council on these matters.

c. Other Creative New Approaches

This Plan sets forth the highest goals ever established in the Commonwealth and, based upon the best information currently available to the PAs, in the United States. In order to achieve these high goals over time, the PAs will need to develop and incorporate creative new approaches to servicing customers and locating untapped or underserved opportunities. In its July Resolution, the Council has expressly supported the exploration in 2016-2018 of creative new approaches and testing new technologies and ideas. The PAs are relying on the Council's support of new approaches in adopting the bold goals set forth in this Plan.

The PAs need the flexibility to pursue these creative new approaches and untapped opportunities to continue to keep Massachusetts as a national leader in energy efficiency. The PAs will look to implement efforts targeting new, niche opportunities that must meet three core tests: (1) serving the opportunity must result in cost-effective savings using the Department's cost-effectiveness screening standards; (2) any resulting savings are not being funded and counted in the context of another mandated activity, for example, grid modernization, provided that the PAs have the ability to provide additional or incremental activities that are complementary or supplemental to these activities being taken pursuant to another mandated activity; and (3) the opportunity is not otherwise being addressed in other capital improvement projects funded through other rate mechanisms (*e.g.*, capital expenditures to reduce gas leaks), again with the understanding that the PAs will have the ability to provide additional or incremental activities that are complementary or supplemental to these capital improvement projects. A possible example of such an effort might be replacing inefficient lighting at a substation with new LED lights, or upgrading utility-owned streetlights.

Another niche opportunity the PAs seek to address in the term of this Plan would be providing services for a limited number of state or federal government agencies that are currently wholesale customers, in way that is consistent with Department directives and regulatory requirements. The PAs believe there may be some unique opportunities to address inefficient facilities within this sector, with benefits for all customers within the service area that are contributing to the payment of utility bills of such agencies through taxes or assessments. The PAs would only explore these opportunities for existing wholesale government customers and must be able to demonstrate the cost-effectiveness of the project and that the approach for a specific project was consistent with Department directives and applicable regulatory requirements.

Looking forward, and with no specific current proposals in this Plan, the PAs would like to explore creative ways in which they can engage new customer segments. For example, there may be opportunities to assist generators in becoming more efficient, enhancing their productivity and decreasing greenhouse gas emissions. Another opportunity that the PAs could explore is providing services to municipalities that do not currently offer energy efficiency services or do not offer the comprehensive suite of energy efficiency services offered by the PAs. As part of their R&D efforts, the PAs want to explore and examine these unique opportunities that, if properly implemented, could increase the efficiency of energy usage for new populations in the Commonwealth and materially assist the Commonwealth in greenhouse gas reduction efforts.

I. Marketing Plan and Activities

1. Introduction

The Program Administrators plan to continue to use public education and marketing as key tools to support a culture of sustainability in Massachusetts. By creating powerful, engaging and motivating education and marketing strategies, PAs can continue to increase awareness of the benefits of energy efficiency and drive increased participation in the available energy efficiency programs and services. Proposed public education and marketing strategies will take into account the unique motivational differences between residential and non-residential customers.

Support of the Mass Save® mark and statewide brand remains a key priority. The PAs commit to statewide marketing efforts that include the prominent integration and placement of the Mass Save® mark as the statewide brand. PAs will include the Mass Save® mark on statewide program, outreach, and marketing materials. In addition, PAs will include a link to the Mass Save® website on the portion of their company's website that is focused on energy efficiency services in Massachusetts.[101] PAs continuously review and evaluate the effectiveness of all joint statewide branding efforts, and engage in on-going refinements to ensure that such brands support clear, consistent, and recognizable messages that help promote program awareness.

Building on the success of digital and social marketing platforms will be a key focus of effort. The Mass Save® website has become a critical focal point in the comprehensive marketing program, providing a consolidated one stop shop for residents and businesses to learn about energy efficiency, program offerings and opportunities. The Mass Save® website and strategies that drive customers to the website will continue to be refined to ensure the highest quality customer experience. Marketing will continue to leverage the strong social media presence built over the 2013-2015 term. With over 110,000 Facebook fans (https://www.facebook.com/MassSavers) and nearly 15,000 Twitter followers (https://twitter.com/masssave), PA marketing and education is able to reach an ever broadening audience. The social media platforms support effective peer to peer marketing, allowing customers to become brand ambassadors.

Reaching out to customers who haven't participated in Mass Save® branded programs remains a fundamental commitment. Under this Plan the Mass Save® website will be translated into additional languages, starting with Spanish and Portuguese, to continue to expand access to diverse linguistic populations. The PAs will explore affinity marketing opportunities to expand the reach to new market segments while offering the added benefit of supporting the community beyond energy efficiency.

The refinements to current strategies and messages developed for statewide energy efficiency education, outreach, and marketing will augment the efforts already in use and will attempt to complement and leverage program-specific marketing and individual PA efforts across the Commonwealth.

2. Marketing Plan Overview

The ultimate goal of all educational, community outreach, and marketing efforts is to develop an effective system of communication with Massachusetts residents and businesses. This system is a critical tool to support customer awareness, understanding and participation in the PAs' comprehensive energy efficiency programs. Independent evaluation studies and a review of the marketing activities over the course of the first two plans (*i.e.*, 2010-2015) illustrate the extraordinary growth and success of the coordinated marketing efforts among the PAs and provide a path for PAs to better understand where improvements can be made.

For the 2016-2018 Plan, core objectives of the PAs' public education and promotion campaign include:

- Maximizing reach to ensure *all* residential and business customers are provided access to information and connection to resources.

[101] Except where expressly limited by internal corporate website policies.

- Providing compelling and accessible messages, which clearly describe the benefits of energy efficiency without excess jargon or overly technical language.
- Exploring and deploying targeted marketing to unique or specific communities throughout the state (including communities where English is not the primary language).
- Utilizing diverse media (*e.g.*, internet, bill inserts, radio, billboards, public transit, social media) to disseminate consistent and clear messages.
- Ensuring that the various strategies work together to ultimately achieve deeper and broader savings.

Through an extensive array of effective messages and an all-inclusive media strategy, the PAs commit to engaging with the broadest cross section of residential and business customers with tailored, targeted, and actionable information.

The careful balancing of breadth, depth, and understanding of customer motivation in the campaigns will drive value to customers and support obtaining the aggressive energy efficiency goals set forth in this Plan.

3. Mass Save®

In 2010, the PAs joined together to bring energy efficiency programs to the Commonwealth through a statewide PA brand. As sponsors of the Mass Save® word service mark, the intent of the PAs was to complement their individual PA brands when communicating with residential and C&I customers about energy efficiency programs.

The PAs are the owners of the Mass Save® word service mark. A trademark or service mark identifies goods and services as originating from a single source. Trademarks, in effect, represent the goodwill that a business has built up through its history of offering quality goods and services. A word mark is the most common form of trademark and simply consists of a word or group of words. The PAs have rights to the word mark Mass Save®, having obtained federal registration of it on August 29, 2006.

Under trademark law, the PAs must monitor and control the use of their marks in order to maintain them and to prevent inferior energy efficiency services from diminishing them. Throughout the past two plan periods, the PAs have overseen significant monitoring efforts with respect to the Mass Save® mark to identify unauthorized uses of the service mark. Legal measures have been successful to stop such unauthorized uses and thus the integrity of the mark has been protected.

4. Marketing for 2016-2018

During the term of the first Three-Year Plan (2010-2012), the PAs joined together to market energy efficiency services on a statewide basis through use of the Mass Save® service and design marks. In 2013-2015, a single website was created as a central repository to educate customers and provide access to energy efficiency program information and participation. The launch of this statewide website was a major and unprecedented undertaking satisfying a core Council priority. The existence and operation of this website demonstrates the commitment of the PAs to working together for the benefit of customers throughout the Commonwealth.

The PAs continued the Mass Save® Awareness Campaign during the 2013-2015 Plan term to increase awareness of energy efficiency and Mass Save® across the Commonwealth. The campaign continues to work across many forms of media, including radio, internet banner adds, social media, smartphone and tablet ads, and print ads. The Statewide Marketing team selected a new vendor for marketing and website services for the 2015 campaign. With the new vendor on board, the PAs completed a full audit of marketing materials used for outreach events and recruitment in Residential New Construction. As a result of this audit, a forward-looking plan for marketing materials was developed.

Additional notable highlights from 2013-2015 include: (1) a redesigned and refreshed the GasNetworks.com site; (2) customer-facing videos on the Mass Save® website that provide information on ductless mini split heat pump and heat pump water heater technologies; (3) successful leveraging of social media outlets, like Facebook and Twitter, to launch creative campaigns; and (4) the addition of Affinity marketing to the mix of promotional strategies.

The PAs also executed a pre-campaign awareness study and a post campaign study, now conducted annually, which allows the PAs to benchmark and evaluate the effectiveness of their messaging and media planning. The PAs will take into consideration the results of this study to develop their marketing campaign for the 2016-2018 Plan. Key findings from the study include: (1) awareness of Mass Save® has increased significantly since December 2013; (2) customer awareness of MassSave.com and self-reported website usage increased in 2014; (3) efforts to drive web traffic have been successful among those who are aware of the Mass Save® website; (4) campaign messaging was clear and resonated with residential and commercial customers; (5) self-reported exposure to Mass Save® messaging increased significantly among residential and commercial customers; and (6) depth of knowledge for program offerings is also increasing among residential and commercial customers.

In January 2015, the PAs began making several significant changes for the 2015 campaign and beyond. Specifically, the new marketing vendor, KSV, now manages the Mass Save® website in addition to serving as the campaign implementer. As part of this transition, KSV will develop new website content and seek to improve the website user experience. In addition to changes to the website, Mass Save® will use new campaign messaging in 2015 and beyond, focused on emphasizing how simple and easy it is for customers to save money on their energy bills.

MassSave.com will continue to be evaluated for content and usability and improvements made. The PAs' focus on total customer experience recognizes the entry of the customer through the website as a critical component of that experience. The website provides the PAs an opportunity to offer streamlined information, including assessment tools such as the online home energy assessment, and on line rebate processing which offer substantial customer experience benefits. The PAs will continue to feature all the PAs' brands in conjunction with the Mass

Save® marks per the findings from the Massachusetts Statewide Marketing Campaign Evaluation Report and consistent with their goal to convey who and what Mass Save® is.

The key themes for the Statewide Marketing efforts for the 2016-2018 planning cycle are as follows:

- Define who and what Mass Save® is and what it means to the customer.
- Increase the message that associates Mass Save® with "A way to lower your energy bills" to both residential and C&I customers.
- Message and graphically tie in the PA Brand Logos with the Mass Save® mark to create a strong association and clarity of message.
- Utilize the segmentation work identified by the RMC and C&IMC so PAs can better and more consistently target customers from a program and statewide awareness level.
- Create awareness and understanding of Mass Save® as a trusted statewide resource for all customers' energy efficiency needs.
- Educate customers about the opportunities to save energy and motivate them to take action.

During the 2016-2018 Plan term, the Statewide Marketing Committee will continue to meet monthly and update DOER, through informal discussions, on any new developments concerning the PAs' statewide marketing efforts. From a market research perspective, the PAs will continue to conduct pre/post campaign studies and track their campaign effectiveness in terms of driving customers to the website and refreshing content.

5. Maintenance of Complementary Individual Efforts

While working diligently on the statewide public education efforts, the PAs will also continue to maintain customer awareness, satisfaction, and participation goals and accordingly, the PAs will also continue outreach efforts utilizing customer representatives and account executives (who enjoy one-on-one/person-to-person relationships that are especially important in the C&I sector) and PA-specific efforts that complement and are consistent with statewide efforts and the findings of the 2014 Marketing Report.

J. **Public Education**

The key objective of the Residential Education initiative is to offer an array of K-12+ educational outreach programs and enhanced consumer education. Several Program Administrators collaborate with the National Energy Education Development ("NEED") Project, bringing energy efficiency curriculum and training to teachers in Massachusetts. An addition to teacher trainings in 2016-2018, some PAs will implement an energy-efficiency take-home initiative involving kits, which will contain instant-savings measures such as light bulbs, showerheads, and faucet aerators, as well as educational materials (budgeted through HES). After in-class lessons about energy-efficiency, students will bring the kits home and report back on which measures their families install. In this way, the PAs can capture additional savings and expand the reach of the education programs beyond teachers and students, to parents, as well.

The PAs' support of educators, students, and parents through program opportunities, curriculum, and materials on energy efficiency and conservation is a critical component in fostering an energy literate society.

Additional efforts directed at consumers focus on educating customers on the benefits of investing in energy efficiency products and services and the multitude of energy efficiency initiatives available to them. Collaborative efforts for consumer education in 2013-2015 included the Energy Savvy online energy assessment tool on the Mass Save® website (budgeted through HES) and kits containing "Kill A Watt" meters available through libraries. This outreach will be continued in 2016-2018.

Some PAs also conduct additional direct outreach and provide additional in-school programming to schools in their service territories. These programs will continue to evolve and expand to reach more students. Many of these programs have earned local and national awards for energy education programs.

The PAs plan to work with DOER, educational institutions, the statewide marketing working group, and PA education and/or marketing departments to develop educational and promotional strategies. Efforts for school-aged education will continue to focus on expanding the existing, in many cases award-winning, PA school programs. Educational outreach strategies for 2016-2018 may include:

- Sponsor energy efficiency related classroom presentations and activities to K-12+ schools.
- Direct educators and children to online educational resources to help educate children about energy safety and conservation.
- Sponsor science fairs, teacher training workshops, and other elementary and secondary educational opportunities in collaboration with DOER, Massachusetts Department of Education, and schools throughout the Commonwealth.
- Encourage schools and informal education programs to participate in the annual NEED Project's Youth Awards Program held in April of each year, with follow-up awards program and ceremony in June in Washington, D.C.
- Explore the program development for youth group summer camps promoting energy conservation and behavioral change.
- Partner with communities to educate and promote energy efficiency through energy fairs, sponsorships, and community-specific outreach.
- Participate in various energy-efficiency employee awareness events.
- Conduct school fundraisers promoting energy-efficient technologies (budgeted through Lighting).
- Offer prompt-based contests for students to showcase their energy and energy efficiency knowledge.

- Direct customers to online calculators and web tools to learn more about home energy usage and to offer energy saving recommendations, including information on available energy-efficiency incentives.

The PAs will work to develop energy efficiency marketing messages aimed at residential customers, educators, students, parent/teacher organizations, and community groups. Proposed collateral will highlight the many benefits of investing in energy efficiency, savings that can be generated by individual efficiency measure upgrades, behavioral changes, and testimonials from past program participants. The PAs will employ a variety of media sources for messaging, which may include bill inserts, bill messages, customer newsletters, www.masssave.com, direct mail, employee and business partnerships, newspapers, social media outlets, and educator workshops.

K. **Community Engagement**

Over the course of the prior Three-Year Plans, the Program Administrators have worked on a variety of community-based outreach and marketing initiatives throughout the Commonwealth. These efforts included collaboration with local community advocates and leaders from various communities, with PAs providing project management and technical support. The PAs continue to view community-based engagement activities as a component of overall marketing and outreach strategies. The PAs consider engagement with entire communities where appropriate, as well as engagement at a smaller scale based on the particular needs of a local municipality or neighborhood. The PAs appreciate the continuing efforts of their dedicated colleagues in community engagement initiatives and their desire to find the best ways to serve harder to reach constituencies.

Program Administrators recognize that the effective delivery of energy efficiency programs is highly dependent on building confidence among customers, as well as an extensive network of service providers. The programs and services offered by the PAs represent wise investments – investments that contribute positively to the well-being of homes, businesses and communities. In 2016-2018, the PAs plan to continue building on the successful relationships they have fostered with a diverse network of outside organizations in order to communicate the many benefits of saving energy.

In the residential programs, the PAs engage with local trade allies, municipalities, community organizations and other appropriate and highly visible outside organizations to deliver information about program opportunities, and to target specific customer segments. PAs establish these relationships, both on a statewide-level and as individual entities working within their communities, to ensure the visibility and success of their programs.

PAs partner with local trade allies such as the Building Performance Institute ("BPI"), Northeast HERS Alliance, Southern Middlesex Opportunity Council's ("SMOC") Green Jobs Academy, Plumbing – Heating – Cooling Contractors Association ("PHCC"), International Association of Plumbing and Mechanical Officials ("IAPMO") and Air Conditioning Contractors of America ("ACCA"). PAs communicate with these trade allies by hosting, attending, and presenting at trade ally conferences and events, through the distribution of direct emails and newsletters, by advertising in trade publications, and through direct conversations with PA program managers and/or service delivery vendors. For example, the PAs' annual GasNetworks® conference attracts hundreds of trade allies from the heating and cooling industry; the 2015 GasNetworks Conference was attended by nearly 400 contractors and industry representatives.

The PAs also actively collaborate with municipalities for geographic specific efforts such as Renew Boston, various municipal-specific Memoranda of Understanding and grant programs, the Nantucket Non-Wires Alternative effort, and partnerships with city and town planning boards and redevelopment authorities.

PAs collaborate with community organizations to ensure energy efficiency is being talked about where people gather in their daily lives. The community action agencies that administer the PAs' income-eligible energy efficiency programs work with multiple community organizations to create partnerships that ensure the success of programming for low-income families. The specific organizations vary from town-to-town; however, typical alliances include the local United Way, Goodwill, Salvation Army, veterans groups, school districts, fuel assistance providers, civic associations, food pantries, shelters, and community development corporations. Community action agencies, by design, engage local resources to increase awareness among qualifying members of their communities of the various program offerings, including the PAs' income eligible programs. Additionally, each year the PAs participate in statewide social service agency meetings, typically held in October, to present to several hundred social service providers to inform them of program offerings.

The residential education fundraisers held in dozens of Massachusetts public and private schools each year help schools raise funds while teaching students about energy efficiency and conservation. Schools receive free educational materials, hands on demonstrations, and support from fundraising coordinators. PAs also answer the needs of their local schools in additional ways, such as in-classroom educational opportunities that educate students on saving energy while promoting the programs to parents.

The PAs also attend and/or sponsor events relevant to their individual communities in an effort to educate people on the programs and energy efficiency in general. Examples include collaborations with local farmer's markets, community centers, civic associations, hospitals, fire-stations, Earth Day and sustainability celebrations, city and county fairs, seasonal festivals, home shows, real estate organizations, media outlets, colleges and universities, hazardous waste/appliance turn in events, and youth baseball teams.

In the commercial programs, the PAs have found that delivery is enhanced when they partner with a variety of organizations that serve, and are respected by, various business actors. For example, the PAs have partnered with the Massachusetts Lodging Association to promote LED room and common area lighting, and the Massachusetts Bankers Association to promote financing for efficiency programs. A listing of the organizations where the PAs have engaged members, either through training and education or joint promotions, in recent years includes BOMA/Boston, the Greater Boston Real Estate Board, the Boston Green Ribbon Commission, Boston Green Tourism, the International Facility Management Association ("IFMA"), Boston

Chapter, Massachusetts Restaurant Association, Municipal Solid-State Street Lighting Consortium (“MSSLC”), and the Northeast Sustainable Energy Association (“NESEA”).

In addition, PAs constantly engage in outreach to local community business groups – chambers of commerce, downtown business alliances, and local economic development and revitalization organizations – to advise them of programs and services available to their constituencies. For more information on C&I engagement strategies, please see the section titled “Education and Training for Customers, Trade Allies, and PA Staff and Contractors” in the C&I Retrofit program description in Section III of the Plan.

L. PA-Specific Programming

The PAs strive for consistency in program offerings with the goal that customers across the Commonwealth can take advantage of comprehensive energy efficiency services. In some instances, however, individual PAs may provide additional services or unique incentive structures that are specific to their territory. These offerings may be specifically related to the unique characteristics of a service area, or may be developed based on unique conditions in that territory, such as gas constraints or reduction in expense related to very large capital improvement projects. They may also be based on the governing structure of a PA, such as the Compact, which has a distinct role as a municipal aggregator. Finally, these efforts may be run as a test case by one PA, with the idea that the programming could be rolled out across PAs if proven successful and cost-effective. Please see Appendix L for information on PA-specific initiatives.

The PA-specific initiatives set forth in Appendix L represent proposals of only the Program Administrator making the proposal. They do not constitute proposals that have been reviewed and agreed to by all PAs, and PAs may have divergent views on the materials contained therein. All PAs reserve their right to comment on these proposals in the future, and the inclusion of these materials does not constitute the consent of any PA to any other PA’s specific initiatives or proposals.

IV. STATEWIDE BUDGETS, SAVINGS, AND BENEFITS

A. Development of Goals

1. Introduction

The PAs engage in a highly collaborative and detailed planning process for setting savings goals and budgets. Programmatic decisions that inform savings goals and budgets are made both at the individual PA level and at the statewide level, including work by the respective management committees, which facilitate ongoing stakeholder input, continuous sharing of best practices, and consistency of offerings among the Program Administrators. While ultimately the results associated with development of a PA's plan are PA-specific and the planning process for savings varies for each program and initiative, certain common processes apply to instruct the development and to facilitate regulatory review.

2. Electric Statewide Budget, Lifetime Savings, Annual Savings, and Benefits

STATEWIDE ELECTRIC BUDGETS ($)	2016	2016-2017	2016-2018

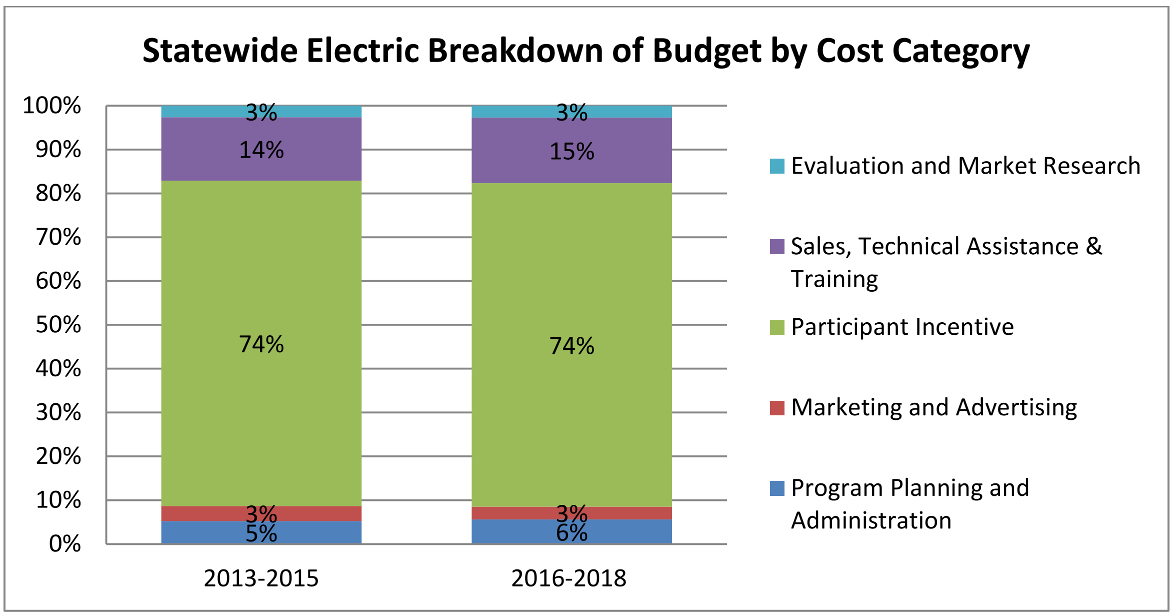
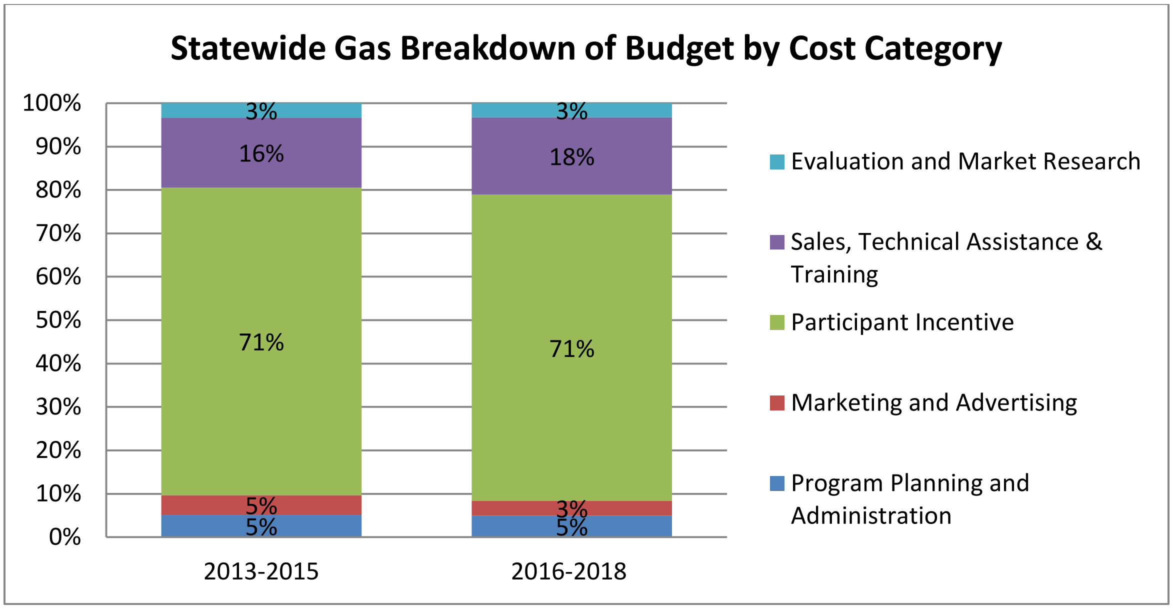
4. Breakdown of Budget by Cost Category

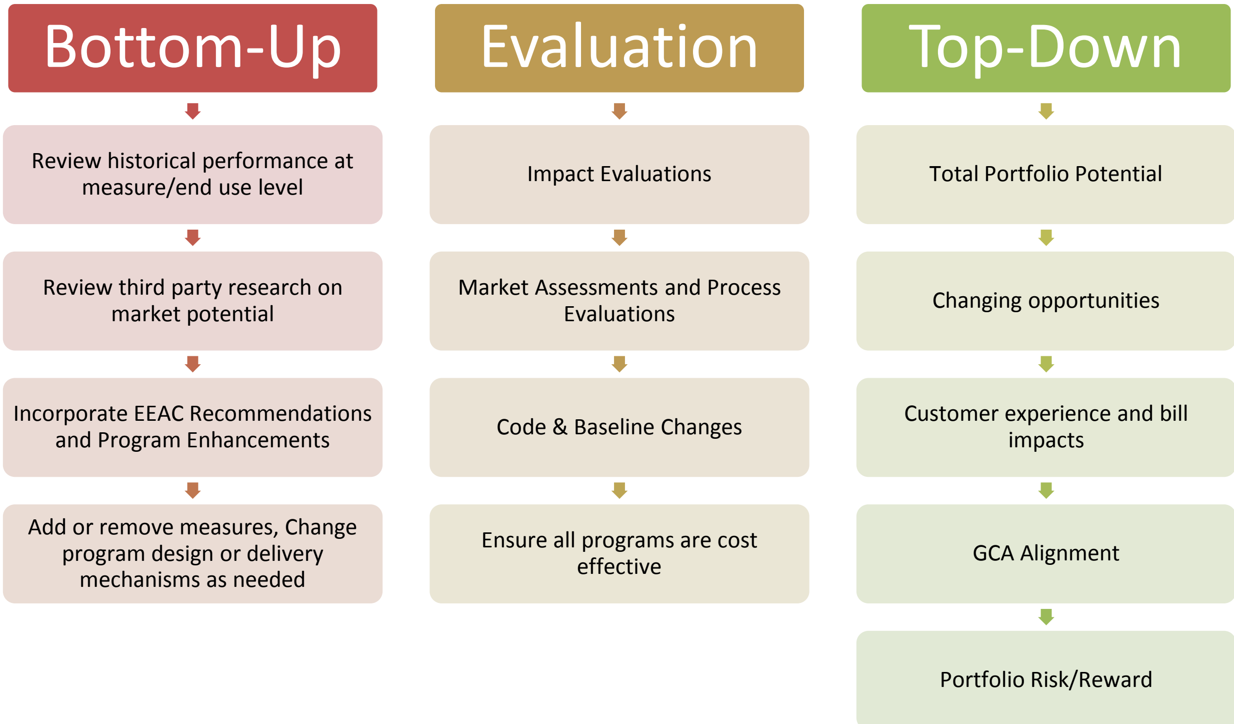
The majority of energy efficiency budgets are delivered directly to customers in the form of incentives that are intended to overcome the financial barrier to investment. In the 2016-2018 Plan, 74 percent of the electric and 71 percent of the gas budget is delivered directly to customers through use of participant incentives. These incentives drive customers to participate and are one of the underlying reasons the programs have been able to achieve historic savings levels. Approximately 15-18 percent of the PAs' costs are budgeted in the Sales, Technical Assistance & Training cost category, supporting the activities of vendors, contractors and other industry professionals. These investments are driving job creation and the evolution of a green economy in the Commonwealth. Approximately 3 percent of the statewide budget is dedicated to the rigorous Massachusetts Evaluation, Measurement and Verification process. Other administrative functions, like Program Planning and Administration and Marketing and Advertising, make up approximately 8-9 percent of the statewide budget. These percentages are in line with historical averages, demonstrating that the Program Administrators have been able to significantly grow their energy efficiency portfolios while keeping administrative costs low and maximizing the value of the programs for participating customers.





5. Process to Determine Goals

The development and determination of the proposed statewide and Program Administrator-specific savings goals takes into account an assessment of savings opportunities in individual PA service areas (bottom-up), consideration of evaluation study findings, and a collaborative consideration of statewide policy objectives that balances savings goals and the consideration of high level energy efficiency costs that are deemed acceptable (top-down). The bottom-up process involves determining savings by measure, including projected quantities and customer incentive amounts for every piece of equipment, type of technology or program service. The top-down process looks at the portfolio as a whole, evaluating the potential for achieving higher goals given markets in which the programs are operating, subject to overall cost. The impact of evaluation results are considered in both bottom-up and top-down planning and may drive other adjustments. The process to determine goals must be and is fluid, flexible and iterative, taking into account information that the PAs learn throughout the planning process related to program design, evaluation, costs and other factors.



The 2016-2018 Plan seeks to capture all available cost-effective energy efficiency for the three-year period beginning January 1, 2016, taking into account many competing considerations, including, but not limited to, bill impacts, cost-efficiency, integrated program delivery, economic and environmental benefits, efforts focused on innovation, and the need to establish as "integrated" effort that can be "sustained" over time, as laid out in the Green Communities Act. G.L. c. 25, § 22(b). Determining sustainability requires the PAs to examine the capability of vendors and contractors as well as that of the PAs themselves to respond to expanded programs, retain a capable workforce over time, and avoid large fluctuations in bill impacts.

The PAs also engaged in detailed discussions with stakeholders to help determine the appropriate budgets and goals for 2016-2018. Following the July 21st Resolution of the Council, the PAs collaborated with the Executive Office of Energy and Environmental Affairs ("EEA"), the DOER and the Attorney General, along with the Council's consultants, to further discuss goals, budgets, and key priorities. As a result of these discussions, the PAs, EEA, DOER, and the Attorney General were able to agree upon the Term Sheet. See Appendix D. The Term Sheet sets forth fundamental core goals for 2016-2018 that have served as a guide for the PAs in developing this Plan. The Term Sheet was developed and agreed to after extensive information sharing between these parties, and a general acknowledgement that there is no exact formula for determining all available cost-effective energy efficiency, that the Department must consider bill impacts, and that the GCA encourages consensus building among the PAs and the Council. Following feedback from the Council on the Term Sheet, the PAs revised electric annual savings to include an upward trajectory, taking into account the Council's desire to set a national example of continued commitment to energy efficiency in Massachusetts, while recognizing that overall results across the entire three-year period will be the measure of success.

The final statewide and PA-specific goals set forth in the Plan represent the effort of each PA over many months reviewing available measures and technologies, efficiency standards, avoided costs, past performance, evaluation studies, potential studies, cost drivers, and many other elements and considerations that go into planning, as well as extensive discussions and consensus-building with stakeholders and the Council to reach goals that represent all cost-effective energy efficiency, taking into account sustainability and bill impacts in accordance with the GCA.

a. Bottom-Up Planning

The planning process varies for each program and initiative. For example, the budgeting process for the core initiatives contained in the Residential Products program is measure-specific and driven by the number of rebates expected to be issued. Other initiatives take a whole-house approach with planning by projected audits, homes, or customer sites. Regardless of the approach, the PAs typically begin each planning process by examining historical data to gain insight into participation trends, savings achieved, and costs to achieve these savings. The PAs also examine any forward-looking data, such as new federal efficiency standards, third-party research on consumer adoption of new technology, and new avoided costs determined through a regional Avoided Energy Supply Cost study. See Appendix J. The PAs then collaborate to decide what changes, if any, need to be made to program offerings. For example, the PAs may decide to discontinue measures that have become standard efficiency practice, or to add new measures and services in response to improved technologies or identified consumer needs, subject to consideration of cost-effectiveness.

These types of overarching decisions are done at the statewide level at the respective management committees, ensuring input from all stakeholders and continuous sharing of best practices, and facilitating consistency of offerings among the Program Administrators. Each PA uses this information to develop a forecast of sustainable delivery in its unique service territory. PAs also consult their vendors to support or augment their forecasts based on field experience and what is in the vendor’s queue, as well as talk to manufacturers and contractors for insight into workforce and technology availability and limitations.

b. Top-Down Planning

While bottom-up planning focuses on what is reasonable for each individual measure, top-down looks at what is reasonable and achievable for the portfolio as a whole. This includes examining impacts to the overall markets that the programs are targeting as well as cost implications to customers.

One of the tools that Program Administrators use in top-down planning is potential studies, which help PAs to better understand the long-term availability of energy efficiency savings within their territory and give insight into three key pieces of information.

- *Technical Potential* is defined as the *complete* penetration of all measures that are feasible given current technology limitations without consideration of cost or likely consumer acceptance.

- *Economic Potential* refers to the subset of *technical potential* that is cost-effective when compared to supply-side alternatives.
- *Achievable Potential* refers to the amount of savings potential that is attainable given actual program infrastructure and societal and market limitations.[102]

The PAs use the results of potential studies to understand the achievable, cost-effective potential opportunity over a period of years. This information helps the PAs to set savings goals in the Plan that are sustainable in the long run, and take into account not only what is available and cost-effective, but also how willing and able customers are to adopt energy efficiency measures. Several PAs have performed new potential studies in advance of the 2016-2018 Plan. The results of those studies, and the lessons learned, have been shared among all PAs so that each PA can learn from these studies.

c. Evaluation Results

As noted above, PAs also look at EM&V results to inform proposed goals. As part of the statewide EM&V framework, the PAs collectively conduct many different types of evaluation studies. Each type of study serves a different purpose in the planning process, as outlined below.

- *Impact Evaluation* refers to the measurement of net or gross savings achieved within overall program populations. Results from these studies typically show impacts at a detailed measure or end-use level and assist the Program Administrators with their bottom-up approach to planning.
- *Market Evaluation* refers to the measurement of the effects that programs have on the structure and functioning of their target markets. This type of evaluation is useful in top-down planning and in consideration of projected net-to-gross ratios used to derive net savings.
- *Process Evaluation* refers to the systematic assessment of programs for the purpose of documenting their operations and developing recommendations to improve their effectiveness. This evaluation can be useful for both bottom-up and top-down planning.
- *Market Characterization or Assessment* refers to the systematic assessment of energy efficiency markets for the purpose of improving the effectiveness of programs targeting those markets. These types of evaluation studies are most often used to guide implementation strategy. For example, the results from a market evaluation study may help the PAs understand that the market for certain technologies is saturated and that the PAs need to plan to incentivize newer technologies to meet the needs of an evolving market. Again, this evaluation can be useful for both bottom-up and top-down planning.
- *Evaluation of Pilots* refers to EM&V activities intended to assess the effectiveness of pilot programs and demonstration projects, determine their potential for full-scale implementation, and develop recommendations for any changes in program approach.

[102] Potential definitions are based on ACEEE definitions available at http://aceee.org/topics/efficiency-potential-and-market-analysis.

In advance of the 2016-2018 Plan, the PAs completed 25 new studies, in addition to other studies that have been filed in previous Plan-Year Reports. These new studies include a wide range of evaluation topics in the residential, low-income, C&I, and cross-sector evaluation areas. A summary of each of these studies is included in the Plan at Appendix T, and the full set of studies is available at Appendix U.

d. Cost Drivers

A final step in goal setting is to assess the cost impact of the programs in support of "right sizing" proposed budgets. The Program Administrators' statewide energy efficiency programs have evolved significantly since the development of the first Three-Year Plan in 2009. In part as a result of their success, the Program Administrators are currently facing a new series of challenges – changes in projected program costs and the hurdles associated with achieving historically high savings levels on a sustained basis after having already had notable success in penetrating markets.

To address these challenges and deliver the most cost-effective energy efficiency programs to their gas and electric customers, the Program Administrators seek to develop a thorough understanding of current and future cost drivers and savings levels for their proposed energy efficiency programs. Each Program Administrator is affected differently by each cost driver, and variations in savings goals and the cost to achieve these goals are to be expected due to unique characteristics in service territories. Building demographics, income types, fuel type, economic conditions, and population demographics vary widely across each PA's service territory and influence how each PA plans to set and achieve its goals.

From 2009-2011, the cost to achieve savings for electric energy efficiency programs throughout the state was trending down.[103] During that same period, the cost to achieve savings for gas programs was trending upwards. From 2012-2014, the cost to achieve savings for electric and gas energy efficiency programs throughout the state has been relatively stable with a modest increase for gas programs. The PAs project the cost trend for 2016-2018 will be upwards.[104] This trend reflects continued market penetration and the expectation that savings per participant are expected to decline. That means that although the number of customers to be served in 2016-2018 is likely to be greater than the number served in 2013-2015, the average savings per participant will be lower in 2016-2018 when compared to 2013-2015. These trends are also influenced by increasing costs due to a shift to a more expensive measure mix (*e.g.*, moving from rebating inexpensive CFLs to more expensive LEDs), by decreasing levels of savings due to changes in codes and standards, and by impact evaluation findings that have

103 The PAs note that the costs and savings of large, one-time projects can skew the historical costs to achieve savings, often making the costs appear lower than the average. Because large projects are not typical or replicable, they should not be included in the planning process to estimate budgets or savings, or when calculating costs to achieve savings, without careful analysis and appropriate adjustments. For example, some PAs had large CHP projects in 2011, making the cost per kWh appear to decrease in 2011 compared to previous years. When excluded, however, costs were relatively flat.

104 "Cost to achieve" is typically discussed in terms of net savings. Net to gross factors are only updated at the beginning of a three-year term and their impact may therefore be more pronounced when looking at differences between two different Three-Year Plans.

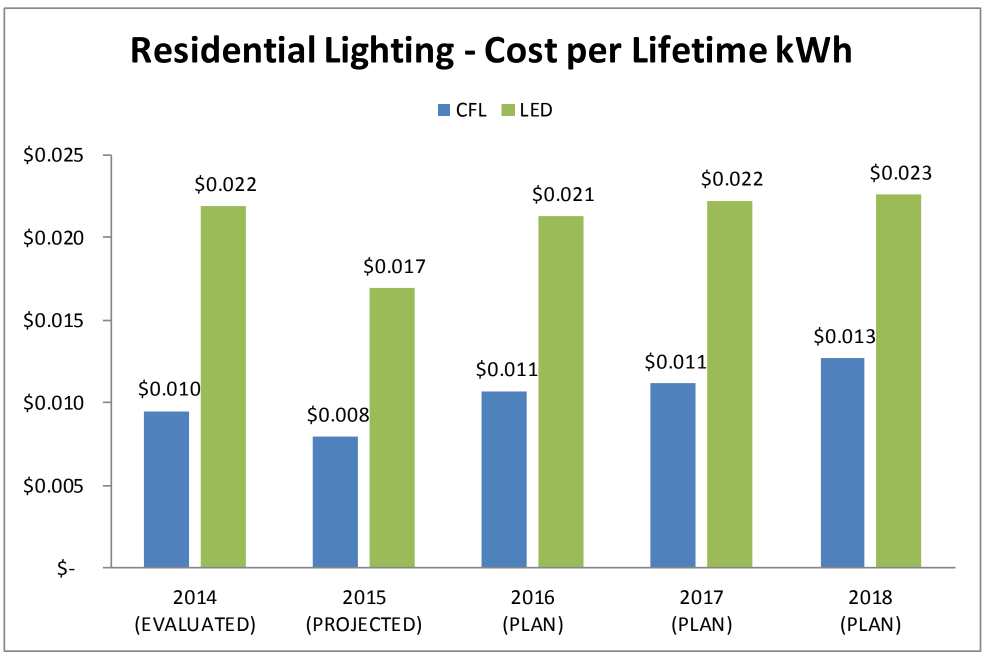
caused the PAs to temper their expectations about savings achievable in some initiatives. Additional details on key cost driver considerations include the following:

- **Codes and Standards –** As federal and state codes and standards become increasingly rigorous, the amount of incremental savings from installing energy efficiency measures decreases (unless the efficiency of the program measures rise as well). This decrease in savings results in a higher cost per unit of savings. Codes and standards that are posing a pronounced challenge to program savings include EISA lighting standards, federal water heater standards, a new 2015 User Defined Reference Home, adoption of the 2015 International Energy Conservation Code for new building construction and renovation, and federal heat pump standards, all of which raise baselines and reduce the savings the PAs can claim.
- **Going Deeper and Broader –** Another factor that is impacting the cost to achieve in this Plan is the need for new approaches to drive customer participation. As certain programs begin to saturate markets, PAs must find ways to encourage participation in more difficult, and often more expensive to reach, markets. New approaches for 2016-2018 include enhanced focus on encouraging renters to participate in the HES core initiatives, offering augmented incentives to consumers whose income is 61-80 percent of the statewide median, planning for weatherization jobs for oil-heated multi-family participants in the Residential Whole House program and the Low-Income Whole House program, which can lead to an increase in benefits for electric PAs (but do not increase electric savings).
- **Cost-Effectiveness Limitations –** The 2015 Avoided Cost Study found that with declining natural gas prices, the benefit of gas savings was reduced throughout the Commonwealth. Lower benefits can make it more challenging for measures to be cost-effective; as a result, some measures, and even entire initiatives, may have to be discontinued to retain program cost-effectiveness. The result is that PAs have fewer options available to them to attain savings, and this reduction in flexibility and program reach increases the cost to achieve savings.
- **Low-Income Funding –** Historically, the Program Administrators have partnered with the Community Action Agencies that receive funding from the federal Weatherization Assistance Program ("WAP") to deliver programs to income-eligible customers. Going forward, however, the availability of WAP funding will be sharply reduced due to national program cuts, and the Program Administrators will need to fund a greater portion of each project when providing services to this important sector.
- **Unique Service Area Drivers –** Despite consistent program offerings, some variations among PAs in savings goals and costs to achieve are appropriate due to the unique characteristics of each PA's service territory and the goal of fostering creativity among PAs. Each PA has a distinct mix of customers and sectors, which affects energy efficiency programs in different ways. Each PA has unique demographics, with different mixes of building types, income types, fuel types, fuel constraints, economic conditions, and population density. Reasonable variances among PAs are appropriate, consistent with sound regulatory policy, the GCA, and previous recognition of PA differences.

e. Cost to Achieve Example

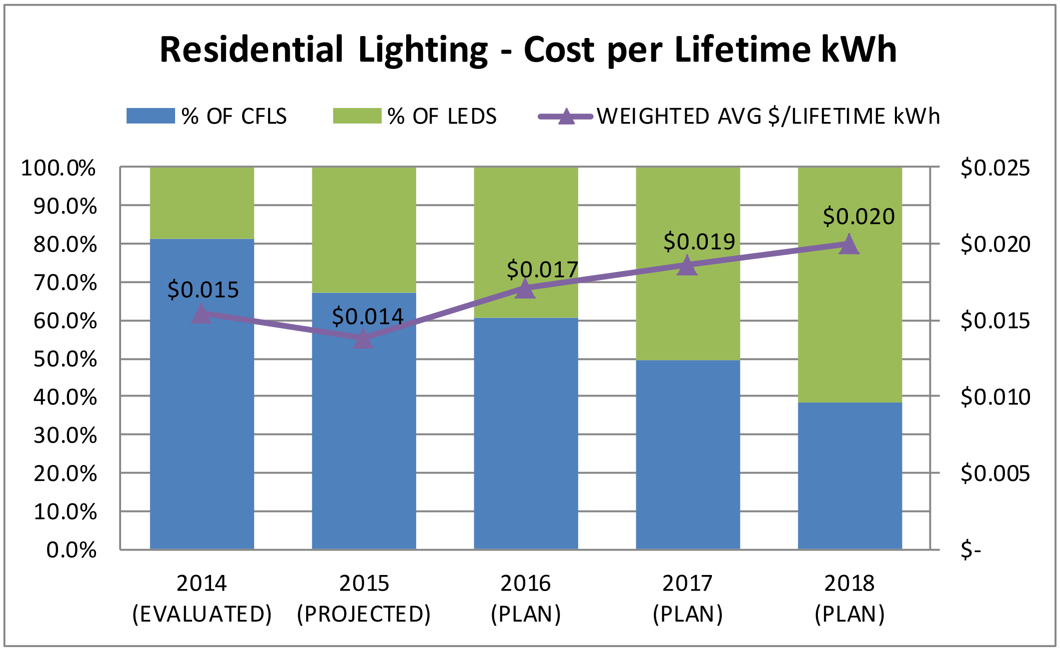
One initiative that is experiencing multiple simultaneous impact challenges is Residential Lighting. Historically, this initiative, an upstream buy-down delivery model, has been a relatively low-cost opportunity to achieve energy savings. However, a combination of factors, including continued implementation of federal EISA standards, a shift from rebating inexpensive compact fluorescent bulbs to more expensive LEDs, and an anticipated increase in free-ridership in each of the three plan years, has put significant upward pressure on the cost to achieve savings.

The first graph below shows the comparison in rebate cost per lifetime kWh saved between CFL lamps and LED lamps that are being impacted by code changes in the Residential Lighting initiative. While PAs have anticipated and planned for declining CFL and LED costs in each year, the net lifetime savings for each type of bulb are also decreasing in each year. LEDs remain nearly twice as expensive per lifetime kWh saved as CFLs.[105] The second graph below shows the statewide allocation between CFLs and LEDs, and the significant shift to LEDs in each year.[106] In 2014, LEDs made up approximately 19 percent of total lamps rebated in this initiative. By 2018, PAs anticipate that LEDs will make up over 60 percent of this total.



105 Note that the 2015 projections use the 2014 evaluation factors as an estimate for this example. The evaluation factors that will ultimately be applied to 2015 will differ from both the 2014 evaluation factors and the assumptions made for the 2016-2018 Plan.

106 The numbers in the graphs reflect the estimated amount of A-Line CFL and LED bulbs that are expected to be sold over the term.



- **Adoption of EISA Standards**: In 2014, the average lifetime of LEDs and CFLs was eleven and six years, respectively per the Massachusetts TRM. In the 2016-2018 Plan, the average lifetime of LEDs and CFLs drops to eight and four years, respectively. In the graph above, the impact is shown most clearly in the decrease in lifetime savings between 2014 and 2016.
- **Market Shift**: The market is shifting away from CFLs toward LEDs. However, as shown in the graph above, LEDs yield approximately twice the lifetime savings as CFLs but at worst (the constant scenario) cost over six times as much per lifetime kWh and at best (the decline scenario) cost nearly twice as much per lifetime kWh. Both scenarios show a marked increase over the 2014 cost of savings.
- **Net-to-Gross Ratios**: As residential LEDs transition from a specialty application into a commercialized product, the PAs expect that free ridership will grow. Those customers who would have purchased LEDs whether or not the PA programs offered an incentive must be subtracted from the calculation of savings PAs claim from the lighting program. The PAs planned for 2016-2018 with an assumption that free-ridership for LED purchases within the lighting program would be 10 percent in 2016 and increase 10 percent each year through 2018. In the graph above, the impact is shown in the decrease in lifetime savings from 2016 to 2018.
- **Combined Impact**: Considering all the factors listed above, by 2018, the PAs will need to rebate 2.7 times the number of LEDs and 1.25 times the CFLs just to equal the lifetime savings achieved in 2014.

This example shows the interplay of just two measures in a single initiative. While these are particularly sensitive measures, changes like this are becoming more common across dozens of measures within the PAs' portfolios. The PAs must continually refine cost and savings assumptions throughout the planning process, working to balance innovation and deeper savings with cost increases.

f. Unique Service Area Drivers

The Program Administrators have successfully worked together to provide comprehensive, statewide programs that are available for all customers across service territories. Despite these consistent program offerings, some variations among PAs in savings goals and costs to achieve are appropriate due to the unique characteristics of each PA's service territory.

Each PA has a distinct mix of customers and sectors, which affects energy efficiency programs in different ways. Each PA has unique demographics, with different mixes of building types, income types, fuel types, fuel constraints and population density. For example, the service territory of one PA may have a smaller percentage of commercial customers than the statewide average, and thus may not be able to benefit from the higher savings opportunities that tend to correspond with that customer segment. Similarly, a PA may serve a lower-income population, which is more expensive to serve. In setting their goals, each PA has used their knowledge of their unique service territory to design programs that best meet the needs of their customers, and all PAs are committed to achieving all available cost-effective energy efficiency in accordance with the GCA. The Council and the Department should continue to support reasonable variances among PAs, consistent with sound regulatory policy, the GCA, and previous recognition of PA differences.

Several PAs have conducted potential studies to look at the unique characteristics of their territories and customers. Those studies have confirmed the existence of real and reasonable variances among PAs, and are attached at Appendix M. Maps reflecting the service territories of each PA are attached at Appendix N.

In this Plan, Berkshire, Liberty, Unitil and Cape Light Compact are proposing aggressive savings goals that are tailored to the conditions within, and the characteristics of, their service areas in compliance with the GCA's mandate to acquire all cost-effective and sustainable energy efficiency. Some PAs have included presentations outlining the unique challenge in their specific service territories that justify variations from statewide targets in Appendix O. The Term Sheet recognizes the need for PAs with unique service territory characteristics to have flexibility from statewide targets and have determined their goals are appropriate. Reasonable variances in savings and goals that reflect the unique strengths and challenges among service areas are entirely appropriate.

g. Conclusion

The development of the proposed statewide and Program Administrator-specific savings goals involved a detailed review of energy efficiency opportunities and costs from all angles. This analysis included a bottom-up approach to assess savings opportunities by measure, a top-down look at savings potential and costs, consideration of evaluation study findings and other market changes, and statewide policy objectives. Additionally, development of goals for 2016-2018 was influenced by collaborative discussions with EEA, the DOER, the Attorney General, and the Council's consultants to better understand key savings and costs drivers across the Commonwealth, taking into account sustainability of delivery efforts and bill impacts. Using all of these methods, the Program Administrators were able to develop and determine savings goals to achieve all available cost-effective energy efficiency that have ultimately received the approval and support of the Council.

6. Common Assumptions

a. Overview

By reviewing all assumptions included in the development of this Plan and harmonizing them to the greatest extent practicable, the PAs have been able to reduce variances among themselves. This review has allowed the PAs to collectively provide the best available data in the most consistent manner.

The Program Administrators have common program designs, and continuously work together to develop assumptions and apply those assumptions in the RMC, C&IMC, low-income best practices, Evaluation Management Committee, common assumptions working group, and other PA working groups and discussions. Additionally, PAs have worked to harmonize assumptions related to the calculation of savings and benefits. They have developed a set of definition guidelines that guide each PA's participant calculation in order to be able to review participants in a consistent manner.

The PAs have confirmed common approaches to various cost and savings data and have determined collectively the manner by which evaluation results are applied, including non-energy impacts. Specific program assumptions have been accounted for uniformly, and algorithms will be applied in the same manner across PAs, with such assumptions set forth in the TRM. The PAs have also reviewed the 2015 AESC study in order to ensure that all avoided costs are applied in the same manner. Transmission and distribution costs have been updated and inflated consistently.

Additionally, PA cost categories are now consistent as described in more detail in Section III.B.

b. Participant Definitions

Participant definitions are common for all electric and gas PAs. These definitions are designed to more accurately reflect unique participants in each program and core initiative, and continue to be refined over time. The definitions that the PAs have used for participants in this Plan are set forth in Appendix P. Using these common definitions, the PAs have worked together to determine how best to apply them to estimate the number of participants for this Plan in a consistent manner. In some instances, variances in participant numbers or table columns such as costs per participant may not reflect true differences. This is because the definitions of participants require some assumptions, which may have been chosen for a particular reason, but may not make as much sense for another purpose. For instance, in HES - Measures, the definition is "Unique Account Number for a customer with at least one major measure installed." At this point in time, "major measure" only includes air sealing and insulation for most PAs. This definition was chosen to help approximate HES closure rates. However, many other measures, such as upgraded heating systems, early replacements of boilers, duct sealing, and Wi-Fi thermostats have material savings and costs and thus may be considered to be "major." Without these included, at first glance it appears that the cost per major measure is high, but the reality is that many other measures are installed for additional customers.

The category of participants reflects an approximation of customers who participate in individual core initiatives. If an individual customer participates in more than one program or core initiative, that customer will be counted as a participant in each core initiative. Therefore, the number of participants does not correspond directly to the number of unique customers participating in any program for a particular PA or across PAs. This is complicated by overlap between PA territories and by program delivery models, such as upstream, which do not get delivered to a customer, but rather work through manufacturers and distributors. The PAs are using Customer Profile Studies to better understand customers participating in energy efficiency programs across core initiatives, fuels, and PAs. See Appendix T, Appendix U, and Appendix X for more information on Customer Profile Studies.

7. Updates to Tables

In preparation for the filing of the first Three-Year Plan, the Department convened a working group in D.P.U. 08-50 to review, among other things, draft data tables to be filed with the Three-Year Plan. The content and format of the tables were developed collaboratively through the course of many productive sessions convened by the D.P.U. 08-50 Working Group. The working group intended for the tables to serve as a quantitative anchor for the review of the ambitious programs set forth in the Three-Year Plan. The D.P.U. 08-50 tables have continued to provide useful data to the Department, Council, and stakeholders. In preparation for the 2016-2018 Plan, the PAs have reviewed these tables, along with the comments and suggestions made by stakeholders over the years, and have made revisions to the tables. The data tables prepared by each PA and attached hereto as statewide roll-ups at Appendix C reflect the updates and revisions that improve upon the D.P.U. 08-50 comprehensive tables. These updates clarify certain data points, and are presented in pivot table format to allow stakeholders to create various outputs using the data. Made in the spirit of the original D.P.U. 08-50 Working Group mandate, the changes take into account lessons learned since 2009. Specific changes to the tables include:

- Added a Master Data tab
    - This tab allows the PAs to input their data for use in the pivot tables.
    - Includes data for 2010-2014 (evaluated), and 2015-2018 (planned). Includes all gas and electric PAs.
    - Includes lifetime savings for other fuels, as well as gross savings for some types of savings.
- Added a Master Sector tab
    - This tab is similar to the Master Data tab, but only includes sector-level data that is needed for sales, outsourced costs, and historical comparisons.

- Added an Additional Sources tab
    - This tab serves as an introduction to the tables, and directs reviewers to where they can find additional information as well as information that is no longer included in the plan tables.
- Funding Tables
    - Removed the Other Funding table and added that information to the Additional Sources tab because the electric PAs assume no other funding sources for 2016-2018.
    - SBC: Removed columns indicating how SBC collections were allocated to each sector because, consistent with the EE Guidelines, SBC collections are allocated to each customer sector consistent with how the funds are collected from each customer sector. Therefore, the removed columns were redundant.
    - FCM: Edited the annual tables to be more flexible and therefore more accurate for each PA, because each PA adopts different FCM bidding strategies. Further, the previous version of the FCM table did not clearly indicate the kW bid and the clearing prices associated with each auction, so the edited version of the table is more transparent in this regard.
    - RGGI: Edited to be better reflect: (a) the allowances and prices associated with auctions in each year, (b) the actual expected proceeds available for energy efficiency after accounting for other costs, and (c) the PA's annual receipt of RGGI proceeds from each auction.
    - Carryover: Edited to be the three years in total, rather than just 2015, to be consistent with streamlining efforts to view the plan in the three-year term construct.
    - EERF: Removed columns indicating how the low-income costs are subsidized by residential and C&I because each PA applies a different approach consistent with their PA-specific rate cases.
- Avoided Costs
    - Removed the Avoided Cost table and added that information to the Additional Sources tab because the PA-specific Benefit-Cost Screening Models better provide this information.
- Low-Income Allocation
    - Removed the columns that provided a comparison to the SBC, to better focus the reviewer on the GCA's requirement for low-income spending, which is unrelated to SBC collections.
- Competitive Procurement
    - This data is now presented for the total budget at the sector level, instead of by program and budget category. This done to better review the PA's procurement processes at a higher level.

- GHG
    - Added a table for greenhouse gas reductions, consistent with the 2013-2015 Term-Report Template.
- Master Sum
    - Removed the DRIPE column. Broke out Gas separately from other Resources. Removed lifetime capacity savings. Added propane, oil, and water savings instead of one sum of the three. Only shows annual savings.
- Other, Unused Savings/Benefits
    - Deleted columns for No. 4 Oil, Kerosene, and Wood, as well as lifetime kW and the summer and winter peak/off peak energy breakouts in the tables that they appeared in, because the PAs determined that these columns were either consistently unused or were no longer useful.
- Cost-Effectiveness
    - Combined the TRC Cost Summary table and the Cost-Effectiveness table into one table to streamline the data, because the two previous tables were providing similar information.
- Historical Comparison
    - Historical comparisons are reformatted based on how Pivot Tables can present data. The information included in the tables is consistent with previous table formats.
    - Revamped the historical benefits tables to match the edits in the benefits table and to streamline the reviewer's analysis of historical benefits.
    - Competitive procurement data is now presented for the total budget at the sector level, instead of by program and budget category. This done to better review the PA's procurement processes at a higher level.
- General Formatting
    - The table numbering (*e.g.*, IV.B.1) has been maintained from previous table formats even though some tables have been removed. This is to better allow comparisons to historical tables.
- Additional Filing Requirements
    - This tab includes the additional information requested in Question 2 of the Hearing Officer Memorandum regarding Additional Filing Requirements (10-2-2015). <u>See</u> Appendix X.

B. <u>**Budget Cost Categories**</u>

1. <u>Overview</u>

Since the establishment of the GCA, the PAs have worked to develop common assumptions and definitions with respect to implementation of their energy efficiency programs.

Historically, due to their varying sizes and business models, the PAs have managed their programs in different ways. In the 2013-2015 Order, the Department directed the PAs to develop consistent definitions and methods of assigning costs across all five program implementation cost categories. 2013-2015 Order at 74. With respect to salaries, the Department directed PAs to report all non-administrative employee costs in the cost category that applies to the employee's job description. Id. With respect to vendor costs, the Department directed the PAs to develop uniform practices to the extent possible (noting tracking system differences), and, where limitations exist, to adopt reasonable alternative allocation methods based on cost-causation principles (actual factors underlying the incurrence of costs). Id. In accordance with the 2013-2015 Order, the PAs submitted a report on their progress towards meeting these requirements on July 31, 2014. In that report, the PAs noted that changes would be made for the 2016-2018 Plan.

2. Budget Category Definitions

PAs have refined the budget category definitions developed over the last several years in order to clarify certain details and to include additional details within the definitions. The statewide definitions used by all Program Administrators in this Plan are as follows.

Program Planning and Administration ("PP&A") - includes costs associated with developing program plans, including market transformation plans, R&D (excluding R&D assigned to Evaluation and Market Research), day-to-day program administration, including labor, benefits, expenses, materials, supplies, overhead costs, any regulatory costs associated with energy efficiency activities, database/data repository development and maintenance, sponsorships and subscriptions, and energy efficiency services contracted to non-affiliated companies, *e.g.*, outside consultants used to prepare plans, screen programs, improve databases and perform legal services. This category also includes internal salaries for administrative employees/ tasks, including program managers who do not have direct sales and technical assistance contact with customers.

Marketing and Advertising - includes costs for the development and implementation of marketing strategies and costs to advertise – through television, radio, billboards, brochures, telemarketing, web-sites and mailings – regarding the existence and availability of energy efficiency programs or technologies, and to induce customers or trade allies to participate in energy efficiency programs. These costs include internal salaries for employee functions related to marketing and advertising.

Participant Incentives - includes funds paid by the reporting Program Administrator to or on behalf of customers or trade allies as rebates or in other forms. Participant incentives includes costs that directly benefit customers, including permit fees, pre-weatherization expenses, repairs, and interest buy-down.

Sales, Technical Assistance & Training ("STAT") - includes administration, sales technical assistance and training costs to motivate: (1) customers to install energy efficiency products and services; (2) retailers to stock energy efficiency products; (3) trade professionals to offer energy efficiency services; (4) manufactures to make energy efficiency products; and (5) use of vendor services and suppliers that demonstrate benefits of energy efficiency. This category also includes costs not directly tied to savings, including residential assessments, technical assistance studies, contractor fees and performance bonuses, vendor cost of money; lead vendor fees and internal salaries for employees with direct customer sales and technical assistance contact.

Evaluation and Market Research - includes costs associated with evaluation activities: costs related to cost-effectiveness evaluation, market research (*e.g.*, baseline studies, market assessments and surveys), impact and process evaluation reports, tracking and reporting program inputs and outputs, funding studies, and other costs clearly associated with evaluating the program. This category also includes internal salaries for employee functions related to evaluating the programs.

Costs are assigned to the relevant category within the relevant program, core initiative, or hard-to-measure program. For example, HES assessments are assigned to STAT in the HES-RCS core initiative in the Whole House program; similarly, all training is assigned to STAT in Workforce Development. Costs that cannot be assigned directly to a program are allocated among relevant programs on an appropriate basis and tracked accordingly.

3. Salaries

For the 2013-2015 Plan, Berkshire, CMA, Liberty, and NSTAR Gas assigned all salaries to PP&A, while National Grid Electric, National Grid Gas, NSTAR Electric, Western Massachusetts Electric Company, Unitil, and Compact reported all non-administrative employee costs in the cost category that applied to the employee's job description. In accordance with the 2013-2015 Order, all PAs have developed allocation methods based upon cost causation principles to assign expenses to the appropriate non-administrative budget category.

For PA staff performing multiple functions, which is a common practice for smaller PAs, employee salaries have been allocated across the appropriate budget categories based on the percentage of employee time spent on various functions within energy efficiency. Beginning with the 2016-2018 Plan, all PAs will treat salaries as follows: (1) assign salaries of staff performing a single function to the appropriate cost category in the appropriate program/sector (*e.g.*, the salary of an employee specializing solely in residential evaluation will be assigned to the Evaluation and Market Research category in all residential programs); and (2) assign salaries of staff performing multiple functions to multiple cost categories in multiple programs/sectors, as appropriate, based on an allocation for each employee in accordance with assigned job tasks.

One specific area in which PAs were not previously consistent was allocation of salaries for program managers. PAs have reviewed these differences and have determined that salaries of program managers with direct sales and technical assistance customer contact are appropriately allocated to STAT, while salaries of program managers without direct contact are more appropriately allocated to PP&A. For example, the salary of a C&I program manager who works directly with customers will be allocated to STAT, while the salary of a residential program manager who does not deal directly with customers due to the lead vendor model will be allocated to PP&A.

4. Vendor-Related Costs

The PAs have performed a detailed review of vendor costs and related cost categories to determine changes that need to be made in order to achieve consistency. PAs have developed a chart, attached at Appendix Q, showing vendor cost types and the related cost category to support consistency and serve as a guide going forward.

5. Identification of Any Costs That are Difficult to Assign to One of the Five Cost Categories

At this time, the PAs have not encountered any costs that are difficult to assign to one of the five cost categories. All costs have been assigned based on type and function. The PAs will continue to review current and new costs as they come into the programs and assign appropriate cost categories.

6. Continuous Improvement

The PAs recognize that there may be instances in which differences in cost categorization are discovered in the future, but are committed to consistency and continued improvement. The PAs have established consistent budget cost category definitions, determined methods for allocating salaries across cost categories, and harmonized vendor cost categorization, and are committed to continuing to review new costs and to seek and maintain consistency across PAs throughout the Plan term.

C. **Performance Incentives**

On January 28, 2010, the Department issued the 2010-2012 Electric Order and 2010-2012 Gas Order ("2010-2012 Orders") on the first Three-Year Plans. The 2010-2012 Orders approved most aspects of the performance incentive mechanism proposed by the Program Administrators in their 2010-2012 Plans.[107] However, for certain aspects of the proposal regarding the allocation method of the statewide pool and performance metrics, the Department ordered the Program Administrators to work further with the Council and re-file these components with the Department for its review and approval. For 2011, the Program Administrators worked closely with the Council in order to update the allocation method in compliance with the 2010-2012 Orders, as well as to propose updated performance metrics. As a result of this effort, a comprehensive settlement was achieved on this and other matters, which was filed on April 15, 2011. Similarly, for 2012, the Program Administrators used the extensively reviewed 2011 method and performance incentive model as a basis for 2012 performance incentive allocations and updated performance metrics. Performance incentive proposals applicable to 2012 efforts were filed with the Department on October 28, 2011. The

[107] See 2010-2012 Electric Order at 93-125, 165, and 168-169; 2010-2012 Gas Order at 79-115, 168-169, and 172-173.

Department approved the 2011 and 2012 proposals on November 26, 2014, including the proposed method of allocating statewide incentives to each Program Administrator and all but one of the proposed performance metrics, the 2012 Cost Efficiency Metric. See 2011 Mid-Term Modification for Energy Efficiency Programs, D.P.U. 10-140 through D.P.U. 10-150 (2014); 2012 Mid-Term Modification for Energy Efficiency Programs, D.P.U. 11-106 through D.P.U. 11-116 (2014). For the 2013-2015 Plan, the Program Administrators retained the performance incentive model that included the Savings Mechanism, the Value Mechanism, and Performance Metrics. 2013-2015 Performance Metrics, D.P.U. 13-67 (2014). In its review of that proposal, the Department determined that Performance Metrics were no longer needed and directed the Program Administrators to reallocate the funds that had been allocated to that component of the incentive mechanism to the Savings and Value Mechanisms. Id.

For the 2016-2018 Plan, the Program Administrators have retained the focus on benefits through the Savings Mechanism and on net benefits through the Value Mechanism. In this discussion, the Program Administrators summarize the 2016-2018 performance incentive amounts in the following manners: statewide, by component, and by Program Administrator. Performance incentive models are attached at Appendix R.

I. Summary of the Orders on Performance Incentives in the 2010-2012 Plan.

In the 2010-2012 Orders, the Department noted its support of the following elements of the proposed incentive design:

1. The proposed statewide incentive pool.
    a. The electric statewide incentive pool goals equal $22 million in 2011 and $25.5 million in 2012, assuming that goals on a statewide basis are equal to the goals established by the Council. 2010-2012 Electric Order at 93. The actual incentive pool can be adjusted up or down according to actual goals. Id. at 111. The Department approved the statewide goals. Id. at 112.
    b. The gas statewide incentive pool goals equal $4.5 million in 2011 and $5.5 million in 2012, assuming that goals on a statewide basis are equal to the goals established by the Council. The actual incentive pool can be adjusted up or down according to actual goals. 2010-2012 Gas Order at 100. The Department approved the statewide goals. Id. at 101.
2. The structure of the proposed incentive mechanism includes three components: the Savings Mechanism (focusing on the dollar value of benefits); the Value Mechanism (focusing on the dollar value of net benefits); and Other Performance Metrics.
    a. The three-pronged structure of the incentive mechanism was approved in the 2010-2012 Electric Order at 113, 124 and the 2010-2012 Gas Order at 101-102, 114. The Department noted that similar mechanisms have been approved in the past.
3. Common payout amounts under both the Savings and Value Mechanisms.
    a. The approval for common payout rates in the 2010-2012 Electric Order is found on pages 113-114 with reference to Table D at 96.

   b. The approval for common payout rates in the 2010-2012 Gas Order is found on pages 102-103 with reference to Table C at 83.

4. The proposed allocation of the statewide incentive pool to each Program Administrator for 2010 but not for 2011 or 2012.

   a. The allocation of the statewide electric incentive pool to each Program Administrator was based on that Program Administrator's contribution to the statewide savings goals as expressed in MWh. However, the allocation for each of the three components was not consistent among the Program Administrators; the savings component amount was allocated on the basis of the dollar value of savings, the value component amount was allocated on the basis of the dollar value of net benefits, and the performance metrics component was derived to total the overall allocation method based on savings goals. Although the Department approved the allocation of the components for 2010, the Program Administrators were directed to revise the allocation method for 2011 and 2012 so that, to the extent possible, the revised allocation method would result in (1) uniform statewide payout rates for the savings and value components, and (2) an allocation of incentive dollars across the three components for each Program Administrator that, on a percentage basis, approximates the statewide allocation across the three components, as endorsed by the Council and approved by the Department. See 2010-2012 Electric Order at 114-116.

   b. The allocation of the statewide gas incentive pool to each Program Administrator was based on a similar methodology. This methodology produced some anomalous results for certain Program Administrators that required special adjustments. Similar to the electric side, the Department approved the gas Program Administrators' component allocation for 2010, but the Program Administrators were ordered to revise the allocation methodology in 2011 and 2012. See 2010-2012 Gas Order at 103-105.

   c. A revised allocation methodology was proposed in the 2011 Mid-Term Modifications settlement proposal. The revised methodology was created following extensive discussions with the Council, and addressed the concerns of the Department, as noted in the Orders.

5. Specific limitations on how EM&V results would be used to determine performance for both the electric and gas Program Administrators. 2010-2012 Electric Order at 124; 2010-2012 Gas Order at 114.

However, the Department did not accept: (1) the proposed allocation method for 2011 and 2012 as mentioned above; or (2) the proposed performance metrics for 2010. The Department stated that it did not accept an EM&V "Omnibus Metric," and directed the Program Administrators to include a financing and funding metric.[108] The Department further ordered that a cap on the earned incentive mechanism apply both in total and by component. The cap by

[108] In response to the 2010-2012 Orders, the Program Administrators filed a revised performance metric proposal on March 12, 2010. The Department subsequently approved the revised performance metrics on August 10, 2010 with the exception of the Deeper Savings metric. On September 14, 2010 the Program Administrators filed a compliance filing in regard to changing the baseline year of that metric.

component and overall has been set at 125 percent of design level performance.[109]

II. Summary of the Orders on Performance Incentives in the 2013-2015 Plan.

In the 2013-2015 Order, the Department approved the 2013-2015 Plan statewide incentive pool structure of the PI mechanism, as revised, for the savings and value components (metrics were reviewed separately), calculation of the savings and value payout rates, and adjusted threshold levels (the slightly different mechanism for PAs with goals that exceed Council targets). The Department directed the PAs to recalculate the threshold levels to be consistent over the three years and provided the calculation method in the appendix to the Order.

The Department reviewed the performance incentives in light of the D.P.U. 11-120-A, Phase II Order, which among other things, creates a true three-year PI structure. The D.P.U. 11-120-A, Phase II Order requires PAs to calculate design-level incentive payments based on projections of performance for the entire three-year term, not based on annual projections, and directs both electric and gas PAs to collect performance incentives in the EES at the design level during the three-year term. The Department will review PI at the end of the three-year term.

Citing previous approvals of PI pools that were a greater percent of budget than proposed in the 2013-2015 Plan, the Department approved the PI pool. Additionally, the Department approved the full increase to the statewide PI pool, as set forth in the updated tables, noting the link between the statewide incentive pool and projected savings. The Department found that the PAs had kept performance incentive funds as low as possible consistent with the Guidelines.

The Department had previously approved the PI mechanism and its components, and the Council had endorsed the components and allocation of incentive dollars to each component. For these reasons, the Department found the savings and value components to be reasonable and consistent with the GCA and precedent and approved the PI mechanism, with the exception of the metrics which were reviewed in a separate docket.

The Department found that the application of uniform statewide payout rates for the savings and value components was consistent with the goals of the GCA and Department precedent, and, because the rates do not vary by year, found that the payout rates were consistent with the D.P.U. 11-120-A, Phase II Order. The Department approved the method used to calculate the statewide savings and value components payout rates. The Department approved the PAs' adjusted threshold levels for the savings and value components of the PI mechanism for those PAs with savings targets in excess of the Council's goals.

The Department found that the PI mechanism must be revised to be consistent with the D.P.U. 11-120-A, Phase II Order. Mid-term or annual adjustments that result in payout rates that vary over the three-year term are inconsistent with the D.P.U. 11-120-A, Phase II Order. The Department addressed the issue of updates to the Avoided Energy Supply Costs and stated that they will be reviewed in the context of streamlining working groups. The Department reviewed

---

[109] The Program Administrator proposals had thresholds for the savings and value incentive mechanisms of 75 percent of design or target level performance.

the one-year nature of metrics in a separate proceeding on metrics. With respect to the threshold levels proposed by the PAs, because they varied in the third year, the Department noted that they are inconsistent with the D.P.U. 11-120-A, Phase II Order, and directed the PAs to recalculate the threshold as described in the appendix and as shown for each PA in the Order. The Department directed the PAs to implement a revised PI model with one combined threshold level for the entire three-year term. On or before February 21, 2013, each PA filed a compliance filing with a revised PI model, including all tables, using the revised thresholds.

In D.P.U. 13-67, the Department concluded that performance metrics are no longer a necessary component of the PAs' performance incentive mechanism and, therefore, did not approve the metrics for 2013. As noted in this Order and the 2013-2015 Order, the portion of the statewide incentive pool allocated to performance metrics will be reallocated to the savings and value components of the performance incentive mechanism. Therefore, the PI pool will remain intact and PAs retain the ability to earn the total amount of PI allocated to them.

In D.P.U. 13-67, the Department stated that metrics were originally intended to incentivize specific activities, but now that the GCA requires all available cost-effective energy efficiency, metrics would only seek to incentivize activities that are already required. The Department also stated that the PAs do not need the guidance traditionally provided by metrics, noting that the "Program Administrators, in conjunction with the Council and other stakeholders, have developed a comprehensive infrastructure to promote statewide energy efficiency program integration and continuous improvement in program delivery." D.P.U. 13-67, at 11. The Department specifically noted that the Management Committees and low-income best practices address program implementation barriers and foster communication with the Council and other stakeholders. The Department also found that "[n]egotiating, satisfying, and documenting performance metrics is costly and time consuming." Id. at 13, n.25. The Department found that such an investment of time and resources solely for the purpose of verifying metric performance is out of proportion with the potential benefit of metrics. Further, verifying performance of these metrics would divert PA and stakeholders focus from the successful implementation of the Three-Year Plans and is inconsistent with the Department's obligation to fulfill its oversight responsibilities in an administratively efficient and effective manner.

III. Allocation Proposal for 2016 – 2018

Based upon the well-developed principles and precedent described above, the Program Administrators propose an incentive mechanism for 2016-2018 that is comprised of a Savings Mechanism and a Value Mechanism with common payout rates in each component applicable to the electric and gas Program Administrators, respectively with performance assessed at the portfolio level using cumulative three-year results. In 2016-2018, the statewide incentives for the savings component of the incentive pool are allocated on the basis of the dollar value of benefits using common payout rates as approved by the Department. The statewide incentives for the value component of the incentive pool are allocated on the basis of the dollar value of net benefits using common payout rates as approved by the Department. The total incentive is the sum of the two components. This methodology was followed for allocating the incentive dollars among Program Administrators, as well as to each sector and to each program.

This proposed allocation model results in a similar distribution of each Program Administrator's incentives among the two components. The proposed payout rates for 2016-2018 remain constant for all Program Administrators and for each year in the Plan, consistent with the focus on the comprehensive three-year effort as a single Plan.

Distribution of Performance Incentive for Electric Program Administrators in 2016-2018:

Percent of Total Incentive

State	Residential	Low Income	C&I	Total
Savings	23.5%	3.3%	34.8%	61.5%
Value	14.3%	1.3%	22.9%	38.5%
Total	37.7%	4.6%	57.7%	100.0%

Value	19.4%	3.7%	13.1%	36.2%
Total	54.2%	13.1%	32.7%	100.0%

IV. Statewide Incentive Pool for 2016-2018

Statewide, the design level incentive is set at $100 million for electric efforts and $18 million for gas efforts. These amounts reflect the challenge of continuing to adopt aggressive savings goals in 2016-2018 in light of achievements to date, the remaining savings opportunities identified in each service territory, and the success the Program Administrators are cultivating as markets are transformed. In addition, these electric and gas incentive pools are consistent with the Term Sheet that has been supported by DOER, the AG, and the PAs, attached hereto at

Appendix D. The statewide incentive pool will not change as a result of changes to avoided costs that may occur during the term of this Plan.[110]

V. Summary of 2016-2018 Incentives

The models set forth as Appendix R – Part 1 (Electric) and Appendix R – Part 2 (Gas) provide calculations of the 2016-2018 incentives based on the Three-Year Plan proposals of each of the Program Administrators for electric and gas, respectively. For the electric Program Administrators this is a 19 page exhibit and for the gas Program Administrators this is a 25 page exhibit. The calculations are described below. Additionally, a summary of the 2016-2018 incentives is provided below.

A. Calculation Exhibits

Appendix R – Part 1 (Electric) provides the derivation of the 2016-2018 electric incentives at the design level of performance. Similarly, Appendix R – Part 2 (Gas) provides the derivation of the 2016-2018 gas incentives at the design level of performance.

Pages 1 and 2 of both Appendix R - Part 1 (Electric) and Part 2 (Gas) are input pages that summarize each Program Administrator's 2016-2018 goals, benefits and costs (excluding performance incentives and demand reduction-related costs).

Page 3 in both Appendix R - Part 1 (Electric) and Part 2 (Gas) derives the common payout rates used to calculate projected design level incentives under the Savings and Value Mechanisms given the electric and gas statewide incentive pools. The Program Administrators note that if avoided costs change compared to what has been used here, either as a result of orders issued by the Department in D.P.U. 11-120 or due to a study where avoided costs are updated, the common payout rates applicable under the savings and value components will need to be updated. However, these changes would not impact the size of the incentive pool or PA-specific design-level incentives. At a statewide level for both electric and gas, 61.5 percent of the incentive has been allocated to the Savings Mechanism and 38.5 percent to the Value Mechanism. To determine the payout rate under the Savings Mechanism, the electric or gas statewide incentive pool is multiplied by 61.5 percent, the portion of the statewide performance incentives allocated to the savings component, and the resulting amount is divided by the projected dollar value of benefits statewide from proposed electric or gas efforts. Similarly, to determine the payout rate under the Value Mechanism, the electric or gas statewide incentive pool is multiplied by 38.5 percent, the portion of the statewide performance incentives allocated to the value component, and the resulting amount is then divided by the projected dollar value of net benefits statewide from proposed electric or gas efforts.

Pages 4-11 of Appendix R – Part 1 (Electric) and pages 4-17 of Appendix R – Part 2 (Gas) provide the calculation of potential design level incentives under the savings mechanism and the value mechanism on a statewide basis and for each individual Program Administrator. Lines 1 through 3 determine the savings amount by multiplying the dollar value of benefits by

---

110 The PAs do not currently anticipate updating avoided costs applicable to 2016-2018 efforts at this time.

the savings mechanism payout rate. Lines 4 through 6 determine potential design level incentives under the value mechanism by multiplying the dollar value of net benefits by the value mechanism payout rate. Line 7 provides the total performance incentive.

Pages 12 - 15 of Appendix R – Part 1 (Electric) and pages 18 - 21 of Appendix R – Part 2 (Gas) provide summary information about performance incentives by sector and by component of the incentive mechanism in real dollars ($2016). Pages 16-19 of Appendix R – Part 1 (Electric) and pages 22 – 25 of Appendix R – Part 2 (Gas) provide the same information in current year (nominal) dollars.

Appendix R – Part 1 (Electric) and Appendix R – Part 2 (Gas) do not show how the performance incentives are further allocated to specific programs for benefit/cost screening purposes. Rather, the program allocation assumptions are summarized below:

- The savings component amount is allocated to programs on the basis of program dollar of benefits.
- The value component amount is allocated to programs on the basis of program dollar of net benefits.
- Any programs with negative allocations (efforts with projected costs without identified projected savings) are reallocated to other programs within the sector.

B. Summary

A summary of the threshold, design, and exemplary performance incentive amounts by component of the proposed incentive mechanism for 2016-2018 is provided for each electric and gas Program Administrator, below. The threshold level is set at 75 percent of the design level incentive while the exemplary level is set at 125 percent of the design level incentive.

Electric:

Summary of 2016 - 2018 Performance Incentives by Program Administrator ($2016)

		Threshold	Design	Exemplary
National Grid		Threshold	Design	Exemplary
	Savings	$21,499,886	$28,666,515	$35,833,144
	Value	$12,917,889	$17,223,852	$21,529,815
	Total	$34,417,775	$45,890,367	$57,362,958
Eversource		Threshold	Design	Exemplary
	Savings	$24,183,684	$32,244,913	$40,306,141
	Value	$15,616,431	$20,821,908	$26,027,385
	Total	$39,800,116	$53,066,821	$66,333,526
Unitil		Threshold	Design	Exemplary
	Savings	$441,429	$588,573	$735,716
	Value	$340,680	$454,240	$567,800
	Total	$782,109	$1,042,812	$1,303,516

Gas:

Summary of 2016 - 2018 Performance Incentives by Program Administrator ($2016)

		Threshold	Design	Exemplary
National Grid				
	Savings	$4,368,695	$5,824,927	$7,281,159
	Value	$2,346,539	$3,128,719	$3,910,898
	Total	$6,715,234	$8,953,646	$11,192,057

	Savings	$181,043	$241,390	$301,738
	Value	$101,725	$135,633	$169,541
	Total	$282,767	$377,023	$471,279
Liberty		Threshold	Design	Exemplary
	Savings	$129,585	$172,780	$215,974
	Value	$73,531	$98,041	$122,552
	Total	$203,116	$270,821	$338,526

D. <u>Bill Impacts</u>

Consistent with directives of the GCA and the goal of the 2016-2018 Plan to provide for the acquisition of all available energy efficiency and demand reduction resources that are cost effective or less expensive than supply, the Program Administrators sought to develop a statewide energy efficiency plan that acquires these resources with the lowest reasonable customer contribution. G.L. c. 25, § 21(b). Additionally, the Program Administrators worked collaboratively to review and analyze the rate and bill impacts associated with the implementation of the 2016-2018 Plan in order to ensure compliance with the requirements of the GCA, the Department's Orders in D.P.U. 08-50-A and D.P.U. 11-120-A, Phase II and with the Department's ratemaking precedent. The PAs have sought to balance the value of the long-term benefits expected from proposed energy efficiency efforts with short-term customer bill impacts. Proposed budgets reflect these considerations along with a focus on the equitable distribution of costs and benefits for customers.

The Department convened a technical session on August 16, 2012, at which the Department reviewed the history of bill impacts, implementation of D.P.U. 08-50, the GCA requirements, the Department's goals with respect to rate continuity, and different aspects of the traditional bill impact models as well as the Department-developed D.P.U. 08-50 bill impact models. Ultimately, the Department explained that the short-term information provided in traditional bill impact models satisfies the GCA requirement that the Department consider the effect of any rate increases on residential and commercial customer bills before approving ratepayer funding of energy efficiency programs. See G.L. c. 25, § 19(a).

On October 19, 2012, the Department issued its order acknowledging the efforts of the Bill Impact Working Group, but declining to adopt the bill impact models under discussion. D.P.U. 08-50-D; see also Section III.L, supra. Instead, the Department directed the PAs to submit traditional bill impacts for non-participants under the following scenarios:

1. the current (*e.g.*, 2012) energy efficiency surcharge ("EES") to the proposed EES for the first year of the three-year plan (*e.g.*, 2013);
2. the EES from the first year of the three-year plan (*e.g.*, 2013) to the proposed EES for the second year of the three-year plan (*e.g.*, 2014);
3. the EES from the second year of the three-year plan (*e.g.*, 2014) to the proposed EES for the third year of the three-year plan (*e.g.*, 2015);
4. the current EES (*e.g.*, 2012) to the proposed EES for the third year of the three-year plan (*e.g.*, 2015).

D.P.U. 08-50-D at 12. The Department also directed the PAs to submit bill impacts for participants, "where consumption is reduced for three levels of savings -- low, medium, and high -- and [to] provide a description of how these savings levels were determined." Id. The Department later clarified the bill impact requirements for non-participants by providing a spreadsheet to the PAs, directing them to use average monthly usage levels under the first and fourth scenarios listed above.

Accordingly, to calculate bill impacts for participants, the PAs will populate the Department's spreadsheet (with peak and off-peak rates on separate sheets), using the average monthly kWh and/or therm usage for non-participants for each rate class, and the percentages set forth in the table below. To best approximate low, medium and high annual savings consistent with the Department's directive in D.P.U. 08-50-D, the PAs collaborated on appropriate assumptions for residential, low-income and C&I programs to develop statewide percentages that best approximate savings for those types of participants. The PAs determined that the percentages in the table below will provide directional information on the bill impacts that a residential, low-income or C&I participant may experience.

The PAs determined that there is no low, medium and high savings scenario for low-income participants. These participants typically receive a comprehensive "whole house" energy efficiency approach, meaning potential measures are installed in most cases (the work that can be done is done). Similarly, the PAs determined that there is no low, medium and high savings scenario for residential and low-income gas non-heating participants and street lighting. Accordingly, the PAs determined that the percentages in the table below best approximate savings for those types of participants.

	Low	Medium	High
Residential- Electric:	2%	10%	30%
Residential- Gas:	2%	15%	30%
Residential Gas Non-Heating:		2%	
Low-Income Gas Non-Heating:		2%	
Low-Income:		25%	
Street Lighting:		10%	
C&I- Electric:	1%	10%	20%
C&I- Gas:	1%	10%	20%

Each PA has provided traditional bill impacts for all rate classes in each individual PA's filing.

E. Evaluation, Measurement & Verification

1. EM&V Framework

Consistent with past Three-Year Plans and the Council's September 8, 2009 EM&V Resolution, the PAs propose to continue the evaluation framework that has successfully allowed the PAs to engage in high quality third-party EM&V efforts. The Council and the PAs find that it is critical that the programs be evaluated, measured, and verified in a way that provides confidence to the public at large that the savings are real and in a way that enables the Program Administrators to report those savings to the Department with full confidence. Additionally, the Council stated that there is a need to ensure both the reality and the perception of the independence and objectivity of EM&V activities, as well as the need to help ensure consistency, timeliness, and credibility of the results. Accordingly, the Council will continue to have an oversight role over the EM&V activities of the Program Administrators to ensure the objectivity and independence of those activities, and the perception of such, and to help ensure consistency, timeliness, and credibility. The Council's oversight role will be accomplished through the Council's EM&V consultant ("EM&V Consultant"), a third-party expert consultant who has primary responsibility for working with the PAs to plan and implement high-quality EM&V in Massachusetts.

While PAs and the EM&V Consultant will continue to work diligently to reach a consensus on evaluation issues, where there are areas of difference that may arise that cannot be resolved through consensus during the on-going interactive process between the EM&V Consultant and the PA evaluation staff, authority for decision-making will reside with the EM&V Consultant and the Council.

To enable the Program Administrators to fulfill their responsibility to report program savings to the Department with full confidence, an appeals process has been established, through which the PAs may bring decisions made by the EM&V Consultant or the Council for review and resolution. This process will be implemented through the formation of an evaluation appeals committee ("Appeals Committee") of the Council, whose responsibility in this area will be to hear the matter under dispute and rule so that the study may proceed in a timely way. In general, it is expected that this review process will be completed within 72 hours once an issue is elevated to the Appeals Committee. This Appeals Committee will consist of three voting members of the Council, including DOER. Consistent with general Council proceedings, the Appeals Committee will include and consult with, in both deliberations and decision-making, a representative of both the PAs and the Council's consultant team, neither of whom shall have a vote in the standing committee. The Appeals Committee will review the issues related to the disputed matter, hear from the PA evaluation staff and EM&V Consultant, and make a determination on the outcome of the matter. The decision will be recorded, along with a description of the applicable issues. The participants in the appeal will sign the record of the decision, indicating their acceptance of, the representation of the issues and of the decision. In exceptional cases, where the PAs perceive there to be significant risk to their ability to manage the energy efficiency programs in the near term, the PAs will note their disagreement with the decision of the Appeals Committee on the record of the decision and reserve the right to immediately petition the Department on the Appeal's Committee's decision. The PAs shall be able to submit any such documents to the Department in conjunction with the filing of the Three-Year Plans, mid-term modifications, and term reports. The Department will be able to review the record of this decision in its review of Three-Year Plans, mid-term modifications, plan-year reports, and term reports.

To date, the EM&V Consultant and PA Evaluation staff have been able to resolve all areas of differences without proceeding to the Appeals Committee (as defined in this Section IV.E.1.). This is a testament to the hard work and collaborative engagement of the PAs and the EM&V Consultant.

The PAs will maintain a statewide focus to the maximum extent possible, will review EM&V budgets with the EM&V Consultant, and will integrate electric and gas evaluation efforts to the maximum extent possible. The Program Administrators will be the main mechanism for contracting with the independent evaluation contractors, and will work with evaluation contractors to maintain privacy of customer data.

2. Evaluation Management Committee

The PAs and the EM&V Consultant established the EMC to be similar to other management committees. The EMC serves as a steering committee for statewide evaluation issues, providing guidance and direction to each of the evaluation research areas. The EMC works to plan, prioritize and delineate the research studies to be undertaken over the Three-Year Plan term.

The Program Administrators and the EM&V consultant have worked to consistently improve the EM&V process over time. As issues arise, the EMC has established working groups to review and address new topics, areas of concern, or disagreement. In 2014, the PAs and the EM&V Consultant determined that the current research into baselines associated with energy efficiency measures was not clearly defined. Due to the lack of definition, disagreements arose surrounding the way to apply evaluation results to baseline parameters. In response to those issues, the EMC formed a Baseline Working Group, and established guidelines to handle such concerns in the future. The EMC will continue to establish appropriate working groups to address issues as they arise and keep the EM&V process running transparently, efficiently, and effectively.

3. Descriptions of Research Areas

Consistent with the experience since the establishment of the GCA, the EMC worked collaboratively to develop and refine three market research areas. These research areas are organized primarily by target markets, which design is intended to help maximize the statewide effectiveness of EM&V, while presenting minimal overlap among areas. The research areas identified are as follows:

a) **Residential**

Originally, this research area consisted of three separate categories: Residential Retrofit and Low-Income, Residential Retail Products, and Residential New Construction. Residential still includes these categories, but as a single overarching research area. As currently defined, the residential research area will include all residential and low-income core initiatives.

b) **Commercial & Industrial**

This research area previously consisted of two separate categories: Non-Residential Large Retrofit and New Construction and Non-Residential Small Retrofit. C&I still includes these categories, but as a single overarching research area. As currently defined, the C&I research area will include all C&I core initiatives.

c) **Special and Cross-Sector Studies**

This research area reflects the fact that not all studies will fall into the two market categories above, and some studies may be cross-sector in nature. Some types of studies in this research area can include: cross-sector free ridership and spillover studies, non-energy impacts, behavioral programs, community-based pilots, and marketing, public education, and outreach activities.

The research areas were consolidated to improve administrative efficiency and cross-sector coordination. Cross-sector coordination has been an area that the EMC has been working to consistently improve in order to leverage data and research done by the various research teams to improve depth and quality of research, while lowering cost. More details regarding these research areas and specific research topics can be found in the Strategic Evaluation Plan, which is attached at Appendix S.

4. Evaluation Budgets

The EM&V budget available to the research areas for the 2016-2018 Plan is projected to be in line with historical program budget levels. Twenty percent of each sector's available evaluation budget is allocated to the Cross-Cutting research area. The remaining evaluation budget in the residential and low-income sector is allocated to the Residential research area; the remaining evaluation budget in the C&I sector is allocated to the Non-Residential research area. Total evaluation budgets for the 2016-2018 Plan term are expected to be $18.7 million for gas programs and $41.3 million for electric programs.[111]

5. Types of Evaluation Functions

EM&V refers to the systematic collection and analysis of information to document the impacts of energy efficiency programs and improve the effectiveness of these programs. EM&V includes the following types of studies:

- *Impact Evaluation* refers to the measurement of net or gross savings achieved within overall program populations.
- *Market Effects Evaluation* refers to the measurement of the effects that programs have on the structure and functioning of their target markets.
- *Process Evaluation* refers to the systematic assessment of programs for the purpose of documenting their operations and developing recommendations to improve their effectiveness.
- *Market Characterization or Assessment* refers to the systematic assessment of energy efficiency markets for the purpose of improving the effectiveness of programs targeting those markets.
- *Evaluation of Pilots* refers to EM&V activities intended to assess the effectiveness of pilot programs, determine their potential for full-scale implementation, and develop recommendations for any changes in program approach.

6. Evaluation Planning and Strategic Evaluation Plan

The EMC has sought to establish a long-term strategic view of EM&V for the 2016-2018 Plan, including developing evaluation strategy and determining priorities that the EMC expects to research during the three-year term. These priorities were developed based on the findings of current research, a three-day Strategic Evaluation Planning Summit in February 2015, and discussions in the EMC and with Councilors and other stakeholders. The Strategic Evaluation Plan expands upon and prioritizes the important research topics that were discussed and established at the summit and during EMC and other discussions. These details and priorities are attached at Appendix S.

111 It is noted that since evaluation activities typically occur after program implementation activities, evaluation costs can lag up to several years.

7. Evaluation Studies Completed in Advance of the 2016-2018 Plan

Twenty-five studies were completed in advance of the 2016-2018 Plan that were not previously filed with the Department as follows:

STUDY NAME	STUDY LOCATION AND NUMBER	FUEL
Residential Program Studies		
Massachusetts Residential Lighting Cross-Sector Sales Research	App. U, Study 1	Electric
Multistage Lighting Net-to-Gross Assessment: Overall Report	App. U, Study 2	Electric
Lighting Market Assessment and Saturation Stagnation Overall Report	App. U, Study 3	Electric
Baseline Sensitivity Analysis 2016 - 2018	App. U, Study 4	Electric/Gas
Lighting Interactive Effects Study Preliminary Results	App. U, Study 5	Electric/Gas
Program Assessment Tube TV Recycling	App. U, Study 6	Electric
Cool Smart Incremental Cost Study	App. U, Study 7	Electric
Home Energy Services Initiative and HEAT Loan Delivery Assessment	App. U, Study 8	Electric/Gas
Residential Customer Profile Study	App. U, Study 9	Electric/Gas
Multifamily Impact Findings Memo	App. U, Study 10	Electric/Gas
Ductless Mini-Split Heat Pump (DMSHP) Final Heating Season Results	App. U, Study 11	Electric
Ductless Mini-Split Heat Pump (DMSHP) Baseline Determination	App. U, Study 12	Electric
Low-Income		
Massachusetts Low-Income Multifamily Initiative Impact Evaluation	App. U, Study 13	Electric/Gas
Special & Cross Sector Studies		
Comprehensive Review of Non-Residential Training and Education Programs, with a Focus on Building Operator Certification	App. U, Study 14	Electric/Gas
Comprehensive Review of Behavior and Education Programs	App. U, Study 15	Electric/Gas
Massachusetts Behavioral Programs Process Evaluation	App. U, Study 16	Electric/Gas
2014-2015 Commercial and Industrial Natural Gas Programs Free-ridership and Spillover Study	App. U, Study 17	Gas
Efficient Neighborhoods + Incremental Cost Assessment	App. U, Study 18	Electric/Gas
Commercial & Industrial Program Studies		
Prescriptive Gas Impact Evaluation - Steam Trap Evaluation Phase 1	App. U, Study 19	Gas
Prescriptive Programmable Thermostats	App. U, Study 20	Gas
Impact Evaluation of PY2013 Custom Gas Installations	App. U, Study 21	Gas
Massachusetts Commercial New Construction Energy Code Compliance Follow-Up Study	App. U, Study 22	Electric/Gas
Massachusetts LED Spillover Analysis	App. U, Study 23	Electric
Impact Evaluation of Prescriptive Chiller and Compressed Air Installations	App. U, Study 24	Electric
Impact Evaluation of 2012 Custom HVAC Installations	App. U, Study 25	Electric

Summaries of these evaluations are attached at Appendix T and full copies are available at Appendix U. Additionally, all currently completed studies are available on the Council's website at: http://ma-eeac.org/studies/.

F. Technical Reference Manual/Library

The TRM documents how the energy efficiency Program Administrators consistently, reliably, and transparently calculate savings resulting from the installation of prescriptive energy efficiency measures. The TRM provides methods, formulas, and default assumptions for estimating energy, peak demand, and other resource impacts from energy efficiency measures. The TRM, which did not exist until the PAs developed their initial Three-Year Plan, is an excellent example of how the PAs work together, share data and best practices and work to develop common assumptions that reflect state-of the-art EM&V results. The complete TRM is available at Appendix V.

In 2014, the PAs also began developing an electronic version of their TRM, which documents impact factors and input assumptions, with sources and references. This electronic version is still under development and will be available during the term of the Plan, but was not complete in time for this filing. In recent years, the PAs have developed and provide a paper copy of the TRM for each Three-Year Plan and annual performance report filed with the Department. The PAs provided a paper copy of the TRM in Appendix V of this Plan, and will supplement it with the electronic version, when it is complete and usable.

The electronic product associated with the development of the TRM will be known as the Technical Reference Library ("TRL"), and will allow the public to access information from a central website. The development of this product is a collaborative effort of the PAs. The TRL will reflect the efforts of the PAs to align common measure naming across all PAs, where appropriate. The PAs have been working diligently on developing the TRL, but development has been more complex than anticipated; the PAs expect that the TRL will be complete in 2016.

G. Core Benefits and Cost-Effectiveness

1. Energy and Demand Savings

The savings goals and program budgets set forth in this Plan are presented on an aggregate, statewide basis by program. In the Energy Efficiency Data tables, each Program Administrator provides its individual recommended savings and budget levels for the three-year term commencing January 1, 2016, consistent with the overall goals and budgets developed in the statewide Plan review process, which are included as supplemental enclosures with this Plan. The statewide Plan review process is a phased process that first requires the filing of a joint statewide plan by all Program Administrators in April, followed in October by individual PA-specific plans, after the conclusion of the review process of the statewide plan at the Council. G.L. c. 25, §§ 21(b)-21(d).

In developing the proposed statewide goals and budgets in this Plan, the Program Administrators first submit an initial Plan on April 30, 2015, and file a final Plan with the Department by October 30, 2015. In advance of these filings, the Program Administrators engage in intensive internal and statewide discussions regarding savings goals, budgets, benefits, and incentives. The PAs also participate in Council meetings and workshops related to 2016-2018 planning and engage in discussion with the Council consultants, individual Councilors and other interested stakeholders. The savings goals and budgets presented on a statewide basis by the Program Administrators in this Plan represent the results of that collaborative process.

Following historic aggregate three-year savings levels, this Plan reflects the current market after years of energy efficiency in Massachusetts, the unique characteristics of each Program Administrator's service area, and the specific needs of its customers as appropriate for 2016-2018. The Program Administrators developed PA-specific filings that are consistent with, and flow out of, the overall goals developed in the statewide Plan review process.[112] Please see Section IV.A for the annual savings goals proposed by the Program Administrators in this Plan, on a per sector basis, by year and in total. Please also see Appendix C for statewide Energy Efficiency Data Tables for budgets, savings, benefits, and cost-effectiveness.

2. Environmental Benefits

The reduction in the amount of electricity and natural gas required to run the Commonwealth's economy through energy efficiency program development brings significant environmental benefits to Massachusetts and the region. Benefits include reduced air pollution, improved air quality and additional resource benefits, such as oil and water savings. Decreasing energy consumption results in less demand for energy from fossil fuel power plants and natural gas pipelines. Reduced plant operating time can lessen air pollutants and greenhouse gas emissions.

Generating electricity or heat from non-renewable fossil fuels (*e.g.*, coal, oil, or natural gas) produces nitrogen and sulfur oxides - two of the six "criteria pollutants" defined by the Clean Air Act and identified as air quality indicators by the U.S. Environmental Protection Agency. Nitrogen oxides are precursors to ozone, a primary component of summer smog and exacerbate public health problems, such as asthma, and contribute to acid rain. Reducing the amount of fossil fuel needed to operate our homes and businesses through the adoption of energy efficiency improvements reduces these impacts both in Massachusetts and in neighboring states. One particularly impactful measure is the conversion of customers from old, often oil-fired, heating equipment to new, high-efficiency units, which can significantly reduce local pollution levels.

Water resources also benefit from energy efficiency. With fewer pollutants in the air and acid rain abatement, fresh water resources have less opportunity for particulate contamination or potential acidification. Additionally, some energy efficiency measures offer the co-benefit of providing water savings. For example, aerators reduce the volume of water flowing from a faucet, thus lessening the energy needed to heat the smaller volume of water. Reducing water

112 Program Administrators are not required to make all changes or revisions recommended by the Council in their October filing to the Department. G.L. c. 25, § 21(c)-(d)(1). Each Program Administrator supports the statewide Plan and their PA-specific filings are built upon and consistent with the statewide Plan and the best interests of their customers.

usage limits stress on reservoirs and water treatment facilities. The 2016-2018 Plan projects saving over 470 million gallons of water annually and approximately 4 billion gallons over the lifetime of installed measures.

In addition to providing cleaner air and water for Massachusetts, the 2016-2018 Plan's programs provide climate benefits in the form of reduced emissions of nitrogen oxide, sulfur dioxide and carbon dioxide. Information on the reductions in these emissions from energy efficiency is available on the GHG Reductions tab of Mass Save Data, the PAs' energy efficiency database. This tab can be accessed at http://www.masssavedata.com/Public/GreenHouseGases.aspx. The GHG Reductions tab allows for conversions between metric and short tons and displays conversion factors and sources.

Collectively, the programs contained in the 2016-2018 Plan are expected to provide three-year adjusted gross electric annual savings of 4,512,325 MWh, and three-year adjusted gross gas annual savings of 61,280,092 therms. Over the three years of this Plan, these savings equate to the following:

2016-2018 Annual Savings	
	**410,162**
Number of cars removed from the road through electric and gas savings	
	**601,643**
Number of homes powered through electric savings	
	**64,710**
Number of homes heated through gas savings	

Information from the table above will be available on Mass Save Data for 2016-2018. This information is currently available for 2010-2015.

For reference, as of 2010, there were 272,481 homes in Boston and 2,802,254 homes in Massachusetts. Using the combined number of homes powered through electric and gas savings, the 2016-2018 Plan allows the state to power 24 percent of its homes through energy savings.

Investment in energy efficiency is recognized as the most effective cost-containment and climate protection tool of the Commonwealth under climate cap and trade programs such as RGGI, other climate regulation such as the Clean Power Plan proposed by the Environmental Protection Agency, and the Commonwealth's climate change initiatives under the GWSA. Energy efficiency lowers energy consumption, which reduces GHG emissions and the demand for allowances. The result is a lower price for carbon allowances and lower overall cost of the cap and trade program.

3. Net Benefits and Cost-Effectiveness

a. Introduction

The Program Administrators have projected the expected benefits and costs associated with this statewide 2016-2018 Plan consistent with the requirements of the Guidelines and D.P.U. 08-50-A, in which the Department reaffirmed that "the Total Resource Cost test is the appropriate test for evaluation of the cost-effectiveness of ratepayer-funded energy efficiency programs." D.P.U. 08-50-A at 14. To conduct the TRC test, the Program Administrators routinely update their benefit/cost screening models to reflect new assumptions relating to program costs and benefits, the discount rate, the general rate of inflation, and avoided costs. In general, the benefit categories in the TRC test include the value of energy savings, gas and electric system benefits, and other measurable benefits (*e.g.*, participant resource benefits, participant non-resource benefits and benefits due to measurable market effects).

Costs included in the TRC test include all PA costs and program participant costs. PA costs include program implementation expenses, evaluation costs, proposed performance incentives, and tax liability for performance incentives. Program-participant costs include initial costs incurred by customers as a result of their participation in the program.

The benefit/cost screening model uses this data to calculate the present value of the program benefits and costs, and then calculates ratios of these values to produce BCRs for the TRC test. The present value of costs and benefits is calculated over the expected duration of the useful life of the measures installed in the program.

The tables below summarize the expected benefits, costs, and BCRs at the sector level for the portfolio of programs the Program Administrators propose to implement over the three-year term.

STATEWIDE ELECTRIC BENEFIT RATIOS	2016	2017	2018	2016-2018
Residential	2.37	2.33	2.30	2.34
Low-Income	1.65	1.68	1.73	1.68
Commercial & Industrial	2.58	2.59	2.63	2.60
Total	2.42	2.41	2.43	2.42

STATEWIDE GAS BENEFIT RATIOS	2016	2017	2018	2016-2018
Residential	1.63	1.62	1.63	1.63
Low-Income	1.71	1.74	1.77	1.74
Commercial & Industrial	2.61	2.58	2.56	2.58
Total	1.85	1.84	1.85	1.85

b. Avoided Energy Supply Cost Study

To develop avoided supply costs, the PAs participate in the AESC study process, which is a well-established regional and collaborative process.[113] The AESC study determines projections of marginal energy supply costs that will be avoided due to reductions in the use of electricity, natural gas, and other fuels resulting from energy efficiency programs. The AESC study is prepared for the AESC study group, which is comprised of the PAs, as well as utilities throughout New England and other interested non-utility parties. Historically, the AESC study has been developed every two years, but beginning with the 2015 AESC, will move to a three-year cycle.

In order to inform the initial draft of the 2016-2018 Plan, which must be filed with the Council by April 30, 2015, the 2015 AESC study was completed on March 27, 2015, as revised on April 3, 2015. Unlike previous studies, the 2015 AESC study is designed to be updated in synch with the three-year planning cycle of energy efficiency plans required by the GCA. A three-year cycle for the AESC study is consistent with the Department's focus on the three-year planning and performance construct envisioned by the GCA. D.P.U. 11-120-A, Phase II at 2.

The AESC study provides projections of avoided costs of energy in each New England state for a hypothetical future, the "Base Case," in which no new energy efficiency programs are implemented in New England. The 2015 AESC study provides an updated assessment of avoided electricity and natural gas costs using a model that simulates the operation of the New England wholesale energy and capacity markets in an iterative, integrated manner. In the 2015 AESC, there were several factors that changed significantly from the previous study. One significant difference from the 2013 AESC is an increase in the quantity of shale gas production at correspondingly low production costs, resulting in lower avoided gas supply and electric

113 While the PAs are aware of, and have participated at some varying levels in, the ongoing avoided cost of carbon proceeding currently before the Department in D.P.U. 14-86, no final determinations were made in that docket in time to instruct the development of the 2015 AESC study for this Plan.

energy costs. Estimates of electricity costs, natural gas costs, and cross-fuel Demand Reduction Induced Price Effects ("DRIPE") are all lower than estimated in the 2013 Study as well. However, the avoided costs for electric capacity are higher than in the 2013 Study due to changes in generation retirements and costs of new capacity additions. The reduced avoided costs in the 2015 AESC tend to decrease benefits and cost-effectiveness relative to the previous Plan term, making goals harder to achieve. The 2015 AESC is available at Appendix J.

c. *Net Savings*

i. Non-Energy Impacts

A Non-Energy Impact ("NEI") is an additional benefit (positive or negative) for participants in energy efficiency beyond the energy savings gained from installing energy efficient measures. NEIs include benefits such as reduced costs for operation and maintenance associated with efficient equipment or practices, or reduced environmental and safety costs. In the 2010-2012 Orders, the Department instructed the PAs to undertake studies that evaluate NEIs to ensure that updated and reliable values would be developed in time for inclusion in the cost-effectiveness analyses in their subsequent Three-Year Plans. See 2010-2012 Electric Order at 130-131 (called non electric benefits); 2010-2012 Gas Order at 121 (and 48-51) (called non-resource benefits). In the 2013-2015 Order, the Department stated that NEIs are "a well established component of the program cost-effectiveness analyses conducted by the Program Administrators" and noted that many of the NEIs included in the 2013-2015 Plan were the result of studies that the Program Administrators took to comply with this directive. 2013-2015 Order at 61. Finding that the benefits of the NEIs are quantifiable and flow to Massachusetts ratepayers, subject to a few exceptions, the Department approved the NEIs as proposed in the Three-Year Plan. In addition to Department Orders, the Guidelines also specifically state that non-resource benefits should be included in cost-effectiveness. Guidelines at §3.4.4.1, §3.4.4.2.

In accordance with prior Orders and the Guidelines, the PAs have included NEIs in this Plan that are supported by evaluation studies. The PAs have included the benefits established in these studies in the benefit cost testing that determined program cost-effectiveness.

ii. Market Effects

The PAs have sought to study both direct and indirect effects of the energy efficiency programs. Market effects studies look at whether the energy efficiency programs have successfully reduced market barriers and transformed markets. Market effects capture a moment in time. To quantify program impacts that have translated to market effects, first a baseline must be established, and then changes from the assumed baseline can be determined to be program induced. Only then can the market effects be counted in net savings. In this Plan, the PAs have specifically studied market effects related to the Residential New Construction Program and Commercial LED impacts. The PAs note that the methods used to study market effects and claim benefits do not imply that those values can be counted in perpetuity. Current values from market effects may change due to non-program induced shifts in the market, which may be applicable to additional market effects that are determined in the future.

4. Additional Benefits

a. Reduction in Peak Load

Energy efficiency efforts often provide capacity savings in addition to energy savings. These capacity savings and benefits are reflected under the cost-effectiveness screening efforts described in Section III.G.

b. Economic Development and Job Growth/Retention

Another positive effect of the energy efficiency programs in Massachusetts has been job growth. The Massachusetts Clean Energy Center ("MassCEC") has tracked the growth of the Commonwealth's clean energy economy on an annual basis. The 2014 Clean Energy Industry Report looks at Massachusetts-wide employment of people in a broad category of energy efficiency.[114] MassCEC's most recent report from 2014 provides the following information on full time employees ("FTE") in energy efficiency related fields.

Energy Efficiency Technology	**FTE Estimate**
HVAC and Building Controls	17,764
Lighting	10,937
Energy Efficient Appliances	10,318
Energy Efficient Processes and Machinery	5,799
Weatherization Services	5,762
Energy Efficient Building Materials	5,656
Other	3,115
Smart Grid	1,868
Water and Wastewater Technologies	1,535
Demand Response Services	1,256
Energy Storage	1,173

114 http://www.masscec.com/content/2014-clean-energy-industry-report

MassCEC developed these employment numbers through an in-depth survey effort based on the following methodology:

- The primary data included in this study are derived from a comprehensive survey of business establishments in Massachusetts.
- Surveys were administered online and by telephone to a list of known employers as well as to a representative, clustered sample of companies from the North American Industry Classification System ("NAICS") identified by the Bureau of Labor Statistics ("BLS") and BW Research Partnership.
- The research team placed 36,782 telephone calls and sent 3,793 emails to employers.
- The survey effort, with a combined margin of error of approximately +/-2.23 percent at a 95 percent confidence interval, yielded 1,891 survey responses.
- Survey respondents were asked to select the technology to which their firm's work is most closely associated, from a list including renewable energy, energy efficiency, alternative transportation, or greenhouse gas emissions accounting and sequestration.

In addition to the MassCEC, the Northeast Energy Efficiency Council ("NEEC") issued a report on the impact of the GCA on the energy efficiency industry in Massachusetts. The report states:

> Since the passage of the [GCA], Massachusetts has achieved nation-leading energy efficiency success. . . [E]ach year of program activity produce lifetime savings of more than 13 million MWh of electricity and 300 million therms of natural gas. . . The engine behind this achievement has been the state's energy efficiency industry: small, medium, and large companies that deliver, or support the delivery of, energy efficiency-related products and services. Since 2008, this industry has evolved from a small circle of specialty firms to an open, market-driven ecosystem of companies that compete with each other for a piece of the action. . . While program funding increased 335% from 2008-2014, the number of companies participating in the programs increased by even more. We identified more than 7,000 companies participating in the Massachusetts energy efficiency industry today. What's more, the majority of those companies are not energy efficiency-focused companies, but rather are companies that have added energy efficiency to an existing line of business.[115]

115 *An Industry Transformed: The Impact of the Green Communities Act of 2008 on the Energy Efficiency Industry in Massachusetts*, Northeast Energy Efficiency Council (October 2015), available at: http://www.neec.org/wp-content/uploads/2015/10/NEEC_IndustryReport_102715.pdf

c. Supporting the Global Warming Solutions Act ("GWSA")

i. Energy Efficiency Under the GCA Supports the Goals of GWSA

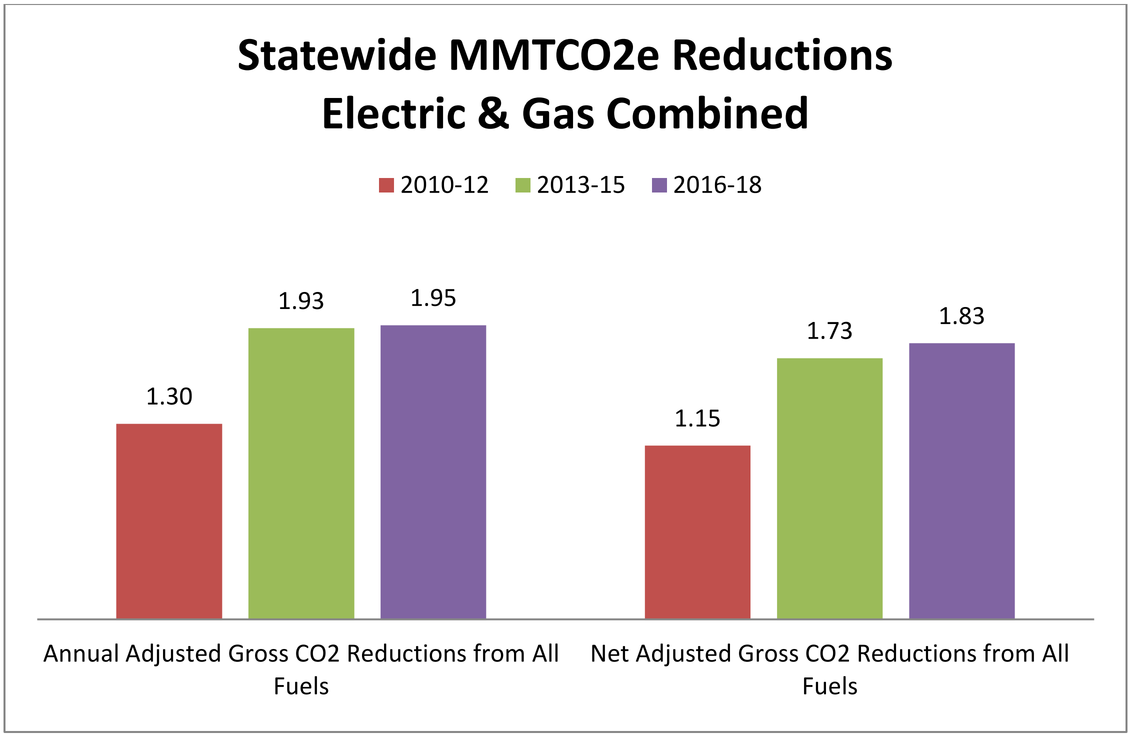
One purpose of the Global Warming Solutions Act ("GWSA") is to reduce Greenhouse Gas ("GHG") emissions within Massachusetts 25 percent below 1990 levels by 2020.[116] Energy efficiency programs implemented pursuant to the Green Communities Act ("GCA") support the goals of the GSWA because reduction of GHG emissions is an important result of the programs. As discussed further below, by delivering on the goals in their Three-Year Plans, the PAs are materially contributing to GHG emissions reductions in the Commonwealth, and each Three-Year Plan to date has reduced more GHG emissions than the one before it. Although the GWSA does not govern the PAs,[117] the PAs remain committed to achieving reductions in GHG emissions through implementation of their Three-Year Plans.

ii. More GHG Reductions Than Prior Plans

The PAs are substantially contributing to GHG emissions reductions in the Commonwealth. In fact, as demonstrated in the graph below, the 2016-2018 Plan will deliver more reductions in GHG emissions than prior plans.

116 The GWSA, which was enacted in 2008, identifies broad statewide GHG reduction goals for the Commonwealth to achieve. G.L. c. 21N. The GWSA requires DEP to "monitor and regulate emissions of greenhouse gases *with the goal of reducing those emissions*." G.L. c. 21N, § 2(a) (emphasis added). The GWSA seeks to encourage early action to reduce GHG emissions. See G.L. c. 21N, § 3(b) (requiring EEA to develop plans to meet limits; § 5(i) (requiring EEA to report on reduction measures, their benefits and whether they encourage early action).

117 The GCA governs the PAs' energy efficiency efforts and requires them to seek to acquire all available cost-effective energy efficiency and demand management resources. The specified purpose of energy efficiency under the GCA is to encourage the efficient use of energy. St. 2008, c. 169 § 11; G. L. c. 164, § 1. The GWSA does not supersede or abrogate the Department's regulatory authority or the Council's role with respect to Three-Year Plans under the GCA. For a more detailed discussion of these issues, please refer to the initial and reply briefs filed by PAs in Method for Calculating Avoided Costs of Complying with Global Warming Solutions Act, D.P.U. 14-86, which is pending before the Department.



*MMTCO$_2$e = million metric tons of carbon dioxide equivalents

To further demonstrate the contribution of energy efficiency to the Commonwealth's GWSA goals over time, the PAs provide a table below that is based upon adjusted gross annual savings. This table is provided to depict how energy efficiency contributes to reductions in GHG emissions in a snapshot annual view. Please note that the GHG emissions calculations for the electric PAs take into account non-electric savings, such as gas and oil savings in addition to electric savings. Similarly, the GHG emissions calculations for the gas PAs take into account non-gas savings such as electric savings that are not claimed by the electric PAs.

Adjusted gross savings are the actual savings achieved due to the installation of energy efficiency measures, as adjusted by impact factors but without factors related to program attribution. Attribution factors determine whether savings are attributable to the efforts of the PA programs pursuant to their Three-Year Plans and in compliance with their GCA mandate to reduce energy use. Attribution looks at free-ridership (*i.e.*, someone would have implemented energy efficiency measures without the program) and spillover factors (i.e., savings resulting from program existence outside of program efforts). While these factors are appropriate for use with the GCA, which seeks to determine which savings resulted from PA program efforts (net savings), the GWSA seeks to quantify all energy efficiency GHG reductions without regard to PA program attribution. Consequently, calculating GHG reductions based upon net savings would undervalue the contribution of energy efficiency to GHG emission reductions.[118]

---

118 Adjusted gross savings represent reliable energy efficiency savings that are used for other reporting purposes but not for the GCA. For example, ISO-NE relies on adjusted gross savings for all capacity and reliability purposes related to competitive wholesale energy markets.

Finally, the PAs used the most current emission factors provided by DEP to convert savings to GHG emission reductions. These factors are available on the GHG Reductions tab of Mass Save Data, the PAs' energy efficiency database. To access the factors, go to http://www.masssavedata.com/Public/GreenHouseGases.aspx and look for "Click here to view Emissions Factors used" in the table labeled "Total CO2 Reductions from All Fuels." The PAs used 2014 factors to estimate the reductions for years 2015-2018. The PAs recognize that these are backward-looking factors and that there is ongoing work related to emissions factors. When more accurate forward-looking factors become available, the PAs will apply them for reporting and on Mass Save Data.

Adjusted Gross Annual Savings and CO2 Reductions (2010 - 2018)				
Year	**Electric Energy Savings (MWh)**	**Gas Savings (Therms)**	**Oil Savings (MMBTU)**	**Annual CO2 Reductions (Short Tons)**
2010	631,568	11,162,323	208,500	363,613
2011	891,117	10,407,225	335,727	461,667
2012	1,226,549	29,562,657	396,068	679,035
2013	1,300,824	26,301,689	433,180	699,358
2014	1,490,550	28,277,668	454,099	787,068
2015	1,450,312	21,225,598	370,033	723,237
2016	1,484,266	22,021,736	42,636	714,802
2017	1,502,951	20,571,227	70,735	715,917
2018	1,525,109	18,687,129	111,489	716,880
Total (2010 - 2018)	**11,503,246**	**188,217,252**	**2,422,467**	**5,861,578**

To place these reductions in context, the PAs have converted their reductions in GHG emissions from 2010-2018 into the equivalent number of (1) cars removed from the road through electric and gas savings; (2) homes powered through electric savings; and (3) homes heated through gas savings.

2010-2018 Annual Savings	
	**1,119,481**
Number of cars removed from the road through electric and gas savings	
	**1,533,766**
Number of homes powered through electric savings	
	**198,751**
Number of homes heated through gas savings	

In making these calculations, the PAs used recent GHG conversion factors from the Energy Information Administration and/or the federal Environmental Protection Agency's Greenhouse Gas Equivalencies. Please note that the information contained in the tables and the conversions to cars and homes is available for 2010-2015 on Mass Save Data at http://www.masssavedata.com/Public/GreenHouseGases.aspx. Data for 2016-2018 will be available after the October 30 filing with the Department. The GHG Reductions tab allows for conversions between metric and short tons and displays both the emissions and conversion factors.

iii. EM&V Study to Fully Quantify Energy Impacts that Result in Reductions in GHG Emissions and Environmental Benefits

As discussed above, energy efficiency under the GCA supports the goals of the GWSA. The plain language of the GWSA makes it clear that all GHG emissions reductions that "are real, permanent, quantifiable, verifiable and enforceable" should be counted.[119] The PAs can, to a large extent, reliably quantify how energy efficiency savings as reported under the GCA contribute to GHG reductions. They are concerned, however, that their quantification does not account for all verifiable GHG reductions resulting from program activity. For example, while the PAs quantify the incremental savings that result from incenting a natural gas customer to purchase a new high-efficiency furnace rather than a new standard-efficiency furnace, the PAs do not quantify the energy savings or emissions reductions related to that customer transitioning from their old furnace to a new furnace. And in the case where the old furnace was oil fired

119 G.L. c. 21N, § 5(ix); see also G.L. c. 21N, § 2(a)(6) (ensure rigorous and consistent accounting of emissions); G.L. c. 21N, § 4(d) (use "the best available economic models, emissions estimation techniques and other scientific methods").

rather than gas, the emissions savings are even higher and are not counted. Quantifying environmental benefits is a specific goal of the GCA and an important goal of the Commonwealth. Accordingly, the PAs will explore efforts through EM&V activities, with the support of the Council's independent EM&V experts and planning consultants, as well as DEP and DOER, to better quantify both the energy impacts used to determine climate and air quality benefits, and the estimates of other environmental benefits.

The implication for PA research differs depending on the scale at which EE impacts would be analyzed. For example, a gross savings analysis may look at the Gas Heating and Cooling program. While the PAs quantify the incremental savings that result from incenting a natural gas customer to purchase a new high-efficiency furnace rather than a new standard-efficiency furnace, the PAs do not quantify the emissions reductions related to that customer transitioning from their old oil furnace to a new gas furnace. While those savings may or may not be attributable to energy efficiency efforts, the savings are not being counted in other areas and estimating the savings can help better quantify the impact of the Massachusetts energy efficiency efforts on reduction of GHG emissions.

If a larger scale view is preferred, other research, such as investigating impacts from a top-down[120] approach, may be needed. In addition to the question of scale, research may need to extend beyond the traditional bounds of the utility system. Quantifying environmental benefits is a specific goal of the GCA and an important goal of the Commonwealth. This study could allow the Commonwealth to reassess the accounting of the GHG emission reductions attributable to energy efficiency. The PAs propose to complete this study before the filing of their 2019-2021 Plan.

iv. Conclusion

In sum, the PAs are proud to be material actors in helping the Commonwealth achieve its GHG emission reduction goals, and to be proposing savings goal for the 2016-2018 Plan that will support the Commonwealth's obligations under the GWSA. To better understand the GHG benefits that result from energy efficiency, the PAs propose to quantify the full suite of GHG reductions and benefits through an EM&V study to be completed before the next three-year plan. The PAs expect that this study will identify additional GHG emissions reductions that result from energy efficiency. In the meantime, the PAs have developed and launched a GHG Reductions tab on Mass Save Data, which provides transparency into the PAs' current calculations as to the effect of energy efficiency on GHG emissions reductions in Massachusetts.

[120] Top-Down methods employ aggregate consumption and macro-economic data to measure reductions in energy use resulting from energy efficiency efforts.

V. GREEN COMMUNITIES ACT REQUIREMENTS AND GOALS

A. <u>**All Cost-Effective or Less Expensive than Supply Resources**</u>

1. <u>Introduction</u>

Pursuant to G.L. c. 25, § 21 (b)(1), the 2016-2018 Plan seeks to capture all available cost-effective energy efficiency for the three-year term beginning January 1, 2016, taking into account many requisite competing considerations, including, but not limited to, bill impacts, cost efficiency, integrated program delivery, economic and environmental benefits, and the need for sustainability. The GCA does not define "all available" cost-effective energy efficiency, and thus developing related values requires a reasonable level of judgment. There is no single study or planning tool that can reliably set forth such a value. Rather, a multifaceted approach is necessarily employed and multiple reference points are considered. As discussed in Section II.D.1, the Department requires the PAs to consider and strike an appropriate balance among six factors in order to determine a reasonable pace for the sustained acquisition of all cost-effective energy efficiency.

In determining the level of savings for 2016-2018 necessary to satisfy the GCA's mandate and the Department's directives, the Program Administrators considered and weighed multiple factors, including: (1) the plain language of the GCA; (2) the input and recommendations of the Council and other stakeholders; (3) the Department's energy efficiency Orders, including those (a) approving previous Three-Year Plans, Mid-Term Modifications ("MTMs") and Annual Reports; (b) in D.P.U. 08-50-A and D.P.U. 08-50-D (bill impact considerations); (c) in D.P.U. 11-120-A Phase I (net savings and application of evaluation results) and D.P.U. 11-120-A, Phase II (revised Guidelines); and (d) in D.P.U. 13-67 (performance metrics); (4) assessments of all available cost-effective energy efficiency; (5) multiple studies and reports, including extensive EM&V results; and (6) the PAs' experience in implementing nationally-recognized energy efficiency programs for over three decades. The Program Administrators met collaboratively on a frequent basis to determine the appropriate savings goals and budgets to propose in this Plan. The Program Administrators also participated in the Council's planning activities and engaged in numerous discussions with Councilors, their Consultants, and other stakeholders.

2. <u>Experience in the Field</u>

First and foremost, the Plan has been developed based on the in-depth experience of the Program Administrators in designing and implementing energy efficiency programs over more than 30 years, and, more specifically, in the course of implementing the Three-Year Plans for the periods 2010-2012 and 2013-2015. This experience includes (1) understanding of the customers' circumstances and the cost of implementing aggressive programs over a sustained period and (2) knowledge that the PAs can successfully deliver impressive savings levels in the field. This experience also informs the PAs that as energy efficiency efforts yielding high savings become more difficult to identify and achieve, and as market penetration increases, there will be challenges in achieving additional savings. Importantly, the Program Administrators are factoring in upward pressures on the cost to achieve energy efficiency savings, especially as EM&V results, the level of CHP projects currently foreseen, and increased efficiency codes and standards make the achievement of incremental efficiencies through PA-sponsored programs more difficult. In short, the PAs' experience in the field provides valuable lessons that inform this planning process in a unique and important way.

3. Review of EM&V Results

Working together and with the Council, the Program Administrators have undertaken extensive EM&V efforts designed to ensure accuracy and accountability in program planning and implementation and to guide the PAs as they focus on improving energy efficiency program efforts. Section III.E of the 2016-2018 Plan includes information regarding the comprehensive EM&V efforts that have been undertaken to date and which have informed program design and savings goals for 2016-2018. EM&V efforts will continue throughout the term of the 2016-2018 Plan, pursuant to the EM&V strategic plan. EM&V results have been used by the Program Administrators to more accurately forecast the actual savings resulting from their energy efficiency activities, in particular, net savings resulting from these activities. EM&V results indicate that strong savings are occurring as a result of the Program Administrators' efforts, but that savings, in particular for several gas programs, are not as high as originally forecasted. This is an important factor in looking to establish goals for 2016 -2018.

4. Potential Studies

a. Introduction

In the Department's Order in the 2013-2015 Plan proceeding, the Department directed "[t]he Program Administrators with an aggregate three-year savings goal of greater than 20 percent below the statewide three-year aggregate goal [to] conduct a study, either jointly or individually, during the upcoming three-year term to document the penetration of energy efficiency within its service territory and the remaining cost-effective energy efficiency opportunities available." 2013-2015 Energy Efficiency Plans, D.P.U. 12-100 through D.P.U. 12-111 at 18-19, 40 (2013). In compliance with this directive from the Department, The Berkshire Gas Company, Liberty Utilities, Unitil, and the Cape Light Compact each completed an assessment of the penetration of energy efficiency in their respective service territories and then used the results of that analysis to inform proposed savings goals and budgets in 2016-2018. In addition, although not directed by the Department to complete a potential study, National Grid completed an assessment of the remaining achievable electric and gas savings that could be secured in the C&I sector to help it to propose appropriate goals in that sector.

b. The Berkshire Gas Company, Liberty Utilities and Unitil

In 2014, Berkshire, Liberty, and Unitil (individually, "Company," collectively "Companies") each retained GDS Associates, Inc., to prepare Remaining Potential Assessments ("Assessments") in accordance with the 2013-2015 Order at 18-19, 40 (2013). The Department directed "[t]he Program Administrators with an aggregate three-year savings goal of greater than 20 percent below the statewide three-year aggregate goal [to] conduct a study, either jointly or individually, during the upcoming three-year term to document the penetration of energy efficiency within its service territory and the remaining cost-effective energy efficiency opportunities available." Id. at 18-19. The Companies also worked with the Council's consultants on the scope of these Assessments. GDS was tasked with performing a program-specific assessment focused on what each Company's current energy efficiency programs had achieved (penetration and savings to date) and what remaining opportunities could likely be achieved within each Company's programs over the 2016-2018 term. The Assessments are available at Appendix M.

In early February 2015, GDS delivered these Assessments to the Companies. The Assessments encompass the demographics, market conditions, and customer attitudes in each Company's service territory. The Assessments also provided Company-specific information regarding savings potential that each Company has used in conjunction with other planning tools to build ambitious and achievable cost-effective energy efficiency goals for the 2016-2018 timeframe. The Assessments were conducted over approximately six months and relied on primary research in the Companies' territories as well as a review of historical data (2013 data was the most recent data available at the time GDS performed its studies). The Assessments estimated remaining potential based on actual in-service territory baseline data collection (phone surveys and site visits) and review of participant and non-participant customer feedback, which revealed a broader assessment of potential that is not solely based on any single year's performance.

The Assessments looked at past performance to set minimum levels of participation that could be achieved over the 2016-2018 term. The high-case potential scenario does not include budget constraints on the part of either customers or the Companies, nor does it take into consideration any territory-specific economic conditions, customer behaviors (as measured by the telephone and in-person surveys), or any physical barriers to measure installation. In determining goals for 2016-2018, the Companies considered these penetration constraining elements as well as the bill impacts that are likely to occur given the funding needed to reach the proposed level of savings.

While the Companies considered 2014 performance in developing goals for 2016-2018, they do not view 2014 performance as the only predictor of future potential. The tendency on the part of the Companies to experience swings in performance from one year to the next has been acknowledged in multiple evaluations, and should be taken into account when making projections for the 2016-2018 cycle. Using results from any given year in isolation, including the associated single-year payback, or cost to achieve savings, cannot in isolation produce a reliable projection of future potential; it is not possible to draw a line estimating any trajectory with a single data point. While considering two or more data points in relation to each other mathematically allows one to estimate a trend, the actual variance in performance is influenced by far too many non-linear variables to produce a reliable forecast of future performance.

c. Cape Light Compact

Consistent with the Department's directive on potential studies, the Compact retained Opinion Dynamics Corporation and Dunsky Energy Consulting to prepare the 2014 Cape Light Compact Penetration, Potential, and Program Opportunity Study (the "Study"). See 2013-2015 Order at 18-19. Prior to finalizing the scope of the Study, the Compact requested that the Council's consultants provide feedback on the proposed scope.

The goal of the Study was to determine the remaining achievable potential from electric measures among residential, low-income, and C&I customers for the six-year period 2016-2021 and to inform Compact's program planning efforts. The results of the Study are based on extensive primary and secondary data collection. The primary data collection activities for the residential and low-income sectors included a mail survey with 2,785 customers, in-home visits at 169 homes, and a telephone survey with 144 customers. The primary data collection activities for the commercial & industrial sector included a telephone survey with 448 customers and on-site visits at 150 facilities. In-depth interviews with a small number of local contractors to inform assumptions for the potential model were also conducted.

The Study identifies the average achievable energy savings representing 1.98 percent of Compact annual sales for the six-year Study period. To achieve the Study savings, it would cost the Compact $220 million (incentive and non-incentive program costs), an average of $37 million per year. The total cost (including the participants' net cost) amounts to $246 million for the six-year period. Total cost to achieve increases over the 2013-2015 planning period, however, all of the 2016-2021 proposed investments are cost-effective, with a Total Resource Cost ratio of 3.6 and a Program Administrator Cost ratio of 2.8. For the 2016-2018 Plan, the Compact Governing Board is considering a higher goal than the 1.98 percent of sales because it is considering the adoption of several new measures that were not addressed as part of the Study.

The Study also affirms the unique service territory of the Compact relative to serving seasonal residential and seasonal commercial customers. Serving seasonal residential and commercial customers is challenging and may require the Compact to consider exploring adjustments to the statewide benefits and savings assumptions.

The Study is available at Appendix M.

d. National Grid

In advance of the 2016-2018 Plan, National Grid engaged DNV GL to assess the potential for electric and natural gas energy and electric demand savings from company-sponsored commercial and industrial demand side management (DSM) programs. The method used for estimating potential is a "bottom-up" approach, in which energy efficiency costs and savings are assessed at the customer segment and energy efficiency measure level. For cost-effective measures (based on the Total Resource Cost (TRC) test), achievable savings potential is estimated as a function of measure economics, rebate levels, and program marketing and education efforts. The modeling approach was implemented using a National Grid specific Excel model which allows for efficient integration of large quantities of measure, building, and economic data to determine energy efficiency potential. The Company focused explicitly on the C&I sector because the Company had greater uncertainty about remaining potential in this sector due to the maturity of the Company's programs.

In order to conduct its assessment of technical potential, DNV GL used National Grid specific data as inputs to its model. The model was populated with data collected from National Grid customers through Wave 1 and a portion of Wave 2 of the Massachusetts Existing Building Market Characterization C&I Customer On-site Assessments (study to be completed in 2016), previous state-wide and National Grid specific evaluation efforts, the Massachusetts Technical

Reference Manual, National Grid's internal documents and tracking data and other secondary sources.

In this study, DNV GL looked at the potential available under three scenarios - a business-as-usual (BAU) scenario where overall incentives levels paid in 2015 are used going forward as well as two additional funding scenarios: 25 percent increase over those BAU levels (25 Percent Plus scenario) and a 75 percent increase (75 Percent Plus scenario). DNV GL first provided preliminary results in May 2015. DNV GL revised these estimates in August 2015, taking into account information from completing additional site visits, revisions to the model to more closely represent the Company's programs, and updates to the savings and costs assumptions. DNV GL provided its final report to the Company on October 26, 2015. While the point estimates of achievable potential changed slightly between the drafts, two key factors that impacted the results of DNV GL's assessment of C&I technical potential emerged.

1. The maturity of National Grid's energy efficiency programs causes awareness among the participant population to be already quite high. Put more simply, much of the "low hanging fruit" is gone in National Grid's territory, while simultaneously there is not an anticipated disruptive change (either in new technology or program design) during the 2016-2018 time frame.[121]

2. The saturation of retrofit upgrades during earlier years of the model result in a noted decline over time in the annual energy savings. Put another way, as retrofits are completed, there are fewer opportunities going forward.[122]

The study identified the average achievable energy savings representing cumulative savings of six to seven percent of National Grid's 2018 C&I electric annual sales (averaging between 2 and 2.3 percent each year) and cumulative savings of two to three percent of National Grid's 2018 C&I gas annual sales (averaging between 0.7 and 1 percent in each year) for the 2016-2018 Plan term.

The Company used the results of this potential analysis as one of many pieces to help inform National Grid's proposed savings goals. The Company used additional information as well, including, but not limited to, reviewing historical performance, intelligence from field personnel, savings attributable to measures not included in the scope of this study (*i.e.*, CHP), and expectations for new technologies to become available and to be cost-effective. Taking these additional factors into account, the Company has proposed savings goals higher than the average results from the potential study, at 2.35 percent of annual sales and 0.90 percent of annual sales for its C&I electric and gas sectors, respectively.

The potential assessed by DNV GL is consistent with other technical potential studies in areas with mature energy efficiency programs, as shown in the table below.

5. Council Coordination

The Program Administrators have also considered presentations at Council meetings by the Councilors, their consultants, industry stakeholders and the general public. The level of interest and commitment evidenced by these presentations affirms that opportunities for energy efficiency remain in Massachusetts because its citizens embrace a culture of energy efficiency

and sustainability. Presentations and comments at Council meetings have suggested, among other things, program design enhancements to target and achieve new savings in 2016-2018.

As discussed in Section II.D.2, the PAs were active and engaged participants in the Council planning process and have worked collaboratively with the Council and its consultants in the development of the 2016-2018 Plan. The Council conducted a number of sector-related workshops, facilitated by Raab Associates, Ltd., to assist in the development of the 2016-2018 Plan. The PAs were active and engaged partners in the development of meeting materials and in the workshops. In February and March 2015, there were three C&I workshops, three residential workshops and one multi-family/low-income workshop. In June 2015, there was one residential/low-income workshop and one C&I workshop.

As discussed in Section II.D.2, the PAs have carefully reviewed the Council's priorities and resolutions that relate to the development of the 2016-2018 Plan. The PAs appreciate the Council's thoughtful feedback on the April plan and their participation in the workshops and planning process. Together with the Council's input,[130] the PAs have developed comprehensive and innovative program designs that they believe will continue to set the standard for the rest of the nation. For ease of reference please refer to the following matrices responding to the Council's recommendations: Appendix F (matrix dated May 25, 2015 responsive to the 150 recommendations contained in the Council's March 31, 2015 Resolution); Appendix H (matrix dated September 23, 2015 responsive to the over 100 recommendations in the Council's July 21, 2015 Resolution). The PAs appreciate working with the Council in a collaborative and productive manner to develop energy efficiency programs for customers that will continue to deliver historic and nation leading savings and benefits.

6. Stakeholder Engagement

The PAs interact with a broad range of stakeholders on a regular basis in order to capture all good ideas and optimize program development and delivery. The breadth of stakeholders with whom the PAs interact on a regular basis spans the entire supply chain, including manufacturers, equipment distributors, contractors and service providers, trade associations, policy makers, community advocates, civic leaders, and customers. Each of these groups, individually and collectively, has an interest in, and is affected by, the energy efficiency plans designed and implemented by the PAs. The legislature recognized this significant scope of interested parties when it created the Council, the formal entity responsible for stakeholder input. The PAs recognize that both formal and informal interactions can yield program benefits, and therefore participate in and lead a multitude of activities and forums to foster this interaction, including: Council meetings, subcommittees, and the workshops facilitated by Raab Associates, Ltd.; MTAC; establishing the Process for Managing Proposals by Stakeholders and Interested Parties; open house meetings for trade allies and vendors; PA speakers for trade associations and meetings; providing collateral materials for customer events; and various ad hoc discussions with Councilors, government agencies, trade groups, and stakeholders. Additionally, the PAs seek

---

[130] The PAs have incorporated many but not all of the Council's recommendations for the 2016-2018 Plan. Each Resolution clearly stated they contained "recommendations," consistent with the Council's advisory role under the GCA, but they were not a consensus view of the Council. See Section I.F.2 and related footnotes.

and benefit from long term, close relationships with their customers, allowing for continual feedback and program refinement.

7. Consultant Assessment

In developing the 2016-2018 Plan, the Program Administrators reviewed analyses of the Council's consultants and worked collaboratively with them to narrow differences of opinion on the assessment of potential for 2016-2018. The PAs appreciate both the efforts of the consultants in analyzing the assessment of potential for 2016-2018 and their willingness to engage in collaborative and productive discussions to refine that assessment. As discussed above and in Section V.A, there are many factors to consider in determining goals, including: potential, costs, bill impacts, AESC study results, EM&V results, changing costs and baselines, new technologies, and performance incentives. These factors interrelate and should be considered together in iterative discussions and through a progressive refinement process.

The PAs specifically considered the following reports from the Council's consultants: (a) report dated March 5, 2015 and entitled "Preliminary Assessment of Potential for 2016-2018," which was presented at the March 10, 2015 Council meeting ("Preliminary Assessment"); (b) report dated April 30, 2015 and entitled "Draft 2016-2018 Energy Efficiency Plan," which was presented at the April 23, 2015 Council meeting ("Draft Plan Goals"); (c) report dated May 12, 2015 and entitled "Comparison of PA 2016-2018 Plan with Consultant Team Goal Framework Analysis, which was presented at the May 19, 2015 Council meeting ("Comparison"); and (d) report dated July 14, 2015 and entitled "2016-2018 Planning Assumptions for Key Driver Update – DRAFT," which was presented at the July 14, 2015 Council meeting ("Key Driver Update"). Having reviewed the consultants' analyses, the PAs provided comments on the written reports of the consultants.

Over the course of the summer and into early fall 2015, the PAs and the consulting team engaged in continued and extensive collaborative discussions, with all parties looking to understand positions better, review data, and narrow gaps in respective analyses of key drivers of costs and savings. In large part, these collaborative efforts helped the PAs, EEA, DOER, and the Attorney General come to common understandings that resulted in the Term Sheet described in this Plan and set forth in Appendix D.

B. **Key Challenges and Market Barriers**

As with the 2010-2012 Plan and the 2013-2015 Plan, the 2016-2018 Plan seeks to acquire all available cost-effective energy efficiency in a sustainable manner. In assessing the level of energy efficiency savings that is possible and sustainable for 2016-2018, the PAs took into account a number of factors. These factors include: (1) quality of program implementation; (2) customer economic conditions; (3) market conditions/seasonality for various measures; (4) lower gas costs relative to recent history; (5) landlord/tenant barriers; (6) other market barriers; (7) equity concerns; (8) the need to avoid "stops/starts" that send negative messages to the contractor community; (9) the need to provide consistency over time to be able to capture time-dependent opportunities such as renovations and new construction; and (10) the need to accommodate new technologies over time. The PAs describe below the key market and policy issues they considered and their approach to assessing the sustainable acquisition of all available energy efficiency resources for 2016-2018.

1. Market Barriers

As in past plans, the 2016-2018 Plan is designed to address significant market barriers. To deliver energy efficiency successfully, the programs must bridge the five major market barriers of awareness, availability, accessibility, affordability, and aversion to risk. These barriers affect customers' adoption of energy efficiency measures and the ability of PAs to achieve savings. This Plan outlines the initiatives that PAs believe are critical in bridging the five major market barriers.

a) **Awareness** is a barrier that historically was not confronted on a large scale, given capped budgets, marketing, and outreach. The 2016-2018 Plan recognizes that continued strong public education, marketing, and outreach, including community-based efforts, are needed to achieve deeper and broader penetration. Deeper penetration refers to the promotion of additional cost-effective technologies and strategies to capture comprehensive, whole-building savings among the traditional base of expected program participants. Deeper penetration requires raising participant awareness and understanding of the value of investing in additional measures that create increased savings. Broader penetration can include outreach to traditionally hard-to-reach customer groups, including economically marginalized communities and groups where English is not the first language.

b) **Availability** is a barrier when manufacturers either do not produce or do not effectively market sufficient quantities of energy efficient products and services. Availability may also be constrained by limited workforce or delivery mechanisms. The challenge for manufacturers in the energy efficiency sector is to respond not only to the Commonwealth's demand for more efficient products, but also to demands on a national or even global scale. This challenge is compounded by economic pressures which reduce the willingness of manufacturers to make additional investments. From a workforce perspective, PAs recognize that continued workforce training and deployment is required to effectively deliver the programs. This is not an insignificant barrier.

c) **Accessibility** is a barrier that refers to customer access to the product. To mitigate this barrier, PAs must continue to connect with mid-stream market actors, such as distributors, to ensure that products are displayed and stocked in sufficient quantity. The program descriptions set forth in this Plan provide for continued work with key market actors, and include campaigns for training and marketing, as well as proposed community mobilization outreach strategies.

d) **Affordability** is a major market barrier resulting from the initial cost of energy efficiency solutions. PAs are concerned that affordability is more difficult to predict as customer buying patterns have changed dramatically with the advent of limited credit. The Plan attempts to mitigate this barrier through the use of incentives, new delivery models for economically challenged neighborhoods, and broadly accessible financing. In some cases, particularly with respect to gas energy efficiency efforts, the PAs propose to increase incentives for measures so that the low commodity cost of natural gas does not impede investments in cost-effective gas energy efficiency measures and services.

e) **Aversion to Risk** is a market barrier that describes customers who are unwilling to take a chance on technologies that they perceive to be unproven. To address this barrier, the PAs seek to provide detailed, clear information to customers about the direct benefits of energy efficiency measures. In some cases, this information will be provided to customers in the form of a case study highlighting the performance of proposed measures, which will help reduce the perceived risk associated with energy efficient measures and practices.

2. Policy Issues

As in past plans, the 2016-2018 Plan also takes into account policy issues, including economic, sustainability, and regulatory issues.

a) **Economic** obstacles continue to be relevant in today's environment. The PAs recognize the 2016-2018 Plan's tremendous value, but must also consider the impact of short-term rate increases related to the ramp-up of these programs. The 2016-2018 Plan discusses the associated preliminary expected bill impacts of program implementation. As noted above, traditional incremental bill impact analyses, as well as participant analyses will be provided for each PA in the PA-specific filings later this year. The detailed bill impact analyses for each PA using traditional bill impact models that will be provided with each PA's Plan will contain the information required by the Department's Orders in D.P.U. 08-50-D.

b) **Sustainability** of the programs is an important consideration for the Three-Year Plan and an expressly repeated priority of the Council. Many advocates, including the Program Administrators and the Attorney General, stress that in achieving all available energy efficiency, the annual efforts must also strive to be sustainable for the long term. This sustainability is vital to support the health of the economy, and the growth of the workforce and infrastructure needed to ensure the long-term benefits of these efforts.

c) **Regulatory Guidance** includes the support of strong regulatory frameworks that complement the Program Administrators' ramp-up of programs. These frameworks create a healthy regulatory infrastructure by which PAs can confidently advance programs knowing that there is clarity in the regulatory rules and process and the opportunity to align shareholder objectives with public policy objectives. The Department's investigation in D.P.U. 11-120 is an example of the strong commitment to regulatory guidance in Massachusetts, which has streamlined energy efficiency regulatory filings and clarified the three-year nature of energy efficiency plans under the GCA.

3. Assessing

As discussed in Section V, the Program Administrators used multiple resources to build a robust understanding of the potential for all available cost-effective energy efficiency and demand reduction resources. These efforts are grounded in the definition of "Technical Potential" as the complete penetration of all measures analyzed in applications where they are deemed technically feasible from an engineering perspective. Technical Potential does not necessarily take into account cost-effectiveness, budget constraints, or whether homeowners or businesses are willing to undertake energy saving actions or investments

"Economically achievable energy efficiency potential" is defined as that portion of the technical potential that is cost-effective. Like past plans, the 2016-2018 Plan aggressively targets all available cost-effective energy-efficiency resources, while taking into account market and policy barriers that can constrain program implementation. In addressing these barriers, the 2016-2018 Plan seeks to allow for sustained energy efficiency efforts that do not create insupportable bill impacts, consistent with the GCA, Department precedent and the PAs' public service obligation to their customers.

Assessing potential takes into account impediments to program implementation, including financial, political, and regulatory barriers that are likely to limit the amount of savings that might be achieved through energy efficiency and demand response programs. This assessment, therefore, recognizes both the market and policy barriers. After more than three decades of successfully implementing energy efficiency programs, the PAs understand these barriers and are able to integrate this knowledge of both market and policy concerns to inform this Plan. The program incentive design, delivery models, and support infrastructure developed by the PAs and discussed throughout this Plan are informed by a careful review of different types of potential.

C. Allocation of Funds for Low-Income Programs and Education

Energy efficiency funds shall be allocated to customer classes in proportion to their contributions to those funds, and, "at least 10 percent of the amount expended for electric energy efficiency programs and at least 20 percent of the amount expended for gas energy efficiency programs shall be spent on comprehensive low-income residential demand side management and education programs." G.L. c. 25, § 19(c). Based on the budget figures set forth in this Plan, for electric Program Administrators, 10.9 percent of the total budget will be allocated to the electric low-income residential sector for 2016-2018. Based on the budget figures set forth in this Plan, for gas Program Administrators, approximately 20.3 percent of the total budget will be allocated to the gas low-income residential sector for 2016-2018.

D. Minimizing Administrative Cost

In accordance with the GCA, the PAs seek to minimize administrative costs to the fullest extent practicable. Administrative costs, also commonly referred to as PP&A costs, include costs associated with:

- Developing program plans, including market transformation plans, research and development ("R&D") activities (excluding R&D assigned to Evaluation and Market Research).
- Day-to-day program administration, including labor, benefits, expenses, materials, supplies, and overhead costs.
- Any regulatory costs associated with energy efficiency activities.
- Costs for energy efficiency services contracted to non-affiliated companies such as outside consultants used to prepare plans, screen programs, improve databases, and perform legal services.
- Internal salaries for administrative employees/tasks, including program managers that do not have direct sales and technical assistance contact with customers.

For the 2016-2018 Plan, approximately 15-18 percent of the PAs' costs are budgeted in the Sales, Technical Assistance & Training cost category, supporting the activities of vendors, contractors and other industry professionals. Approximately 3 percent of the statewide budget is dedicated to the rigorous Massachusetts Evaluation, Measurement and Verification process. Other administrative functions, like Program Planning and Administration and Marketing and Advertising, make up approximately 5 percent of the statewide budget. Importantly, the majority of energy efficiency budgets are returned to customers in the form of incentives that are intended to overcome the financial barrier to investment. In the 2016-2018 Plan, 71 percent of the gas budget and 74 percent of the electric is returned directly to customers through use of participant incentives, which drive customers to participate. These percentages are in line with the budget allocations approved by the Department historically, demonstrating that the Program Administrators have been able to provide direct benefits to customers and contractors and grow the energy efficiency portfolios while minimizing costs.

The most significant factor in the PA approach to minimizing administrative costs is the statewide collaborative process, which is used by the Program Administrators to coordinate planning, the adoption of consistent programs and processes, program design, EM&V studies, statewide marketing, regulatory proceedings, and the development and sharing of all best practices. Sharing of these costs, which would otherwise be borne by each Program Administrator individually, results in economies of scale that reduce the cost for each Program Administrator. For example, joint releases of RFPs lead to minimization of administrative costs in that the cost for preparation and release of the RFP are shared by the PAs. The Program Administrators also minimize administrative costs by coordinating energy efficiency program delivery, where appropriate, with other customer service activities such as customer acquisition, key account management and trade ally relationships.

Notwithstanding any appropriate coordination with other customer service departments, it is necessary and appropriate for all Program Administrators to maintain a skilled and dedicated administrative staff in order to ensure successful delivery of programs, compliance with the GCA, timely responses to the requests of the Council, Department, and DOER, and documentation and achievement of substantial savings. The Program Administrators seek to balance the need to minimize administrative costs to the extent prudent with the need to maximize program quality and oversight. Councilors have emphasized the need to devote sufficient administrative resources to successfully implement the aggressive programs called for in the Three-Year Plans.

While the economies of scale and other steps taken by the PAs to minimize costs are effective, and administrative costs incurred by the PAs are transparent, exact quantification of the minimization of administrative costs is not possible in a meaningful way. This is because the continuous scaling up and evolution of the plans make it impractical to establish a solid baseline for a comparison. When the variables are constantly (and necessarily) shifting, there is no opportunity to make a meaningful quantitative comparison. Further, a direct quantitative comparison would not be useful because it would only provide a comparison of two points in time. The mandate of the GCA is to seek administrative efficiencies, which is a continuous process that evolves along with energy efficiency planning and programming. Program needs and opportunities for administrative efficiency are always changing. The Program Administrators seek to minimize costs at all available opportunities, and not just from one point in time to another. By collaborating, creating consistent programming, and optimizing staffing needs, the PAs are able to minimize administrative costs to the extent practicable while providing quality energy efficiency services for customers.

E. Competitive Procurement

The Program Administrators utilize competitive procurement processes to engage and retain contractors and vendors to perform activities including, but not limited to: (1) audit delivery; (2) quality control; (3) monitoring and evaluation; (4) marketing; and (5) website design. The PAs are committed to continuing to utilize competitive procurement practices to the fullest extent practicable throughout the implementation of the Plan. Therefore, consistent with past practice, the PAs anticipate that they will continue to issue RFPs to engage appropriate third-party vendors to provide energy efficiency services; consider the input of the Council with respect to the retention of necessary consultants; and, where necessary, work collaboratively to ensure that energy efficiency services have been procured in a manner that minimizes costs to ratepayers, while maximizing the associated benefits of those investments. In order to build upon the progress made in prior plans, the PAs will continue to seek to expand the pool of qualified program vendors, promote the entry of new market actors into contractor and subcontractor roles, and ensure the transparency of the contractor bidding process and selection criteria used to evaluate proposals.

F. Demand Response

Achievement of demand savings in 2016-2018 is a key goal shared by the PAs and the Council. Demand savings through demand response (peak shaving and load shifting efforts) can contribute benefits such as reducing prices and price volatility for consumers, avoiding or deferring future generation, transmission and distribution investments, and reducing environmental impacts from electric generation. Demand response is a flexible, low-carbon resource that can also be used to help integrate renewable resources as more renewables come onto the electric system. Viable demand response strategies, combined with planned aggressive energy efficiency efforts, will contribute to the Commonwealth’s economic and environmental sustainability goals.

PAs are seeking ways to understand both the costs and benefits of demand response in a way that will inform full scale deployment where benefits are expected to exceed costs. PAs are exploring ways to augment demand response provided by other market actors and explore opportunities to partner with such actors, where appropriate. In order to better understand the costs and benefits of demand response, individual PAs have developed or are working on developing individual or joint demonstration projects to gain a better understanding of costs and benefits of demand response. PAs will share the results of demonstration projects in order to gain insight, develop best practices, and utilize demand response strategies where appropriate going forward. Following the implementation of demonstration projects and related evaluation, PAs will use the results, along with related research and analysis, to guide the deployment of larger scale demand response initiatives in the latter years of this Three-Year Plan and going forward.

For PA-specific descriptions of these demonstration projects, please see Appendix L.

VI. COST RECOVERY, FUNDING SOURCES & FINANCING INITIATIVES

A. Cost Recovery

Cost recovery is a critical element of this Plan. Cost recovery associated with the implementation of energy efficiency programs includes the recovery of a performance incentive,[131] and, for those PAs without a Department-approved decoupling mechanism,[132] the replacement of revenues that support system operating costs. In order for the Program Administrators to pursue the aggressive goals set forth in this Plan, it is essential that the Plan provide a full and fair opportunity for the Program Administrators to be made economically whole for aggressively pursuing sales-reducing energy efficiency efforts and to earn a reasonable return on this investment based upon their performance and achievement. Although Department approval of the proposed Plan should ensure cost-recovery of Plan-related costs, lost base revenues ("LBR"), and performance incentives, the details related to individual PA cost-recovery mechanisms will be addressed in separate Department proceedings.

Pursuant to the GCA, for electric PAs, the Plan must include a fully reconciling funding mechanism that may include, but which shall not be limited to, a statutorily authorized mandatory SBC of 2.5 mills per kilowatt hour for all consumers, except those served by a municipal lighting plan. G.L. c. 25, §§ 19(a); 21(b)(2)(vii). In addition to this mandatory charge, the fully reconciling funding mechanisms shall be comprised of the funding sources listed in Section VI.B., herein, and other funding sources approved by the Department. G.L. c. 25, § 19(a). For gas PAs, the Plan must include a fully reconciling funding mechanism to collect costs from customers. G.L. c. 25, §§ 19(b); 21(b)(2)(vii).

The Department must approve such fully reconciling funding mechanisms if, after reviewing a Program Administrator's proposed Plan, it determines that the Plan ensures that the PA has identified and shall capture all energy efficiency and demand reduction resources that are cost-effective or less expensive than supply. G.L. c. 25, § 21(d)(2). As part of this determination, the Department must approve recovery of all expenditures for the Program Administrator's energy efficiency programs that are screened through the cost-effectiveness test described herein in Section IV.G. G.L. c. 25, § 21(d)(2). Therefore, in reviewing a Program Administrator's proposed Plan, the Department must assure that the Program Administrator is able to implement all Plan offerings that are found to be cost-effective, even if the costs associated with providing those offerings are in excess of the established funding sources provided for in the statutorily-authorized energy efficiency charge through other sources, as discussed further below. G.L. c. 25, § 19.

B. Funding Sources

1. Introduction

The Program Administrators seek to leverage available funding sources and financing initiatives in order to increase the benefits of Three-Year Plans and minimize customer bill

---

[131] For a discussion of performance incentives, please see supra Section IV.C.

[132] As of January 1, 2016.

impacts. For electric Program Administrators, the GCA identifies four specific funding sources for energy efficiency programs: (1) revenues collected from ratepayers through the SBC; (2) proceeds from the Program Administrators' participation in the FCM; (3) proceeds from cap and trade pollution control programs, including but not limited to the RGGI; and (4) other funding as approved by the Department, including revenues to be recovered from ratepayers through a fully reconciling funding mechanism (*i.e.*, an EES). G.L. c. 25, §§ 19(a); 21(b)(2)(vii). Consistent with the Department's Guidelines, the Program Administrators allocate SBC, FCM, and RGGI revenues to each customer sector in proportion to the kWh consumption of each class.[133] In approving other funding for electric Program Administrators, the Department must consider: (1) the availability of other private or public funds; (2) whether past programs have lowered the cost of electricity to customers; and (3) the effect of any rate increases on customers. G.L. c. 25, § 19(a).

For gas Program Administrators, the GCA does not identify multiple funding sources for energy efficiency programs and instead requires the gas PAs to include a fully reconciling funding mechanism to collect energy efficiency program costs from customers (*i.e.*, EES). G.L. c. 25, § 21(b)(2)(vii); see also G.L. c. 25, § 21(d)(2). In approving funding for gas Program Administrators, the Department considers the effect of any rate increases on customers. Guidelines § 3.2.2.2.

The following funding sources and financing initiatives are currently available to the Program Administrators.

2. Non-EES Revenues

a. System Benefit Charge (electric only)

The SBC is calculated consistent with G.L. c. 25, § 19(a) which states: "The [D]epartment shall require a mandatory charge of 2.5 mills per kilowatt-hour for all customers, except those served by a municipal lighting plant, to fund energy efficiency programs including, but not limited to, demand side management programs." Specifically, each electric PA calculates projected SBC revenues as the product of the statutorily mandated SBC of $0.0025 per kWh and projected sales for the applicable year.

b. Forward Capacity Market Proceeds (electric only)

Pursuant to G.L. c. 25, § 19(a), the Three-Year Plans of electric Program Administrators shall be funded in part by "amounts generated by the distribution companies and municipal aggregators under the Forward Capacity Market program administered by ISO-NE, as defined in section 1 of chapter 164." Specifically, each PA calculates projected FCM revenues as the product of the clearing prices of the FCM in the applicable year and the energy efficiency capacity that is designated by ISO-NE as an FCM capacity resource for the year. The Program Administrators propose to apply all net proceeds from the FCM to energy efficiency programs.

---

133 The low-income sector is allocated at least ten percent of the funds for electric energy efficiency programs and 20 percent of the funds for gas energy efficiency programs pursuant to G.L. c. 25, § 19(c).

To minimize ratepayer funding for energy efficiency efforts, each electric Program Administrator seeks to maximize FCM revenues for its customers. FCM bidding strategies are designed to strike an appropriate balance between maximizing revenues through participation in the FCM and avoiding the risks associated with FCM penalties for failure to deliver their capacity-supply obligations. Each PA employs its own individual strategy in bidding capacity into the FCM. For more information on PA bidding strategy see each electric PA's testimony.

The Department has recognized the challenges PAs face in projecting with precision over the term of a Three-Year Plan the level of planned energy efficiency resources that will be installed before and during each FCM commitment period. 2013-2015 Order at 119. One of these challenges is driven by the timing of the FCM auction cycles, which are conducted three years ahead and begin with a "show-of-interest" submission almost four years before the capacity-delivery period. Another is that there are financial penalties for failing to deliver on FCM supply obligations. However, each PA takes all reasonable steps to maximize FCM revenues during the term of a Three-Year Plan by adjusting, if appropriate, their FCM bids.

In developing a bid, each PA uses the best information available at the time. Each PA takes into account historic achieved annual peak period MW reductions from their energy efficiency programs, as well as ongoing studies and evaluations that may affect savings. Given the difficulty in estimating the actual energy efficiency savings that will be eligible to participate in the FCM and potential penalties, however, PAs do not bid into the FCM the total amount of energy efficiency savings they expect to achieve in their Three-Year Plans. In making conservative FCM bids, the PAs avoid compromising system reliability. In addition, the reconciling nature of the EES ensures that customers are made whole if PA FCM revenue projections are overly conservative and the PAs ultimately collect additional FCM revenues.

As noted above, a portion of the funding for energy efficiency efforts, including customer incentives, is derived through participation in the FCM. Although limited, there are some unique opportunities to further benefit customers and increase savings, as well as the region's capacity requirements. The PAs will provide FCM-supported energy efficiency services to electric customers who are not currently eligible for services due to other factors. For these customers, incentives would be limited to the value of the lifetime revenue stream associated with the demand savings from the project less any administrative expenses that are associated with the project.

c. Regional Greenhouse Gas Initiative Proceeds (electric only)

Pursuant to G.L. c. 25, § 19(a), the Three-Year Plans of electric Program Administrators shall be funded in part by "not less than 80 per cent of amounts generated by the carbon dioxide allowance trading mechanism established under the Regional Greenhouse Gas Initiative Memorandum of Understanding, as defined in subsection (a) of section 22 of chapter 21A, and the NOx Allowance Trading Program." As described further below, the electric Program Administrators typically calculate projected RGGI revenues by multiplying projected RGGI clearing prices by a projection of allowances sales in each RGGI auction, with 80 percent of the revenues allocated to electric efficiency programs. RGGI allowances prices are derived from the Avoided Energy Supply Cost Study. See Appendix J.

The electric Program Administrators consulted with DOER about how best to forecast RGGI proceeds for the 2016-2018 Plan. DOER recommended using a forecast developed using RGGI's Integrated Planning Model ("IPM"), which was developed by ICF International. Specifically, the PAs have used "Scenario 2 - IPM 91 Cap" in developing their budgets based upon DOER's recommendation, as set out below.

State	2015	2016	2017	2018
Scenario 2 - IPM 91 Cap				
MA Remaining Balance	7,925,075	10,218,385	10,062,297	9,709,729
Forward Price	$5.44	$6.76	$7.52	$7.52
Remaining Value	$43,112,408	$69,076,283	$75,668,473	$73,017,162
CCR Value	$0	$0	$0	$0
Total Value	**$57,403,962**	**$69,076,283**	**$75,668,473**	**$73,017,162**

DOER has clarified that there are administrative and other costs that reduce the full value option values of these RGGI forecasts. After discussions with DOER, for the 2016-2018 Plan, the PAs are forecasting that they will receive 75 percent of the RGGI proceeds.

The electric PAs have confirmed that DOER will continue to pay their share of the costs of the Council's consultants retained pursuant to G.L. c. 25, §22(c) out of the 75 percent of RGGI auction proceeds that are allocated to the PAs. In forecasting RGGI revenues, the PAs have reduced their expected RGGI proceeds by the amount payable to the consultants. Because the consultant fees will be paid by DOER directly out of the RGGI proceeds, the electric PAs' proposed budgets do not include separate expense amounts for Council consultant costs.

Projections also take into account anticipated lags between when RGGI auctions occur and when DOER is able to transfer funds to each electric PA. The Program Administrators have worked with DOER to develop a forecast that more accurately projects receipt of funds from DOER. The PAs expect to receive RGGI funds from DOER within 90 days or less of an auction.

3. EES Revenues[134]

The EES is a fully reconciling funding mechanism that the Department approves for funding the Three-Year Plans. G.L. c. 25, § 21(d)(2). Electric Program Administrators collect the EES through EERF or EEPCA tariffs. Guidelines §§ 2(9), 3.2.1.6. The electric PAs recover and reconcile energy efficiency costs pursuant to their EERF/EEPCA tariffs[135] for each year of the three-year term as the difference between: (1) the projected budget for the particular year and (2) projected revenues from non-EES funding sources for that year (*e.g.*, funding from SBC, FCM, RGGI and outside sources). For gas PAs, the EES is collected through the LDAC tariff in

[134] The PAs collect funds related to the RCS Act through their EESs. 220 C.M.R. § 7.00 *et seq.* The Department reviews the reconciliation of any over and under collections of RCS funds in the LDAC filings for the gas PAs and in the EERF/EEPCA tariff filings for the electric PAs.

[135] With the exception of the Compact, EERF/EEPCA filings are made coincident with each PAs' residential basic service rate change, creating a lag between energy efficiency program spending and collection. The Compact's rates are effective January 1 of each year, consistent with the 2013-2015 Order at 125, n.106.

accordance with established Department practice. Guidelines §§ 2(9), 3.2.2. The EERF/EEPCA and LDAC filings of the PAs are separate proceedings from the Three-Year Plan proceeding and are implemented on schedules that vary among the PAs.[136]

4. Carryover Information

In determining its EES, a Program Administrator takes into account funds carried over from the previous year's program, whether positive or negative. These "fund balances" are used to adjust projected funding levels in the Plan.

5. Outside Funding Levels

The 2016-2018 Plan does not contain outside funding assumptions at this time given the absence of material viable funding sources. The Program Administrators, as well as Councilors and government agencies, all actively continue to seek new sources of outside funding. The Program Administrators' approach in this regard reflects lessons learned over the course of two prior Three-Year Plans (2010-2012 Plan; 2013-2015 Plan). There continues to be a low likelihood that a major new federal "cap and trade" program will be implemented in the foreseeable future as had been anticipated when the 2010-2012 Plan was initially developed and approved by the Council.

6. Financing Initiatives

During the first two Three-Year Plans, the Program Administrators developed, deployed, and offered customers several financial products in conjunction with the Massachusetts Bankers Association and Credit Unions - with over 60 financial institutions participating in this initiative. The Program Administrators expect to have enough capital infusion from the diverse Massachusetts lending community to meet customer demand for financing in the next three years. The Program Administrators' collaboratively-developed financing initiatives reflect both the strong coordination among the PAs, as well as the Program Administrators' responsiveness to comments and suggestions from Councilors. Program implementers in other states have frequently contacted the Program Administrators to learn from the Massachusetts experience in development of a state-of-the-art lending initiative that leverages the experience of local banks.

The highly successful Mass Save® HEAT Loan offers zero percent interest financing for qualified energy efficient home improvements. Customers may qualify for loans up to $25,000

[136] In 2014, NSTAR Electric and NSTAR Gas agreed pursuant to a Department-approved settlement agreement with the Attorney General to recover energy efficiency-related pension/ post-retirement benefits other than pensions ("PBOP") costs through their respective pension adjustment factors for the term of the 2016-2018 Plan. See D.P.U. 14-151, at 7. National Grid (electric) also recovers its energy-efficiency related pension/PBOP costs through its pension adjustment factor. The remaining PAs collect such costs through their EES charges. To the extent that NSTAR Electric, NSTAR Gas, and/or National Grid (electric) propose to collect energy efficiency-related pension/PBOP costs through the pension adjustment factor ("PAF") for plan year 2016 and beyond, the company seeking such rate treatment will include pre-filed testimony and exhibits in its 2016-2018 Plan filing to support why collecting such costs through the PAF and not the EES is consistent with G.L. c. 25, §§ 19, 21 and otherwise appropriate. See D.P.U. 14-151, at 13, n.6.

with terms up to 7 years, depending on the PA and the loan provider. Examples of improvements that may be financed with a HEAT Loan include:

- Attic, Wall, and Basement Insulation
- High Efficiency Heating Systems
- Central Air Conditioning/ Air Source Heat Pumps
- Ductless Mini Split Heat Pumps
- High Efficiency Domestic Hot Water Systems
- Solar Hot Water Systems
- 7-Day Digital & Wi Fi Thermostats
- ENERGY STAR® Qualified Replacement Windows

Additionally, with the express support of DOER and the Council, a portion of the HEAT Loan may be used to finance the mitigation of barriers preventing the installation of energy efficient measures (*i.e.*, pre-weatherization measures).

The Mass Save® HEAT Loan initiative is the most successful initiative of its kind in the nation, growing from 532 loans in 2006 to over 11,000 loans in 2014 (annual). Since inception, the Mass Save® HEAT Loan has made over $200,000,000 available to thousands of homeowners implementing home energy efficiency improvements. The following chart shows information supporting the HEAT Loan's great success in Massachusetts.

Largest Volume

- Over $250 million financed (residential) in last three years - more than other leading states, combined

Broadest Lender Participation

- Over 60 local Banks and Credit Unions across the Commonwealth

Broad FICO score acceptance

- Since 2011 Heat Loans approved with FICO well into sub-prime category

Broad income distribution

- ~45% of household incomes taking the Heat Loan in 2014 were between $40 to $80K[1]
- Banks indicate income is not a major barrier for heat loan approval

Lowest Cost

- 5% interest; no credit enhancements; no admin; lenders bear principal risk

1. Annual Lender Survey and Home Energy Services Initiative and HEAT Loan Delivery Assessment.

Massachusetts is a leader in the nation for financing of energy efficiency projects, with a larger quantity of cumulative loans than New York and California combined.

State	Category	Program	Total # of Loans (cumulative)	Total Amount Financed since 2011[2]	2014 Population (est)
NY	Green bank	Green Jobs New York	6,690	$66 million	19 Million
CA	PACE	HERO Pace[1]	11,250[3]	$135 million[3]	38 Million
MA	Utility / 3rd Party	HEAT Loan	29,080	$290 million	7 Million

1. HERO Pace accounts for 95 percent of residential PACE market in US.
2. MA Heat Loan operative since 2006; however numbers only show since 2011; CA and NY active since 2011.
3. Actual cumulative total through 2014 is $432 million; data in table assumes energy efficiency projects represent 45 percent of amount financed and amount of projects with the remainder going to solar projects.

In this Plan, similar to the 2013-2015 Plan, certain gas PAs are proposing to allocate additional budgetary dollars in the Residential Home Energy Services initiative to make the HEAT Loan available in support of gas energy efficiency efforts in service territories where electricity is supplied by a municipal light plant. Customers of electric PAs will receive the HEAT Loan applications. Gas PAs that have municipal electric companies within their territories will offer the HEAT Loan to those natural gas/municipal electric customers. Therefore, all customers that pay into the SBC funds will be able to access the HEAT Loan. The gas PAs that have no line-item budget for the HEAT Loan have no municipal electric customers within their respective territories.

Financing allows customers, who may not be able to raise enough capital to pay for their customer contribution, to borrow funds in order to invest in energy efficiency. To the extent that access to low-cost capital is a barrier for certain customers, financing can alleviate that and encourage energy efficiency investments. The Program Administrators are continuing their efforts to understand the nature of barriers for different customer segments, which may be related to accessing capital, and to explore financing products/solutions to address them.

C. <u>Lost Base Revenues</u>

The Department stated in D.P.U. 10-170-B that LBR, like revenue decoupling, removes the disincentive for companies to fully pursue all cost-effective energy efficiency and demand-side resources, so long as such activities occur within a company's own programs. D.P.U. 10-170-B at 45. Although the Department has expressed its preference for full decoupling in both D.P.U. 07-50-A and D.P.U. 10-170, as a transition to full decoupling, the Department determined in D.P.U. 07-50-A that, electric and gas distribution companies would be allowed to recover LBR resulting from their incremental efficiency savings, until they begin operating under a decoupling plan. D.P.U. 07-50A at 83-84, n.24. [137]

In D.P.U. 07-50-A, the Department stated that electric distribution companies seeking to recover LBR must support such request with full documentation and explanation of: (1) how incremental energy efficiency savings will be achieved and accounted for, and (2) the proposed LBR calculation, in their then-upcoming 2010-2012 Plan. D.P.U. 07-50-A at 83. Gas companies then recovering LBR were allowed to continue to do so through the term of their initial Three-Year Plans consistent with then-existing LBR recovery methods. Id. at 83-84. As of the proposed effective date of the present three year plan (*i.e.*, January 1, 2016), the PAs without Department-approved decoupling mechanisms are NSTAR Electric and Berkshire.[138] As such, each of these PAs intends to seek Department approval of LBR recovery in connection with this Three-Year Plan, supported by evidence of how incremental energy efficiency savings will be achieved and accounted for and a calculation of the LBR requested for approval. Information regarding NSTAR Electric and Berkshire LBR is included those PAs' Energy Efficiency Data Tables.

[137] The Department approved LBR recovery for NSTAR Electric for the years 2009-2011 pursuant to the rate settlement filed in D.P.U. 14-151, and for the years 2012-2015 pursuant to the rate settlement filed in D.P.U. 10-170. The LBR recovery approved for NSTAR Electric for 2012-2015 was a settlement-specific methodology applicable to NSTAR Electric only. In connection with the 2016-2018 Plan (or until the Department approves a decoupling proposal for NSTAR Electric or Berkshire), NSTAR Electric and Berkshire intend to seek LBR recovery consistent with the Department's established methodology for LBR recovery articulated in D.P.U. 07-50-A at 83 and D.P.U. 07-50-B at 30-31. See also EERF Filings, D.P.U. 10-07-A/D.P.U. 10-08-A/D.P.U. 10-09-A.

[138] Assuming Department approval of NSTAR Gas Company d/b/a Eversource Energy's petition to approve a decoupling plan in D.P.U. 14-150.

VII. MISCELLANEOUS

A. Streamlining Processes to Reduce Costs for Customers

In conjunction with approving the 2013-2015 Plan, the Department also streamlined regulatory processes, which allowed the PAs to focus more on successful implementation of their energy efficiency plans. In D.P.U. 11-120-A, Phase II, the Department created a true three-year paradigm for implementing energy efficiency plans and adopted revised Guidelines. Treating Three-Year Plans as a three-year term rather than three separate one-year plans reduced the potential need for MTMs and recurring revisions. In addition, starting with the 2013-2015 Plan, the Department reviews the performance of the PAs at the end of each three-year term in adjudicatory processes rather than every calendar year. Instead, the PAs provide Plan-Year reports for informational purposes only. The Department may investigate a PA's performance on its own motion or if the Council requests such an investigation.

In addition, the Department recently determined that performance metrics were no longer necessary to incentivize the PAs' energy efficiency efforts. The Department found that "[n]egotiating, satisfying, and documenting performance metrics is costly and time consuming." Performance Metrics, D.P.U. 13-67 at 13, n.25 (2014). The Department found that "such an investment of time and resources solely for the purpose of verifying metric performance is out of proportion with the potential benefit of metrics." Id. The Department concluded that verifying performance of these metrics would divert the focus of PAs and stakeholders "from the successful implementation of the three-year plans and is inconsistent with the Department's obligation to fulfill its oversight responsibilities in an administratively efficient and effective manner." Id.

The PAs appreciate the streamlining leadership of the Department and, during the 2016-2018 Plan, the PAs will build on the streamlining improvements that benefitted implementation of the 2013-2015 Plan and will continue to seek to improve administrative efficiencies and minimize costs where possible. One important streamlining improvement the PAs have implemented for the 2016-2018 Plan is aligning the AESC study process with the development of a Three-Year Plan. Historically, the AESC study process was conducted every two years. Starting with the 2015 AESC study, which was completed in time to inform the April 30th draft Three-Year Plan, the study will be conducted every three years. Aligning the AESC study process with the Three-Year Plan development should reduce the potential for MTMs and other mid-term updates to the PAs' energy efficiency filings.

Another process improvement the PAs have made is expanding the stakeholder proposal process, which was successfully employed during the 2013-2015 Plan. This process applies to proposals, inquiries and ideas from stakeholders, private companies or individuals, non-profits, community groups, associations, local government, state government, and others that require significant PA commitment of funds or personnel. The improved proposal process will better manage proposals from stakeholders and interested parties to the RMC and C&IMC. This process is not intended to address general inquiries or suggestions or general notices of funding opportunities. To qualify for consideration by the management committees, proposals are expected to have the appropriate level of proponent research conducted and expertise articulated.

The process outlines the criteria for evaluation and the timeline and process expectations. Documents related to the proposal process are available publicly on MassSave.com.[139]

The PAs will continue to identify streamlining and efficiency opportunities for the 2016-2018 Plan. One potential area of opportunity is to consider ways to improve the efficiency of the Council process in general, as discussed in the Assessment of Massachusetts Energy Efficiency Advisory Council conducted by Dr. Jonathan Raab, Raab Associates, Ltd. with Pat Field, CBI, which was completed on December 1, 2014 ("Assessment"). As noted in the Assessment, while the role of the Council in developing a Three-Year Plan is clear, its role during implementation is not as clear, and has led to some frustrations on the part of the Council and the PAs. The PAs remain committed to being actively and productively engaged with the Council in a collaborative manner consistent with the GCA. The PAs appreciate that Council meetings are an important tool in planning for and implementing Three-Year Plans and that they require an investment of time and resources by all Councilors. As the third Three-Year Plan begins, the Program Administrators will have: (1) six years of GCA-related energy efficiency experience with more mature programs, which will inform future efforts to achieve energy efficiency cost-effectively; (2) a better understanding of the concerns and interests of the Councilors and an effective means of continuing dialogue with them (through Council resolutions and other Council documents, Council Executive Committee meetings and individual communications as well as consultant communications); and (3) an established means of reporting data to the Council (through monthly, quarterly and annual reports).

Given the success and experience with this construct, the Program Administrators will seek additional ways to streamline processes in 2016-2018, including ways to spend more time with customers seeking savings, such as fewer Council meetings during implementation years. The PAs appreciate and recognize the work and time invested by Councilors in preparing for Council meetings to ensure the mandates of the GCA are being achieved. The Program Administrators devote time and attention to being as well prepared as possible for each meeting, and respond to Councilors' concerns during and after Council meetings. The Program Administrators continue to strongly support the role of the Council established in the GCA and recognize that their energy efficiency programs have benefitted from the many excellent suggestions of Councilors. The PAs will seek Councilor input on ways to streamline processes and reduce meetings, especially during implementation years, while maintaining transparency and providing the optimal amount of information to the Councilors.[140] The Program Administrators are seeking to leverage collective experience, identify possible efficiencies and

---

139 The documents related to the proposal process are available at http://www.masssave.com/professionals/business-opportunities/process-for-managing-unsolicited-proposals.

140 According to the Assessment, "the majority of interviewees thought fewer meetings might be justified during implementation years, especially if meetings are run more efficiently and some work is done in Subcommittees or in more focused, topical meetings. Some felt that a move to a quarterly or every other month Council meeting is appropriate during the implementation phase." Assessment at 18. The Assessment recommended that "[d]uring implementation of the three-year plan, the EEAC can probably meet less frequently (*e.g.*, every other month or quarterly), but with ExCom still meeting monthly, and with the ability to form subcommittees for ongoing topics/issues or focused work sessions on specific topics, and call special meetings of the EEAC, if necessary." Assessment at 19.

optimize all stakeholders' time given the experience gained through the first two Three-Year Plans.

B. **Mid-Term Modifications**

1. Introduction

Mid-Term Modifications ("MTMs") are significant adjustments of specified categories made by PAs during the term of a three-year plan. MTMs are not required and PAs submit such filings based on specific triggers as laid out in the Department's Energy Efficiency Guidelines.

2. Purpose of MTMs

The Department has stated that "the primary purpose of a mid-term modification should be to improve upon how a three-year plan provides for the acquisition of all available cost-effective energy efficiency resources." Energy Efficiency Guidelines, D.P.U. 11-120-A, Phase II at 27 (2013). "In establishing guidelines for the review and approval of proposed mid-term modifications, the Department sought to provide Program Administrators with the flexibility to respond to changing circumstance, while ensuring that they implement their plans in a manner consistent with the Department-approved plan." Id., citing D.P.U. 08-50-A at 63-64.

3. The Exception Not the Rule

The Department issued revised MTM guidelines as part of its streamlining docket in D.P.U. 11-120, which was focused on reducing regulatory burdens where possible. In finding that energy efficiency plans should be treated as true Three-Year Plans and not three annual plans, the Department minimized (but did not eliminate) the potential for mid-term changes to the PAs' Department-approved goals. Energy Efficiency Guidelines, D.P.U. 11-120-A, Phase II (2013). Given this context, and the stated purpose of MTMs, the PAs consider MTMs to be the exception and not the rule. Accordingly, the PAs develop Three-Year Plans with the best available information and without an expectation that they will require MTMs.[141] MTMs are important tools to provide flexibility to address changing circumstances while implementing Department-approved plans.

4. The Guidelines Govern MTMs

MTMs are governed by § 3.8 of the revised Energy Efficiency Guidelines approved by the Department on January 30, 2013 in D.P.U. 11-120-A, Phase II. The Guidelines provide for Category One modifications (Council support only required) and Category Two Modifications

[141] This is especially true for Cape Light Compact ("Compact"), which, for example, could not operate on the expectation that MTMs will provide further funding. As a municipal aggregator, the Compact does not have capital reserves to float the shortfalls in revenue that can occur as a result of energy efficiency program spending and collection. Unlike other PAs, the Compact cannot rely on working capital to make up revenue shortfalls and has no authority to issue municipal bonds. 2013-2015 Order at n.106. In view of its unique circumstances, the Department allowed the Compact to make a proposal to collecting energy efficiency revenues on a calendar-year basis. Id.

(Department approval required). The Guidelines include detailed appeal rights to the Department.

5. Category One MTMs

The Department created "Category One MTMs." Pursuant to § 3.8.1 of the Guidelines, a Category One MTM is a significant modification, as described below, to a PA's Department-approved Energy Efficiency Plan, which must be submitted to the Council for review:

1) the addition of a Hard-to-Measure Energy Efficiency Program;
2) the termination of an existing Energy Efficiency Program or Hard-to-Measure Energy Efficiency Program;
3) a change in the three-year term budget of an Energy Efficiency Program or Hard-to-Measure Energy Efficiency Program of greater than (1) 20 percent, or (2) a dollar value to be specified by the Department; or
4) a modification to the design of an Energy Efficiency Program that is projected to result in a decrease in program benefits over the three-year term that is greater than 20 percent.

Pursuant to § 3.8.1.1, if the Council passes a resolution supporting the proposed modification, the Program Administrator may implement the modification.

6. Category Two MTMs

The Department also created a "Category Two MTM." Pursuant to § 3.8.2 of the Guidelines, a Category Two MTM is a significant modification, as described below, to a PA's Department-approved Energy Efficiency Plan, which must be submitted first for review by the Council, and then for review and approval by the Department:

1) the addition of a new Energy Efficiency Program;
2) the transition of a Hard-to-Measure Energy Efficiency Program to an Energy Efficiency Program; or
3) a change in the three-year term budget of a customer sector that would require a cents per kilowatt-hour (calculated using the method described in § 3.2.1.6) or cents per therm charge for the sector that, if it were to replace the Department-approved Energy Efficiency Surcharge for the applicable year, would result in a bill increase for an average customer in the sector exceeding two percent.

The Program Administrator may not implement the modification pending review and approval by the Department.

7. 2013-2015 MTMs

During implementation of the 2013-2015 Plan, the PAs proposed both Category One and Category Two MTMs. The Council approved Category One MTMs in resolutions adopted on: (1) October 15, 2014; (2) March 31, 2015; (3) May 19, 2015; (4) June 29, 2015; and (5) July 14, 2015. The Council also approved Category Two MTMs in resolutions adopted on

March 31, 2015 and July 14, 2015. The Council did not support or oppose MTMs seeking to decrease budgets in certain C&I programs. See Resolutions dated March 31, 2015 and July 14, 2015. As required by the Guidelines, the PAs also filed their Category Two MTMs with the Department for approval.

The MTMs proposed by the PAs during implementation of the 2013-2015 Plan were done sparingly in order to meet changing circumstances such as meeting unexpected customer demand or to satisfy certain triggers in the Department's revised Guidelines. The majority of the MTMs seeking to increase program budgets in order to meet customer demand for program products and services were also expected to result in increased savings.

8. MTMs Do Not Revise Department-Approved Budgets or Goals

In proposing MTMs pursuant to the Department's revised Energy Efficiency Guidelines, the PAs have not revised the goals approved by the Department in their 2013-2015 Plan. The PAs have proposed that all reporting on the 2013-2015 Plan, including the Plan-Year Reports and Term Report, will report and compare actual results to the Department-approved budgets and goals. The PAs will submit the resolutions of the Council to the Department to support any variance explanations related to the MTMs in Plan-Year Reports and Term Reports. In addition, the performance incentive model filed in D.P.U. 14-05 remains unchanged (there is no increase or decrease to the performance incentive pool or any change to the payout rates derived in the performance incentive model).

Historically, as shown in more detail in Appendix B (describing regulatory background), the PAs filed MTMs to adjust certain goals in their 2010-2012 Plans. In those MTM filings, the PAs provided revisions to their Department-approved 2010-2012 Plan goals to reflect the proposed MTMs. These filings led to confusion about what baseline to use in assessing PA performance. It is important to avoid such confusion in the future, while providing transparency into factors affecting the PAs' performance. The PAs believe that their treatment of MTMs for the 2013-2015 Plan strikes an appropriate balance between transparency and simplicity. The PAs will report and compare actual results against the Department-approved goals and explain any variances related to MTMs with supporting documentation from the Council.

C. Statewide Energy Efficiency Database

1. Database Development

The Council has identified the development of a comprehensive, accessible, secure statewide energy efficiency database as a priority. See Resolution of the Council Regarding its Priorities for 2014 (February 25, 2014); Draft Council Priorities for 2015; see also Resolution of the Council Regarding its Priorities for 2013 (February 12, 2013). The Department has also encouraged the development of a "uniform energy efficiency program data tracking system that is efficient, reliable, and useful to all parties." Massachusetts Electric Company, D.P.U. 10-98, at 16 (2011); Western Massachusetts Electric Company, D.P.U. 10-90, at 21 (2011); Fitchburg Gas and Electric Light Company, d/b/a Unitil, D.P.U. 10-89 at 17 (2011).

In compliance with the Department's Order approving the 2013-2015 Plan and the development of a database, the PAs developed an initial statewide energy efficiency database, which became available for use during the second year of the 2013-2015 Plan. Specifically, in 2014, the PAs developed, implemented, maintained and improved a number of initial tabs on Mass Save Data ("MSD"), their publicly accessible energy efficiency database, which is live at http://www.MassSaveData.com. MSD provides quantitative data similar to that in the PAs' public reports, including information related to participants, expenditures, annual and lifetime savings, electric capacity savings, and benefits. MSD provides data on both a PA-specific and statewide basis and allows the public to download data to Excel or PDF formats. The platform can continue to grow and provide accessible, meaningful information to customers and stakeholders over time. The PAs understand that database matters are important and that stakeholders have varying views on the best path forward. The PAs submit that MSD is the most effective approach and is already providing significant benefits for users. MSD can be enhanced and added to over time.

The development of MSD is a direct result of database discussions with stakeholders that began in 2011 and continued throughout much of 2014. See 2013-2015 Plan at III.N & App. I; 2016-2018 Plan Appendix W (chart of database events). Although these discussions included a range of views on the purpose of a statewide database, there was consensus that the extensive data already contained in individual and statewide public reports of the PAs should be more easily accessible. In November 2013, the PAs jointly hired a vendor who had previously developed a similar energy efficiency database project in Connecticut. Cost-effectively building on its prior work, the vendor proposed a scope of work for the initial phase of MSD. The PAs held demonstrations for stakeholders in May 2014 to preview the expected functionality of this database and continued to provide updates to stakeholders throughout 2014 and 2015.

2. EEAC Database Process

After the Department approved the development of a statewide database in 2013, the PAs continued to actively participate in stakeholder database discussions. See Appendix W (chart of database events). As reflected in Appendix W, the PAs participated in 17 EEAC-related database meetings between April 8, 2013 and April 28, 2014. The PAs participated in both EEAC Database Subcommittee and Working Group meetings, which met separately but discussed the same issues. The PAs also met with the consultant hired by the EEAC to develop database specifications.

The PAs, along with other stakeholders, actively participated in the EEAC-related database meetings. The PAs expressed strong support for a statewide database that improves access to the extensive data that the PAs already report. The PAs also provided extensive written feedback to the EEAC on December 23, 2013 with respect to the consultant's conceptual proposal. On April 2, 2014, the PAs provided written comments explaining in more detail the customer privacy issues at issue in the conceptual proposal. On April 15, 2014, the PAs provided detailed comments on a database vision statement and database specifications. See Appendix W.

The PAs were not the only participants with concerns about the proposed database specifications. Indeed, notwithstanding diligent efforts and work by all parties involved, there was not consensus among the participants in the EEAC Database Subcommittee and Working Group about the purpose or contents of a statewide energy efficiency database. This lack of consensus was reflected in the database resolution adopted by the EEAC on May 13, 2014. As stated in the resolution, "A *Massachusetts Statewide Energy Efficiency Database System Specification* and a *Massachusetts Statewide Energy Efficiency Database System Cost and Schedule Estimate* were completed pursuant to the EEAC Database Subcommittee process where there was not full consensus." See Appendix W (database resolution).

Historically, stakeholder working groups and a consensus approach have been the hallmark of energy efficiency programming in Massachusetts. It was through a stakeholder working group that the D.P.U. 08-50 tables, and the data needed to support them, were developed, agreed to, and ultimately, approved by the Department. Energy Efficiency Guidelines, D.P.U. 08-50-B (2009); Energy Efficiency Guidelines, D.P.U. 08-50-C (2011); Energy Efficiency Guidelines, D.P.U. 11-120-A, Phase II (2013).[142] However, consensus is not always possible, notwithstanding good faith efforts by all. For a general discussion of the PAs' perspective and approach to developing a database, please see the PAs' database comments and Appendix W.[143]

Because the EEAC database process did not reach consensus, the EEAC submitted its database resolution to the Department seeking assistance. On December 1, 2014, the Department issued an order in D.P.U. 14-141 in response to the EEAC's database resolution. On December 22, 2014, the PAs jointly filed a motion asking the Department to reconsider its order on various grounds, and filed an informal database update report on March 5, 2015. As reflected in the Hearing Officer's ruling dated February 20, 2015, "[t]he substance of the Program Administrators'' Joint Motion is currently pending before the Commission." Consequently, the Hearing Officer stayed the compliance filing ordered by the Department "until such time as the Commission rules on the substance of the Joint Motion." This matter is currently pending before the Department.

3. MSD Overview

The MSD tabs currently available for the public are the following: home page, portfolio overview, sector overview, performance details, HES activity, GHG reductions, sales and savings, cost to deliver, monthly reporting, and glossary.[144] All of these tabs were developed and deployed in 2014 and 2015. The website is populated with 2010-2012 data (plan and evaluated); 2013-2014 data (plan, preliminary and evaluated), and 2015 plan, quarterly and monthly data. After the October plan filing, the website will display all plan data for 2016 to

[142] The Department has defined stakeholder consensus as those "decisions and documents adopted by the group [that] were acceptable to all members, even if there was not 100 percent agreement about every item." Energy Efficiency Guidelines, D.P.U. 08-50-B at 10 (2009).

[143] Although the Department afforded DOER "a" leadership role in the development of a statewide database, the PAs necessarily played an important leadership role in developing a database since they must comply with the requirements of the GCA, answer to the Department on expenditures of customer funds, and have a fiduciary duty to customers.

[144] The PAs are working on displaying additional data on MSD and are currently developing measure, regulatory reporting and geographic tabs.

2018. The PAs will update the 2016-2018 plan data to comply with the Department's final Order in January 2016. Since launching the website, the PAs have continued to improve MSD by enhancing the home page; providing external links to MassSave.com, evaluations studies, and the websites for the Council and Department; and updating the look and feel to be more user friendly and consistent with www.MassSave.com. The PAs continue to identify other needed improvements as they work with the data in MSD.

4. MSD – Purpose and Benefits

MSD is an online statewide database that improves public and stakeholder access to the extensive data already reported by PAs. It provides a single, reliable and timely data source for currently reported data on an individual PA and statewide basis that can be accessed at any time. MSD enables users to export data to spreadsheets for further analysis and queries. The PAs designed MSD to export data easily for those stakeholders like the Council and DOER who file data-driven reports on energy efficiency and, at the same time, to display data in a user-friendly, understandable manner for those users who prefer charts and graphs. MSD has been implemented in a manner that is cost efficient, protects customer privacy and is compatible with (but not duplicative of) PA tracking systems. The PAs were able to deploy the initial phase of MSD in a cost efficient manner by leveraging similar work the vendor had performed in another state.

One of the primary benefits of MSD is as a single source for the most current data reported by the PAs, both individually and in statewide roll ups. It provides access to the most up-to-date reported initiative-level PA data in easy-to-understand formats and automates the statewide view from eleven individual PAs.[145] As discussed in the Section II.C, the PAs provide monthly, quarterly, annual and term energy efficiency reports, which document their performance in implementing energy efficiency programs. MSD provides one source for the quantitative data contained in these public reports.

In addition, MSD appropriately protects customer privacy and reduces the need for expensive data security measures because the website is populated with aggregated and not customer-specific energy efficiency data.[146] Protecting customer data is a core database concern of the Department, PAs and stakeholders. Safeguarding the confidentiality of sensitive customer-specific account data is both a legal obligation and an important corporate responsibility for the PAs.[147]

145 Data related to Blackstone customers will be reported as part of National Grid gas data.

146 In Massachusetts, the PAs strictly control access to sensitive customer-specific account information like customer names, account numbers, rate class, location, usage and demand data. Customer consent is necessary to permit third-party access to sensitive customer-specific account information outside the conduct of regulated PA business. Disclosure of customer information to a third-party without customer authorization would violate corporate privacy policies and expose a PA to liability under the Massachusetts Right to Privacy Act, M.G.L. c. 214, § 1B or Chapter 93A, and potentially other statutes.

147 The PAs have each adopted strict corporate privacy policies and safeguards to protect sensitive customer-specific account information. These corporate privacy policies explicitly state that customers' personal information will be safeguarded and only disclosed for a regulated PA business purpose.

5. MSD – Future Data Reporting and Considerations

During the 2016-2018 Plan term, the PAs will continue to collaborate with the Council and stakeholders to ensure that MSD is efficient, reliable, and useful. The PAs expect to develop and implement additional MSD tabs as well as update, improve and maintain the existing tabs. Currently, the PAs are working to provide geographic information, with appropriate aggregation to protect customer privacy. The PAs are also working on providing measure level information on Mass Save Data for 2016-2018. These important new enhancements, which are directly responsive to specific Councilor requests, are under development by the PAs. The core focus for the next plan term will be to: (1) ensure that MSD continues to provide accurate statewide data; (2) enhance the usability of the tabs; and (3) improve the user experience and visual presentation, all within the context of enhancing the understanding of energy efficiency and its benefits and costs over time.

The PAs understand that stakeholders have found MSD to be a useful resource for energy efficiency data as part of planning for 2016-2018. The PAs look forward to additional stakeholder feedback to help identify reporting improvements that are cost-efficient and serve a statewide energy efficiency purpose. Additional data reporting on MSD will benefit from clearly identifying: (1) the purpose of the new data; (2) the value of the new data; and (3) whether the benefits of the new data justify the cost. Given cost considerations and the PAs' obligation to protect customer privacy, a statewide database will not be able to answer every possible question or provide all data points possible. Reporting of new data will be prioritized based on the cost and the benefit that can be achieved through the data collection and disclosure. The PAs must also consider the deep wealth of data already tracked and available (including through the extensive EM&V process), while being mindful of cost, customer privacy issues, and differences in individual PA tracking systems when reviewing requests for new or additional data on MSD. All efforts will be taken to minimize costs, consider alternative ways to acquire new data and avoid excessive and redundant data collection, which is a barrier to customer participation. Consideration of these issues will facilitate productive stakeholder discussions and identify meaningful data reporting that can be implemented cost-efficiently and with consideration of administrative costs, consistent with the PAs' statutory obligations.

MSD will also focus on reporting aggregate data that is combined in a manner that leaves individual customers unidentifiable.[148] Disclosure of aggregate data reduces customer privacy risks while still enabling trend analysis.[149] Individual, customer-level account, measure and

---

148 Limited data such as customer name and address information or aggregate data that is combined in a manner that leaves individual customers unidentifiable is generally not considered sensitive, is not required to be under strict PA controls, and is not subject to customer consent requirements.

149 Customers have a reasonable expectation of privacy in their sensitive customer account data and, particularly, their energy usage information, which provides insight into their behavior. In Massachusetts, customer consent is required for third-party access to such information when disclosure is not related to a PA regulated business purpose. The Department has recognized the right to confidentiality of sensitive customer account data, including usage, even in the context of promoting policies mandated by the Legislature. See 220 C.M.R. § 11.04; 220 C.M.R. § 14.03; Low Income Discount Rate Enrollment, D.T.E. 01-106-A at 11-12 (2003) (customer authorization in context of legislative directive to participate in low-income discount matching program); Competitive Market Initiatives, D.T.E. 01-54-A (2001)

usage data is of limited use for analysis of trends or program improvement unless it is studied within the larger context of other customers' data. The EM&V efforts of the PAs, under the supervision of the Council, already provide that necessary context and include robust mechanisms for gathering, aggregating and verifying data.

As part of the PAs' EM&V work, two separate databases have been developed to support two Customer Profile Studies.[150] Direct access by stakeholders to these databases is not possible because of the need for customer consent for access to sensitive customer account and usage information.[151] The PAs will accept Council requests to query the data in these databases and will prioritize these requests based on the cost of providing answers, the purpose and benefit of the data query and the timing of the request relative to study cycles.[152]

6. MSD – Budget

The PAs have collectively budgeted approximately $500,000 in each year for a total statewide database budget of approximately $1.5 million over the term of the 2016-2018 Plan. These funds will be used to improve, add to and maintain MSD. The statewide database budget covers both direct statewide expenses as well as individual PA costs incurred to comply with statewide database reporting.[153] The PAs have invested significant time and resources to develop, test and populate the tabs in the initial phases of MSD. They have not, however, incurred costs to change their current data systems and processes because MSD is consistent with the PAs' internal tracking systems.[154] Direct statewide expenditures for development of the initial phase of MSD have been less than $400,000. The PAs were able to deploy the initial phase cost efficiently by leveraging similar work the vendor had performed in another state.

(customer authorization in context of legislative directive to develop competitive choice under Restructuring Act).

150 These databases support the 2011-2013 C&I Customer Profile Studies and the Residential Profile Study. The creation of these databases was an enormous and expensive undertaking from both a PA resource and vendor cost perspective. There was time and effort required to obtain the data needed to populate the databases from each PA's rate operations, which is separate and distinct from each PA's energy efficiency operations. In addition, the vendor had to clean, estimate, prorate gaps and outliers and otherwise normalize the data from 11 distinct PAs.

151 Neither database is accessible by the public or by the PAs because they contain private customer billing and usage data. Each EM&V vendor secures and controls the data pursuant to strict, legally enforceable, nondisclosure agreements and other important terms and conditions. PA vendors must meet certain privacy, insurance, and security requirements in order to receive sensitive customer-specific data. The contractual terms and conditions imposed on PA vendors require them to, among other things, indemnify the PAs, employ industry standard data system security measures and maintain certain types and levels of insurance.

152 The PAs will obtain estimates from their vendors for running the queries and would anticipate charging the costs to the budget for the statewide database. The PAs reserve the right to limit the scope and number of data queries from the Council in order to preserve their ability to maintain and work on MSD and to prioritize the work of their EM&V vendors.

153 As discussed in the previous section, the PAs anticipate charging certain Council-requested data queries against the budget for the statewide database.

154 The PAs have invested significant customer funds in their tracking systems. These systems have been developed to support PA business purposes, are integrated into other PA business systems, and were designed to comply with Department regulation.

Future phases of MSD, however, are unlikely to be achieved with such economy. Even if PA tracking systems do not require updates, vendor costs are likely to increase as the PAs develop tabs that are specific to Massachusetts and thus new to the vendor.

D. **Effect of Carbon Docket, D.P.U. 14-86**

On May 16, 2014, the DOER and DEP (collectively "Petitioners") filed a joint petition requesting that the Department adopt a value for the avoided cost of complying with the GWSA calculated using a marginal abatement cost curve method. Method for Calculating Avoided Costs of Complying with Global Warming Solutions Act, D.P.U. 14-86. Following the filing of pre-filed testimony and discovery responses, evidentiary hearings were held on December 8^{th} and 10^{th} 2014. Intervenors filed initial briefs on December 31, 2014, and the Petitioners, after seeking an extension, filed their initial brief on January 23, 2015. Intervenors filed reply briefs on February 13, 2015. The PAs (except for the Compact and Blackstone Gas) filed a joint reply brief asking the Department to deny the petition on the grounds that the GWSA does not impose costs on the PAs or their customers, the petitioners did not sufficiently quantify the proposed GWSA compliance value and GHG reductions are an important byproduct, but are not a specific requirement, of energy efficiency programs implemented pursuant to the GCA. The Department later permitted additional discovery on the Petitioners with respect to a record request update filed with their initial brief. Briefs related to this issue were filed on April 10, 2015.

The outcome of this docket may affect the PAs' final 2016-2018 Plan. Approval of the petition may necessitate changes in the avoided costs that are used to assess the cost effectiveness of Plan efforts. Specifically, the Department may approve a GHG emissions add-on to the results of the AESC study. The AESC study process includes, among many other attributes of avoided costs, an assessment of GHG emission costs potentially incurred and reflected in customers' rates absent additional energy efficiency efforts. In order to inform the initial draft of the 2016-2018 Plan, required to be filed with the Council by April 30, 2015, the 2015 AESC was completed on March 27, 2015, and revised on April 3, 2015. The 2015 AESC quantified the reasonably foreseeable effect of carbon dioxide regulations under RGGI through 2020 and under the Clean Power Plan proposed by the Environmental Protection Agency between 2021 and 2030. The PAs have relied on the 2015 AESC in developing the 2016-2018 Plan. Accordingly, changes in the final 2016-2018 Plan may be necessary to either comply with the Department's decision in D.P.U. 14-86, or to implement any final 2016-2018 Plan approved by the Department prior to its order in D.P.U. 14-86.

E. **Effect of DOER's proposed RCS Regulations**

On January 16, 2015, DOER proposed updates to its RCS regulations set forth at 225 CMR § 4.00. The purpose of these proposed regulations, as articulated by DOER, is to encourage broader consumer reach and better consumer protections, update and streamline the regulation, better integrate efficiency and renewable energy opportunities, and provide more consistent, comprehensive services to Massachusetts residents regardless of the fuel being used to heat a building or the number of units in a building. The proposed updates are comprehensive and have been issued for a public comment period that closed on March 31, 2015. The PAs and other stakeholders provided comments on the proposed amendments. The outcome of these updates may affect the PAs' final 2016-2018 Plan, including the savings goals and budgets.

F. Integration of Eversource Companies for Three-Year Plan

For the 2016-2018 term, NSTAR Electric Company ("NSTAR Electric") and Western Massachusetts Electric Company ("WMECo"), each d/b/a Eversource Energy (together, "Eversource" or the "Companies") are seeking approval from the Department of a single electric energy efficiency plan for the 2016-2018 Plan.

The Companies previously requested that the Department approve a single integrated Three-Year Plan for 2013-2015 in D.P.U. 12-110 and D.P.U. 12-111.[155] In support of their request, the Companies filed their D.P.U. 08-50 tables and all other documents relating to the Department's review of the Companies' Three-Year Plans for 2013-2015 both jointly and separately. The Companies specifically requested approval of: (1) common program design and implementation activities; (2) separate energy efficiency surcharges; (3) an aggregate program budget; (4) review of program cost-effectiveness on a combined basis; (5) a common performance incentive mechanism; and (6) aggregate common savings goals. See D.P.U. 12-110, Exh. DPU-NSTAR-2-59; see also D.P.U. 12-111, Exh. DPU-WMECO-2-39.

The Department approved the Companies' request with the following exceptions: (1) the Companies were directed to submit all energy efficiency filings related to the 2013-2015 Three-Year Plans, including tables, in a combined and separate format; (2) the Companies were directed to meet their low-income spending obligations on an individual company-specific basis; and (3) the Companies were directed not to include any costs associated with integrating their energy efficiency tracking systems into the 2013-2015 Plan. See 2013-2015 Order at 137-139. In addition, the Department noted that it would: (1) review the Companies' performance to assess whether their energy efficiency programs, as implemented, are cost-effective on both an individual and combined basis; (2) review performance with respect to savings goals on an individual basis; and (3) review performance incentives on an individual PA basis. See id. at 142. The Companies submitted revised D.P.U. 08-50 tables and performance incentive tables for NSTAR Electric and WMECo consistent with these directives on March 22, 2013. In addition, the Companies have submitted all subsequent filings related to the 2013-2015 Plan, including tables, in individual and combined format for the Department's review.

These filings, submitted in individual and combined format, have provided the Department sufficient documentation in support of approving the Companies request to submit a single, integrated Three-Year Plan.

Below is a brief overview of the Eversource energy efficiency proposal to integrate key aspects of energy efficiency program implementation including: Savings Goals; Program/Pilot Design and Implementation; Program Budgets/Spending; Cost Effectiveness; Funding; Performance Incentives; EM&V; and MTMs.

---

155 On April 4, 2012, the Department approved a merger between Northeast Utilities, parent company for WMECo, and NSTAR, parent company for NSTAR Electric and NSTAR Gas in D.P.U. 10-170. On February 2, 2015 all Northeast Utilities companies, including WMECo and NSTAR Electric, began doing business as Eversource.

1. Savings Goals

The Settlement Agreement between NSTAR Electric, NSTAR Gas Company, WMECo and the DOER approved by the Department in D.P.U. 10-170 required NSTAR Electric and WMECo to increase their aggregate energy efficiency savings target as of January 1, 2013 to at least 2.5 percent of retail sales annually through energy efficiency, so long as there is no material change in the framework for assessing the success of the program and associated incentives, or providing for program funding. NSTAR/NU Merger, (NSTAR/WMECo/DOER Settlement Agreement at Article 2.3, NSTAR/WMECo/DOER/AG Settlement Agreement at Articles 2(3)(Base Rate Freeze) and 2.7 (Lost Base Revenues)). This annual commitment ends at the expiration of the Base-Rate Freeze period (*i.e.*, January 1, 2016). However, the Companies are committed to proposing and achieving a common savings goal for both Eversource electric distribution companies during the 2016-2018 term. Accordingly, pursuing this common savings goal through a single plan is reasonable, and is consistent with the Companies' commitments during the 2013-2015 term.

2. Program/Pilot Design and Implementation

The 2013-2015 Plan contemplated uniform electric energy efficiency programs across Massachusetts. The Companies expect that the statewide electric 2016-2018 Three-Year Plan will similarly include uniform energy efficiency programs. Accordingly consistent with the Department's approval of a single Eversource electric energy efficiency plan in D.P.U. 12-101 through 12-111, at 137-139 for purposes of pursuing common program/pilot designs and implementation, the Companies request approval of a single Eversource electric energy efficiency Plan for the 2016-2018 term.

3. Program Budgets/Spending

The Eversource electric energy efficiency budgets for 2013-2015 were structurally identical. The Companies similarly propose to submit energy efficiency budgets that are structurally identical for the 2016-2018 term. Maintaining separate budgets through separate energy efficiency plans presents unnecessary administrative and regulatory burdens on the Companies that could be eliminated through an integrated budget and plan and streamlined regulatory review. Spending for each operating company for the 2016-2018 term will continue to be tracked separately in each operating company's respective accounting systems.

With respect to low-income energy efficiency programs, the Companies will maintain their spending on such programs at a minimum of 10 percent of the integrated budget, as required by law, with an apportioned low-income budget directly allocated to each company. Operational differences in the low-income programs will be reconciled in cooperation with LEAN.

4. Program Cost-Effectiveness

The Companies' respective energy efficiency programs are designed to be cost-effective, as measured by the Department's Total Resource Cost test. The Companies' 2013 and 2014 Plan

Year reports demonstrated that their energy efficiency programs are also cost-effective if integrated. See D.P.U. 14-87 (2013 NU Electric Plan Year Report at PDF page 32 of 46, citing evaluated cost-benefit ratios) and D.P.U. 15-49 (Eversource Electric 2014 EE Plan-Year Report at PDF page 32 of 46). Based on the foregoing, the Companies request approval for the 2016-2018 term to submit one, integrated cost-effectiveness analysis for the Eversource electric companies, and have their programs reviewed for cost-effectiveness on that basis.

5. Funding/Cost Recovery

a. Funding

Given that the GCA makes funding sources for energy efficiency programs uniform for electric PAs, as demonstrated by the Companies during the 2013-2015 term, an integrated electric energy efficiency plan does not present any issues with respect to the structure and sources of program funding. First, a statewide formula exists for allocating RGGI proceeds to individual PAs. Second, forward capacity auctions applicable to the 2016-2018 term have occurred already, and the proceeds from such auctions will be based on the individual PA's energy efficiency assets and how they are bid into forward capacity auctions. Finally, although the carryover amounts for NSTAR Electric and WMECo differ, as noted previously, the Companies will track and allocate funds appropriately. As directed by the Department in D.P.U. 12-100 through D.P.U. 12-111, the Companies tracked all funding separately with respect to the 2013-2015 term without issue. Thus, funding does not present a barrier to the Department's approval of an integrated energy efficiency plan.

b. Cost Recovery

Although the Companies' plan will integrate key aspects of energy efficiency goals outlined above, the Companies are not proposing at this time to consolidate energy efficiency cost recovery tariffs. LBR recovery will be based on cost recovery proposals specific to NSTAR Electric Company. Lost revenues associated with WMECo's energy efficiency programs are recovered through WMECo's decoupling mechanism.

c. Avoidance of Cross Subsidization

The Companies have demonstrated in their 2013 and 2014 Plan Year Reports that they have served each of the NSTAR Electric and WMECO service territories by maximizing benefits and minimizing overall costs to the extent possible, while being cognizant of the separate funding sources provided by customers in each service area in the form of the NSTAR Electric EERF and the WMECO EEPCA. Each service territory was served within the bounds of their approved budgets, with costs tracked separately, as reported in each service territory's distinct Plan Year Report filing.

6. Bill Impacts

In recognition of the fact that the acquisition of all cost-effective energy efficiency could require funding above that provided through existing funding sources (*i.e.*, the SBC, FCM, and RGGI), the GCA provides that PAs may collect additional revenue from ratepayers through a mechanism such as the EES. G.L. c. 25, § 19(a). Given that the energy efficiency cost recovery tariffs for the Companies are not proposed at this time to be integrated, the Companies do not anticipate adverse bill impact issues arising in the context of plan integration.

7. Performance Incentives

The GCA provides that the Statewide Plan shall include a proposed mechanism that provides incentives to PAs based on their success in meeting or exceeding the goals in the plan. G.L. c. 25, § 21(b)(2). The Companies will follow the performance incentive mechanism ultimately developed by the electric PAs and the Council. Filings submitted to the Department in D.P.U. 12-110 and D.P.U. 12-111, and in subsequent Plan Year reports demonstrated that the Companies have independently satisfied their performance commitments without issue and there is thus no reason to continue to require the Companies to calculate and report performance incentives on an individual basis. Because of the Companies satisfaction of all performance commitments there is no risk that integration would result in using one company's stellar performance to mask the other's subpar performance.

8. EM&V

The Department's Guidelines require each Three-Year Plan to include an evaluation plan describing how the PA will evaluate energy efficiency programs during the course of its plan. Guidelines § 3.5. The Department's Guidelines are intended to create a collaboratively-developed (between the Council and the PAs), statewide EM&V strategy. The Companies will use the same EM&V strategy and apply EM&V results similarly during the 2016-2018 term. Accordingly, EM&V strategy and application will not be affected by plan integration.

9. MTMs

In D.P.U. 08-50-A and the D.P.U. 08-50-B Guidelines, the Department directed the PAs to seek Department approval for certain specified MTMs, including adding or terminating a program, and changes in a program budget, savings goals, or performance incentives of greater than 20 percent. D.P.U. 08-50-A at 64; D.P.U. 08-50-B Guidelines at § 3.8.2. Subsequent to D.P.U. 08-50-A and B, the Department provided further guidance regarding the need for Department approval of proposed mid-term program modifications. Specifically, in Cape Light Compact, D.P.U. 10-106 (2011), the Department clarified that PAs are required to seek Department approval only for a program budget modification that is 20 percent greater than the program's three-year budget.

The Department modified the D.P.U. 08-50 Guidelines with respect to MTM filings in D.P.U. 11-120-A, Phase II. The Department established two categories of MTMs, Category One and Category Two. D.P.U. 11-120-A, Phase II at 28; see also Final Revised Guidelines, §§ 3.8.1 and 3.8.2. A Category One MTM includes (1) addition of a Hard-to-Measure energy efficiency Program; (2) termination of an existing energy efficiency program or Hard-to-Measure energy efficiency program; (3) program budget modifications that are a 20 percent deviation from the Department approved program budget or modifications that are a change to the program-budget greater than a dollar amount specified by the Department; or (4) a modification to an energy efficiency program that is projected to decrease program benefits by greater than 20 percent. See D.P.U. 11-120-A, Phase II at 28; see also Final Revised Guidelines, § 3.8.1. A Category Two modification is (1) the addition of a new energy efficiency program; (2) the transition of a Hard-to-Measure energy efficiency program to an energy efficiency program; or (3) a change in the three-year term budget of a customer sector that would result in a bill increase for an average customer in the sector exceeding two percent. Final Revised Guidelines, § 3.8.2. Category Two modifications require Department approval, while Category One modifications require only a Council resolution. D.P.U. 11-120-A, Phase II, at 28-29; Final Revised Guidelines, §§ 3.8.1, 3.8.2.

Under an integrated plan, the Companies intend to apply the Department's MTM Guidelines to the integrated budgets, savings and performance incentives of the two Companies, and with respect to the addition or termination of an integrated program. The Companies will continue to apply the Department's MTM Guidelines with respect to bill impacts to NSTAR Electric Company and WMECO individually, given their separate energy efficiency cost recovery mechanisms. And, the two-tiered review and approval process set forth in the Final Revised Guidelines ensures that the Department and Council remain apprised of any changes to the Companies' plan.

10. Conclusion

Based on the foregoing, the Companies are requesting that the Department: (1) permit the Companies to submit a single, fully integrated Three Year Plan for the Eversource electric companies as outlined above; and (2) review the Companies' compliance with G.L. c. 25, §§ 19(c) and 21(d) based on their combined performance against their integrated Three Year Plan. NSTAR Electric and WMECo will continue to individually track their energy efficiency costs and savings (and provide such information upon request), and file individual energy efficiency reconciliation factors with the Department for review and approval. The Companies are confident that implementing energy efficiency programs through a single plan will not only fulfill each company's energy efficiency obligations, but also provide the potential for administrative and regulatory efficiencies over time, while imposing no adverse impacts on the customers of either company.

G. **Service of Blackstone Customers**

In the 2013-2015 Order, the Department stated, "with the Council's help and support, we encourage Blackstone Gas to pursue an agreement with another Program Administrator to deliver energy efficiency services in its service territory." 2013-2015 Order at 155. In accordance with that direction, Blackstone entered into discussions with National Grid, the electric Program Administrator that provides electric distribution services to Blackstone's gas customers, to determine an appropriate manner in which National Grid may provide comprehensive electric and gas energy efficiency services for Blackstone's customers. Following agreement in principle on an arrangement through which National Grid would provide gas energy efficiency services to all Blackstone customers, under the same terms and conditions as it provides energy efficiency services to its native load customers, on March 31, 2015, the Council voted to approve the proposal. In June 2015, Blackstone and National Grid entered into a formal agreement to implement the proposed service arrangement, and filed a joint petition for approval of the arrangement with the Department, docketed as D.P.U. 15-79. On October 7, 2015 the Department approved the service arrangement commencing on January 1, 2016. Blackstone Gas Company, and Boston Gas Company and Colonial Gas Company, each d/b/a National Grid, D.P.U. 15-79, at 3 (2015).

In summary, National Grid and Blackstone have agreed to an arrangement under which National Grid, commencing with the 2016-2018 Energy Efficiency Plan, will provide gas energy efficiency services to all Blackstone customers under the same terms and conditions as it provides energy efficiency services to its native load customers. Blackstone's customers and all related budgets, savings, and performance incentives will be fully integrated into National Grid's gas territory and filings, with no separate goals, tracking, or reporting related to Blackstone's customers to be required of National Grid as a result of this arrangement. This integration will allow Blackstone's customers to take full advantage of all the energy efficiency programs that are available in Massachusetts without placing any additional burdens on National Grid's customers. This agreement would also provide Blackstone's customers with representation at the Council through National Grid.

Accordingly, National Grid has included bill impacts for Blackstone's customers in its Three-Year Plan filing pursuant to the Department's directive. Id.

VIII. APPENDICES

A. **Glossary**

GLOSSARY OF TERMS AND ABBREVIATIONS	
2012-2012 Electric Plan	2010-2012 Electric Three-Year Energy Efficiency Plan, D.P.U. 09-116 through D.P.U. 09-120
2010-2012 Gas Plan	2010-2012 Gas Three-Year Energy Efficiency Plan, D.P.U. 09-121 through D.P.U. 09-128
2010-2012 Orders	Orders issued by the Department on January 28, 2010 for the 2010-2012 Plans in dockets D.P.U. 09-121 through D.P.U. 09-128 and D.P.U. 09-116 through D.P.U. 09-120
2010-2012 Plans	2010-2012 Electric Plan and 2010-2012 Gas Plan
2013-2015 Order	Order issued by the Department on January 31, 2013 for the 2013-2015 Plans in in dockets D.P.U.12-100 through 12-111
2013-2015 Plan	2013-2015 Three-Year Energy Efficiency Plan, D.P.U. 12-100 through D.P.U. 12-111
2015 AESC	Avoided Energy Supply Cost in New England: 2015 Report
2016-2018 Plan	2016-2018 Three-Year Energy Efficiency Plan
AB	Advanced Buildings
ABCD	Action for Boston Community Development
ACEEE	American Council for an Energy-Efficient Economy
Act Relative to Competitively Priced Electricity in the Commonwealth	Chapter 209 of the Acts of 2012. Signed into law on August 23, 2012.
AE	Account Executive
AESC	Avoided Energy Supply Costs
AESP	Association of Energy Service Professionals
AFUE	Annual Fuel Utilization Efficiency
AG	Office of the Attorney General of Massachusetts
AIA	American Institute of Architects
AIM	Associated Industries of Massachusetts
ARRA	American Recovery and Reinvestment Act
BBRS	Board of Building Regulations and Standards
BCR	Benefit/Cost Ratio
BPI	Building Performance Institute
C&F	Chain & Franchise
C&I	Commercial and Industrial
C&IMC	Commercial and Industrial Management Committee
CAP	Community Action Program
CDA	Comprehensive Design Approach
CECP	Massachusetts Clean Energy and Climate Plan for 2020
CFL	Compact Fluorescent Lightbulb

CHP	Combined Heat and Power
CMI	Community Mobilization Initiatives
Consultants	Consultants employed by the Energy Efficiency Advisory Council
Council	Energy Efficiency Advisory Council
Department	Massachusetts Department of Public Utilities
DEP	Massachusetts Department of Environmental Protection
DER	Deep Energy Retrofit
DHCD	Massachusetts Department of Housing and Community Development
DOE	Department of Energy
DOER	Massachusetts Department of Energy Resources
DPU	Massachusetts Department of Public Utilities
D.P.U. 08-50	Energy Efficiency Guidelines, D.P.U. 08-50 (2008)
D.P.U. 08-50-B Guidelines	Energy efficiency guidelines established in D.P.U. 08-50-B (2009)
D.T.E. 98-100 Guidelines	Energy efficiency guidelines established in Investigation to Establish Methods and Procedures to Evaluate and Approve Energy Efficiency Programs, D.T.E. 98-100 (2000)
D.P.U. 11-120 Guidelines	Energy efficiency guidelines established in D.P.U. 11-120-A, Phase II (2013)
DSM	Demand-Side Management
ECM	Electronically Commutated Motor
EEAC	Energy Efficiency Advisory Council
EEPCA	Energy Efficiency Program Cost Adjustment
EERF	Energy Efficiency Reconciliation Factor
EES	Energy Efficiency Surcharge
EISA	Energy Independence and Security Act
Energy Act of 2012	Act Relative to Competitively Priced Electricity in the Commonwealth
EMC	Evaluation Management Committee
EM&V	Evaluation, Measurement and Verification
EM&V Consultant	A third-party expert consultant who has primary responsibility for working with the PAs to plan and implement high-quality EM&V in Massachusetts.
ENERGY STAR®	Brand name for the voluntary energy efficiency labeling initiative sponsored by the U.S. Environmental Protection Agency and Department of Energy.
EPA	U.S. Environmental Protection Agency
FCM	Forward Capacity Market
FR	Free Rider

Free Riders	Customers who participate in an energy efficiency program but would have installed the same measure(s) on their own if the program had not been available.
Free-Ridership Rate	The percent of savings attributable to Free Riders.
FTE	Full-Time Equivalent.
GCA	Green Communities Act
GHG	Greenhouse Gas
Green Communities Act	An Act Relative to Green Communities, Chapter 169 of the Acts of 2008. Signed into law on July 2, 2008.
Guidelines	Department's D.P.U. 11-120 Guidelines
GWSA	Global Warming Solutions Act, St. 2008, c. 298
HEHE	High Efficiency Heating and Water Heating
HERS	Home Energy Rating System
HES	Home Energy Services
HPCs	Home Performance Contractors
HVAC	Heating, Ventilation, and Air Conditioning
IECC	International Energy Conservation Code
IIC	Independent Installation Contractors
Impact Factor	Generic term for persistence, realization rates, in-service rates, non-coincident connected demand factors, etc., developed during the evaluation of energy efficiency programs and used to calculate net savings.
ISO-NE	Independent System Operator – New England
JMC	Joint Management Committee of PA and non-PA parties that manages the Residential and Low-Income New Construction Core Initiatives
LDAF	Local Distribution Adjustment Factor
LDAC	Local Distribution Adjustment Clause
LEAN	The Low-Income Energy Affordability Network
LED	Light Emitting Diode
LBR	Lost Base Revenue (For companies not operating under decoupled rate structure, these costs account for revenues not collected by the Company's distribution business as a result of the energy efficiency undertaken during the program year)
LCIEC	Large Commercial & Industrial Evaluation Contractor
Lifetime	The expected length of time, in years, that an installed measure will be in service and producing savings.
MassCEC	Massachusetts Clean Energy Center
Measure	Specific technology or practice that produces energy and/or demand savings for which the Company provides financial incentives.

MFNC	Multi-Family New Construction
Mid-Term Modification	Modification to approved Three-Year Plan during term of Plan.
MMI	Multi-Family Market Integrator
MOU	Memorandum of Understanding
MSD	Mass Save Data
MTAC	Massachusetts Technical Assessment Committee
MTM	Mid-Term Modification
NBI	New Building Institute
NCP	Negotiated Cooperative Promotions
NEED	National Energy Education Development
Net to Gross Ratio or NTGR	A factor representing net program savings divided by gross program savings that is applied to gross program impacts to convert them into net program load impacts.
NEI	Non-Energy Impacts
Network	Low-Income Weatherization and Fuel Assistance Program Network
NPS	Non Participant Spillover
NTG	Net-to-Gross
NWA	Non-Wires Alternative
PA	Program Administrator
PAF	Pension Adjustment Factor
PBOP	Post-Retirement Benefits Other than Pensions
Participant Cost	The total cost of a project or measure less the customer incentive.
Performance Incentive	Compensation for the Company's successful execution of the energy efficiency programs during the program year as determined by Massachusetts Department of Public Utilities.
PEx	Program Expediter
PI	Performance Incentive
Plan	Three-Year Energy Efficiency Plans approved by the Department by its Orders, dated January 28, 2010, in dockets D.P.U. 09-121 to D.P.U. 09-128 and D.P.U. 09-116 to D.P.U. 09-120, and dated January 31, 2013 in dockets D.P.U.12-100 through 12-111.
PP&A	Program Planning and Administration
Program Administrators	Utilities and municipal aggregators that offer energy efficiency programs.
QA/QC	Quality Assurance/Quality Control
RCS	Residential Conservation Service, established in An Act Establishing The Massachusetts Residential Conservation Service, Chapter 465 of the Acts of 1980, July 11, 1980.

RFP	Request For Proposal
RGGI	Regional Greenhouse Gas Initiative
RMC	Residential Management Committee
RNC	Residential New Construction
SBC	System Benefit Charge
SO	Participant Spillover
STAT	Sales, Technical Assistance & Training
Spillover	Additional energy efficient equipment installed by customers that was influenced by the Company's sponsored program, but without direct financial or technical assistance from the program. Spillover is separated into Participant and Non-participant factors. Non-participating customers may be influenced by product availability, publicity, education and other factors that are affected by the program.
Spillover Rate	Estimate of energy savings attributable to spillover effects expressed as a percent of savings installed by participants through an energy efficiency program.
T&D	Transmission and Distribution
Term	Three-year term of the energy efficiency plan
Three-Year Plan	Energy Efficiency Investment Plans required by the GCA every three years. To date, the Department has approved two Three-Year Plans by its Orders in dockets D.P.U. 09-121 to D.P.U. 09-128 and D.P.U. 09-116 to D.P.U. 09-120 (January 28, 2010), and dockets D.P.U. 12-100 to D.P.U. 12-111 (January 31, 2013).
TRC	Total Resource Cost
TRL	Technical Resource Library
TRM	Technical Reference Manual
WAP	Weatherization Assistance Program

B. **Regulatory Background and History**

Regulatory Background and History

1. Regulatory Context
   a. Green Communities Act
   b. Residential Conservation Service Act
   c. Energy Act of 2012
   d. Investigation instituting a rulemaking pursuant to the Energy Act of 2012, D.P.U. 14-53 (2014)
   e. Proposed updates to DOER RCS Regulations

2. Orders Approving Three-Year Plans
   a. 2010-2012 Plan Orders
      i. Gas Plan Order, D.P.U. 09-121 through D.P.U. 09-128 (2010)
      ii. Electric Plan Order, D.P.U. 09-116 through 09-120 (2010)
   b. 2013-2015 Plan Order, D.P.U. 12-100 through 12-111 (2013)

3. Energy Efficiency Guidelines
   a. D.P.U. 08-50-A (2009)
   b. D.P.U. 08-50-B (2009)
   c. D.P.U. 08-50-C (2011)
   d. D.P.U. 08-50-D (2012)
   e. D.P.U. 11-120, Phase I (2012)
   f. D.P.U. 11-120-A, Phase II (2013)

4. Mid-Term Modifications
   a. Compact's 2010 MTM, D.P.U. 10-106 (2011)
   b. 2011 MTMs, D.P.U. 10-140 through 10-150
   c. 2012 MTMs, D.P.U. 11-106 through D.P.U. 11-116
   d. Order approving 2011 and 2012 MTMs (2014)

5. Annual Reports
   a. 2010 Annual Report Orders - D.P.U. 11-63 through D.P.U 11-73, D.P.U. 11-126
      i. Gas Orders (2013)
      ii. Electric Orders (2014)
   b. 2011 and 2012 Annual Report Orders (2014) - D.P.U. 12-51 through D.P.U 12-61; D.P.U. 13-110 through D.P.U. 13-122
      i. Gas Orders
      ii. Electric Orders

6. Miscellaneous
   a. 2013-2015 Performance Metrics, D.P.U. 13-67 (2014)
   b. 2013 Avoided Energy Supply Component Study Energy Efficiency Updates, D.P.U. 14-05
   c. Method for Calculating Avoided Costs of Complying with Global Warming Solutions Act, D.P.U. 14-86

1. Regulatory Context		
a.	Green Communities Act	The GCA was signed into law on July 2, 2008. The legislation promotes enhanced energy efficiency throughout the Commonwealth and requires the PAs to develop energy efficiency plans that will "provide for the acquisition of all available energy efficiency and demand reduction resources that are cost effective or less expensive than supply." G.L. c. 25, § 21(b)(1). The GCA requires the PAs to submit a statewide energy efficiency investment plan every three years on or before April 30 to the Council. The contents of those plans, which are specified in the statute, are to be prepared by the PAs in coordination with the Council. In accordance with the GCA, the PAs are required to file their respective PA-specific three-year plans, "together with the Council's approval or comments and a statement of any unresolved issues, to the Department . . . on or before October 31." Id. § 21(d).
b.	Residential Conservation Service Act	The RCS, as established through chapter 465 of the Acts of 1980, was Massachusetts' response to federal efforts for consumer protection and energy independence, and sought to encourage increased energy efficiency in residential buildings.
c.	Energy Act of 2012	On August 23, 2012, Chapter 209 of the Acts of 2012, "An Act relative to competitively priced electricity in the Commonwealth" was signed into law. Notably, the Energy Act of 2012 increased the membership of the Council, amended statutory provisions concerning RCS, established an energy policy review commission, and implemented an accelerated rebate pilot program. Section 5 of the Energy Act of 2012 implemented a voluntary accelerated rebate pilot program, which the PAs offered and is now completed. Sections 8 through 11 of the Energy Act of 2012 amended the existing statutory provisions concerning the Council by expanding the membership from 11 to 15 members, with the additional 4 members representing: the Massachusetts Non-profit Network, a Massachusetts city or town, the Massachusetts association of realtors and a small energy efficiency contractor. Section 32 of the Energy Act of 2012 amended the RCS by permitting the inclusion of RCS service as part of an efficiency investment plan under the GCA, in order to slightly reduce the administrative burdens of separate filings and hearings on utilities. Section 41 of the Energy Act of 2012 established an energy policy review commission to study and report to the Legislature on energy policy in Massachusetts, and the PAs participated in the commission under the statute.
d.	Investigation instituting a rulemaking pursuant to the Energy Act of 2012, D.P.U. 14-53 (2014)	On November 5, 2014, the Department issued an Order Adopting Final Regulations revising 220 C.M.R. § 7.00 et seq., Residential and Commercial Energy Conservation Service Program Cost Recovery to comply with the Energy Act of 2012 by reducing the administrative burden of reporting RCS separately from weatherization for cost-effectiveness, but declining to adopt the additional recommendations proposed by the PAs, including the suggestion that PAs report RCS as a part of weatherization for budget purposes.
e.	Proposed updates to DOER RCS Regulations	On January 16, 2015, DOER proposed regulatory updates to the RCS to encourage broader consumer reach and better consumer protections. The proposed updates have been issued for a public comment period that closed

	on March 31, 2015.
2. Orders Approving Three-Year Plans	
a. 2010-2012 Plan Orders -Gas Plan Order, D.P.U. 09-121 through D.P.U. 09-128 (2010) -Electric Plan Order, D.P.U. 09-116 through D.P.U. 09-120 (2010)	For the plan term 2010-2012, the PAs developed separate gas and electric energy efficiency plans. On October 31, 2009, the PAs filed their respective PA-specific 2010-2012 Plans, together with the Council's Resolution of October 27, 2009 (which Resolution constituted the Council's approval, comments and statement of any unresolved issues) with the Department pursuant to G.L. c. 25, § 21(d). The 2010-2012 Plans sought to capture all available cost-effective energy efficiency for the three-year period beginning January 1, 2010, with the consideration of factors and concerns noted at the Council, including, but not limited to, bill impacts, environmental benefits, and the need for a reasonable ramp-up schedule. On January 28, 2010, the Department issued Orders approving the 2010-2012 Plans subject to limited specified exceptions and directives.
b. 2013-2015 Plan Order, D.P.U. 12-100 through 12-111 (2013)	For the plan term 2013-2015, the PAs developed a single integrated gas and electric energy efficiency plan. On November 2, 2012, the PAs filed their respective PA-specific 2013-2015 Plans with the Department pursuant to G.L. c. 25, § 21(d).. On November 13, 2012, the Council approved a resolution (which constituted the Council's approval, comments and statement of any unresolved issues). The 2013-2015 Plans sought to capture all available cost-effective energy efficiency for the three-year period beginning January 1, 2013, with the consideration of factors and concerns noted at the Council, including, but not limited to, bill impacts, environmental benefits, and sustained energy efficiency efforts. On January 31, 2013, the Department issued an Order approving the 2013-2015 Plans subject to limited specified exceptions and directives. The Department found each program cost-effective, approved each PA's savings and budgets, and with a limited threshold level exception, approved the performance incentive mechanism. The Department found each PA's Plan to be consistent with the GCA, the Guidelines, and Department precedent.
3. Energy Efficiency Guidelines	
a. D.P.U. 08-50-A (2009)	After the passage of the GCA, and in conjunction with the PAs' well-established energy efficiency programs, the Department opened an investigation to update the Department's energy efficiency guidelines, as previously established in the D.T.E. 98-100 Guidelines, to ensure that they were consistent with the GCA. During the Department's proceedings in D.P.U. 08-50, it solicited comments from the PAs, governmental bodies, and other interested stakeholders. The PAs participated with the Department, DOER, and other interested stakeholders in various collaborative D.P.U. 08-50 working group sessions convened and moderated by the Department. The resulting first Order, D.P.U. 08-50-A, issued on March 16, 2009, provided a clarification of the criteria to be applied in demonstrating cost-effectiveness and the process by which three-year energy efficiency plans should be prepared and reviewed. In D.P.U. 08-50-A, the Department mandated that the PAs seek Department approval for certain specified MTMs. As a result, the PAs filed MTMs for 2011 and 2012 in accordance with D.P.U. 08-50-A and D.P.U. 08-50-B, discussed below.
b. D.P.U. 08-50-B (2009)	The Department supplemented its D.P.U. 08-50-A Order with the issuance of an Order in D.P.U. 08-50-B, which was issued on October 26, 2009. In D.P.U. 08-50-B, the Department provided further directives clarifying how the PAs are to conduct and present their bill impact analysis and EM&V

	processes, and established the D.P.U. 08-50-B Guidelines. The revised guidelines addressed issues such as: (1) funding sources; (2) budgets; (3) cost-effectiveness test; (4) evaluation plans; (5) performance incentives; (6) review of three-year plans; and (7) MTMs. Through the D.P.U. 08-50-A and D.P.U. 08-50-B Orders, the Department established standards that sought to balance the need for PAs to make improvements to energy efficiency programs during the course of a three-year plan, with the need for adequate regulatory review and stakeholder input of significant changes to the PAs' planning assumptions and parameters.
c. D.P.U. 08-50-C (2011)	Following its Order in D.P.U. 08-50-B, the Department established a working group to review existing practices and develop an annual report template for review and comment, resulting in an Order in D.P.U. 08-50-C issued on May 5, 2011, which established a template for energy efficiency annual reports. The Department noted that the purpose of the annual report template is: (1) to clearly identify the information that a PA is required to provide to fully review the PA's energy efficiency program performance for a particular year; and (2) to specify the format for providing the required information. The PAs have used the annual report template, in preparing their respective annual reports for 2011 and 2012, which were filed with the Department each year on or about August 1st, and in compliance with G.L. c. 25, § 21(b)(3).
d. D.P.U. 08-50-D (2012)	On October 19, 2012, the Department issued an order on bill impacts, explaining that the pace at which the PAs acquire all available cost-effective energy efficiency resources "is moderated in part by the requirement that the Department consider the effect of any rate increases on residential and commercial customers' bills before the approval of ratepayer funding for energy efficiency programs." D.P.U. 08-50-D, *Order on Bill Impacts*, at 9 (2012). The Department acknowledged the efforts of the D.P.U. 08-50 bill impact working group, a large group of stakeholders who developed various bill impact models consistent with Department directives in D.P.U. 08-50. The Department, however, declined to adopt the bill impact models under discussion. The Department determined that its statutory mandate to consider the effect of any rate increases on residential and commercial customers is "best satisfied through a traditional bill impact analysis which, with its short-term perspective that isolates the effect of a proposed change in the [energy efficiency surcharge], will provide an accurate and understandable assessment of the increase that will actually appear on customers' bills." Id. The Department agreed "with the stakeholders who argue that, when considering the reasonableness of a short-term bill impact from energy efficiency activities, it is important to look at it the long-term benefits that energy efficiency will achieve." D.P.U. 08-50-D, at 11. The Department stated that the "long-term benefits of energy efficiency are fully documented by the PAs and reviewed by the Department and stakeholders in the context of evaluating program cost-effectiveness" and that the Department will consider bill impacts through "the lens of the long-term benefits that energy efficiency can achieve." Id. at 11-12 (citations omitted). The Department directed the PAs to conduct bill impact analyses going forward for energy efficiency participants as well as non-participants. This methodology is discussed in more detail in Section III.E.
e. D.P.U. 11-120, Phase 1 (2012)	On November 29, 2011, the Department opened an investigation to examine issues associated with the PAs' Three-Year Plans, through D.P.U. 11-120. In the first phase of the investigation, the Department announced that it

	would examine the following issues associated with energy efficiency program benefits that are included in the cost-effectiveness determination: (1) the method used to calculate program net savings; and (2) the method used to calculate reasonably anticipated environmental compliance costs, in particular those associated with the emission of carbon dioxide. Interested parties filed initial and reply comments and participated in a Department technical session to discuss issues related to net savings. On August 10, 2012, the Department issued D.P.U. 11-120-A, *Order on Program Net Savings and Environmental Compliance Costs* (2012), addressing two issues related to program net savings: (1) alternate methods to determine program net savings; and (2) the prospective or retrospective application of evaluation study results. In addition, the Department declined to adopt an interim proxy value for carbon dioxide to be used in the cost-effectiveness determination of energy efficiency programs. With respect to net savings, the Department indicated support for alternative approaches to determining net savings that look at effects that occur over multi-year periods and across programs, which is consistent with the approach recommended in the joint comments of the PAs, DOER, DEP, ENE and NEEP. The Department announced that it would convene a working group to explore if and how an alternate (i.e., market-focused) approach to determine program net savings could be developed and implemented. With respect to EM&V results, the Department found that it is appropriate for PAs, when calculating post-implementation program savings (gross and net), to use: (1) the most recently updated gross savings impact factors; and (2) the net savings impact factors that were used when the programs were designed and developed.
f. D.P.U. 11-120-A, Phase II (2013)	On May 25, 2012, the Department opened a second phase of this investigation with D.P.U. 11-120, Phase II to examine issues associated with the PAs' Three-Year Plans. In the second phase of this investigation, the Department decided to examine recurring filings that the Department has reviewed during the term of the first Three-Year Plans, including: (1) MTMs; (2) the performance reports submitted by each PA annually, which include the calculation of a performance incentive payment; and (3) the calculation and reconciliation of each PA's energy efficiency surcharges. Interested parties filed comments and attended a Department-convened technical session. On January 31, 2013, the Department issued D.P.U. 11-120-A, Phase II, *Order Approving Revised Energy Efficiency Guidelines* (2013). Key themes of the revised guidelines include treating the PAs' Three-Year Plans under the GCA as one Three-Year Plan as opposed to three one-year plans, and reducing (but not eliminating) the potential for MTMs and recurring annual Department energy efficiency reviews. The Department also determined that only performance reports at the end of each three-year term will be litigated instead of litigating each annual performance report. The Department also addressed performance incentives, energy efficiency surcharges, and MTMs.
4. Mid-Term Modifications	
a. Compact's 2010 MTM, D.P.U. 10-106 (2011)	On August 13, 2010, Cape Light Compact filed a request with the Department for a MTM of its 2010-2012 Plan, consisting of an adjustment of its 2010 program budgets. The Cape Light Compact sought Department approval for a program budget change that was 20 percent greater than the

	program's annual budget. While § 3.8.2 of the D.P.U. 08-50-B Guidelines describes the conditions that require a filing of a MTM, that section did not state whether the 20 percent thresholds should be applied on a three-year or an annual basis. On January 10, 2011, the Department issued D.P.U. 10-106, stating that the three-year plan review process should move away from routine MTMs, and clarifying that D.P.U. 08-50-B Guidelines "§ 3.8.2 should be interpreted such that Department approval is required for a program budget change that is 20 percent greater than the program's three-year budget." D.P.U. 10-106, at 7-8. Additionally, the Department noted that the D.P.U. 08-50-B Guidelines are not fixed and are intended to be updated over time.
b. 2011 MTMs, D.P.U. 10-140 through D.P.U. 10-150	Each PA individually filed MTMs to its 2010-2012 Plan for effect in calendar year 2011 on or about October 29, 2010, pursuant to § 3.8 of the Department's D.P.U. 08-50-B Guidelines and the Department's 2010-2012 Orders. The PAs developed their MTMs for 2011 based on a set of four operating assumptions which were based on their interpretation of D.P.U. 08-50-B Guidelines, particularly §3.8.2 which relates to the timing and substantive requirements for MTMs. The PAs responded to numerous statewide and individual information responses from the Department and intervenors. Finally and significantly, on December 14, 2010, the Council adopted a resolution in support of the MTMs for 2011. On April 15, 2011, following comprehensive negotiations, the PAs, DOER, the Low-Income Weatherization and Fuel Assistance Network, Massachusetts Energy Directors Association, the Low-Income Energy Affordability Network and Environment Northeast jointly filed for approval with the Department a Memorandum of Agreement intended to resolve all issues related to the respective requests for the 2011 MTMs. The Memorandum of Agreement resolved eleven docketed matters of first impression and had the support of a broad array of stakeholders, including the approval of the Council. On July 1, 2011, the AG filed comments in the 2011 MTM proceedings, making a number of recommendations but not opposing approval of the Memorandum of Agreement by the Department.
c. 2012 MTMs, D.P.U. 11-106 through D.P.U. 11-116	Each PA individually filed MTMs to its 2012-2015 Plan for effect in calendar year 2012 on October 31, 2011, also pursuant to § 3.8 of the Department's D.P.U. 08-50-B Guidelines and the Department's 2010-2012 Orders. The PAs responded to numerous statewide and individual information requests from the Department and other intervenors. On December 12, 2011, DOER filed with the Department the Council's resolution in support of the MTMs for 2012, which was adopted on November 8, 2011. On May 2, 2012, the Department approved a Partial Settlement on Scope of the Proceedings, submitted jointly by the PAs and the AG, DOER, and the Low-Income Weatherization and Fuel Assistance Program Network, the Massachusetts Energy Directors Association, the Low-Income Energy Affordability Network, and Environment Northeast. Accordingly, any issue with respect to the use of estimated avoided costs based on the 2011 Avoided Energy Supply Costs in New England: 2011 Report (July 21, 2011, amended August 11, 2011) and estimated non-energy benefits (also known as non-energy impacts) based on the Massachusetts Special and Cross-Sector Studies Area, Residential and Low-Income Non-Energy Impacts Evaluation (August 15, 2011) would not be addressed in the proceedings for the MTMs for 2012.
d. Order approving 2011 and	On November 26, 2014, the Department issued an order approving, with

2012 MTMs, D.P.U. 10-140 through D.P.U. 10-150; and D.P.U. 11-106 through D.P.U. 11-116 (2014)	exceptions the PAs' 2011 and 2012 MTMs. The Department found the MTMs for 2011 and 2012 were consistent with the D.P.U. 08-50-B Guidelines and resulted in a modified Plan that is designed to capture all available energy efficient and demand reduction resources that are cost-effective or less expensive than supply. With regard to the 2011 and 2012 statewide incentive pool allocations, the Department approved the PI payout allocations of the statewide incentive pool as proposed. The Department did not approve the Cost-Efficiency Metric for 2011 or 2012, finding that the PAs had not sufficiently demonstrated that the Cost Efficiency metric will cause the PAs to undertake actions that they otherwise would not have taken. The Department approved the electric pilot program budgets for 2011 and 2012, as well as the proposed 2011 and 2012 statewide EM&V plan. With regard to the AG's recommendations for additional documentation and/or the development of a common project screening tool, the Department did not adopt the recommendations because cost-effectiveness is reviewed at the program level and not the project level. The Department also allowed the PAs to claim incremental energy efficiency savings associated with the ARRA-funded residential gas program. For the Low-Income Single Family Retrofit and the Multi-Family Retrofit programs, the Department directed the PAs to track spending and savings associated with each pre-consolidated programs, but the Department concluded not require the PAs to report data on pre-consolidated programs.
5. Annual Reports	
a. 2010 Annual Reports - D.P.U. 11-63 through D.P.U 11-73, D.P.U. 11-126	
i. Gas Orders (2013)	
D.P.U. 11-64 NSTAR Gas Company D.P.U 11-65 Bay State Gas Company, d/b/a Columbia Gas of Massachusetts D.P.U. 11-66 New England Gas Company D.P.U. 11-67 The Berkshire Gas Company D.P.U. 11-70 Fitchburg Gas & Electric Light Company d/b/a Unitil D.P.U. 11-73 Boston Gas Company and Colonial Gas Company, d/b/a National Grid D.P.U. 11-126 Blackstone Gas Company	On November 21, 2013, the Department issued orders approving the 2010 Gas Energy Efficiency Annual Report, as outlined to the left. While the Department found certain programs were not cost-effective in program year 2010, the Department did find the decision to continue each such program as reasonable because of projections that such programs will be cost-effective in the future. The Department found that each company clearly presented and sufficiently explained with adequate supporting documentation their residential, low-income, and C&I EM&V program evaluations. The Department found that each company that requested may collect lost base revenues resulting from the savings and each Company shall submit all necessary documentation supporting the calculation of lost base revenues for program year 2010 in its next LDAF filing. The Department determined the companies have minimized its administrative costs to the fullest extent practicable. The Department found that the companies either met the statutory requirement to spend at least 20 percent of total program costs on low-income programs, or will work to improve delivery of low-income programs in future program years if the company did not meet the statutory minimum for low-income expenditures because it is first program year with the 20 percent requirement. The Department found each company used competitive procurement processes to the fullest extent practicable. Where requested, the Department found that each company may recover performance incentives. Additionally, the Department recognized that collaboration among PAs is beneficial, but stated that a PA must demonstrate its clear and distinct role in bringing about the desired outcome. The Department declined to address the recommended policy changes of the AG and DOER, as such changes were outside the scope of the annual report proceedings.

ii. Electric Orders (2014)	
D.P.U 11-63 NSTAR Electric Company D.P.U. 11-68 Cape Light Compact D.P.U. 11-69 Western Massachusetts Electric Company D.P.U. 11-71 Fitchburg Gas and Electric Light Company d/b/a Unitil D.P.U. 11-72 Massachusetts Electric Company and Nantucket Electric Company, d/b/a National Grid	On May 2, 2014, the Department issued orders approving the 2010 Energy Efficiency Annual Reports, as outlined to the left. The Department found that nearly all energy efficiency programs were cost-effective as implemented. In the instances where a program was not cost-effective, the Department found decisions to continue such programs reasonable because of projections that the programs would be cost effective going forward. The Department found that each company clearly presented and sufficiently explained with adequate supporting documentation their residential, low-income, and C&I EM&V program evaluations. The Department found that each company minimized its administrative costs to the fullest extent practicable. In instances where there was administrative cost overrun, the Department expects such Companies will continue to work to minimize its administrative costs. The company has met the statutory requirement to spend at least 10 percent of total program costs on low-income programs. The Department found each company used competitive procurement processes to the fullest extent practicable. Where requested, the Department found that each company may recover performance incentives. Additionally, the Department recognized that collaboration among PAs is beneficial, but stated that a PA must demonstrate its clear and distinct role in bringing about the desired outcome. The Department declined to address the recommended policy changes of the AG and DOER, as such changes were outside the scope of the Annual Report proceedings.
b. 2011 and 2012 Annual Reports (2014) - D.P.U. 12-51 through D.P.U 12-61; D.P.U. 13-110 through D.P.U. 13-122	
i. Gas	
D.P.U 12-51; D.P.U. 13-113 The Berkshire Gas Company D.P.U. 12-52; D.P.U. 13-112 Bay State Gas Company D.P.U. 12-53; D.P.U. 13-115 New England Gas Company D.P.U. 12-59; D.P.U. 13-114 Fitchburg Gas and Electric Light Company d/b/a Unitil Gas Company D.P.U. 13-110; D.P.U. 13-111 Blackstone Gas Company D.P.U. 12-56; D.P.U. 13-116 Boston Gas Company and	On November 26, 2014, the Department issued orders approving the 2011 and 2012 Gas Energy Efficiency Annual Reports, as outlined to the left. The Department found that each company's energy efficiency programs were cost effective as implemented for program years 2011 and 2012, and in instances where the program was not cost-effective, the Department determined that the decision to decision to continue these programs, as modified, was reasonable because of projections to be cost-effective going forward. The Department determined, after review of each company's invoices, that expenditures were reasonable and prudently incurred. The Department found each Company, that requested may collect lost base revenues resulting from the savings and shall submit all necessary documentation supporting the calculation of lost base revenues for program years 2011 and 2012, as applicable, in its next LDAF filing. The Department found that each company clearly presented and sufficiently explained with adequate supporting documentation their residential, low-income, and C&I EM&V program evaluations. The Department determined each company minimized its administrative costs to the fullest extent practicable. The Department found that the companies either met the statutory requirement to spend at least 20 percent of total program costs on low-income programs, or will work to improve participation in its low-income programs in future years. The Department found each company has used competitive procurement processes to the fullest extent practicable in program years 2011 and 2012. The Department approved the performance incentives requested by each company with some limited exceptions. The Department allowed the companies to include NEIs in the calculation of performance incentives, even though these NEI values were not originally planned. The Department declined to implement a uniform cap on administrative costs or a threshold for competitive procurement as requested by the AG because the Department evaluates performance on a company-by-company basis. The Department did not

Colonial Gas Company d/b/a National Grid D.P.U. 12-61; D.P.U. 13-117 NSTAR Gas Company	address DOER's issues regarding the consistency of nomenclature and reporting because such issues were outside the scope of the annual reports proceeding.
ii. Electric	
D.P.U. 12-54; D.P.U. 13-118 Cape Light Compact D.P.U. 12-55; D.P.U. 13-122 Western Massachusetts Electric Company D.P.U. 12-57; D.P.U. 13-120 Boston Gas Company and Colonial Gas Company d/b/a National Grid D.P.U. 12-58; D.P.U. 13-119 Fitchburg Gas and Electric Light Company d/b/a Unitil Gas Company D.P.U. 12-60; D.P.U. 13-121 NSTAR Electric Company	On December 19, 2014, the Department issued and order, approving the 2011 and 2012 Electric Energy Efficiency Annual Reports submitted, as outlined to the left. The Department found that each company's energy efficiency programs were cost effective as implemented for program years 2011 and 2012, and in instances where the program was not cost-effective, the Department determined that the decision to decision to continue such program as modified, was reasonable. The Department determined, after review of each company's invoices, that expenditures were reasonable and prudently incurred. The Department found that each company has demonstrated that actual savings, at the levels documented in annual reports, resulted from activities during program years 2011 and 2012. The Department found that each company clearly presented and sufficiently explained with adequate supporting documentation their residential, low-income, and C&I EM&V program evaluations. The Department determined each company minimized its administrative costs to the fullest extent practicable. The Department found that the companies met the statutory requirement to spend at least 10 percent of its energy efficiency budget on low-income programs. The Department found each company used competitive procurement processes to the fullest extent practicable in program years 2011 and 2012. The Department found that NEIs were properly included in calculation of performance incentive, including the NEIs for National Security, Refrigerator/Freezer Turn-in and Economic Development (although these three NEIs may not be included going forward). Where requested, the Department found that each company may recover performance incentives. The Department declined to implement a uniform cap on administrative costs or a threshold for competitive procurement as requested by the AG because the Department evaluates performance on a company-by-company basis. The Department did not address DOER's issues regarding the consistency of nomenclature and reporting because such issues were outside the scope of the annual reports proceeding.
6. Miscellaneous	
A. 2013-2015 Performance Metrics, D.P.U. 13-67 (2014)	In D.P.U. 13-67, the Department concluded that performance metrics are no longer a necessary component of the PAs' performance incentive mechanism and, therefore, did not approve the metrics for 2013. As noted in this Order and the 2013-2015 Order, the portion of the statewide incentive pool allocated to performance metrics will be reallocated to the savings and value components of the performance incentive mechanism. Therefore, the PI pool will remain intact and PAs retain the ability to earn the total amount of PI allocated to them. This Order states that metrics were originally intended to incentivize specific activities, but now that the GCA requires all available cost-effective energy efficiency, metrics would only seek to incentivize activities that are already required. This Order also states that the PAs do not need the guidance traditionally provided by metrics to the PAs, noting that the "Program Administrators, in conjunction with the Council and other stakeholders, have developed a comprehensive infrastructure to promote statewide energy

	efficiency program integration and continuous improvement in program delivery." D.P.U. 13-67, at 11. The Order specifically notes that the PA management committees and low-income best practices working group address program implementation barriers and foster communication with the Council and other stakeholders. The Department also found that "[n]egotiating, satisfying, and documenting performance metrics is costly and time consuming." Id. at 13, n.25. The Department found that such an investment of time and resources solely for the purpose of verifying metric performance is out of proportion with the potential benefit of metrics. Further, verifying performance of these metrics would divert PA and stakeholders focus from the successful implementation of the Three-Year Plans and is inconsistent with the Department's obligation to fulfill its oversight responsibilities in an administratively efficient and effective manner.
B. 2013 Avoided Energy Supply Component Study Energy Efficiency Updates, D.P.U. 14-05	Following discussions at Department technical sessions on application of the 2013 AESC, on January 27, 2014, the Department issued a Memorandum indicating that each PA shall submit: (i) individually, revised D.P.U. 08-50 tables with a revised benefit-cost ratio screening model to incorporate the AESC 2013 avoided cost factors for program years 2014 and 2015; and (ii) jointly, revised statewide electric and gas D.P.U. 08-50 tables with a revised performance incentive model to incorporate the AESC 2013 avoided cost factors. PAs submitted revised PA-specific and statewide electric and gas D.P.U. 08-50 tables and performance incentive models that incorporated the Avoided Energy Supply Cost study ("AESC") 2013 avoided cost factors on February 28, 2014. As part of the revised electric and gas performance incentive models, the PAs proposed to eliminate performance metrics as a component of the performance incentive mechanism, while retaining the savings and value mechanisms and their relative weights. Several parties, including DOER, the AG, LEAN, Environment Northeast (n/k/a Acadia Center), and the PAs filed comments in this docket.
C. Method for Calculating Avoided Costs of Complying with Global Warming Solutions Act, D.P.U. 14-86	On May 16, 2014, DEP and DOER (collectively "Petitioners") filed a joint petition requesting that the Department adopt a value for the avoided cost of complying with the Global Warming Solutions Act ("GWSA") calculated using a marginal abatement cost curve method. Method for Calculating Avoided Costs of Complying with Global Warming Solutions Act, D.P.U. 14-86. Following the filing of pre-filed testimony and discovery responses, evidentiary hearings were held on December 8 and 10, 2014. Intervenors filed initial briefs on December 31, 2014, and the Petitioners, after seeking an extension, filed their initial brief on January 23, 2015. Intervenors filed reply briefs on February 13, 2015. The PAs (except for the Compact and Blackstone Gas) filed a joint reply brief asking the Department to deny the petition on the grounds that the GWSA does not impose costs on the PAs or their customers, the petitioners did not sufficiently quantify the proposed GWSA compliance value and GHG reductions are an important byproduct, but are not a specific requirement, of energy efficiency programs implemented pursuant to the GCA. The Department later permitted additional discovery on the Petitioners with respect to a record request update filed with their initial brief. Briefs related to this issue were filed on April 10, 2015.

C. **<u>Statewide Energy Efficiency Data Tables</u>**

Energy Efficiency Tables

Overview

DPU 15-160 - 15-169

Statewide Electric
October 30, 2015

OVERVIEW

The following data tables provide a summary of the Program Administrator's benefits, costs, savings, and cost-effectiveness for 2013 through 2018. The 2013 through 2015 planned values are consistent with each Program Administrator's 2013-2015 Three-Year Plan. The 2013 and 2014 evaluated values are consistent with each Program Administrator's 2013 and 2014 Plan-Year Reports. The 2015 year-to-date data represents the most up-to-date estimated actual values available. Specifically, 2015 year-to-date costs and each Program Administrator's primary-fuel savings are estimated actuals through August 2015, while the 2015 year-to-date benefits and each Program Administrator's non-primary-fuel savings are estimated actuals through June 2015 consistent with the 2015 Second Quarterly Report. The 2016-2018 planned values are consistent with each Program Administrator's 2016-2018 Three-Year Plan.

The data included in these tables is based on other supporting models. The primary supporting models used by the Program Administrators are the Benefit-Cost Screening model, each Program Administrator's EES calculation support documents, and the Performance Incentive model. These exhibits should be referenced when looking for more detailed analyses, such as measure level detail and EES calculations. High-level summaries for each of these models are provided below, along with information on plan details that are not summarized in the following plan tables.

BENEFIT-COST SCREENING MODEL

The Benefit-Cost Screening model provides measure level savings and benefits. This model uses the avoided cost values from the 2015 Avoided Energy Supply Cost study prepared by Tabors Caramanis Rudkevich.

EES CALCULATIONS

Each Program Administrator's Energy Efficiency Surcharge analysis provides supporting information on the EES rates proposed for effect in 2016-2018, including how the rates are calculated for each customer sector, and how revenue is collected from each customer sector.

PERFORMANCE INCENTIVE MODEL

The Performance Incentive model filed as part of the Joint Statewide Three-Year Plan provides support for the performance incentive dollars proposed for collection by the Program Administrator. Note that performance incentives are not applicable to the Cape Light Compact.

EM&V ACTIVITIES

The Evaluation, Monitoring & Verification Section of the Joint Statewide Three-Year Plan describes in detail the EM&V activities planned for 2016-2018.

OTHER FUNDING

For the electric Program Administrators, "Other Funding" are those funds, private or public utility administered or otherwise, that may be available for energy efficiency or demand resources and do not include SBC Funds, FCM Revenue, or RGGI Proceeds. The electric Program Administrators assume no other funding sources for 2016-2018.

Notes:

On September 29, 2015, the Department of Public Utilities issued a Hearing Officer Memorandum from Jeffrey Leupold identifying additional information that the Program Administrators must include in their respective 2016-2018 plan filings (revised October 2, 2015). The above tables provide the information requested in 2.a through 2.e of that Memorandum. Note that 2.c, Resource Benefits Per Program Costs, is also provided on the Budget Summary table (Table IV.C.1).

*Note that performance incentives and participant costs are not available for 2015 at this time. Therefore, the 2015 YTD table analyzes the Program Administrator's costs in 2013$, rather than the TRC Costs in 2013$.

IV.B. Electric PA Funding Sources

1. Summary Table

Statewide Electric

October 30, 2015

2016 Total Electric Funding Sources

Notes:

For supporting information on SBC collections, see Table IV.B.3.1.
For supporting information on FCM revenue, see Table IV.B.3.2.
For supporting information on RGGI proceeds, see Table IV.B.3.3.
For supporting information on other funding see, Additional Sources of Information.
For supporting information on estimated carryover, see Table IV.B.3.5.
For supporting information on the EERF, see Table IV.B.3.6.
Funding sources for each year in 2016-2018 are represented in nominal dollars (2016$, 2017$, 2018$).

IV.B. Electric PA Funding Sources

3.1. System Benefit Charge Funds

DPU 15-160 - 15-169

Statewide Electric

Exh. 1, Appendix C

October 30, 2015

H.O.s Leupold and Hale

2016 System Benefit Charge Collections				
Sector	Sales (kWh)	SBC Charge ($/kWh)	Collections ($)	Collections (% of Total)

Grand Total	**46,571,797,549**		**116,429,494**	**100%**

2016-2018 System Benefit Charge Collections				
Sector	Sales (kWh)	SBC Charge ($/kWh)	Collections ($)	Collections (% of Total)
A - Residential	46,526,651,409	0.0025	116,316,629	33.2%
B - Low-Income	6,454,903,670	0.0025	16,137,259	4.6%
C - Commercial & Industrial	87,336,260,914	0.0025	218,340,652	62.2%
Grand Total	**140,317,815,992**		**350,794,540**	**100%**

Notes:

Collections are the sales multiplied by the SBC charge.

Consistent with the Department's Energy Efficiency Guidelines § 3.2.1.2, electric Program Administrators allocate revenue from the System Benefits Charge to the residential, low-income, and commercial and industrial customer sectors in proportion to the sector’s kilowatt-hour consumption.

2016 Forward Capacity Market Revenue

Notes:

Revenue is allocated across customer sector based on percentage allocation of kWh sales. See Table IV.B.3.1.

Each Program Administrator completes this table according to how their FCM resources have cleared in each auction.

IV.B. Electric PA Funding Sources

3.3. RGGI Proceeds

Statewide Electric

October 30, 2015

Forecasted Massachusetts RGGI CO_2 Allowances and Proceeds

Annual Allowance Base Budget	**2015**	**2016**	**2017**	**2018**
Allowance Budget, based on the RGGI Adjusted Cap	10,591,981	10,238,857	10,079,934	9,739,612
Voluntary Renewable Energy (VRE)	25,214	20,472	17,637	29,883
Final Allowances Available for Auction	10,566,767	10,218,385	10,062,297	9,709,729
2015 Auction Results	**Auction 27**	**Auction 28**	**Auction 29**	
Allowances Sold	2,641,692	2,641,692	4,255,660	
Clearing Price ($/allowance)	$ 5.41	$ 5.50	$ 6.02	
Proceeds from Allowances Sold	$ 14,291,554	$ 14,529,306	$ 25,619,073	
Forecasted Proceeds	**2015**	**2016**	**2017**	**2018**
Remaining Allowance Budget	1,027,723	10,218,385	10,062,297	9,709,729
Forward Price, based on IPM 91 Cap ($/allowance) (2010$)	$ 5.44	$ 6.76	$ 7.52	$ 7.52
Forward Price, based on IPM 91 Cap ($/allowance) (nominal dollars)	$ 6.04	$ 7.68	$ 8.74	$ 8.94
Proceeds from Remaining Allowance Budget	$ 6,207,447	$ 78,477,197	$ 87,944,476	$ 86,804,977
Cost Containment Reserve (CCR)	$ -	$ -	$ -	$ -
Total Massachusetts RGGI Proceeds	**$ 60,647,380**	**$ 78,477,197**	**$ 87,944,476**	**$ 86,804,977**

Notes:

The information in the above table was provided to the Massachusetts Program Administrators by the Massachusetts Department of Energy Resources. The forecasts are based on the modeling tool used to forecast RGGI, Integrated Planning Model (IPM). The 91 Cap refers to the 2014 total RGGI Cap of 91 million allowances for all RGGI states. The RGGI Adjusted Cap accounts for banked allowances. For more information, refer to https://www.rggi.org/design/overview/cap.

The Forward Prices from the IPM results were converted from 2010$ to nominal dollars (2016$, 2017$, 2018$) using the consumer price index (CPI) for 2010 through 2015, and the ten year average CPI.

Allocation of Forecasted Massachusetts RGGI Proceeds

Allocation of Total Massachusetts RGGI Proceeds	**2015**	**2016**	**2017**	**2018**	**Total**
DOER's RGGI Administration Costs (about 6% of total proceeds)	$ 3,790,461	$ 4,904,825	$ 5,496,530	$ 5,425,311	
Remaining Proceeds After Allocation to DOER	$ 56,856,919	$ 73,572,372	$ 82,447,946	$ 81,379,666	
80% of Remaining Proceeds Allocated to Energy Efficiency	$ 45,485,535	$ 58,857,898	$ 65,958,357	$ 65,103,733	
EEAC Consultants Budget, based on 2015 EEAC Consultant Budget	$ 560,000	$ 560,000	$ 560,000	$ 560,000	
Proceeds Allocated to Program Administrators	$ 44,925,535	$ 58,297,898	$ 65,398,357	$ 64,543,733	
PA Proceeds Received in 2016 (last 2015 auction, first three 2016 auctions)	$ 11,231,384	$ 43,723,423			$ 54,954,807
PA Proceeds Received in 2017 (last 2016 auction, first three 2017 auctions)		$ 14,574,474	$ 49,048,768		$ 63,623,242
PA Proceeds Received in 2018 (last 2017 auction, first three 2018 auctions)			$ 16,349,589	$ 48,407,800	$ 64,757,389
Allocation of Proceeds to Statewide Electric	**2015**	**2016**	**2017**	**2018**	**Total**
Allocation to Statewide Electric, based on Percentage of Statewide Customers	100.00%	100.00%	100.00%	100.00%	
Statewide Electric's Forecasted Proceeds	$ 44,925,535	$ 58,297,898	$ 65,398,357	$ 64,543,733	
Proceeds Received in 2016 (last 2015 auction, first three 2016 auctions)	$ 11,231,384	$ 43,723,423			$ 54,954,807
Proceeds Received in 2017 (last 2016 auction, first three 2017 auctions)		$ 14,574,474	$ 49,048,768		$ 63,623,242
Proceeds Received in 2018 (last 2017 auction, first three 2018 auctions)			$ 16,349,589	$ 48,407,800	$ 64,757,389

Notes:

There is an approximately three-month lag between the completion of an auction and receipt of proceeds from that auction by the Program Administrators. The Program Administrators have accounted for this time lag in the table above to better reflect calendar-year energy efficiency revenue.

Program Administrator Allocation of RGGI Proceeds to Customer Sectors

Sector	**2016**		**2017**		**2018**		**TOTAL**	
	RGGI Funds	**% of Total RGGI Funds**	**RGGI Funds**	**% of Total RGGI Funds**	**RGGI Funds**	**% of Total RGGI Funds**	**RGGI Funds**	**% of Total RGGI Funds**

3.5. Carryover

Statewide Electric
October 30, 2015

Estimated 2015 Carryover into 2016

Sector	2013-2015 Planned		2013-2015 Actual		2013-2015 Beginning Balance (Carryover from 2012)	2015 Ending Balance w/o Interest (Carryover from 2015)	Interest on Carryover	Total 2015 Carryover into 2016	Total 2015 Carryover into 2017	Total 2015 Carryover into 2018
	Funding	Budget	Revenue	Expenditures						
A - Residential	$ 549,502,015	$ 528,845,016	$ 641,748,477	$ 629,904,107	$ (48,367,510)	$ (7,549,001)	$ (709,264)	$ (20,720,107)	$ (8,257,664)	$ (8,257,664)
B - Low-Income	$ 98,219,924	$ 170,815,303	$ 182,993,838	$ 178,886,813	$ (10,269,444)	$ 881,972	$ (157,327)	$ (946,419)	$ (2,686,119)	$ (2,686,119)
C - Commercial & Industrial	$ 902,746,139	$ 942,911,857	$ 843,513,684	$ 817,190,685	$ 37,908,484	$ 51,310,509	$ 300,805	$ 35,474,166	$ 14,525,319	$ 14,525,319
Grand Total	**$ 1,550,468,077**	**$ 1,642,572,175**	**$ 1,668,255,998**	**$ 1,625,981,605**	**$ (20,728,470)**	**$ 44,643,480**	**$ (565,785)**	**$ 13,807,640**	**$ 3,581,536**	**$ 3,581,536**

Notes:
The above table provides an estimate of the carryover from the 2013-2015 Three-Year Plan. The Program Administrator's actual 2013-2015 carryover for collection in 2016 will be presented in its Energy Efficiency Reconciliation Factor filing.

The 2015 Carryover into 2016 includes carryover from the 2010-2012 plan into the 2013-2015 plan, as well as the ending balance from the 2013-2015 plan.
A positive carryover value indicates an under-spending/over-recovery, while a negative carryover value indicates an over-spending/under-recovery.
2015 Actuals are projected through the end of the year.
The 2015 Carryover into 2017 and 2018 is intended to be completed by National Grid only.

Notes:

For supporting information on the Total Program Administrator Budget, which includes Performance Incentives, see Table IV.C.1.

EERF Revenue Required = Total Program Administrator Budget + Lost Base Revenue - (SBC + FCM + RGGI + Other Funds + Carryover Funds)

For supporting information on the EERF calculation, refer to the Program Administrator's EERF exhibit.

Eversource (NSTAR) is the only electric Program Administrator that collects Lost Base Revenue (LBR). All other electric Program Administrators except for the Cape Light Compact have a revenue decoupling mechanism in place and do not estimate LBR. LBR is not applicable to the Cape Light Compact.

Notes:
Budgets for each year in 2016-2018 are represented in nominal dollars (2016$, 2017$, 2018$).
Refer to common definitions for allocation of costs.
The electric Program Administrators do not budget for the EEAC Consultant fees, as these costs are paid by the DOER using RGGI proceeds.

Notes:

2013-2015 planned values are from the Program Administrators' 2013-2015 Three-Year Plans, in nominal dollars (2013$, 2014$, 2015$).

2013 evaluated values are from the Program Administrator's 2013 Plan Year Report, D.P.U. , in 2013$.

2014 evaluated values are from the Program Administrator's 2014 Plan Year Report, D.P.U. , in 2014$.

2015 YTD values are estimated actual cost through August 2015, in 2015$.

For supporting information on the 2016-2018 values, see Table IV.C.1. Budgets for each year in 2016-2018 are represented in nominal dollars (2016$, 2017$, 2018$).

The Program Administrators have better aligned cost allocations across Program Administrators for the 2016-2018 Three-Year Plan, consistent with the Department's directives in the 2013-2015 Three-Year Plan Order (January 31, 2013). As a result, historical budget categories may not be directly comparable for each Program Administrator.

Notes:

The Benefit-Cost Ratio is the Total TRC Test Benefits divided by the Total TRC Test Costs.
The Net Benefits are the Total TRC Test Benefits minus the Total TRC Test Costs.
For supporting information on the Total TRC Test Benefits, see Table IV.D.3.1.i.
For supporting information on the Total Program Costs, see Table IV.C.1.
For supporting information on the Performance Incentive, refer to the Performance Incentive Model.
The Total TRC Costs are the sum of the Total Program Costs, Performance Incentives, and Participant Costs.

Notes:

2013 values are from the Program Administrator's 2013 Plan Year Report D.P.U. .

2014 values are from the Program Administrator's 2014 Plan Year Report, D.P.U. .

2015 values are from the Program Administrator's 2013-2015 Three-Year Plan, D.P.U. .

For supporting information on the 2016-2018 values, see Table IV.D.3.2.i.

The Progam Administrators have developed new participant definitions through the common assumptions working group for the 2016-2018 Three-Year Plan. Historical participant numbers may not be comparable.

IV.D. Cost-Effectiveness

3.3.iii. T&D Avoided Costs Comparison Table - Three Year Plan vs. Previous Years

Statewide Electric
October 30, 2015

NSTAR & CLC Avoided Cost Factors ($/kW)		
Year	Distribution	Transmission
2013	$68.79	$21.00
2014	$70.32	$21.47
2015	$71.88	$21.94
2016	$122.34	$36.53
2017	$122.34	$36.53
2018	$122.34	$36.53

WMECO Avoided Cost Factors ($/kW)		
Year	Distribution	Transmission
2013	$76.08	$22.27
2014	$77.77	$22.76
2015	$79.49	$23.27
2016	$56.02	$0.00
2017	$56.02	$0.00
2018	$56.02	$0.00

National Grid Avoided Cost Factors ($/kW)		
Year	Distribution	Transmission
2013	$111.37	$20.62
2014	$111.37	$20.62
2015	$111.37	$20.62
2016	$82.57	$10.52
2017	$82.57	$10.52
2018	$82.57	$10.52

Unitil Avoided Cost Factors ($/kW)		
Year	Distribution	Transmission
2013	$171.15	$0.00
2014	$174.95	$0.00
2015	$178.84	$0.00
2016	$182.58	$0.00
2017	$182.58	$0.00
2018	$182.58	$0.00

Notes:
2013 values are from the Program Administrator's 2013 Plan Year Report D.P.U. , in 2013$.
2014 values are from the Program Administrator's 2014 Plan Year Report, D.P.U. , in 2013$.
2015 values are from the Program Administrator's 2013-2015 Three-Year Plan, D.P.U. , in 2013$.
For supporting information on the 2016-2018 values, refer to the Program Administrator's Benefit-Cost Screening Model. The 2016-2018 values are in 2016$.

IV.H. Performance Incentive

1. Summary Table

Statewide Electric
October 30, 2015

DPU 15-160 - 15-169
Exh. 1, Appendix C
H.O.s Leupold and Hale

2016 Performance Incentives				
Sector	**After-Tax Performance Incentives**	**% of Program Costs**	**Pre-Tax Performance Incentives**	**% of Program Costs**
Residential	7,819,374	3.0%	12,901,780	4.9%
Low-Income	932,738	1.4%	1,542,230	2.3%
Commercial & Industrial	11,199,531	4.2%	18,507,927	6.9%
Grand Total	**19,951,644**	**3.3%**	**32,951,937**	**5.5%**

2017 Performance Incentives				
Sector	**After-Tax Performance Incentives**	**% of Program Costs**	**Pre-Tax Performance Incentives**	**% of Program Costs**
Residential	7,782,160	2.9%	12,843,417	4.7%
Low-Income	948,186	1.4%	1,567,953	2.3%
Commercial & Industrial	11,907,451	4.2%	19,671,915	7.0%
Grand Total	**20,637,797**	**3.3%**	**34,083,285**	**5.5%**

2018 Performance Incentives				
Sector	**After-Tax Performance Incentives**	**% of Program Costs**	**Pre-Tax Performance Incentives**	**% of Program Costs**
Residential	7,672,454	2.8%	12,663,459	4.6%
Low-Income	981,610	1.4%	1,623,166	2.4%
Commercial & Industrial	12,871,775	4.4%	21,261,737	7.2%
Grand Total	**21,525,839**	**3.4%**	**35,548,361**	**5.6%**

2016-2018 Performance Incentives				
Sector	**After-Tax Performance Incentives**	**% of Program Costs**	**Pre-Tax Performance Incentives**	**% of Program Costs**
Residential	23,273,988	2.9%	38,408,655	4.8%
Low-Income	2,862,535	1.4%	4,733,348	2.3%
Commercial & Industrial	35,978,757	4.2%	59,441,579	7.0%
Grand Total	**62,115,280**	**3.3%**	**102,583,583**	**5.5%**

Notes:
Performance Incentives for each year in 2016-2018 are represented in nominal dollars (2016$, 2017$, 2018$).
For supporting information on the Performance Incentive, refer to the Performance Incentive Model.
Performance Incentives are not applicable to the Cape Light Compact.

V.B. Allocation of Funds

1. Low-Income Minimum

Statewide Electric
October 30, 2015

DPU 15-160 - 15-169
Exh. 1, Appendix C
H.O.s Leupold and Hale

2016 Sector Cost Allocation		
Sector	**Program Budget**	
	($)	**(% of Total)**
A - Residential	261,977,427	43.8%
B - Low-Income	67,526,840	11.3%
C - Commercial & Industrial	269,276,486	45.0%
Grand Total	**598,780,754**	**100%**

2017 Sector Cost Allocation		
Sector	**Program Budget**	
	($)	**(% of Total)**
A - Residential	270,415,016	43.5%
B - Low-Income	67,979,499	10.9%
C - Commercial & Industrial	282,846,041	45.5%
Grand Total	**621,240,557**	**100%**

2018 Sector Cost Allocation		
Sector	**Program Budget**	
	($)	**(% of Total)**
A - Residential	275,247,527	43.2%
B - Low-Income	67,730,777	10.6%
C - Commercial & Industrial	294,576,727	46.2%
Grand Total	**637,555,030**	**100%**

2016-2018 Sector Cost Allocation		
Sector	**Program Budget**	
	($)	**(% of Total)**
A - Residential	807,639,970	43.5%
B - Low-Income	203,237,116	10.9%
C - Commercial & Industrial	846,699,254	45.6%
Grand Total	**1,857,576,341**	**100%**

Notes:
General Laws c. 25, § 19(c) requires that at least 10 percent of the amount expended for electric energy efficiency programs and at least 20 percent of the amount expended for gas energy efficiency programs be spent on low-income programs.

V.D. Outsourced/Competitively Procured Services

Grand Total		
Total Cost of Services	507,105,518	100%
In-House Activities	112,986,348	22%
Outsourced Activities	394,119,170	78%
Competitively Procured	319,655,300	63%
Non-Competitively Procured	74,463,870	15%

Notes:
General Laws c. 25, § 19(b) requires the Department to ensure that energy efficiency programs use competitive procurement processes to the fullest extent practicable.
Costs for the Competitively Procured Services analysis include Program Planning and Administration; Marketing and Advertising; Sales, Technical Assistance & Training; and Evaluation and Market Research.
Costs for each year in 2016-2018 are represented in nominal dollars (2016$, 2017$, 2018$).

Notes:
General Laws c. 25, § 19(b) requires the Department to ensure that energy efficiency programs use competitive procurement processes to the fullest extent practicable.
Costs for the Competitively Procured Services analysis include Program Planning and Administration; Marketing and Advertising; Sales, Technical Assistance & Training; and Evaluation and Market Research.
The 2013-2015 costs are from the Program Administrator's 2013-2015 Three-Year Plan, D.P.U. , in nominal dollars (2013$, 2014$, 2015$).
For supporting information on the 2016-2018 values, see Table V.D.1. Costs for each year in 2016-2018 are represented in nominal dollars (2016$, 2017$, 2018$).

VII. Appendix

GHG reductions are provided for information purposes only. They are not included in the TRC test.

Notes:

The Program Administrators are working with DEP to determine the best method for properly and precisely capturing the full impact of energy efficiency measures on GHG emissions. As part of this process, the Program Administrators have included this additional table on greenhouse gas reductions, based on continuing discussions with the DEP. These reductions are calculated using factors proposed by DEP, which are based on adjusted gross annual electric energy, natural gas, and oil savings. The Program Administrators look forward to discussing these proposed factors with DEP and are committed to ensuring that the full impact of energy efficiency measures on GHG emissions are captured.

15	**Commercial & Industrial (total)**	**39,887,335**	**23,259,384**	**63,146,720**
16	**GRAND TOTAL**	**$ 53,959,874**	**$ 31,436,282**	**$ 85,396,156**

Notes:

(1) Represents total incremental savings to the base year 2007 for each period, net of expired savings

(2) Monthly as Installed

(3) (D)+(E)

(4) LBR rates are in 2014 dollars, which will be reconciled in the EERF to the actual LBR rate for each year.

(5) (F)*(G)

(6) (D)+(E)+(F)

(7) (H)*(I)

(8) This amount representes the full annualized rate of LBR that would be collected in 2017, however the Company is only proposing to collect LBR until the time Department approved decoupled rates would go into effect.

(9) Amount adjusted for 6 months of savings, which assumes NSTAR Electric is operating under decoupled rates by July 1, 2017. If the Company is not operating under decoupled rates by July 1, 2017, the Company will collect LBR until the effective date of the decoupled rates consistent with the Department's rulings in D.P.U. 10-06-A through D.P.U. 10-09-A. LBR would equate to approximately $30m through the end of 2017, and $70m through the end of 2018.

OVERVIEW

The following data tables provide a summary of the Program Administrator's benefits, costs, savings, and cost-effectiveness for 2013 through 2018. The 2013 through 2015 planned values are consistent with each Program Administrator's 2013-2015 Three-Year Plan. The 2013 and 2014 evaluated values are consistent with each Program Administrator's 2013 and 2014 Plan-Year Reports. The 2015 year-to-date data represents the most up-to-date estimated actual values available. Specifically, 2015 year-to-date costs and each Program Administrator's primary-fuel savings are estimated actuals through August 2015, while the 2015 year-to-date benefits and each Program Administrator's non-primary-fuel savings are estimated actuals through June 2015 consistent with the 2015 Second Quarterly Report. The 2016-2018 planned values are consistent with each Program Administrator's 2016-2018 Three-Year Plan.

The data included in these tables is based on other supporting models. The primary supporting models used by the Program Administrators are the Benefit-Cost Screening model, each Program Administrator's EES calculation support documents, and the Performance Incentive model. These exhibits should be referenced when looking for more detailed analyses, such as measure level detail and EES calculations. High-level summaries for each of these models are provided below, along with information on plan details that are not summarized in the following plan tables.

BENEFIT-COST SCREENING MODEL

The Benefit-Cost Screening model provides measure level savings and benefits. This model uses the avoided cost values from the 2015 Avoided Energy Supply Cost study prepared by Tabors Caramanis Rudkevich.

EES CALCULATIONS

Each Program Administrator's Energy Efficiency Surcharge analysis provides supporting information on the EES rates proposed for effect in 2016-2018, including how the rates are calculated for each customer sector, and how revenue is collected from each customer sector.

PERFORMANCE INCENTIVE MODEL

The Performance Incentive model filed as part of the Joint Statewide Three-Year Plan provides support for the performance incentive dollars proposed for collection by the Program Administrator. Note that performance incentives are not applicable to the Cape Light Compact.

EM&V ACTIVITIES

The Evaluation, Monitoring & Verification Section of the Joint Statewide Three-Year Plan describes in detail the EM&V activities planned for 2016-2018.

OTHER FUNDING

For the electric Program Administrators, "Other Funding" are those funds, private or public utility administered or otherwise, that may be available for energy efficiency or demand resources and do not include SBC Funds, FCM Revenue, or RGGI Proceeds. The electric Program Administrators assume no other funding sources for 2016-2018.

Notes:

On September 29, 2015, the Department of Public Utilities issued a Hearing Officer Memorandum from Jeffrey Leupold identifying additional information that the Program Administrators must include in their respective 2016-2018 plan filings (revised October 2, 2015). The above tables provide the information requested in 2.a through 2.e of that Memorandum. Note that 2.c, Resource Benefits Per Program Costs, is also provided on the Budget Summary table (Table IV.C.1).

Note that performance incentives and participant costs are not available for 2015 at this time. Therefore, the 2015 YTD table analyzes the Program Administrator's costs in 2013$, rather than the TRC Costs in 2013$.

B - Low-Income	44,988,485	834,280		45,822,765
C - Commercial & Industrial	44,893,412	2,048,479		46,941,890
Grand Total	**221,138,405**	**6,103,984**	**-**	**227,242,389**

2018 Gas Ratepayer Funds				
Sector	**Total Program Costs**	**Performance Incentives**	**Lost Base Revenues**	**Total Ratepayer Funds**
A - Residential	135,468,460	3,400,695		138,869,155
B - Low-Income	45,635,214	868,487		46,503,701
C - Commercial & Industrial	46,442,384	2,122,085		48,564,469
Grand Total	**227,546,058**	**6,391,266**	**-**	**233,937,325**

2016-2018 Gas Ratepayer Funds				
Sector	**Total Program Costs**	**Performance Incentives**	**Lost Base Revenues**	**Total Ratepayer Funds**
A - Residential	395,105,545	9,772,790	-	404,878,335
B - Low-Income	135,176,393	2,511,460	-	137,687,853
C - Commercial & Industrial	135,271,340	6,179,663	-	141,451,003
Grand Total	**665,553,278**	**18,463,913**	**-**	**684,017,191**

Notes:
Ratepayer funds for each year in 2016-2018 are represented in nominal dollars (2016$, 2017$, 2018$).
Berkshire Gas is the only gas Program Administrator that will collect Lost Base Revenue (LBR) during the 2016-2018 term, assuming the Department approves NSTAR Gas Company d/b/a/ Eversource Energy's petition for a decoupling plan in D.P.U. 14-15. All other gas Program Administrators have a revenue decoupling mechanism in place and do not estimate LBR.

IV.C. Program Administrator Budgets

1. Summary Table

Statewide Gas

October 30, 2015

2016 Program Administrator Budget										
Program	Program Costs						Performance Incentive	Total Program Administrator Budget	Program Cost per Participant	Energy Benefit per Program Cost

Notes:

Budgets for each year in 2016-2018 are represented in nominal dollars (2016$, 2017$, 2018$).

Refer to common definitions for allocation of costs.

Notes:

2013-2015 planned values are from the Program Administrator's 2013-2015 Three-Year Plan, D.P.U. , in nominal dollars (2013$, 2014$, 2015$).

2013 evaluated values are from the Program Administrator's 2013 Plan Year Report, D.P.U. , in 2013$.

2014 evaluated values are from the Program Administrator's 2014 Plan Year Report, D.P.U. , in 2014$.

2015 YTD values are estimated actual cost through August 2015, in 2015$.

For supporting information on the 2016-2018 values, see Table IV.C.1. Budgets for each year in 2016-2018 are represented in nominal dollars (2016$, 2017$, 2018$).

The Program Administrators have better aligned cost allocations across Program Administrators for the 2016-2018 Three-Year Plan, consistent with the Department's directives in the 2013-2015 Three-Year Plan Order (January 31, 2013). As a result, historical budget categories may not be directly comparable for each Program Administrator.

IV.D. Cost-Effectiveness

Notes:

The Benefit-Cost Ratio is the Total TRC Test Benefits divided by the Total TRC Test Costs.
The Net Benefits are the Total TRC Test Benefits minus the Total TRC Test Costs.
For supporting information on the Total TRC Test Benefits, see Table IV.D.3.1.i.
For supporting information on the Total Program Costs, see Table IV.C.1.
For supporting information on the Performance Incentive, refer to the Performance Incentive Model.
The Total TRC Costs are the sum of the Total Program Costs, Performance Incentives, and Participant Costs.

Notes:

2013 values are from the Program Administrator's 2013 Plan Year Report D.P.U. .

2014 values are from the Program Administrator's 2014 Plan Year Report, D.P.U. .

2015 values are from the Program Administrator's 2013-2015 Three-Year Plan, D.P.U. .

For supporting information on the 2016-2018 values, see Table IV.D.3.2.i.

The Progam Administrators have developed new participant definitions through the common assumptions working group for the 2016-2018 Three-Year Plan. Historical participant numbers may not be comparable.

Sector	Program Budget	
	($)	(% of Total)
A - Residential	395,105,545	59.4%
B - Low-Income	135,176,393	20.3%
C - Commercial & Industrial	135,271,340	20.3%
Grand Total	**665,553,278**	**100%**

Notes:
General Laws c. 25, § 19(c) requires that at least 10 percent of the amount expended for electric energy efficiency programs and at least 20 percent of the amount expended for gas energy efficiency programs be spent on low-income programs.

Notes:
General Laws c. 25, § 19(b) requires the Department to ensure that energy efficiency programs use competitive procurement processes to the fullest extent practicable.
Costs for the Competitively Procured Services analysis include Program Planning and Administration; Marketing and Advertising; Sales, Technical Assistance & Training; and Evaluation and Market Research.
The 2013-2015 costs are from the Program Administrator's 2013-2015 Three-Year Plan, D.P.U. , in nominal dollars (2013$, 2014$, 2015$).
For supporting information on the 2016-2018 values, see Table V.D.1. Costs for each year in 2016-2018 are represented in nominal dollars (2016$, 2017$, 2018$).

VII. Appendix

GHG reductions are provided for information purposes only. They are not included in the TRC test.

Notes:
The Program Administrators are working with DEP to determine the best method for properly and precisely capturing the full impact of energy efficiency measures on GHG emissions. As part of this process, the Program Administrators have included this additional table on greenhouse gas reductions, based on continuing discussions with the DEP. These reductions are calculated using factors proposed by DEP, which are based on adjusted gross annual electric energy, natural gas, and oil savings. The Program Administrators look forward to discussing these proposed factors with DEP and are committed to ensuring that the full impact of energy efficiency measures on GHG emissions are captured.

Exemplary - Cap	*%*			125%

These tables represent only PA energy efficiency costs; they do not include additional cost for new demand programs. The PAs will provide an updated set of detailed energy efficiency data tables consistent with and derived from this Term Sheet in the October 30, 2015 final Plan. These data tables provide extensive additional information such as benefits, program-specific budgets, MW savings, etc. Performance incentives are not applicable to Cape Light Compact.

This Term Sheet outlines savings and budget terms that have been negotiated, with supporting details to be provided in the Plan. This framework is designed with an expectation of a detailed review of the full Three-Year Plan. The costs to achieve and other terms in this Term Sheet are negotiated with the understanding that the final Plan will reflect the majority of Council input and recommendations from the July 21, 2015 resolution and that all recommendations adopted by the PAs are able to be accommodated consistent with the overall provisions of this Term Sheet.

Additional Commitments

The following 2016-2018 Plan priorities of the Council will be specifically addressed in the final Plan:

1) **New Demand Reduction/Peak Reduction Efforts**.

The PAs and the Council recognize the growing economic importance of achieving demand reduction goals and mitigating winter and summer peaks. The Term Sheet does not include targets for potential new statewide summer and winter demand peak reduction initiatives, and does not reflect costs, benefits or incentives associated with such initiatives. Subject to open meeting law requirements, PA representatives will work with a small Demand Savings Group that includes the DOER, the Attorney General's Office, the Low-Income Energy Affordability Network, interested expert and qualified stakeholders and the Council's consultants to explore approaches to cost-effective new demand reduction/peak reduction electric and gas initiatives. This Demand Savings Group will be addressing challenging and important matters, and all parties are committed to the successful development and actual implementation in-the-field during the 2016-2018 Plan period of new demand/peak reduction initiatives. To ensure that this in-the-field implementation goal is reached, the PAs will provide a report to the Council setting forth the specific scope, tasks, and detailed timelines for this group by the end of Q1 2016. This report will also provide an anticipated, high-level in-the-field deployment schedule for 2016-2018 based upon the then most current information. Deployment in-the-field will be subject to approval by the Department of Public Utilities and confirmation of cost-effectiveness. The PAs will also provide a report to the Council on the ongoing "super peak" avoided cost study on or before December 31, 2015 (if that study is delayed, this PA deliverable date will be appropriately adjusted).[1]

2) **Continued Commitment to Innovation and Technology**.

The Council and the PAs agree on the importance of implementation of new technologies and program approaches. The PAs are committed to increasingly develop and deploy new technologies, delivery models and business strategies with performance-based results that are appropriate for the customers and that are proven to be cost-effective. The Plan will reflect a continuous commitment by the PAs to exploring and adopting cost-effective innovations and new technologies in the residential, low-income and C&I sectors. In addition to specific efforts identified in the Plan, the PAs commit to continuous collaboration on innovation, including appropriate program updates and evaluation efforts with the Council.

[1] CLC reserves its right to raise issues at any time with either the Demand Savings Group or the EEAC generally regarding its unique role as a municipal aggregator that may affect its ability to fully participate in the development and implementation of demand/peak reduction initiatives.

3) **Contractor Engagement**.

The Council and the PAs recognize that the successful implementation of the Three-Year Plan requires an engaged contractor community. The PAs and the Council will collaborate to identify opportunities to continue to maximize the impact of the contractor community in order to maintain high quality, cost-effective/efficient, high impact programs and increase penetration and success in new sectors. As part of this effort, the PAs will participate in a new Residential Contractor engagement effort to be convened by the DOER. PAs will participate in residential program related topics as appropriate, which may include how residential program contractors can be most effectively engaged in the programs, quality assurance/quality control related topics, appropriate data collection and analysis, and suggestions from the contractor community and the PAs for enhancements and improvements. This DOER effort is not in replacement of the ongoing contractor Best Practices group and does not constitute the formation of a new regulatory or adjudicatory body. The PAs will continue to have the right and responsibility to require contractor engagement and contract terms that protect customers consistent with their corporate/institutional quality and safety standards.

NOTES

- **Core Electric Terms**. Annual savings goal for 2016-2018 of 2.93% of retail sales (based upon April 2015 sales forecast). At least 40.3M MWh lifetime savings goal, with lifetime savings goal showing year-over-year growth from 2016-2018. Annual cost-to-achieve budget for 2016-2018 of $0.453 or below. Performance incentive pool of $100M at design, with threshold of 75% and cap of 125%.[2]
- **Core Gas Terms**. Annual savings goal for 2016-2018 of 1.24% of retail sales (based upon April 2015 sales forecast). At least 1.1B therms lifetime savings goal, with lifetime and annual savings goals showing year-over-year growth for 2016-2018. Annual cost-to-achieve budget for 2016-2018 of $7.81 or below. Performance incentive pool of $18M at design, with threshold of 75% and cap of 125%.[3]
- **Confirmation**. All savings and budget figures are subject to confirmation and quality control checks as the PAs develop detailed tables consistent with this term sheet. Final savings and budget numbers may be slightly higher or lower than these values, but all within a reasonable, non-material bandwidth that does not reduce the overall statewide annual savings target. Retail sales projections reflect forecasts that were available in April 2015 and may not reflect each PA's most up-to-date sales forecast; forecasts are updated periodically.

[2] Performance incentives are not applicable to Cape Light Compact.

[3] National Grid Gas goals and performance incentives incorporate savings and benefits of both the National Grid and Blackstone Gas service areas, consistent with the Council Resolution of March 31, 2015, and are subject to the Department of Public Utilities issuing an order in support of this approach endorsed by the Council, including the Council-supported conditions that there are not separate reporting requirements for the Blackstone and National Grid services areas, and that savings and benefits secured in the Blackstone service area count toward National Grid's performance incentive.

- **Aggressive Goals**. The PAs have utilized an integrated, statewide approach to commit to the increased aggressive statewide savings levels set forth in this term sheet at costs that reflect reductions from those proposed costs presented to the Energy Efficiency Advisory Council in the April 30, 2015 draft 2016-2018 Plan. The individual PA savings levels and costs reflected in Attachment A are appropriate for the 2016-2018 Plan and have been developed through analysis and consideration of evaluation and potential studies.

  Savings goals assume consistent treatment for co-generation facility-related savings as in the past. Consistent with other measures, this includes that new projects installed after the end-of-life of an existing project are given full credit for all cost-effective project savings.

- **Effect of New Legislation or Regulations**. The PAs may be required to offer an Accelerated Rebate Pilot Program ("ARPP") or similar effort by new legislation. Additionally, DOER is currently in the process of issuing new RCS regulations and guidelines. In the event that material impacts occur from an ARPP, a new municipal aggregator program, the RCS regulations or guidelines, or any other new legislation or regulations issued prior to or during the three-year plan term, any affected PA shall have the opportunity to make appropriate adjustments to its costs and savings goals based upon the nature of the impacts, subject to the Council review under G.L. ch. 25, § 21(c) and the approval of the Department of Public Utilities.

- **Performance Incentives**.
  - Statewide performance incentive pool at design level: $100 million (electric); $18 million (gas).
  - Two components of PI mechanism: Savings (dollar value of benefits) and Value (dollar value of net benefits).
  - Incentive component weights: 61.5% Savings, 38.5% Value.
  - The threshold for earning performance incentives shall be 75% of target, with a cap of 125% of design level of performance incentive, each at the at the portfolio level of performance for each PA by component.[4]

[4] Performance incentives are not applicable to Cape Light Compact.

E. **<u>Council's Resolution of March 31, 2015</u>**

MA ENERGY EFFICIENCY ADVISORY COUNCIL

EEAC Resolution Concerning Its Priorities for the Development, Implementation, and Evaluation of the 2016-2018 Three-Year Energy Efficiency Plans

Adopted March 31, 2015

Part 1: Introduction

Under the Green Communities Act ("GCA"), the Energy Efficiency Advisory Council ("EEAC" or "Council") is charged with reviewing the Massachusetts Program Administrators ("PAs") energy efficiency investment plans and budgets, which are prepared in coordination with the EEAC. The EEAC has worked with, and will continue to collaborate with, the PAs to develop and deliver nation leading energy efficiency and demand reduction programs.

In this resolution, the EEAC again re-affirms its understanding that the GCA requires bold action to acquire all available cost effective energy efficiency and demand resources. In addition, the emission reduction targets established by the Global Warming Solutions Act ("GWSA") and the Commonwealth's Clean Energy and Climate Plan to implement the GWSA include a key role for energy efficiency and demand reduction programs. Given these statutory commitments, the economic and energy benefits that energy efficiency is providing to Massachusetts consumers, and the precedent that the PAs have established in leading the nation in developing comprehensive energy efficiency programs, the Council has great expectations for the development of a third balanced, cost-effective, robust, and innovative statewide electric and natural gas plan, inclusive of individual PA efficiency investment plans (i.e., "Three-Year Plans").

This resolution articulates the EEAC's priorities for program planning, analysis, implementation, and evaluation. It represents input from councilors, gathered through workshops and meetings. The Council also highlights for the PAs the importance of considering public comment and other stakeholder input. Developing the 2016-2018 Plans will be an iterative process between the Council, the PAs, and the EEAC's Consultant, as well as interested stakeholders. The Council looks forward to continuing collaboration with the PAs and interested stakeholders to plan and implement creative, effective approaches that meet or exceed the intended impact of this resolution.

Part 2: Priorities

The Green Communities Act mandates the acquisition of "all available cost-effective energy efficiency". The EEAC affirms this goal and, in striving to meet this statutory requirement, shall only approve 2016-2018 Plans that include savings that build on the achievement of the prior Three-Year Plans and conform with, and support the successful attainment of all available cost-effective energy efficiency.

The Council prioritizes continuous improvement in lifetime savings, benefits, and customer experience for the energy efficiency programs set forth in the 2016-2018 Plans, in order to ensure delivery of cost-effective programs that:

- Achieve all cost effective energy efficiency and demand reduction in accordance with the Green Communities Act.
- Align with the greenhouse gas reduction targets of the Global Warming Solutions Act and Clean Energy and Climate Plan.
- Deliver consistent and equitable service to all segments of businesses and residents statewide.
- Prioritize lifetime savings and benefits.
- Realize electric demand savings to significantly mitigate peak demand costs to the electric sector.
- Achieve data transparency and enable robust planning and analysis of the available energy efficiency resource through a comprehensive and detailed statewide database.
- Effectively communicate program and initiative successes, effectiveness, and progress to ratepayers.
- Continue to improve the cost efficiency of program delivery, with due regard for comprehensiveness, changes in avoided costs, and changes in technologies.

Part 3: Recommendations

Consistent with the priorities articulated above, the Council, PAs, and Council consultants conducted and participated in a collaborative planning process from December 2014 through March 2015. Seven workshops were held during which Voting and Non-voting councilors received briefing materials on prioritized topics, engaged in discussions, and developed the following informed recommendations for the PAs to consider when developing the 2016-2018 Plans. The Council appreciates that the cost-effectiveness, budgeting, and bill impact implications of each of these recommendations individually and in total will be considered by the PAs. The PAs shall provide updates to the Council on progress and implementation timeline of adopted recommendations as part of the PAs' quarterly reports. The Council looks forward to reviewing the draft 2016-2018 Plans and the PAs' written response to these recommendations, as well as to continuing collaborative discussions.

Cross-Cutting

1. The PAs, in coordination with the Council, shall develop a methodology and report accurate program penetration and participation numbers that are linked to individual account holders as opposed to participation in various programs.
2. The PAs shall support products and practices that reduce winter and summer peak demand by taking the following actions:
    a. Design, implement, and evaluate a demand reduction or demand response offering in each PA's service territory.
    b. Present to the EEAC a joint report with EEAC consultants on the impacts, opportunities and challenges of time varying rates on the energy efficiency programs, within 3 months of the Department's order approving such rates. Such report shall also include an analysis of incorporation of technologies like advanced metering in the efficiency programs, including potential adverse impacts on particular customer segments, such as low-income.
    c. Support the EEAC consultants in investigating the potential impact on efficiency savings if the Council were to place more emphasis on demand savings or peak demand savings.
3. The PAs shall proactively promote efficient renewable thermal technologies.
    a. Develop and implement a methodology in coordination with DOER and the EEAC Consultants to claim savings associated with the installation of renewable thermal equipment and fully account for savings associated with the reduction in use of the prior fuel source.
    b. Provide rebates and incentives for renewable thermal technologies, where deemed appropriate and cost-effective at the program level pursuant to the above methodology, not later than Q3 2016.
    c. Coordinate with the Massachusetts Clean Energy Center and DOER to provide information to customers and promote rebates and incentives for renewable thermal technologies.

Commercial & Industrial (C&I)

C&I Reporting

4. The PAs shall report on the following as separate initiatives within the C&I New Construction Program:
    a. Upstream
    b. End of life replacement
    c. New Construction/Major Modifications
5. The PAs shall report on the following as separate initiatives within the C&I Retrofit Program:
    d. Combined Heat and Power
    e. Retrofit Programs
    f. Control systems (including retro-commissioning, control upgrades, sub-metering and performance metrics)
    g. Engagement programs (continuous energy improvement, strategic energy management, behavioral programs)

Segment Specific Approaches

6. The PAs shall continue to improve their delivery of efficiency services via C&I market segment specific approaches using the following strategies:
    a. Provide more targeted communication materials to different market segments, explaining the benefits from, and availability of, energy savings opportunities to drive participation.
    b. Improve of the Mass Save® website to provide these sector-specific materials, including PA-specific materials, such as marketing materials, case studies and educational opportunities.
    c. Leverage partnerships with trade associations and other sector-specific partners to tailor efficiency program implementation to address sector-specific barriers and opportunities.
    d. Inform the EEAC in semi-annual reports about sector specific approaches (e.g., municipal, health care, commercial real estate, education, non-profits, hospitality, mid-size and small C&I), including:
        i. The impacts of sector specific strategies being implemented across the state.
        ii. How the results of EM&V studies and market research are being incorporated in program design.

Commercial Real Estate

7. The PAs shall continue to improve the efficiency programs targeted to the commercial real estate sector through the following strategies.
    a. Implement recommendations from Commercial Real Estate Working Group Roadmap, Massachusetts Commercial Real Estate Survey Analysis and Office Market profile report.
    b. Expand the Sustainable Office Design program features, including streamlined review of incentives to technologies beyond lighting. Implement pre-packaged offerings to address multiple end-uses.
    c. Use a whole building approach to target mid-size office buildings.
    d. Leverage energy reporting and disclosure ordinances to identify commercial real estate participants and explore the use of low-cost, streamlined whole building audits to support multi-year engagements on energy efficiency with interested property managers.

e. Explore market transformation opportunities, including updated advanced building operator training, sub-metering, wireless controls and better financing opportunities.
f. Investigate the main drivers for commercial real estate energy efficiency investment opportunities.

Small Businesses

8. The PAs shall continue to improve their delivery of efficiency services to small businesses through the following strategies.
    a. Provide deeper savings to each participating customer.
        i. Expand the menu of prescriptive services to better advance natural gas energy efficiency opportunities and non-lighting electric measures;
        ii. Use more comprehensive (e.g. integrated gas/electric) marketing programs for small businesses.
    b. Increase participation in the program.
        i. Use building analytics and benchmarking to target small business customers;
        ii. Increase outreach and awareness programs;
        iii. Continue to work with trade groups and associations.
    c. Continue to customize services based upon customer size and type.
        i. Investigate the potential for varied program implementation approaches to better serve the various strata of Small Business customers.
        ii. Determine which implementation strategies, technologies and building diagnostic capabilities employed in other programs are transferable and effective for serving Small Business customers.
        iii. Explore a Home Energy Services-type approach for the smallest business customers.

Combined Heat and Power

9. The PAs shall increase the overall number of Combined Heat and Power (CHP) installations.
    a. Provide additional education and outreach on CHP technology, including cost-effectiveness and other implementation barriers.
    b. Deliver a report on CHP by the end of 2016 that:
        i. Provides a statewide, bottom-up analysis of potential for custom, pre-packaged and third-party CHP projects;
        ii. Identifies technical, policy, financial, legislative, and market barriers and potential solutions, including, but not limited to, custom, pre-packaged and third-party CHP;
        iii. Determines the costs and feasibility of the PAs' implementing the identified solutions;
        iv. Investigates the challenges for installing CHP systems posed by natural gas availability and volatility in fuel prices, and potential programmatic approaches to mitigating those risks; and
        v. Assesses the interconnection challenges in area networks and how these challenges have been addressed in other cities, states or countries.
    c. Implement cost effective CHP program enhancements according to the findings of the report.

Continuous Technology Improvements

10. Given the importance of ongoing research and development of energy efficiency technologies, the Council recommends the PAs fully utilize all pilot funds.
11. The PAs shall develop a piloting or demonstration process and guidelines to facilitate and incentivize a more rapid and nimble adoption of emerging technologies, products, services, and strategies that enable energy efficiency savings. To that end, the PAs shall:
    a. Assess products that reflect rapid innovations in the marketplace, are of high customer interest, and/or have dependence on the customer for persistent savings (not limited to: data analytics, advances in sub metering, and advanced controls). As appropriate, adopt these measures into the C&I Programs.
    b. Examine combinations of products, services and strategies that enable energy efficiency savings or measurement of savings to assess their effectiveness.
    c. Report to the EEAC semi-annually on program selection, design, key performance indicators, and results.
    d. Complement the existing Massachusetts Technical Assessment Committee (MTAC). However, unlike the MTAC, the PAs will take the lead to identify and pilot these new technologies, services, and strategies.

Retro-Commissioning, Building Controls and Sub-metering

12. The PAs shall increase participation in retro-commissioning, building controls and sub-metering initiatives by enhancing the current offerings and incentives.
    a. Use data analytics and benchmarking processes to identify ideal retro-commissioning candidate projects.
    b. Promote continuous commissioning projects for retrofit and new construction projects by changing incentive structure to promote program participation, offering appropriate incentives, sponsoring new technologies, and training system operators.
    c. Where appropriate, incentivize the replacement of legacy building controls and open architecture in control systems to facilitate simpler system upgrading.
    d. Educate customers and vendors about new technologies and education opportunities, including regularly posting webinars, case studies, and videos on the Mass Save® website.
    e. Update and expand building operator training offerings, with input from customers, and explore the impact of combining these trainings with peer-to-peer based group learning.
    f. Expand training to increase the number of vendors who provide retro-commissioning and building controls in the marketplace.

Behavioral and Engagement

13. In recognition of the significance of C&I customer behavior on energy efficiency, the PAs shall:
    a. Deliver a report by the end of 2016 on Strategic Energy Management (SEM)/ Continuous Energy Improvement (CEI) programs for large commercial and industrial customers that:
        i. Researches SEM/ CEI programs to determine their applicability, cost effectiveness, and feasibility of implementation in Massachusetts;
        ii. Evaluates the potential savings from SEM/CEI programs;

   iii. Develops guidelines for how energy savings from SEM/CEI programs can cost-effectively be measured and verified; and
   iv. Explores leveraging such programs for dispatchable load control.
b. Based on the reports, if appropriate, implement SEM/CEI with large commercial and industrial customers, including providing technical assistance to identify opportunities and/or project management support for implementation.
c. Deliver a report by the end of 2016 on behavioral programs for small and mid-size commercial customers that:
   i. Investigates successful commercial behavioral programs to determine the critical elements for success and their cost-effectiveness;
   ii. Evaluates the potential savings from commercial behavioral programs;
   iii. Develops guidelines for how energy savings from commercial behavioral programs can cost-effectively be measured and verified; and
   iv. Explores leveraging such programs for dispatchable load control.
d. Assess and, if appropriate, implement upfront incentives for building operators and owners for behavior-based and operational savings, building operator training around behavioral strategies, and support for peer-to-peer cohorts.

LED Streetlights

14. The PAs shall:
    a. Retrofit the majority of utility-owned street lights with LED technology statewide by 2018 and create a plan to retrofit the remainder by 2020, or sooner if possible.
    b. Work with municipalities to retrofit the remainder of municipally-owned street lights to LED technology by 2018.
    c. Enable and incentivize advanced controls for LED street lights for both municipally and utility-owned street lights.

Delivered Fuels and Thermal Efficiency

15. The PAs shall promote non-gas customers' ability to self-fund the thermal portion of a comprehensive energy assessment using a PA auditor.

Hockey Stick Pattern

16. To address the uneven distribution of C&I savings occurring primarily at the end of the calendar year, the PAs shall:
    a. Improve C&I pipeline forecasting and reporting to the Council to increase visibility and predictability.
    b. Avoid offering incentives that create inequities or unintended consequences of delay and deferral.

Net Zero Energy Ready Buildings

17. The PAs shall assess offering a tier within the C&I New Construction initiative to enable net zero energy readiness.

Residential

New Initiatives

18. The PAs shall develop and implement by Q2 2016, a moderate income specific initiative designed to increase participation from this specific customer sector.
    a. Assess and determine appropriate population (within the 60-120% Area Median Income range) to serve and ensure that there is continuity with the low-income programs.
    b. Consider proxy means of income qualification (e.g. by zip code, rent costs), with protocols to assure that households eligible for low-income services are referred to the low-income programs.
    c. Develop and leverage partnerships with community groups to help with marketing and education, and coordinate with municipal efforts, that yield savings.
19. The PAs shall develop and implement by Q2 2016, a separate renter specific initiative, designed to address the split incentive and increase participation from this specific customer sector.
    a. Develop and leverage partnerships with community groups to help with marketing and education and coordinate with municipal efforts and/or consider alternative program models to better serve renters.

Home Energy Services Initiative

20. The PAs shall achieve deeper savings per household in the Home Energy Services (HES) Initiative through the following strategies.
    a. Increase the closure rate for weatherization jobs:
        i. Assess why home energy assessments are not resulting in installation of recommended weatherization
        ii. As soon as practicable, use findings to implement changes to increase the close rate
        iii. Report findings and progress in the quarterly reports to the EEAC.
    b. Assess the potential impacts of adjusting the insulation incentive, including maximum dollar value and percentage, and consider eliminating the cap on these incentives. Assess offering different tiers for market rate vs. moderate income households, while allowing for broad awareness marketing.
    c. Provide customized approaches, technical assistance, and offerings to specific customer types/segments (e.g., homes doing remodeling work, high energy users and electric heat resistance customers).
    d. Track all measures implemented at the household level where technically feasible to provide the Council with more comprehensive information on the penetration rates, and the depth of savings achieved when multiple measures are implemented.
    e. Continue to create incentives for lead vendors, Home Performance Contractors (HPCs), and contractors to achieve overall savings targets through a whole building approach.
    f. Reassess the structure of the Best Practices Working Group to ensure HPCs have an equitable role in decisions.
    g. Integrate renewable thermal technologies into the HES delivery model, building on the success of the early boiler/early furnace replacement offering.
21. The PAs shall optimize the effectiveness of the Home Energy Assessment (HEA) and the HEA delivery channel.

a. Improve the integrated "one-stop shop" customer experience:
    i. Provide the customer with comprehensive information about Mass Save®, state and federal incentives for HVAC, hot water, and renewable thermal technologies, regardless of the customer's existing fuel source.
    ii. Direct lead vendors and HPCs to provide customers with comprehensive HVAC/hot water and renewable thermal technology options, regardless of the customer's fuel source, when recommendations to upgrade are made.
b. Identify, assess, and, where appropriate, implement ways to streamline and better customize the offer and information presented at the HEA through strategies such as pre-screening customers and additional customer follow-up protocols.
c. By Q1 2016, collaborate with DOER and EEAC Consultants on a report that:
    a. Identifies actions needed to provide customers with an asset-based "home energy scorecard", similar to the one implemented in the Home MPG initiative and;
    b. Quantifies costs and benefits associated with providing customers with such a scorecard.

Products Program

22. The PAs shall fully incorporate LEDs in both the Products and Whole House programs, and phase out CFLs, as follows:
    a. As soon as pricing allows, and no later than Q4 2016, offer only LEDs in the Whole House program and specialty lighting in the Products program.
    b. As part of ongoing assessment activities conducted in conjunction with EEAC consultants, progress towards providing only LEDs for general lighting in the Products program, and report on such assessments and progress in the quarterly reports to the EEAC.
    c. To support and maintain Massachusetts' position as a leader in accelerating the adoption and installation of new technologies and practices, the PAs, in conjunction with the EEAC consultants, shall assess upstream program designs for HVAC and DHW-related technologies no later than Q3 2016.

HEAT loan/financing

23. The PAs shall, by Q2 2016, evaluate the following proposed changes to the HEAT loan program. The PAs shall report findings to the EEAC no later than Q2 2016:
    a. Provide low interest (e.g. 2%) loans for market rate customers, and maintain 0% for moderate income customers.
    b. PAs fund a loan loss reserve for moderate income customers and customers with marginal (e.g. 600-650) credit scores.
24. The PAs shall coordinate with DOER to expand the HEAT loan-eligible measures to include those currently funded by DOER under the Expanded HEAT Loan program.
25. The PAs shall identify and implement appropriate ways to simplify and accelerate the HEAT Loan application and approval process.

New Construction Initiative

26. The PAs shall enhance the New Construction Initiative:
    a. By Q1 2016, implement a "renewable ready" requirement in the highest two performance-based tiers and the top prescriptive incentive tier.
    b. By Q2 2016, deliver a report to the EEAC that assesses:
        i. Creating a Zero Net Energy (ZNE) incentive top performance tier.
        ii. Adding a performance path for multi-family housing (4+ stories).
        iii. Increasing incentives for rental housing new construction as a way of mitigating rental split-incentives.

Behavior Initiative

27. The PAs shall expand savings from behavior programs and explore the incorporation of home automation technology into their behavior initiative and report to the EEAC on the results of their findings.

Multi-Family Retrofit Initiative

28. The PAs shall increase savings from, and improve the customer experience in, the multi-family retrofit initiative:
    a. Provide weatherization incentives and HVAC and hot water equipment rebates to multi-family buildings that heat with unregulated fuels (e.g., oil or propane) to the same extent provided to gas or electric resistance-heated multi-family buildings.
    b. By Q2 2016, for buildings that benchmark, use benchmarking to:
        i. Institute or demonstrate a "pay for performance" approach to retrofits using pre- and post-retrofit baselines for evaluation.
        ii. Customize incentives to facilitate participation and deeper savings per building.
    c. By Q2 2016, develop and implement a plan or initiative for benchmarking in the multi-family sector.
    d. Seamlessly deliver services, rebates and incentives to the customer, regardless of whether such services, rebates or incentives are supported by the commercial or residential program.
        i. Provide customers with a single point of contact to act as a project manager offering whole building services for both residential and commercially metered buildings, including overseeing energy efficiency installations and coordinating with the PAs and their vendors.
        ii. For each building, link all services, rebates and incentives provided, regardless of whether such services, rebates or incentives are supported by the commercial or residential program, to provide a comprehensive view of commercially- and residentially-metered energy use and savings.
        iii. For each building, track and report both commercially-metered energy use and savings, and residentially-metered energy use and savings.
    e. Segment the sector (e.g. according to ownership patterns, building types, or meter configurations) and implement tailored approaches to facilitate increased participation and savings per building within such segments.
    f. Prioritize comprehensive whole building based performance.
    g. By Q2 2016, implement an initiative, in partnership with housing finance institutions, to integrate efficiency work into opportunities such as refinancing or retrofitting of larger multi-family buildings.

Low Income Programs

29. The Low Income Energy Affordability Network (LEAN) shall expand their eligible scope of services:
    a. Provide weatherization, HVAC, and hot water technology services to low income multi-family buildings that heat with unregulated fuels (e.g., oil or propane).
    b. Define low-income multi-family buildings as those with at least 50% of tenants earning up to 80% of Area Median Income (AMI).
    c. Assess and report to the Council on expanding 1-4 family program to serve customers up to 80% AMI.
    d. Evaluate and, if appropriate, serve non-profit organizations that primarily serve low income customers, provided that:
        i. Such services are clearly defined, and synched with Mass Save® C&I sector non-profit initiatives;
        ii. There is adequate funding such that providing such services does not reduce services to pre-existing LEAN markets or exacerbate the low income residential program queue;
        iii. The PAs and LEAN report annually to the EEAC on which non-profits are served, what services are provided, and the cost per building.

F. **<u>PA Response Matrix to March Resolution</u>**

#	DESCRIPTION	STATUS 1 Plan to implement & in Plan 2 = Plan to implement, not in plan 3 = Still under consideration 4 = Not in plan, not being implemented	COMMENTS	REFERENCES
Recommendations				
Cross-Cutting				
1	**The PAs, in coordination with the Council, shall develop a methodology and report accurate program penetration and participation numbers that are linked to individual account holders as opposed to participation in various programs.**	**4**	The PAs work to create common participant definitions for each program and initiative. The definitions are designed to most accurately reflect unique participants and are constantly being refined over time. Appendix G has draft participant definitions for 2016-2018. Accurately assessing program penetration and the number of unique customers participating in energy efficiency programs across the Commonwealth is a more complicated process. It is a difficult number to derive for two reasons: 1) because of customer overlap between PA territories and 2) because certain program delivery models, such as upstream, work through manufacturers and distributors rather than customers. For example, lighting incentives through the products program are delivered by hundreds of retailers across Massachusetts. It is not practical to ask every customer that buys an incentivized light bulb to provide enough information to track individual customer participation for that extensive initiative. The PAs use periodic Residential and C&I Customer Profile Studies to accurately determine penetration and an approximate count of customers being served across the Commonwealth. The first Residential Customer Profile Study will be complete in summer 2015. The 2013 C&I Customer Profile Study was completed in April 2015. A 2014 C&I Customer Profile Study will be complete in Spring 2016.	Section III.A.5.b, page 179 Appendix G, page 258
2	**The PAs shall support products and practices that reduce winter and summer peak demand by taking the following actions:**	**1**	The PAs recognize the special value of products and practices that can reduce winter and summer peak demand. The PAs have not fully developed all of their strategies for addressing these issues in the April 30 draft, but the discussions are active; the PAs expect to provide further detail as the Plan is refined. This draft of the 2016-2018 Plan projects electric demand savings of 514,175 kW (summer) and 617,294 kW (winter). In 2010-2014, the PAs achieved over 650,000 kW of summer capacity savings. Current 2016-2018 Plan expectations for demand savings are included in Table 3.2.i., Savings Summary. Issues relating to demand savings can be complex. The PAs have formed an *ad hoc* group to discuss these matters informally with the Council's consulting team. The PAs are sensitive to designing efforts that take into account unintended negative consequences, such as increased energy usage (which, for example, can be an unintended result of subsidizing ice storage plants that reduce demand). The *ad hoc* group is also exploring demand response, load-shifting and geo-targeting. Efforts like time-varying rates and advanced metering are also recognized by the PAs as an important part of our energy future and are being addressed by many PAs under	Section II.H.3.a, page 153
a	Design, implement, and evaluate a demand reduction or demand response offering in each PA's service territory.	3		
b	Present to the EEAC a joint report with EEAC consultants on the impacts, opportunities and challenges of time varying rates on the energy efficiency programs, within 3 months of the Department's order approving such rates. Such report shall also include an analysis of incorporation of technologies like advanced metering in the efficiency programs, including potential adverse impacts on particular customer segments, such as low-income.	4		
c	Support the EEAC consultants in investigating the potential impact on efficiency savings if the Council were to place more emphasis on demand savings or peak demand savings.	4		

			their Grid Modernization efforts. With respect to reports or investigations requested of the EEAC consultants in the Council recommendations, the PAs believe that is a matter for the Council and its consultants to develop and implement directly between themselves. The PAs will remain actively engaged with the Council, but any reports requested of the consulting team should be the responsibility of the consultants, at the direction of the Council, and not a responsibility of the PAs.	
3	**The PAs shall proactively promote efficient renewable thermal technologies.**	**3**	The PAs have not fully developed plans for renewable thermal technologies at this time, but are carefully examining these exciting technologies. At the heart of the PAs process are four questions 1) Are there cost-effective energy efficiency renewable thermal options, as opposed to renewable supply side measures? 2) Which renewable thermal technologies should be prioritized (if any) 3) What are the quantifiable energy savings and benefits?, and 4) What funding sources would be available for renewable thermal strategies under consideration? The PAs currently work with the Massachusetts Clean Energy Center and DOER to promote rebates and incentives for renewable thermal that work under current program design and delivery.	Section II.H.3.b, pages 154-155
a	Develop and implement a methodology in coordination with DOER and the EEAC Consultants to claim savings associated with the installation of renewable thermal equipment and fully account for savings associated with the reduction in use of the prior fuel source.	3		
b	Provide rebates and incentives for renewable thermal technologies, where deemed appropriate and cost-effective at the program level pursuant to the above methodology, not later than Q3 2016.	3		
c	Coordinate with the Massachusetts Clean Energy Center and DOER to provide information to customers and promote rebates and incentives for renewable thermal technologies.	3		
Commercial & Industrial (C&I)				
C&I Reporting				
4	**The PAs shall report on the following as separate initiatives within the C&I New Construction Program:**	**1**	The PAs share the Council's desire for increased transparency. Following a review of the C&I programs, the PAs have decided to separate out elements of those programs for budget/planning/reporting purposes. Within the New Construction Program, the PAs have created a Core Initiative for “New Buildings & Major Renovations” and another for “Initial Purchase & End of Useful Life” thereby increasing the granularity with which the Program, and its component elements, will be tracked during the course of the 2016-2018 Plan period. In summary, the PAs New Construction Program will consist of two Core Initiatives: - New Buildings & Major Renovations - Initial Purchase & End of Useful Life	Section II.G.2.a, page 100
a	Upstream	1		
b	End of Life Replacement	1		
c	New Construction/Major Modifications	1		
5	**The PAs shall report on the following as separate initiatives within the C&I Retrofit Program:**	**1**	Similar to New Construction, the PAs reviewed the Retrofit Program and, to facilitate increased transparency and granularity and clarity of reporting, have decided to include two new stand-alone core initiatives -- Multifamily Retrofit and Upstream Lighting. C&I Multifamily Retrofit aligns with the parallel Residential Multifamily Retrofit Core Initiative. Together, these two initiatives present a seamless approach to all elements of multi-family housing and represent the PAs’ commitment to harmonizing these important offerings across both sectors. Upstream Lighting has been moved from New Construction to Retrofit based on a determination that the vast majority of upstream lighting purchases have been, and will continue to be, for purposes of retrofitting existing equipment. After careful consideration, the PAs have decided not to separately plan for and report on CHP, control systems, or engagement programs as separate core initiatives. CHP results are, by nature of the complexity, relative risk, and long lead times of projects, highly variable and exhibit large fluctuations year to year, usually due to both the size and unpredictability of individual projects. It should be noted, however, that CHP measure level information is available in the electric PAs BCR screening models.	Section II.G.2.b, page 116
d	Combined Heat and Power	4		
e	Retrofit Programs	1		
f	Control systems (including retro-commissioning, control upgrades, sub-metering and performance metrics)	4		
g	Engagement programs (continuous energy improvement, strategic energy management, behavioral programs)	4		

			Controls related offerings, as well as engagement initiatives, have been and will continue to be important components of the PAs portfolio of C&I offerings and are often effectively included in the context of an MOU/SEMP. However, in light of their narrow applicability and relatively small (lifetime) savings relative to other parts of the portfolio, the PAs have concluded they do not warrant the level of attention of a separate Core Initiative. In Summary, the PAs Retrofit Program will consist of four Core Initiatives: - Existing Building Retrofit - Small Business - Multifamily Retrofit - Upstream Lighting	
			Segment Specific Approaches	
6	**The PAs shall continue to improve their delivery of efficiency services via C&I market segment specific approaches using the following strategies:**	**1**	The PAs have been early and longstanding proponents and practitioners of segment-based approaches to serving C&I customers and are pleased that the Council appreciates and supports that those efforts are key to achieving both broad and deep savings. The PAs will continue to develop additional customized approaches for specific segments of their C&I customers, making use of local EM&V studies, the experience of peer programs around the country, and data reported in studies and program evaluations from Massachusetts and other jurisdictions. The PA's Draft Plan specifically addresses a number of segments -- large customers, municipalities and water/wastewater treatment, commercial real estate, industrial, and non-profits, etc. -- and the PAs have or will develop customized approaches to serve additional segments within their unique customer bases and across the state. The PAs have and will continue to address evaluation recommendations in their Plan Year Reports in detail. In order to avoid redundancy and manage costs, the PAs will continue to emphasize EM&V and the impacts of EM&V on program design and delivery in Plan-Year and Term Reports, and will not provide separate reports on these efforts. As they have historically done, the PAs will continue to provide periodic presentations/reports to the EEAC on segment-specific activities and associated results and lessons learned. The PAs feel that reports presented closer to real time activity is more effective and impactful than reporting that is dependent on a rigid calendar schedule. Accordingly, while the PAs are not adopting a semi-annual approach, they do fully embrace continued and timely reporting related to incorporation of EM&V recommendations into program design and delivery.	Section II.G.2.b, pages 130-131 and 134-141
a	Provide more targeted communication materials to different market segments, explaining the benefits from, and availability of, energy savings opportunities to drive participation.	1		
b	Improve of the Mass Save® website to provide these sector-specific materials, including PA-specific materials, such as marketing materials, case studies and educational opportunities.	2		
c	Leverage partnerships with trade associations and other sector-specific partners to tailor efficiency program implementation to address sector-specific barriers and opportunities.	1		
d	Inform the EEAC in semi-annual reports about sector specific approaches (e.g., municipal, health care, commercial real estate, education, non-profits, hospitality, mid-size and small C&I), including:	4		
i	The impacts of sector specific strategies being implemented across the state.	4		
ii	How the results of EM&V studies and market research are being incorporated in program design.	4		
			Commercial Real Estate	
7	**The PAs shall continue to improve the efficiency programs targeted to the commercial real estate sector through the following strategies.**	**1**	As described in the PA's Draft Plan, once available, the results of the CRE Working Group will be reviewed and used to develop strategies for more effectively engaging with commercial real estate customers. In the interim, the PAs have and will continue to utilize a number of approaches specifically targeted to CRE customers -- sustainable office design (SOD), whole building approach, and MOU/SEMPs with large CRE customers across their portfolio of properties.	Section II.G.2.a, pages 105-106 Section II.G.2.b, pages 127 and 139
a	Implement recommendations from Commercial Real Estate Working Group Roadmap, Massachusetts Commercial Real Estate Survey Analysis and Office Market profile report.	1		
b	Expand the Sustainable Office Design program features, including streamlined review of incentives to technologies beyond lighting. Implement pre-packaged offerings to address multiple end-uses.	3		
c	Use a whole building approach to target mid-size office buildings.	3		

d	Leverage energy reporting and disclosure ordinances to identify commercial real estate participants and explore the use of low-cost, streamlined whole building audits to support multi-year engagements on energy efficiency with interested property managers.	3		
e	Explore market transformation opportunities, including updated advanced building operator training, sub-metering, wireless controls and better financing opportunities.	3		
f	Investigate the main drivers for commercial real estate energy efficiency investment opportunities.	3		
	Small Businesses			
8	**The PAs shall continue to improve their delivery of efficiency services to small businesses through the following strategies.**	**1**	The PAs have included a lengthy description of Small Business in their Draft Plan including plans to thoroughly review every aspect of the Small Business Core Initiative – administration and delivery, target markets, measures, marketing, etc. -- in order to develop the next generation version of this already extremely successful model. Examples of the options under consideration include: addition of more gas measures, including thermal measures; better and more referral follow-up services for measures not amenable to the direct install delivery model (such as thermal measures and heating systems so that deeper treatments can be undertaken); further segmentation to reach the smallest of the small customers through consideration of web portals, self-service delivery concepts, further development of the "Main Streets" or other geographically-focused delivery models, adaptation of successful residential delivery models such as HES, etc.; and more targeted marketing and measure mixes by business type.	Section II.G.2.b, pages 118, 125-127 Section II.G.2.b.ii, pages 147-148
a	Provide deeper savings to each participating customer.	1		
i	Expand the menu of prescriptive services to better advance natural gas energy efficiency opportunities and non-lighting electric measures;	1		
ii	Use more comprehensive (e.g. integrated gas/electric) marketing programs for small businesses.	1		
b	Increase participation in the program.	1		
i	Use building analytics and benchmarking to target small business customers;	3		
ii	Increase outreach and awareness programs;	1		
iii	Continue to work with trade groups and associations.	1		
c	Continue to customize services based upon customer size and type.	1		
i	Investigate the potential for varied program implementation approaches to better serve the various strata of Small Business customers.	1		
ii	Determine which implementation strategies, technologies and building diagnostic capabilities employed in other programs are transferable and effective for serving Small Business customers.	1		
iii	Explore a Home Energy Services-type approach for the smallest business customers.	1		
	Combined Heat and Power			
9	**The PAs shall increase the overall number of Combined Heat and Power (CHP) installations.**	**1**	The PAs have included a lengthy description of CHP in their Draft Plan and plan to aggressively target CHP opportunities during the 2016-2018 period including a commitment to increase education and outreach as well as the commissioning of a best practices review of CHP programs nationally and a reassessment of CHP potential in Massachusetts. While sharing the Council's strategic commitment to excellence with regard to CHP delivery and the undertaking of research to enhance performance, the PAs do not feel it appropriate to adopt a specific time line for reporting on CHP activities or the results of any related research.	Section II.G.2.b, pages 132, 141-143
a	Provide additional education and outreach on CHP technology, including cost-effectiveness and other implementation barriers.	1		
b	Deliver a report on CHP by the end of 2016 that:	1		
i	Provides a statewide, bottom-up analysis of potential for custom, pre-packaged and third-party CHP projects;	3		
ii	Identifies technical, policy, financial, legislative, and market barriers and potential solutions, including, but not limited to, custom, pre-packaged and third-party CHP;	3		
iii	Determines the costs and feasibility of the PAs' implementing the identified solutions;	3		
iv	Investigates the challenges for installing CHP systems posed by natural gas availability and volatility in fuel	3		

	prices, and potential programmatic approaches to mitigating those risks; and			
v	Assesses the interconnection challenges in area networks and how these challenges have been addressed in other cities, states or countries.	3		
c	Implement cost effective CHP program enhancements according to the findings of the report.	1		
	Continuous Technology Improvements			
10	**Given the importance of ongoing research and development of energy efficiency technologies, the Council recommends the PAs fully utilize all pilot funds.**	**1**	There are no budgeted funds for pilots in the PAs Draft Plan, but the PAs plan to continue their long-standing practice of regularly evaluating and field testing new/emerging technologies.	N/A
11	**The PAs shall develop a piloting or demonstration process and guidelines to facilitate and incentivize a more rapid and nimble adoption of emerging technologies, products, services, and strategies that enable energy efficiency savings. To that end, the PAs shall:**	**1**	The PAs plan to continue assessing new, market ready, technologies and determine their eligibility for incorporation in program offerings, as well as technologies that are on the near horizon for marker-readiness. MTAC, a group comprised of PA technical and engineering representatives, provides a consistent statewide approach for identifying and evaluating new efficiency technologies. In furtherance of this work, MTAC communicates and cooperates with similar emerging technology assessment groups around the country. MTAC, with assistance as necessary from other C&I Subcommittees, will continue to maintain summaries of the results of all such technology reviews and make available information regarding approved technologies on the Mass Save website. Additionally, the C&IMC and other related subcommittees will continue to discuss the programmatic structures that best serve the introduction of emerging technologies and associated strategies. To support these efforts, the PAs have specifically budgeted R&D funds in the hard-to-measure line item to pursue technologies of interest.	N/A
a	Assess products that reflect rapid innovations in the marketplace, are of high customer interest, and/or have dependence on the customer for persistent savings (not limited to: data analytics, advances in sub metering, and advanced controls). As appropriate, adopt these measures into the C&I Programs.	3		
b	Examine combinations of products, services and strategies that enable energy efficiency savings or measurement of savings to assess their effectiveness.	3		
c	Report to the EEAC semi-annually on program selection, design, key performance indicators, and results.	3		
d	Complement the existing Massachusetts Technical Assessment Committee (MTAC). However, unlike the MTAC, the PAs will take the lead to identify and pilot these new technologies, services, and strategies.	2		
	Retro-Commissioning, Building Controls and Sub-metering			
12	**The PAs shall increase participation in retro-commissioning, building controls and sub-metering initiatives by enhancing the current offerings and incentives.**	**1**	The PAs will continue to support and facilitate the implementation of RCx strategies, building systems optimization, and advanced controls operations wherever appropriate and consistent with energy efficiency program guidelines. To this end, the PAs will proactively implement the recommendations of the recently completed Retro-Commissioning Best Practice Study to streamline the RCx offerings and to achieve greater implementation of these strategies. For example, the PAs have already tested some of the RCx Best Practices recommendations by developing and implementing customized approaches to providing targeted RCx services to hospitals with a similar approach for labs currently in development. In addition, the PAs are committed to developing a common tool for RCx measures and expanding training for RCx for providers.	Section II.G.2.b, pages 118 and 120-121
a	Use data analytics and benchmarking processes to identify ideal retro-commissioning candidate projects.	1		
b	Promote continuous commissioning projects for retrofit and new construction projects by changing incentive structure to promote program participation, offering appropriate incentives, sponsoring new technologies, and training system operators.	3		
c	Where appropriate, incentivize the replacement of legacy building controls and open architecture in control systems to facilitate simpler system upgrading.	3		
d	Educate customers and vendors about new technologies and education opportunities, including regularly posting webinars, case studies, and videos on the Mass Save® website.	3		

e	Update and expand building operator training offerings, with input from customers, and explore the impact of combining these trainings with peer-to-peer based group learning.	3		
f	Expand training to increase the number of vendors who provide retro- commissioning and building controls in the marketplace.	3		
	Behavioral and Engagement			
13	**In recognition of the significance of C&I customer behavior on energy efficiency, the PAs shall:**	**4**	There is a significant investment in staff time and expense required of both customer and the PA to implement successful Strategic Energy Management (SEM) initiatives. For that reason SEM has only been applied successfully to a very small universe of the largest, primarily industrial and large commercial customers in a few parts of the country. Additionally, SEM approaches are generally designed to provide incremental savings over and above the traditional capital investments, which typically provide substantially greater and more predictable and sustainable savings. Many experts in the field also believe the results of SEM and related behavioral efforts remain inconclusive in terms of their ability to produce significant savings and whether those savings can be produced and sustained cost effectively. At this juncture, the PAs believe SEM remains a narrowly applicable approach to energy efficiency that does not warrant significant investment of time and resources. However, the PAs do understand the value of SEM to specific subsets of customers, and will be refining and expanding existing approaches to better serve those customers. The PAs also examine methods to expand SEM approaches to a broader market as the concept becomes a more familiar model in the business community, and as various emerging models demonstrate a record of success. Activities that the PAs have supported and will continue to support include retro-commissioning, an array of training and education opportunities, and customized process and behavioral approaches within the broader context of a customer-specific Memorandum of Understanding (MOU)/Strategic Energy Management Plan (SEMP). It should also be noted that behavioral approaches will also be considered as part of the PAs reexamination of approaches to serving small business customers	Section II.G.2.b, pages 120-125, 129-130, and 136
a	Deliver a report by the end of 2016 on Strategic Energy Management (SEM)/ Continuous Energy Improvement (CEI) programs for large commercial and industrial customers that:	4		
i	Researches SEM/ CEI programs to determine their applicability, cost effectiveness, and feasibility of implementation in Massachusetts;	3		
ii	Evaluates the potential savings from SEM/CEI programs;	3		
iii	Develops guidelines for how energy savings from SEM/CEI programs can cost-effectively be measured and verified; and	3		
iv	Explores leveraging such programs for dispatchable load control.	3		
b	Based on the reports, if appropriate, implement SEM/CEI with large commercial and industrial customers, including providing technical assistance to identify opportunities and/or project management support for implementation.	4		
c	Deliver a report by the end of 2016 on behavioral programs for small and mid-size commercial customers that:	4		
i	Investigates successful commercial behavioral programs to determine the critical elements for success and their cost-effectiveness;	3		
ii	Evaluates the potential savings from commercial behavioral programs;	3		
iii	Develops guidelines for how energy savings from commercial behavioral programs can cost effectively be measured and verified; and	3		
iv	Explores leveraging such programs for dispatchable load control.	3		
d	Assess and, if appropriate, implement upfront incentives for building operators and owners for behavior-based and operational savings, building operator training around behavioral strategies, and support for peer-to-peer cohorts.	3		
	LED Streetlights			
14	**The PAs shall [support LED street lighting technologies]:**	**1**	The PAs remain committed to providing their municipal customers with the most up-to-date street lighting technology options -- including lighting and controls -- as well as providing options for them to assume ownership and maintenance of lighting where it is cost-effective and they so desire. The PAs remain committed to working with any community wishing to explore the process of conversion to municipal ownership. Local conditions and priorities of the local governing body in each unique city or town will control the rate at which the conversion can be accomplished.	Section II.G.2.b, page 143
a	Retrofit the majority of utility-owned street lights with LED technology statewide by 2018 and create a plan to retrofit the remainder by 2020, or sooner if possible.	4		
b	Work with municipalities to retrofit the remainder of municipally-owned street lights to LED technology by 2018.	4		

c	Enable and incentivize advanced controls for LED street lights for both municipally and utility-owned street lights	3	The PAs have to date successfully supported the conversion of a very large number of customer-owned streetlights to LED technology. For example, in the eastern portion of Eversource's territory where roughly 90% of the streetlights are already customer-owned, over 60% of those streetlights have been converted to LED. Somewhat by contrast, in National Grid's territory, less than 20% of municipalities have purchased their streetlights thereby limiting the opportunity to convert to LED technology. Cape Light Compact has also completed a large number of street lighting conversions spanning a number of communities during the current 2013-2015 Plan period. The PAs are also committed to supporting the conversion of utility-owned streetlights to LED technology once the electric utilities in the state have developed, filed, and had approved the necessary tariffs.	
	Delivered Fuels and Thermal Efficiency			
15	**The PAs shall promote non-gas customers' ability to self-fund the thermal portion of a comprehensive energy assessment using a PA auditor.**	**2**	When working with customers whose heating fuel is neither electricity nor natural gas, the PAs have and will continue to make those customers aware of the efficiency opportunities that may nonetheless exist to reduce energy consumption related to space heating, and direct them to other funding sources that may be available to help them do so. The PAs always explain to these customers that, due to regulatory constraints, the PAs are not able to provide financial support for any engineering assessment of those opportunities, but that the customer should consider undertaking that analysis on their own behalf and, should the customer so desire, the PAs can direct them to qualified engineer firms with whom they work regularly on such projects.	N/A
	Hockey Stick Pattern			
16	**To address the uneven distribution of C&I savings occurring primarily at the end of the calendar year, the PAs shall:**	**2**	The so-called "Hockey Stick Pattern" is a reliably predictable phenomenon, which the PAs factor into their forecasting efforts. The PAs will continue to provide reasonable and accurate forecasts of expected year-end results and increased visibility regarding those forecasts to the Council. The PAs assist their business customers in understanding, evaluating, and implementing the energy efficiency opportunities that maximize the benefits of those efforts. In so doing, the PAs must be aware of and adapt to the financial and operating constraints that influence customer decision-making -- both in terms of the projects they may undertake and the timing of those projects.	N/A
a	Improve C&I pipeline forecasting and reporting to the Council to increase visibility and predictability.	2		
b	Avoid offering incentives that create inequities or unintended consequences of delay and deferral.	2		
	Net Zero Energy Ready Buildings			
17	**The PAs shall assess offering a tier within the C&I New Construction initiative to enable net zero energy readiness.**	**3**	The PAs have an interest in staying closely engaged in the Net Zero movement. This may take a number of forms including participation in research and development efforts, particularly where Massachusetts participation can be used to leverage resources from program administrators in other jurisdictions and/or government research investments. It may also take the form of support for demonstration projects in partnership with developers or owners who are motivated to have a Net Zero building, or a building along the continuum to Net Zero: e.g., "Net Zero Ready" (highly efficient but renewables not yet in place) or "Near Net Zero" (highly efficient). The ZNE market remains very immature and as such it would be premature to design and implement a separate tier within the C&I New Construction Program; however, as the market develops in the future, a variety of options for enabling this market will be considered including perhaps a tier within the New Construction Program.	Section II.G.2.a, pages 102-103

Residential & Low-Income

New Initiatives

18	**The PAs shall develop and implement by Q2 2016, a moderate income specific initiative designed to increase participation from this specific customer sector.**	**1**	The PAs are exploring a moderate income offer. PAs are committed to ensuring moderate income customers are able to successfully access and participate in all Mass Save® efficiency opportunities in 2016-2018. The 2016-2018 Plan includes the strategic commitment to ensuring designs effectively serve moderate income customers. The PAs will be addressing this within the first year of the three-year plan. Some of the details of implementation are not included, both because they are evolving and because they may be inappropriate to the Plan level. PAs must maintain the ability to be nimble and flexible in delivery, allowing the program's design to adapt to learning, especially as PA's trial new offerings. We have provided detail on some of the areas PAs are exploring to provide context and depth to our strategic commitment. As these efforts evolve they will be tested and refined and may begin to take different design direction. In addition to a moderate income specific offering, PAs recognize that approaches focused on renters and 2-3 family properties will have overlap with moderate income populations. Therefore while PAs discuss a renter specific offer in the comments under recommendation 19, PAs consider the renter-specific efforts to be part of our holistic design to reach all customers and specifically moderate income customers. It is also important to note the whole house program is not the only opportunity to serve moderate income customers. The products program also reaches moderate income customers. PAs are very mindful of this in our program and will explore how to leverage locations or special promotions to ensure access for moderate income consumers. This is noted in the plan. PAs initial planning of the moderate income offer has focused on concerns raised during the workshop discussions and in the recommendations regarding the need for continuity with the low-income programs and "simplification" of entry for customers to weatherization. In response, and in consideration of other program factors, PAs have focused on an offer that: 1) targets the 61-80% state median income, i.e., moderate income, population just above "low-income" service definition, and 2) preserves the Mass Save brand awareness and current penetration success of the HEA channel. The preliminary exploration has focused on entry and service through HES –HEA. Customers with identified weatherization opportunities, uncovered as part of an HEA, can be offered an opportunity to be "qualified" for an increased incentive where income is a barrier. This has the advantages of maintaining the ability to market the Mass Save® initiative broadly, being fair and available to all customers, and allowing customers to decide if they want to be "income qualified". It further limits the pool of participants for increased support to customers with realizable weatherization opportunities, increasing the balance of funds expended for customer's direct incentive and energy savings, while controlling the growth in program administration overhead from adding a unique "offer" to a targeted sub-segment. PAs are still examining methods and costs for the income verification element of this more prescribed offering. Using the same scale for income qualification as is currently used by the low-income program will allow customers who enter through the low-income portal to be more easily transitioned into this offer. Customers who have completed income verification	Section I.A.2, page 11 Section II.E.2, pages 34 and 37 Section II.E.3, pages 39-40 Section II.E.4.c, pages 54 and 60 Section II.E.4.h, page 85
a	Assess and determine appropriate population (within the 60-120% Area Median Income range) to serve and ensure that there is continuity with the low-income programs.	1		
b	Consider proxy means of income qualification (e.g. by zip code, rent costs), with protocols to assure that households eligible for low-income services are referred to the low-income programs.	3		

c	Develop and leverage partnerships with community groups to help with marketing and education, and coordinate with municipal efforts, that yield savings.	2	prior to assessment through the low-income program and are over income for low-income services can be triaged into HES for an HEA and the existing low-income qualification will go with the customer into the HES program. Details on this process will be developed in close partnership with LEAN. • Learning from Efficient Neighborhoods+® (EN+) and Renew Boston is still on-going in evaluations. There may be more information coming in that can help inform an approach to moderate income. Our review and incorporation of this information is part of how we approach "assess and determine appropriate population." PAs initial focus on 61-80% state median income is to respond to the need for continuity of services with low-income programs. • A primary concern PAs have with proxy methods of income verification is that they restrict the ability of PAs to broadly market the program through traditional, low cost, effective marketing mediums. Proxy methods also can cause customer confusion and result in poor customer perception of the program. Finally there is no evidence that such proxy methods would actually have lower overhead costs relative to direct income verification. So far, we have indications from the EN+ evaluation that at least one proxy method of targeting paired with targeted outreach has a very high cost per opportunity secured. PAs are interested in exploring opportunities that can put more of the program dollars directly to work benefiting customers and securing weatherization opportunities. • One advantage of the opt-in design is the continuity with the low-income programs, achieved by utilizing the same "qualification" scale and maintaining the two program structure. Details on how to refer customers and methods and costs to income verification for "opt-in" customers all need and will receive further examination. • PAs are very enthusiastic about the ideas discussed in workshops regarding existing municipal efforts and local community organizations that currently serve this target market of moderate income customers. PAs have noted in the Plan their commitment to learn more and leverage opportunities to use such connections to increase access for moderate income customers to Mass Save® opportunities, with an emphasis on increasing installations. As these opportunities and relationships are inherently service area based, more detail and differing specific implementation opportunities are likely for each PA.	
19	**The PAs shall develop and implement by Q2 2016, a separate renter specific initiative, designed to address the split incentive and increase participation from this specific customer sector.**	1	PAs have begun planning for the introduction of a renter-specific initiative within the first year of the 2016-2018 Plan. The PAs are currently exploring program enhancements that provide effective screening and direction of renters to a specially designed visit that responds to renter opportunities and constraints. PAs see the potential for a well-designed special renter visit to increase participation in HES offerings, both by renters and landlords. The visit will focus on installation of instant savings measures such as efficient lighting, water saving devices and advanced power strips and will inform the customer of other appropriate opportunities for renters. Given the potential overlap of renters and moderate-income households, this effort	Section I.A.2, page 11 Section II.E, pages 37-38 Section II.E.4.c, page 57

a	Develop and leverage partnerships with community groups to help with marketing and education and coordinate with municipal efforts and/or consider alternative program models to better serve renters.	2	may simultaneously increase access and participation by moderate-income households, a high priority for the PAs, LEAN, and the Council (Council recommendation #18). Deployment of a special renter visit may also help to increase cost-effective program delivery by providing the right level of service at a reduced delivery time and cost. Triaging customers in this way may also help vendors providing HEAs to effectively serve renters while garnering information on landlord interest, thus increasing the opportunity to convert to deeper measures, consistent with the shared goal of increasing closure rates (Council recommendation #20). PAs are very enthusiastic about the ideas discussed in workshops regarding leveraging existing municipal efforts and local community organization that currently serve this target market of rental housing (renters and landlords). PAs have noted in the plan their commitment to learn more and leverage opportunities to use such connections to increase access for renters and moderate income customers to Mass Save® opportunities, with an emphasis on increasing installations. As these opportunities and relationships are inherently service area based, more detail and differing specific implementation opportunities are likely for each PA.	
		Home Energy Services Initiative		
20	**The PAs shall achieve deeper savings per household in the Home Energy Services (HES) Initiative through the following strategies.**	**1**	PAs plan to conduct an extensive review of the customer experience to identify opportunities for increased streamlining, simplifying and better targeting time and content of customer information to maximize our opportunity to influence customers taking action. This will include investigating digital and online options that improve the customer experience, and exploration of enhanced customer follow-up strategies that continue to track and reach out to customers at key moments, helping them pursue deeper measures and stay on track with open recommendations from their HEA. This holistic assessment process is fundamental to PA program design and implementation. It includes continuous review of cost effective incentive levels, for customers and vendors within the context of all elements of the program as a system to maximize savings realization. Most PAs have adopted a reporting/rating system to help contractors understand their performance in a holistic manner. These systems award work and/or financial bonuses based on performance. This is an ongoing effort and is discussed in the Plan Mass Save® Data, www.masssavedata.com, updated quarterly, already provides information on weatherization jobs, closure rates and savings. PAs are conscious of redundant reporting and the attendant overhead costs and do not plan to add new layers to the existing robust tracking and reporting in place. Tracking data at the customer or household level is an outstanding issue in an open docket with the DPU. Based on the Council recommendation, PAs reviewed the current composition of the best practices working group and determined it currently provides a higher representation of HPCs as a proportion of participating contractors statewide. HPCs hold 45% of the contractor seats while representing approximately 18% of the contractors in the program. The current structure is working well, and PAs have not included adjustments in the plan. PAs are open to discussing balancing the representation to better reflect proportionate representation (i.e., increase proportionate representation of IICs) if this remains a critical concern to the Council. PAs currently provide incentives for heat pump technologies and are continuously reviewing /screening heat pump technology in specific applications in the residential sector. To date, heat pumps have not screened as being cost effective as a whole house heating system replacement for any heat source, including electric resistance heat (baseboard). The technology is rapidly evolving along with complementary technologies, which may, in time, support optimizing heat pumps as primary heating	Section II.E.1, page 33 Section II.E.2, page 34 Section II.E.2.c, page 36 Section II.E.3, pages 38 and 40 Section II.E.4.c, pages 52-54, 56, and 60 Section II.E.4.f, page 73
a	Increase the closure rate for weatherization jobs:	1		
i	Assess why home energy assessments are not resulting in installation of recommended weatherization	1		
ii	As soon as practicable, use findings to implement changes to increase the close rate	1		
iii	Report findings and progress in the quarterly reports to the EEAC.	4		
b	Assess the potential impacts of adjusting the insulation incentive, including maximum dollar value and percentage, and consider eliminating the cap on these incentives. Assess offering different tiers for market rate vs. moderate income households, while allowing for broad awareness marketing.	3		
c	Provide customized approaches, technical assistance, and offerings to specific customer types/segments (e.g., homes doing remodeling work, high energy users and electric heat resistance customers).	3		
d	Track all measures implemented at the household level where technically feasible to provide the Council with more comprehensive information on the penetration rates, and the depth of savings achieved when multiple measures are implemented.	4		
e	Continue to create incentives for lead vendors, Home Performance Contractors (HPCs), and contractors to achieve overall savings targets through a whole building approach.	1		
f	Reassess the structure of the Best Practices Working Group to ensure HPCs have an equitable role in decisions.	4		
g	Integrate renewable thermal technologies into the HES delivery model, building on the success of the early boiler/early furnace replacement offering	3		

			systems. As cost effective implementation opportunities ripen, PAs will adjust program offers to respond. The early boiler/furnace model may or may not represent an optimal mechanism for deployment.	
21	**The PAs shall optimize the effectiveness of the Home Energy Assessment (HEA) and the HEA delivery channel.**	**1**	Massachusetts' HES is a mature initiative with over 20 years of program delivery experience, including many refinements and expansions. The core initiative consistently delivers strong energy savings while reaching over 80,000 participants statewide in 2014 and continues to grow. The Massachusetts HES core initiative has the greatest reach of any whole home program in the nation. Nevertheless, PAs remain committed to continuous improvement and this 2016-2018 Plan focuses strongly on optimizing all aspects of the HES-HEA delivery channel. As discussed above in response to Recommendation #20, PAs plan to conduct an extensive review of the customer experience to identify opportunities for increased streamlining, simplifying and better targeting to maximize opportunities to influence customers to take action. The current design and implementation of the initiative includes a one stop shop approach and provides comprehensive information to customers on Mass Save® opportunities with a fuel blind approach. The Mass Save® website has become a critical focal point in the comprehensive marketing program, providing a consolidated one stop shop for residents and businesses to learn about energy efficiency, program offerings, and opportunities. The Mass Save® website and strategies that drive customers to the website will continue to be refined to ensure the highest quality customer experience. A majority of residential customers are aware of the website and 30% report using the website more than once in the past year. The Mass Save® assessment collateral links customers to a federal website with updated information on tax credits and additional incentives. If the Commonwealth would like to provide a link to a static URL that is updated on a regular basis and encompasses all available state incentives, the PAs would be pleased to link to that as well. Under current RCS regulations the PA's Lead Vendors and HPCs are providing comprehensive HVAC and hot water recommendations in a fuel blind manner during the HEA. Modifications may be necessary based on anticipated RCS regulation changes and will be made when RCS regulations become final. Recommendation of renewable thermal technologies may expand based on RCS regulation changes but will also need to be screened for cost effectiveness. The deployment of the online assessment tool, speaks to the on-going commitment of PAs to reach out broadly and provide an effective and creative entry point for customers. The on-line assessment tool is beginning to offer what the Council has highlighted in their recommendation as a desire to "optimize" the effectiveness of the HEA and the HEA delivery channel. The on-line assessment effectively provides customers with a no–cost home energy score card, tied directly to customer-specific actionable Mass Save® energy efficiency opportunities based on the resident's unique circumstances, all from the comfort of their keyboard and at their leisure. Each user can be tracked and followed up with, regardless of whether they move on to an HEA or are better suited to another Mass Save® opportunity. PAs look forward to exploring how our existing on-line assessment tool and resultant score card, a cost effective customer centric approach, already addresses the Council's interest in ensuring customers have access to actionable home energy score cards. PAs will also continue to monitor DOEs ongoing research in neighboring states on alternative score cards. The plan will not be including artificial deadlines or additional reporting or research requirements. This level of design detail is not appropriate to the plan and runs the risk of distracting effort and effectiveness from providing customers with the highest quality information and greatest access to efficiency opportunities, a strategic commitment shared by both the PAs and the Council. PAs are particularly concerned with	Section II.E.2, page 35 Section II.E.4.c, page 54 Section II.I.1, page 156
a	Improve the integrated "one-stop shop" customer experience:	1		
i	Provide the customer with comprehensive information about Mass Save®, state and federal incentives for HVAC, hot water, and renewable thermal technologies, regardless of the customer's existing fuel source.	2		
ii	Direct lead vendors and HPCs to provide customers with comprehensive HVAC/hot water and renewable thermal technology options, regardless of the customer's fuel source, when recommendations to upgrade are made.	1		
b	Identify, assess, and, where appropriate, implement ways to streamline and better customize the offer and information presented at the HEA through strategies such as pre-screening customers and additional customer follow-up protocols.	1		
c	By Q1 2016, collaborate with DOER and EEAC Consultants on a report that:	4		
i	Identifies actions needed to provide customers with an asset-based "home energy scorecard", similar to the one implemented in the Home MPG initiative and;	1		
ii	Quantifies costs and benefits associated with providing customers with such a scorecard.	4		

			explorations of offerings, such as review of alternative score cards which are already being studied by neighboring jurisdiction, that increase administrative overhead without connecting to energy savings.	
		Products Program		
22	**The PAs shall fully incorporate LEDs in both the Products and Whole House programs, and phase out CFLs, as follows:**	**1**	The Plan clearly commits to fully incorporating LEDs and phasing out CFLs, as market factors allow, and with attention to ensuring the highest value investment and benefits for ratepayers over the 2016-2018 Plan period. PAs have shown their commitment over the 2013-2015 period with major advancement in this arena – driven entirely by PA long term research efforts, professional program design, and effective procurement strategies that have allowed the program to lead the nation and market in technology deployment and cost effective savings. PAs remain committed to sharing information through quarterly reports with the Council and using the existing EMV and research frameworks to continue their success in this area. The Plan will not be including artificial deadlines for the phase out or additional reporting or research requirements that are a level of design detail not appropriate to the Plan and run the risk of distracting effort and effectiveness in achieving the shared strategic commitment of the PAs and the Council to fully incorporate LEDs in both the Products and Whole House programs, and phase out CFLs.	Section II.E.1, pages 33-34 Section II.E.2, page 34 Section II.E.2.a, page 36 Section II.E.3, page 40 Section II.E.4.h, pages 80 and 85
a	As soon as pricing allows, and no later than Q4 2016, offer only LEDs in the Whole House program and specialty lighting in the Products program.	1		
b	As part of ongoing assessment activities conducted in conjunction with EEAC consultants, progress towards providing only LEDs for general lighting in the Products program, and report on such assessments and progress in the quarterly reports to the EEAC.	4		
c	To support and maintain Massachusetts' position as a leader in accelerating the adoption and installation of new technologies and practices, the PAs, in conjunction with the EEAC consultants, shall assess upstream program designs for HVAC and DHW-related technologies no later than Q3 2016.	4		
		HEAT loan/financing		
23	**The PAs shall, by Q2 2016, evaluate the following proposed changes to the HEAT loan program. The PAs shall report findings to the EEAC no later than Q2 2016:**	**4**	The Mass Save® HEAT Loan initiative is the most successful initiative of its kind in the nation, growing from 532 loans in 2006 to over 11,000 loans in 2014 (annual). Since inception, the Mass Save® HEAT Loan has made over $200,000,000 available to thousands of homeowners implementing home energy efficiency improvements. With over $250 million financed (residential) - more than other leading states, combined- the Mass Save® HEAT Loan initiative has the largest volume of loans. It also has the broadest lender participation with over 60 local Banks and Credit Unions across the Commonwealth offering this product. Since 2011, the initiative has incorporated a broad FICO score acceptance, well into the sub-prime category. Approximately 45% of households taking the HEAT Loan in 2014 had incomes between $40 and $80 K, and banks indicate that income is not a major barrier for HEAT loan approval (detail found on page 229 of the DRAFT 2016-2018 Plan). The current HEAT Loan developed, deployed, and offered to customers by the PAs in conjunction with the Massachusetts Bankers Association and Credit Unions, has low costs to the Programs, a very attractive interest rate, no credit enhancements, no loan administrative costs passed back to PAs, and lenders bear the principal risks. All customers of electric PAs receive the HEAT Loan application. Gas PAs that have municipal electric companies within their territories will offer the HEAT Loan to those natural gas/municipal electric customers. In this way, all customers that pay into the funds are able to access the HEAT Loan. This universal access and common 0% interest rate has tremendous marketing and brand value for energy efficiency and the PAs' energy efficiency programs. The Mass Save® HEAT Loan is a major success story. The PAs have given the Council's recommendation serious attention. At this time the value of the current structure, including the single 0% interest rate, is working effectively both in terms of costs to administer and results in broadly serving the Massachusetts market place by	Section II.E.2.a, pages 35-36 Section II.E.4.b, pages 47-48 Section II.E.4.c, page 55 Section II.E.4.e, page 66 Section II.H.2, page 152 Section V.B.5, pages 228-230
a	Provide low interest (e.g. 2%) loans for market rate customers, and maintain 0% for moderate income customers.	4		
b	PAs fund a loan loss reserve for moderate income customers and customers with marginal (e.g. 600-	4		

24	**The PAs shall coordinate with DOER to expand the HEAT loan-eligible measures to include those currently funded by DOER under the Expanded HEAT Loan program.**	**3**	leveraging the expertise and capital of the existing lending community. Similarly it does not appear at this time that there is reasonable justification for a loan loss reserve given the programs current success in serving moderate income customers and current broad FICO score acceptance. The PAs will continue their efforts to understand the nature of barriers for different customer segments, which may be related to accessing capital, and to explore financing products/solutions to address them. The PAs will also continue to review the cost to administer the HEAT Loan offer and seek out efficiencies and cost savings.	Section II.E.4.a, pages 47-48 Section II.H.3.b, page 155
25	**The PAs shall identify and implement appropriate ways to simplify and accelerate the HEAT Loan application and approval process.**	**2**	PAs have not fully developed strategies for addressing all possible technologies. PAs are reviewing these matters, while also seeking to ensure that each technology is addressed in the most appropriate forum. The outcomes of the anticipated RCS regulation changes and cost effectiveness screening will be critical to understanding which technologies may be eligible for a HEAT Loan and whether efficiency resources may be appropriately applied. PAs are open to leveraging their highly successful HEAT Loan infrastructure to support additional related energy technologies but only if additional funding is available. It is contemplated that HEAT Loan expansion will require additional funding sources that could vary by measure. The current HEAT Loan offering was developed, deployed, and offered to customers in conjunction with the Massachusetts Bankers Association and Credit Unions. PAs will continue this successful partnership working closely with our partners in the lending community who are best positioned to offer advice on loan application and approval processes. The current loan volume is a strong indication that the current process is well designed and administered. PAs remain ever vigilant to ensure the best possible customer experience across all customer/program touch points and work continuously to simplify and accelerate the process.	Section V.B.5, page 230
		New Construction Initiative		
26	**The PAs shall enhance the New Construction Initiative:**	**1**	The PAs are enthusiastic about continuing to enhance the new construction initiative in ways that motivate builders to use the most energy efficient technologies and building practices for Massachusetts homes. PAs are committed to promoting the value of net zero and renewable ready measures to builders in the New Construction Initiative. Currently, multiple builders in the highest performance tier are including renewable ready elements along with super-efficient designs and construction resulting in homes that achieve net zero or renewable ready status. PAs have already begun to share these success stories and promote the approaches used in training and educational offerings and through marketing. In this way, PAs support the industry in achieving increased numbers of high performance homes and support customer understanding of their value within the market. For 2016-2018 the PAs will be increasing their education and marketing on how builders can use the existing initiative to reach net zero or net zero ready in the current new construction training programs. The High Rise path (serving buildings that are 4+ stories) offers a custom option, which is prescriptive based. The Joint Management Committee ("JMC"), including residential and commercial new construction technical experts from the PAs staff and the lead vendor, will continue to assist in defining performance targets, establishing incentive structures, recruiting developers, completing energy analysis, and providing technical guidance on energy efficiency construction practices. A more detailed or clearer articulation of how the custom path reflects a "performance path" will be considered.	Section II.E.2.c, page 37 Section II.E.3, page 39 Section II.E.4.a, pages 41 and 45
a	By Q1 2016, implement a "renewable ready" requirement in the highest two performance-based tiers and the top prescriptive incentive tier.	4		
b	By Q2 2016, deliver a report to the EEAC that assesses:	4		
i	Creating a Zero Net Energy (ZNE) incentive top performance tier.	3		

ii	Adding a performance path for multi-family housing (4+ stories).	3	The plan will not be including artificial deadlines or additional reporting or research requirements that are a level of design detail not appropriate to the plan and run the risk of distracting effort and effectiveness in achieving the shared strategic commitment of the PAs and the Council to achieving the deepest savings possible in the New Construction Initiative.	
iii	Increasing incentives for rental housing new construction as a way of mitigating rental split-incentives.	4	The PAs are unable to include increased incentives for rental housing in the plan. The New Construction Incentives are not stratified by housing type, and incentives are provided to the builder. Savings are calculated based on the unit level savings above an agreed upon baseline. PAs cannot currently claim different savings based on planned occupancy. The new construction initiative experiences some difficulty in maintaining cost effectiveness, leaving no room for incentive increases without some corresponding increased savings. This is also a concern for adding new incentives for non-energy savings items such requiring renewable ready, net zero, or achievement of these elements. Incentives and requirements of the program shall remain focused on maximizing energy efficiency savings. Although not specifically recommended by the Council, the PAs will be exploring the savings opportunities home automation technologies can provide to the new construction initiative. The PAs feel home automation could be an exciting advancement in new construction market that could also help make the initiative more cost effective.	
		Behavior Initiative		
27	**The PAs shall expand savings from behavior programs and explore the incorporation of home automation technology into their behavior initiative and report to the EEAC on the results of their findings.**	**1**	The PAs are actively deploying behavioral programming, specifically through the Home Energy Report initiatives that the majority of PAs intend to continue. Two gas PAs have been unable to secure a reasonable cost for the HER deployment in their service areas, though given the broad reach of the electric PA programs, many of these customers may already have been treated, thus a spillover effect is in play. PAs intend to continue to monitor opportunities for amendments to the current HER model and new behavioral initiatives. The field of behavioral energy efficiency is evolving, with new product offers from vendors as well as new opportunities created by technology and engagement tools. PAs share the Council's enthusiasm for supporting cost-effective emerging technologies and will continue exploration of how home automation technology can be woven into initiatives, including exploring its use in combination with behavioral elements. There is considerable discussion in the Plan on this topic (see narrative under New Construction Initiative above). PAs are also continuing to evaluate and explore opportunities to leverage home automation technologies including eligible wireless enabled thermostats and their associated communication tools as well as other custom engagement tools for behavioral savings. The Plan further notes that some PAs may explore offering behavior initiatives that have the ability to provide near real time electric consumption feedback, and have the ability to offer a mobile based application in addition to traditional web based or paper reporting. Some PAs may also look to see what potential exists to tie in home automation, smart appliances, and other controls where applicable. Some electric PAs may leverage funding from their Grid Modernization Plan in areas where energy efficiency and grid modernization cross over.	Section II.E.2.b, page 36 Section II.E.3, page 38 Section II.E.4.d, pages 62-64
		Multi-Family Retrofit Initiative		
28	**The PAs shall increase savings from, and improve the customer experience in, the multi-family retrofit initiative:**	**1**	PAs remain committed to continuous improvement of the multi-family program to increase savings and improve the customer experience. PAs expressly commit in the Plan to continued improvement of the customer's single point of contact experience,	Section I.A.2, page 11 Section II.E.1, page 33 Section II.E.2.a, page 35

a	Provide weatherization incentives and HVAC and hot water equipment rebates to multi-family buildings that heat with unregulated fuels (e.g., oil or propane) to the same extent provided to gas or electric resistance-heated multi-family buildings.	1	leveraging and expanding from the success of the MMI model to further support customers. PAs also commit to seamless program delivery, linking rebates, incentives and services to the customer in a way that provides a comprehensive energy efficiency offer and maximizes savings. PAs are committed to coordinating the residential multi-family and commercial initiatives through the joint participation of the Multi-Family Working Group of Residential and C&I program management staff and vendors, working together to streamline delivery of packaged, comprehensive energy efficiency services to the multi-family sector. PAs are also committed in the Plan to tracking and reporting residential and commercial meter savings separately. PAs have planned for expansion of weatherization, HVAC, and water heating to multi-family customers utilizing oil and propane, pending (and dependent on) finalization of RCS regulations. PAs currently offer and will continue to offer support for Multi-Family properties to benchmark their properties through the EPA Benchmarking tool (Portfolio Manager). The link to this nationally recognized tool is included on the website page(s) associated with the Multi-Family Retrofit core initiative. EPA Portfolio Manager is a publicly available and free tool accessible to all property owners. PAs have supported data upload through the Green Button Initiative and have extensively coordinated with disclosure efforts such as the Boston Energy Reporting and Disclosure Ordinance to support customers' ease of access to benchmarking and compliance with reporting requirements.	Section II.E.2.c, page 37 Section II.E.3, pages 39-40 Section II.E.4.b, pages 47 and 51-52
b	By Q2 2016, for buildings that benchmark, use benchmarking to:	NA		
i	Institute or demonstrate a "pay for performance" approach to retrofits using pre- and post-retrofit baselines for evaluation.	4		
ii	Customize incentives to facilitate participation and deeper savings per building.	1		
c	By Q2 2016, develop and implement a plan or initiative for benchmarking in the multi-family sector.	1		
d	Seamlessly deliver services, rebates and incentives to the customer, regardless of whether such services, rebates or incentives are supported by the commercial or residential program.	1		
i	Provide customers with a single point of contact to act as a project manager offering whole building services for both residential and commercially metered buildings, including overseeing energy efficiency installations and coordinating with the PAs and their vendors.	1		
ii	For each building, link all services, rebates and incentives provided, regardless of whether such services, rebates or incentives are supported by the commercial or residential program, to provide a comprehensive view of commercially- and residentially-metered energy use and savings.	1		
iii	For each building, track and report both commercially-metered energy use and savings, and residentially-metered energy use and savings.	1		
e	Segment the sector (e.g. according to ownership patterns, building types, or meter configurations) and implement tailored approaches to facilitate increased participation and savings per building within such segments.	1		
f	Prioritize comprehensive whole building based performance.	1		
g	By Q2 2016, implement an initiative, in partnership with housing finance institutions, to integrate efficiency work into opportunities such as refinancing or retrofitting of larger multi-family buildings.	3		
	Low-Income Programs			
29	**The Low-Income Energy Affordability Network (LEAN) shall expand their eligible scope of services:**	**1**	PAs have planned for expansion of weatherization, HVAC and water heating for eligible participants in the low – income multi-family program utilizing oil and propane, pending finalization of the anticipated revised RCS regulations. PAs will work with their partners at LEAN to ensure any efforts designed to serve moderate income customers up to 80% of state median income are coordinated. This is discussed above in response to Council recommendation # 18. With respect to recommendation #29.b, the PAs believe that changing the 60% state median income standard used with consistency at the DPU for low-income EE matters is beyond the scope of these current program design efforts.	Section II.E.2, page 11 Section II.E.3, page 38-39 Section II.E.4.a, page 85 Section II.E.4.b, page 90
a	Provide weatherization, HVAC, and hot water technology services to low-income multi-family buildings that heat with unregulated fuels (e.g., oil or propane).	1		
b	Define low-income multi-family buildings as those with at least 50% of tenants earning up to 80% of Area Median Income (AMI).	4		
c	Assess and report to the Council on expanding 1-4 family program to serve customers up to 80% AMI.	Refer to #18		

d	Evaluate and, if appropriate, serve non-profit organizations that primarily serve low-income customers, provided that:	3	It should be noted that non-profits are served as commercial entities and therefore any program or initiative activity will be the province of the C&I programs, regardless of delivery vendor.	
e	Such services are clearly defined, and synched with Mass Save® C&I sector non-profit initiatives;	NA		
i	There is adequate funding such that providing such services does not reduce services to preexisting LEAN markets or exacerbate the low-income residential program queue;	NA		
ii	The PAs and LEAN report annually to the EEAC on which non-profits are served, what services are provided, and the cost per building	NA		

G. **<u>Council's Resolution of July 21, 2015</u>**

Massachusetts Energy Efficiency Advisory Council

Comments regarding the April 30th Draft 2016-2018 Energy Efficiency Plan

Resolution approved July 21, 2015

I. <u>Introduction</u>

Under the Green Communities Act ("GCA"), the Energy Efficiency Advisory Council ("EEAC" or "Council") is charged with reviewing the Massachusetts Program Administrators' ("PAs") draft Statewide Electric and Gas Energy Efficiency Plan ("the Draft Plan"), submitted to the EEAC on April 30, 2015. Having reviewed the Draft Plan, the EEAC provides the following comments to the Department of Public Utilities ("the Department") and the PAs.[1]The EEAC recognizes and commends the PAs on the significant achievements made during the first two years of the current 2013-2015 Plan, in particular surpassing the 2014 Plan savings goals on a state-wide level. The Council looks forward to building on that success by leveraging the collective experiences and shared commitment to design and deliver programs to achieve all available, cost-effective energy efficiency savings consistent with the GCA goals. The EEAC also recognizes and appreciates the significant hard work that the PAs have put into the development of the Draft Plan, and encourage the continuing cooperation among PAs, the EEAC and its consultants, and interested stakeholders through the planning process.

The following comments represent input from councilors, stakeholders, legislators, and EEAC consultants, gathered through EEAC meetings, two public comment sessions and nine workshops to engage councilors and PAs in discussion. The EEAC notes and appreciates the PAs' contributions to engage fully in these workshops.The Council looks forward to continuing collaboration and the exchange of information among the PAs, the EEAC and its consultants, and interested stakeholders throughout the summer and fall. It is the EEAC's expectation that the PAs will work with the EEAC and its consultants to continue to refine and improve the Draft Plan, through timely interim updates on program design that respond to this resolution with a Revised Plan to the Council no later than September 18th , leading to filing a Final Plan with the Department in October. In this spirit of collaboration, the Council provides the following comments on the Draft Plan as the next step in its role in shaping the 2016-2018 Final Plan.

A. Savings Goals and Program Costs

The EEAC's first priority in evaluating the Draft Plan is to consider the level of targeted lifetime savings

and benefits achieved by the programs. The EEAC resolved on March 31, 2015 that it "shall only approve 2016-2018 Plans that include savings goals that build on the achievement of the prior Three-Year Plans and conform with and support the successful attainment of all available cost-effective energy efficiency." The Draft Plan falls short of both objectives: to build on the programs' prior savings and

[1] Only voting members of the EEAC may vote to approve this resolution, therefore this resolution does not necessarily represent the views of the all parties who have participated in the 2016-2018 Draft Plan development.

benefits achievement and to meet the GCA's mandate to achieve all available cost-effective energy efficiency. The PAs' proposed savings goals for gas and electric in the Draft Plan are too low and are below the level of current achieved savings. Consistent with the GCA, the PAs must take advantage of all cost-effective innovations on the demand side, especially at a time when other energy sources are constrained.

The EEAC supports savings goals higher than proposed in the Draft Plan and in line with the Consultants' estimate of savings, as updated July 13th, in which they recommended savings goals (on average across the 3 years of the 2016-2018 Plan) of 3.09% of annual savings as a percentage of retail sales for electric; 1.44% of annual savings as a percentage of retail sales for gas; with 44,696,836 megawatt hours (MWh) of lifetime electric savings and 1,321,607,043 therms of lifetime gas savings.

The EEAC sees many indications that the PAs can pursue and achieve additional energy savings and benefits, beyond those reflected in the Draft Plan. Among the more significant indications are:

- The historical PA achievements, including the evaluated level of savings in 2014 (for electric: 2.76% of annual savings as a percentage of retail sales, and 13,554,964 MWh of lifetime savings; and for gas: 1.35% of annual savings as a percentage of retail sales, and 382,857,716 therms of lifetime savings);
- The EEAC Consultants' March 10th Assessment of Potential for energy efficiency savings (3% of annual sales for electric and 1.5% for gas);
- The energy efficiency savings goals in line with the Massachusetts Clean Energy and Climate Plan for 2020; and
- The robust benefit/cost ratios for the electric programs in the PAs' Draft Plan (2.38 overall and increasing across the three years).

Given the differences in savings goals and program costs between the Council's consultants and the Draft Plan, it is clear that some of the planning assumptions made by the PAs in the Draft Plan differ from those assumptions made by the EEAC consultants in their April 30th recommendation, and updated recommendations from July 13th. The EEAC appreciates the collaborative effort that the PAs and Consultants have expended in recent weeks exploring the main assumptions that account for these differences and expects that the results of this "key drivers" analysis will be reported to the EEAC for consideration at its August EEAC meeting.

The EEAC also notes that, in 2014, the PAs achieved savings significantly above plan year goals while spending close to budgeted costs. The PAs hard work in overcoming sector level challenges to achieve these nation-leading levels of savings is appreciated. Notwithstanding the potential for assumptions to change through the "key drivers" analysis, the PAs' most recent results indicate that the steep increase in levels of program costs in the Draft Plan is not merited without a commensurate increase in savings. Where budget increases are proposed above 2014 actual levels, the EEAC requires a detailed and reasonable justification of any higher costs in the Revised Plan, with factual support linked to program redesign, specific baseline changes, new initiatives, deeper savings, incorporation of the EEAC's informed recommendations, or other rationale(s).

The EEAC expects that the Revised Plan will provide significantly higher savings goals at similar or lower program costs, while clearly demonstrating that the PAs seek to achieve all available cost-effective energy efficiency consistent with GCA. The EEAC requires that the next draft provide more specificity and back-up data for the proposed goals in general, and, more specifically, complete and updated cost-benefit screening tool data by PA. If any PAs propose goals below 2014 evaluated levels of lifetime savings in MWh, therms, gallons of oil, or British thermal units (BTUs) of propane achieved by any sector for any year within 2016-2018, the Revised Plan must include detailed and specific relevant data that informed the decision to reduce the savings goal, including any independent market assessments of achievable savings goals.

B. Other EEAC Priorities

The EEAC reiterates its priority of continuous improvement in lifetime savings, benefits, and customer experience for the 2016-2018 Plan expressed in the March 31, 2015 Resolution. In refining the plan, the EEAC encourages the PAs to maintain an emphasis on lifetime savings and benefits. The Council further supports greater integration of gas and electric programs and additional winter and summer peak demand savings. Although there are line items in the EEAC reviewed term sheet template for summer and winter electric demand savings, the EEAC does not see much emphasis in the Draft Plan on demand reduction. The Council encourages additional efforts to realize electric demand savings.

The EEAC also appreciates the PAs' creation in the Draft Plan of offerings that target historically underserved segments of businesses and residents statewide, such as renters, moderate income customers, and small businesses. These efforts are the type of market segmentation and targeting that will enable the programs to continue to grow, capture further savings, and equitably serve ratepayers throughout the Commonwealth. The Council expects the PAs to include much more detail in the Revised Plan about these offerings and additional offerings that target other customer segments.

The EEAC thinks that the Mass Save Data website is a useful tool and greatly appreciates the PAs' continual improvement to this website. However, the Council continues to request a comprehensive statewide database with sufficiently granular inputs and this website should not be framed as such. Instead, the Revised Plan should more accurately reference the status of the EEAC stakeholder process, including the Department's December 2014 decision. A comprehensive database is still seen by the Council as a significant aid in: identifying untapped opportunities for savings, enabling better comparisons between PAs and incorporating best practices across territories, streamlining and reducing costs of EM&V, and addressing many of the EEAC's requests for additional reporting.

Finally, the EEAC recognizes that performance incentives are an integral part of the planning process and of program implementation. The Council does not provide any comments on the performance incentives proposed in the Draft Plan at this stage. Before October, the EEAC will review the overall framework of the current performance incentive model with the PAs and EEAC consultants, in order to optimize and calibrate the performance incentive structure to reflect the priorities of the EEAC and ensure the best results.

C. Major Overarching Comments

The Draft Plan describes in detail the existing programs already established and underway, but provides little specificity regarding changes or enhancements proposed by the PAs to these programs for 2016-2018. The EEAC requires that the Revised Plan include additional detail and clarity regarding the program elements being newly introduced for the 2016-2018 timeframe, elements being continued from previous years, and elements the PAs propose to continue with specific improvements. The Council expects additional details in the Revised Plan including implementation strategies, budgets, and timelines for all substantial changes the PAs plan to introduce relative to the 2013-2015 Plan.

The Draft Plan provides few firm commitments, specifics, or dates by which program enhancements and new initiatives will be introduced. Similarly there are only rarely descriptions of action plans or timeframes for deciding on and implementing the various options the PAs are exploring. Taken as a whole, the lack of specificity in the Draft Plan is such that the EEAC cannot, at this stage, determine whether it can support the programmatic changes the PAs propose. The EEAC requests that dates, milestones and additional detail for all changes to programs and initiatives be included in the Revised Plan.

The EEAC encourages more innovation by the PAs through pilots and/or demonstration projects, as well as through programmatic changes. The Council urges the PAs to take advantage of opportunities to introduce new approaches to advance the energy efficiency market further. In particular, the PAs have the opportunity to continue driving the light emitting diode (LED lighting) market and the related phase-out of compact fluorescent lightbulbs (CFLs), rather than simply reacting to current market trends as described in the Draft Plan.

The EEAC recognizes that lighting baselines and certain building code provisions are changing in the coming years, and that these changes will affect the level of claimed savings. However, the EEAC remains confident that the PAs can deliver new and improved programs that continue to grow cost-effective and deeper savings by leveraging increasing customer awareness, reaching historically underserved sectors, and taking advantage of rapid changes in technologies such as lighting, controls, and heat pumps, aligned with decreasing capital and installation costs of these and other technologies.

Finally, the EEAC has prepared detailed comments regarding the PAs' responses to the informed recommendations the Council provided in its March 31, 2015 resolution. The Council's more specific comments on the Draft Plan are included below in Section II.

The EEAC re-emphasizes its appreciation for the hard work and efforts of the PAs in developing the Draft Plan and implementing the current nation-leading and award-winning programs. The EEAC recognizes that the planning process is an ongoing one and the PAs are continually working on further refinements. The Council is ready and willing to work with the PAs, prior to the October filing with the Department, to improve the Draft Plan and align the details of the Revised and Final Plan with the GCA and the Council comments and recommendations.

II. EEAC Recommendations

In support of the priorities articulated above, and in order to achieve the high levels of benefits, lifetime electric and natural gas savings, and demand reduction consistent with the GCA, the Council makes the following recommendations. The recommendations in this section may not represent the opinion or position of every Councilor on certain issues, but on the whole, the EEAC has determined that the recommendations should be considered and addressed in the Revised Plan. The EEAC appreciates that some of these recommendations have cost-effectiveness, budgeting, and bill impact implications that the PAs will consider alongside benefits. At the same time the EEAC thinks that the Revised Plan must innovate in order to set the stage for future plans where lighting is expected to contribute a lower percentage of overall savings and benefits.

Cross-Cutting Recommendations

a. The PAs, in coordination with the EEAC, should develop a methodology for reporting accurate program penetration and participation numbers that will be reported regularly to the EEAC. The EEAC appreciates the difficulty of reporting on upstream programs. As such, it is appropriate for the PAs to develop building-level tracking with zip-code level reporting[2] for building level measures and to report on upstream programs at a measure level by PA territory.
b. The PAs should support products and practices that reduce winter and summer peak demand by taking the following actions:
    i. Design, implement, and evaluate a demand reduction or demand response offering in each PA's service territory.
    ii. Detail the results of the PAs' ad hoc group that is exploring demand reduction strategies, including a description of subsequent actions to be taken, and a timeline for implementation of such strategies in the Revised Plan.
    iii. Collaborate with the EEAC consultants in investigating the potential impact on efficiency savings from a greater emphasis in program design on demand savings or peak demand savings, including reviewing whether changes to the cost-benefit screening tools are appropriate.
c. The PAs should work with the Department of Energy Resources (DOER) to identify appropriate incentives in the Mass Save programs for renewable thermal technologies.
    i. DOER and the PAs shall jointly develop a methodology to claim savings associated with the installation of renewable thermal equipment and fully account for savings where appropriate associated with the reduction in use of the prior fuel source.
    ii. The PAs should provide rebates and incentives for renewable thermal technologies, where deemed appropriate and cost-effective at the sector level pursuant to the above methodology, not later than Q3 2016.
    iii. The PAs should continue to coordinate with the Massachusetts Clean Energy Center and DOER to provide information to customers and promote coordinated rebates and incentives for renewable thermal technologies.

[2] Reporting at higher aggregations than a single zip-code may be warranted on a case-by-case basis for certain C&I measures, but the default should be to provide geographic information while maintaining client confidentiality.

Commercial and Industrial (C&I) Recommendations

A. Segment Specific Approaches

The Draft Plan includes several examples of existing segment-specific approaches such as coordination with municipalities, and it is clear that these are an important part of the PAs' C&I strategies.

a. The PAs should provide more specifics about segment-specific approaches in the Revised Plan, including:
    i. Which segments will be and are being served with segment-specific approaches, and the timeframes and strategies for introducing new approaches.
    ii. The PAs' forthcoming on-line application and energy conservation measure portal.
    iii. How the PAs are leveraging industry, professional and Councilor associations and networks.
    iv. More details and timeframes on staff and vendor training to better communicate with customers the value proposition of energy efficiency, address concerns, and stimulate interest in moving forward with recommendations.
    v. How the PAs are addressing demand and peak load reduction through segment-specific approaches.
    vi. How the PAs are addressing the topic of statewide consistency and best practice sharing for segment-specific approaches.
    vii. More information about targeted communication materials for sectors as well as improvements to the Mass Save website to provide these materials
b. The EEAC requests that the PAs report regularly on progress and innovations with respect to how the PAs are implementing segment specific approaches. The PAs should propose a format and schedule in the Revised Plan for these less formal updates.
c. *Healthcare* - The PAs shall provide information about how recommendations from the joint PA/EEAC Consultant Healthcare Best Practices study, or other segment strategy, will be implemented, including commitments to specific timelines for adoption.
d. *Mid-Size Customers* - The PAs shall provide a timeline and details for new mid-size customer strategies.
e. *Non-Profits* – The PAs shall provide a timeline and details of strategic outreach, for serving non-profits beyond what is included in the Draft Plan.
f. *Commercial Real Estate (CRE)* - The CRE sections were not included in the Draft Plan. The EEAC requests that the PAs develop a CRE section of the Plan, informed by the findings of the CRE Working Group before August 1st, if not sooner.
    i. This section should include the following information:
        1. Plans for evaluating sub-metering for the CRE sector, including whether it will be considered as part of PAs' offerings, and a date by which that determination will be made or implementation will occur.
        2. An assessment of all recommendations for CRE from the EEAC's March resolution, and a specific response to each.

B. Continuous Technology Improvement

The PAs did not propose in the Draft Plan any pilot programs, as the EEAC recommended in March, but note that they will undertake a "consolidated research and development ('R&D') effort to (a) support the work of the Massachusetts Technology Assessment Committee (MTAC), and (b) pursue technologies of interest in order to remain at the top of the 'innovation curve.'" However, there is little detail on how this work will be undertaken. New for the Draft Plan is the PA inclusion of a budget line item for "C&I R&D and Demonstration". The Revised Plan should include:

a. More details about the scope and operation of R&D projects, including work performed at the MTAC and PA innovations outside the MTAC.
b. Commitment to implement demonstration projects that advance innovation, especially as it relates to products that reflect rapid innovations in the marketplace, are of high customer interest, and/or have dependence on the customer for persistent savings.
c. Regular updates to the EEAC on R&D and demonstration projects. The PAs should propose a format and schedule for these less formal updates in the Revised Plan.

C. C&I Reporting

The PA Draft Plan has included more initiatives in the C&I programs, largely in line with the Council recommendations. These initiatives will have their own goals and budgets associated with them and will be part of the regular PA tracking data. In the Revised Plan, the PAs should:

a. Establish a three-year Combined Heat and Power (CHP) goal (not necessarily as a separate initiative in C&I Retrofit) and track/report on this CHP-specific goal as part of the PAs' annual reports to the EEAC/Department.
b. Consider adding an Upstream Products break-out for New Construction that includes products beyond lighting, such as water heaters.
c. Commit to continuing to report annually on C&I segment-specific approaches (e.g. CRE, healthcare, mid-size, industrial, etc.).
d. Increase goals for LED lighting, and C&I Retrofit in accordance with the results of the key drivers analysis.
e. Commit to semi-annual reporting to the EEAC on LED streetlight conversions.

D. C&I Updates

The PAs deliver significant energy savings and benefits through the programs through hard work and innovation. Updates from the PAs help inform the EEAC of these efforts and innovations. In the March 31, 2015 resolution, the EEAC asked for regular PA updates on a number of topics. For some topics, like the CHP potential analysis, these requests will require formal reports. Other areas, like the updates on sector-specific approaches or small business program innovations, will not necessarily require regular formal written reports. For topics not needing a formal written report, the EEAC would like the PAs to commit to a less formal reporting method to keep the Council informed of these and other efforts through means such as presentations to the EEAC or periodic (quarterly) PA C&I webinars. The PAs should propose a format and schedule for these updates in the

Revised Plan. The Council thinks these less formal program updates will also provide checkpoints for the PAs to share program success.

E. Retro-Commissioning, Building Controls, and Sub-metering

The Draft Plan notes that the PAs will align the PAs' retro-commissioning (RCx) programs with the recommendations from the "Retro-commissioning Best Practices Study" completed by the PAs and the EEAC Consultants. Existing building operator training programs are discussed, but no new training programs are proposed. The Draft Plan does not address benchmarking in the context of commissioning or legacy controls. In the Revised Plan, the PAs should:

a. Address issues of persistence of savings from RCx projects. Monitoring-based commissioning can increase and ensure persistence of savings and should be further explored and demonstrated.
b. Address how legacy controls will be included in the PAs' retrofit and RCx programs.
c. Address how the use of benchmarking, sub-metering and pre/post metering will be integrated into programs.
d. Commit to a strategy that expands building operator training programs, beyond the Draft Plan and traditional Building Operator Certification (BOC) offerings, including soliciting input from customers.
e. Commit to specific program enhancements and timelines for adoption of best practices identified in the RCx Best Practices Study.
f. Commit to increasing the availability of qualified RCx providers.

F. Behavioral and Engagement

The PAs note that they engage in Strategic Energy Management (SEM) in the context of existing programs and will consider expanding SEM offerings by engaging with early SEM adopters from the Pacific Northwest. The Draft Plan contains little information about behavioral programs and does not commit to deliver reports on either SEM or behavioral programs as requested by the Council. The PAs should include the following information in the Revised Plan:

a. Commitment to assess cost effectiveness of SEM projects in line with the EEAC March 31, 2015 Resolution and, if deemed cost-effective at the sector level, a commitment to develop and evaluate an SEM demonstration project.
b. More detail on behavior approaches outside of memoranda of understanding (MOUs) and on whether and how savings are claimed from customer behavior changes.
c. More detail on direct load control and methods for how the PAs could engage customers in demand response.
d. Commitment to using the Consortium for Energy Efficiency (CEE) Minimum Elements document as a reference when discussing SEM programs, in order to ensure a common understanding of what is included.
e. Commitment to implement and evaluate behavioral demonstration projects for small and medium C&I customers.

G. Small Business

The Council appreciates the PAs' commitment to the Small Business program. The Draft Plan addresses a number of Council recommendations including realizing deeper savings, expanding gas measures, and expanded sector-specific approaches. The PAs intend to make program enhancements though a series of incremental improvements. Using building analytics is under consideration by the PAs and web-based customer engagement portals will be implemented by the PAs. The PAs should include the following information in the Revised Plan:

a. Specific commitments to program enhancements for the Small Business program, and a timeline for these enhancements. Some of the enhancements the EEAC thinks are important include: expanding offerings for gas measures, more comprehensive marketing/outreach/awareness programs, and more customized approaches for Small Business customers (by size and segment).
b. A timeline for evaluating potential and cost effectiveness of building analytics and portals for small business customers (EEAC Councilors discussed a Q3 2016 deadline).
c. An action plan, including timelines, for using the data collected by online portals to analyze and benchmark energy use to effectively target small businesses.

H. Combined Heat and Power

The PA Commitment to CHP is clear and the PAs largely incorporated the Council's recommendations. The PAs should include the following information in the Revised Plan:

a. A firm commitment to complete the CHP potential report and implement findings including:
    i. Deliverable dates for a best practices review and potential study (EEAC suggested end of 2016)
    ii. Specific mention of pre-packaged and third party CHP options
b. A clear CHP goal and a schedule for annual reporting on the progress toward the three-year goal, even if this is not a separate initiative outside of C&I Retrofit.
c. Higher goals for CHP, in accordance with the results of the key drivers analysis.

I. LED Streetlights

LED Streetlights represent a significant source of savings in the Commonwealth. The Draft Plan notes success with streetlight retrofits by Cape Light Compact and other PAs. However the Draft Plan does not commit to any innovations around streetlights, or to the EEAC-requested goal of retrofitting the majority of utility owned streetlights and all municipal owned streetlights by 2018. The PAs should include the following information in the Revised Plan:

a. An action plan for stimulating rapid conversion for municipally-owned street lights; for example:
    i. Cape Light Compact managed a joint conversion process for all of its municipalities, providing technical assistance and project management through the entire process.
    ii. Upstream or bulk purchase pricing for municipalities.
b. A strategy and timeline to retrofit the majority of utility-owned street lights to LEDs within this Plan's timeframe (including a timeframe and commitment for filing of an appropriate

tariff for utility-owned LED streetlights at the Department). The EEAC intends to support such a tariff at the Department, to aid in removing this barrier for the PAs.

c. Higher savings goals attributable to LED streetlights in accordance with the results of the key drivers analysis.

J. Zero Net Energy (ZNE) Ready Buildings

In the Draft Plan, the PAs propose to establish a basis of technical knowledge and expertise, and a framework for program support for ZNE ready buildings. However there is no timeline or commitment to implement a Zero Net Energy Buildings (ZNEB) program. The PAs should commit to assessing a ZNE ready building tier and include a timeline for a new construction offering in the Revised Plan.

K. Delivered Fuels and Thermal Efficiency

There is no mention of the PAs' marketing comprehensive assessments to non-gas C&I customers. The PAs should include the following information in the Revised Plan:

a. A strategic plan for marketing, in-print, online, and in-person, a non-gas customer's ability to self-fund the thermal portion of a comprehensive energy assessment using a PA auditor.
b. A timeline for assessing any barriers or limitations to implementing the strategic plan, and a commitment to work with the EEAC to seek ways to address any barriers/limitations.

Residential Recommendations

A. New Initiatives

Moderate Income Initiative

The EEAC supports the Draft Plan proposals to develop a new moderate income offering within the Home Energy Services (HES) core initiative and the PAs' proposal to initially focus on households earning 61-80% of state median income (SMI). This initial offering should be developed further into an initiative to attract new participants to the HES and multi-family retrofit programs, as well as support follow-through of existing customers with deeper savings opportunities. Therefore, the Revised Plan should include:

a. Detail on the proposed scope of measures and program marketing plan, including plans to leverage partnerships with community groups, possible points of entry, and qualification for eligible customers.
b. Detail about the customers in this income range, including number and proportion of residential customers in the 61-80% SMI in each PA territory and the number of those customers that the PAs expect to serve.
c. Commitment to provide and incorporate, as appropriate, lessons learned from the Efficient Neighborhoods +® (EN+) evaluation and other pilots, demonstrations, or applicable programs by Q1 2016.
d. Commitment to assess by Q2 2017 the potential for serving customers at 81-100% and 101-120% of state median income as part of an expanded moderate income offering.

Renter-Specific Initiative

The EEAC supports the PAs' inclusion of a renter-specific initiative in the Draft Plan that recognizes a large and relatively underserved customer base. In order for the EEAC to fully comment on and understand this initiative, the PAs should include the following clarifying details in the Revised Plan:

a. The implementation strategy and schedule for the renter-specific offering, providing dates, milestones, and a date in 2016 by which the offering will be available to qualified HES and multi-family customers. The PAs should provide details on program marketing, including plans to leverage partnerships with community groups.
b. The PAs' proposed engagement strategy to ensure immediate benefits to renters, with a plan for securing landlord buy-in and follow-through with whole-house/building measures.
c. The savings measures that will be offered to renters and how such measures compare to the measures currently provided under the HES and multi-family retrofit initiatives.

B. Whole House Program

The Council recognizes the great need for deeper and diversified savings in the Whole House Program, which was not fully addressed in the Draft Plan. The EEAC supports the PAs' plan to conduct an extensive review of the customer experience through HES, to streamline, simplify and maximize opportunities to influence customers to pursue deeper savings. The Revised Plan should include:

a. A commitment to household-level tracking of all non-upstream measures, where technically feasible.
    i. Include a proposal, with dates and milestones, for linking rebates and incentives provided to the same household across programs and PAs, together with a plan for reporting this whole house coordinated information at a zip-code level.
b. Dates for: completion of the extensive review of the HES program, development of a plan for implementation of identified opportunities, and a report back to Council.
c. Details, dates, and milestones regarding improvement of the integrated "one-stop shop" customer experience, including providing customers with both Mass Save and non-Mass Save incentive/rebate information, regardless of heating fuel source, consistent with the proposed Residential Conservation Services (RCS) regulations.
d. Details of the expected oil and propane savings by PA, based on an analysis of their service territory.
e. Commitment to collaborating with DOER and the EEAC consultants to identify the actions and implementation steps needed to provide customers with an asset-based "home energy scorecard", including cost estimates for each step.
f. Strategies (including continuation of existing strategies) tailored to specific customer groups or segments, such as targeted approaches, technical assistance, or offerings (e.g., homes undergoing remodeling work, high energy users, and customers using electric resistance heat).
g. A description of efforts to ensure equitable treatment of Home Performance Contractors (HPCs) compared to lead vendors, including 3rd party quality control inspections and regular opportunities to engage and present to the Residential Management Committee (RMC).

C. HEAT Loans and Financing

The Council appreciates the success of the HEAT Loan program to date. The Draft Plan proposes no changes to the HEAT loan or other financing initiatives. In the Revised Plan, the PAs should include:

a. Strategy, dates, and milestones to assess how moderate income customers are currently served and could be better served by the HEAT Loan program, including assessment of the cost and effectiveness of a loan loss reserve, taking due account for the economic vulnerability of some customers.
b. A date by which the PAs will finalize additional measures to be financed through the HEAT loan, including those currently funded through DOER's Expanded HEAT Loan Program.

D. Multifamily Retrofit

The EEAC understands the complexity of the multifamily sector, including the dual residential-commercial meters that may serve them, the diversity of building types, ownership entities, and resident profiles. The Council is supportive of improving the customer experience through the PAs' proposed single point of contact for multifamily projects. The PA C&I team should be engaged in refinements to the multi-family program. In the Revised Plan, the PAs should:

a. Provide detail on the PAs' proposed single point of contact and commit to assessing what changes are necessary to integrate commercial and residential rate codes into a whole building approach.
b. Commit to developing and providing targeted offerings to different segments of the multifamily building market.
c. Provide plans for improving the integration of efficiency into refinancing events, such as through a proposed partnership with the state's housing finance agencies or commercial lending institutions.
d. Commit to providing multi-family customers with user-friendly benchmarking tools to track unit-level energy usage and comparisons against peers.
e. Implement a pay-for-performance demonstration program.

E. Behavior

The PAs include consideration of positive additions to behavior programs in the Draft Plan, including home automation, near real-time feedback, smart appliances and controls. In addition to these enhancements, in the Revised Plan the PAs should:

a. Commit to expand behavior program participation and include dates and milestones to implement this expansion. PAs not implementing behavior programs should document why these measures are not cost-effective and why the PA is not partnering with other PAs that are implementing behavior programs.

F. New Construction

The Draft Plan does not address the initial Council recommendations on New Construction. The Council supports the Draft Plan's inclusion of marketing and education efforts around zero net energy (ZNE) homes. In the Revised Plan, the PAs should:

a. By Q4 2016, commit to working with the EEAC consultants to explore how to claim savings for renewable energy systems in the cost/benefit analysis.
b. Add a performance path for multi-family housing.
c. Implement a renewable-ready requirement in the highest two performance tiers and the top prescriptive tier.
d. By Q4 2016, commit to working with the EEAC consultants to assess the impact of creating a ZNE incentive top performance tier and report findings to the Council. Use findings to inform implementation of a ZNE top performance tier.

G. Renewable Thermal

The Draft Plan does not explicitly address the growing market for renewable thermal technologies, though it references the expected updates to the RCS regulations that allow fuel switching away from pre-existing heating fuels.

a. The PAs should actively collaborate with DOER on the development and implementation of RCS guidelines, and by Q4 2016, update and maintain the cost-benefit screening tools for renewable thermal technologies.

H. Products Program

Lighting

The EEAC supports the commitment in the Draft Plan to phase out incentives for specialty CFLs by 2016. However, the Draft Plan does not fully address the Council's recommendations on LEDs and appears to use inconsistent and overly conservative volume and cost projections for 2016-2018. In the Revised Plan, the PAs should:

a. Increase savings projections to reflect a growing market share of LEDs and increasing sales volumes for retail lighting.
b. Commit to quarterly reporting to the EEAC on progress of LEDs during Plan implementation.

Heating and Hot Water

The PAs did not propose residential upstream incentives for hot water heaters in the Draft Plan, although this is being implemented for C&I customers. The Council recognizes that the PAs need to understand the market potential for this incentive and the effects of implementing an upstream program on savings. In the Revised Plan, the PAs should:

a. Include an assessment of implementing upstream incentives for residential tankless water heaters and other potential HVAC measures and report back to the Council by Q3 2016.

Low-Income Recommendations

The EEAC acknowledges the establishment of the income guideline for Low Income programs at 60% of state median income (SMI) in the Green Communities Act, and the PAs' inclusion of a moderate income offering within the residential Whole House programs in the Draft Plan. The Council recognizes the need for flexibility in programs that serve buildings with high tenant turnover or families living on the margin of eligibility in the Low Income programs. In addition, the Council recognizes the variety of organizations that hold nonprofit status and that some of those organizations own buildings that serve low income populations and may have opportunities for energy savings. The Revised Plan should commit to:

a. Explore ways to flexibly serve low-income multi-family buildings with at least 50% of residents earning up to 80% SMI.
b. Explore alternative incentives or service approaches for non-profit organizations that primarily serve low income customers.

H. **PA Response Matrix to July Resolution**

Submitted: September 23, 2015

PA RESPONSE TO EEAC RESOLUTION ADOPTED ON 7-21-15

	Resolution Language	PA Response	Plan Section
	Introduction		
1.	It is the EEAC's expectation that the PAs will work with the EEAC and its consultants to continue to refine and improve the Draft Plan, through timely interim updates on program design that respond to this resolution with a Revised Plan to the Council no later than September 18th, leading to filing a Final Plan with the Department in October.	The PAs have worked intensively with EEAC members (with a special focus on work with DOER and the Attorney General) and the Council's consultants during the summer and into this month to refine and improve the 2016-2018 Plan in response to the Council's July resolution. In addition, the PAs, the Council's consultants, DOER, and the AG have engaged in extensive discussions, data sharing and analysis to refine assumptions, close the gaps, and come to agreement on appropriate budget, savings, and performance incentive levels for 2016-2018. These discussions have resulted in the Term Sheet being filed herewith, which provides for the highest savings goals ever put forward in the Commonwealth (and, to the PAs' knowledge, in the United States), at costs-to-achieve that are materially lower than the costs in the April 30, 2015 draft plan. To finalize productive discussions, the parties agreed that the PAs should push back submission of the September 18 draft until the week of September 21. The PAs express their appreciation and respect for the extensive efforts of DOER, the Attorney General, the Council's consultants and the EEA in developing and finalizing the historic commitment to energy efficiency. The PAs hope the Council will support unanimously the Term Sheet and the 2016-2018 Plan and look forward to reviewing the Plan with Councilors.	Appendix (Term Sheet)
	Savings Goals and Program Costs		
2.	The EEAC supports savings goals higher than proposed in the Draft Plan and in line with the Consultants' estimate of savings, as updated July 13th, in which they recommended savings goals (on average across the 3 years of the 2016 - 2018 Plan) of 3.09% of annual savings as a percentage of retail sales for electric; 1.44% of annual savings as a percentage of retail sales for gas; with 44,696,836 megawatt hours (MWh) of lifetime electric savings and 1,321,607,043 therms of lifetime gas savings. The EEAC sees many indications that the PAs can pursue and achieve additional energy savings and benefits, beyond those reflected in the Draft Plan. Among the more significant indications are:	The PAs engage in a collaborative and iterative planning process for setting savings goals and budgets. As part of this process, the PAs engaged in extensive, productive, and collaborative discussions with the Council's consultants, as well as DOER and the Attorney General, in an effort to resolve differences and narrow gaps. These discussions resulted in adjustments on the part of both PAs and other parties as they shared, reviewed and analyzed different data sets and assumptions. The PAs necessarily employ a multi-faceted approach and consider and weigh multiple reference points, including the following three distinct analyses: (1) bottom-up; (2) evaluation; and (3) top-down. The bottom-up process involves building plan goals and budgets from the measure level up whereas the top-down process looks at the portfolio as a whole, evaluating the potential for achieving higher goals given markets in which the programs are operating . The impact of evaluation results are considered in both bottom-up and top-down planning and may drive other adjustments. The process to determine goals must be and is fluid, flexible and iterative because PAs receive information throughout the planning process relating to program design, evaluation, costs, and other factors. As discussed in more detail in the Plan, in developing goals for 2016-2018, the PAs conducted a comprehensive assessment of the energy efficiency landscape, including considering changes in baselines, codes, and standards, evaluation studies, PA potential studies, consultant assessments, and other market factors. As a result, the 2016-2018 Plan takes into account many competing considerations to set goals that	II.D; IV; V

Submitted: September 23, 2015

	Resolution Language	PA Response	Plan Section
		satisfy the GCA's mandate to achieve all available cost-effective energy efficiency and the Department's directive to do so at a sustainable pace. As a result of this process, the PAs are submitting savings goals for 2016-2018 that are at the highest level ever for the Commonwealth, and to the PAs' knowledge, in the United States. See Term Sheet being filed herewith.	
3.	• The historical PA achievements, including the evaluated level of savings in 2014 (for electric: 2.76% of annual savings as a percentage of retail sales, and 13,554,964 MWh of lifetime savings; and for gas: 1.35% of annual savings as a percentage of retail sales, and 382,857,716 therms of lifetime savings);	See above response. The 2016-2018 Plan is expected to deliver more lifetime MWh and therm savings than the 2013-2015 Plan. Looking at the PAs' performance in terms of percent of sales does not always provide an accurate comparison of actual savings levels because forecasted sales change from one three-year plan to the next based on factors including weather, economic activity and other factors outside the PAs' control. For example, if savings levels stayed the same or increased, the percent of sales could decline if sales increased. Additionally, other factors outside the PAs' control affect the PAs' ability to achieve savings, including updates to codes, baselines, and standards.	II.D; IV; V
4.	• The EEAC Consultants' March 10th Assessment of Potential for energy efficiency savings (3% of annual sales for electric and 1.5% for gas);	See above two responses.	II.D; IV; V
5.	• The energy efficiency savings goals in line with the Massachusetts Clean Energy and Climate Plan for 2020; and	The 2016-2018 Plan delivers more GHG emissions reductions than prior plans, and has major environmental benefits for the Commonwealth that support the goals of the GWSA. In order to maximize environmental benefits, a goal of the GCA, the PAs, with the support of the Council's independent EM&V expert, propose to conduct a new EM&V study to better quantify the full suite of GHG reductions and benefits that result from energy efficiency efforts.	IV.G.4.d.
6.	• The robust benefit/cost ratios for the electric programs in the PAs' Draft Plan (2.38 overall and increasing across the three years).	In accordance with the GCA and the directives of the Department, the PAs seek to acquire all available cost-effective energy efficiency through a sustained statewide effort. The 2016-2018 Plan provides a strategic plan for acquiring all cost-effective energy efficiency resources at a reasonable pace during this three-year period.	II.B; II.D; IV; V.A
7.	Where budget increases are proposed above 2014 actual levels, the EEAC requires a detailed and reasonable justification of any higher costs in the Revised Plan, with factual support linked to program redesign, specific baseline changes, new initiatives, deeper savings, incorporation of the EEAC's informed recommendations, or other rationale(s).	As discussed above, the PAs engage in a collaborative and iterative planning process for setting budgets. As part of this process, the PAs engaged in extensive, productive, and collaborative discussions with the Council's consultants, as well as DOER and the Attorney General, in an effort to resolve differences and narrow gaps. These discussions resulted in adjustments on the part of both PAs and other parties as they shared, reviewed and analyzed different data sets and assumptions. In developing budgets, the PAs took into account changes in the cost of program delivery, baselines, codes, and standards, evaluation studies, potential studies, consultant assessments, and other market factors.	II.D; III, IV; V
8.	The EEAC expects that the Revised Plan will provide significantly higher savings goals at similar or lower program costs, while clearly demonstrating that the PAs seek to achieve all available cost - effective energy efficiency consistent with GCA.	As noted above, the Plan adopts higher savings goals than the April 30, 2015 draft at reduced costs, consistent with the EEAC's recommendations in the July Resolution.	IV, Appendix (Data Tables)

	Resolution Language	PA Response	Plan Section
9.	The EEAC requires that the next draft provide more specificity and back - up data for the proposed goals in general, and, more specifically, complete and updated cost-benefit screening tool data by PA.	As they did with the April draft, PAs will provide benefit cost screening tools, with detailed assumptions on costs, savings, and benefits (with measure level data) to the DOER, Attorney General and the Council's consultants for the September draft Plan. Final BCR models will be provided to the EEAC and the DPU at the time of the PAs' final October Plan filing. The September Plan includes significant discussion of key drivers of the savings and costs proposed in the Plan.	IV; Appendix (Data Tables)
10.	If any PAs propose goals below 2014 evaluated levels of lifetime savings in MWh, therms, gallons of oil, or British thermal units (BTUs) of propane achieved by any sector for any year within 2016 - 2018, the Revised Plan must include detailed and specific relevant data that informed the decision to reduce the savings goal, including any independent market assessments of achievable savings goals.	See Term Sheet for individual PA goals. All goals have been calibrated based upon Term Sheet negotiations supported by an extensive array of data and associated analysis. Please also refer to the potential studies discussed in the Plan and included as an Appendix, as well as discussion on unique service area characteristics in the Plan and in the Appendices.	IV.A.5.f, V.A.4, Appendices (Term Sheet, Potential Studies, Unique PA Materials)
	Other EEAC Priorities		
11.	In refining the plan, the EEAC encourages the PAs to maintain an emphasis on lifetime savings and benefits.	The PAs report both annual and lifetime savings and benefits.	
12.	The Council further supports greater integration of gas and electric programs and additional winter and summer peak demand savings.	The PAs have integrated electric and gas programs throughout the program design process. For example, the Residential Heating and Cooling - Electric core initiative will continue to work with the Residential Heating and Cooling – Natural Gas core initiative (GasNetworks®) on joint offerings, and co-promote through marketing, contractor training, and trade ally outreach including circuit rider. By collaborating, the PAs offer a near seamless integration of the gas and electric energy efficiency programs. PAs explore electric and gas technologies through MTAC, participate in management committees, and cross-promote between programs and initiatives.	III
13.	The Council encourages additional efforts to realize electric demand savings.	Achievement of demand savings in 2016-2018 is a key goal shared by the PAs and the Council. PA representatives will work with a small Demand Savings Group that includes the DOER, the Attorney General's Office, the Low-Income Energy Affordability Network, and the Council's consultants to explore demand savings opportunities such as demand savings from traditional energy efficiency, demand response, load shifting, and geo-targeting.	III.H.3
14.	The EEAC also appreciates the PAs' creation in the Draft Plan of offerings that target historically underserved segments of businesses and residents statewide, such as renters, moderate income customers, and small businesses. These efforts are the type of market segmentation and targeting that will enable the programs to continue to grow, capture further savings, and equitably serve ratepayers throughout the Commonwealth. The Council expects the PAs to include much	Please refer to the program specific recommendations and Plan sections for additional detail on new and improved efforts, such as the renter-specific visit, moderate income customer enhancements, and optimization of the Multi-Family Initiative. Like its predecessors, the 2016-2018 Plan includes multiple parts that taken together as an integrated whole describe the PAs' strategy for acquiring all cost-effective energy efficiency resources through a sustained effort. While detailed, a Three-Year Plan is a statewide strategic plan and not a detailed implementation guideline. A statewide strategic plan provides the PAs with the flexibility necessary to make implementation changes to meet changing circumstances in order to deliver on their Plan goals and satisfy the GCA.	II.D.1, III

Submitted: September 23, 2015

	Resolution Language	PA Response	Plan Section
	more detail in the Revised Plan about these offerings and additional offerings that target other customer segments.		
15.	The EEAC thinks that the Mass Save Data website is a useful tool and greatly appreciates the PAs' continual improvement to this website. However, the Council continues to request a comprehensive statewide database with sufficiently granular inputs and this website should not be framed as such. Instead, the Revised Plan should more accurately reference the status of the EEAC stakeholder process, including the Department's December 2014 decision. A comprehensive database is still seen by the Council as a significant aid in: identifying untapped opportunities for savings, enabling better comparisons between PAs and incorporating best practices across territories, streamlining and reducing costs of EM&V, and addressing many of the EEAC's requests for additional reporting.	The PAs appreciate the Council's positive comment on Mass Save Data and know that access to data is important to all. In addition, the PAs recognize that competing needs to protect confidential customer data, manage costs, and provide detailed and transparent information must be considered and weighed. The PAs submit that they have developed a publicly accessible statewide energy efficiency database with Mass Save Data, but appreciate that even more information and enhancements may be appropriate. In this spirit and as part of ongoing improvements to Mass Save Data, the PAs are working to provide geographic information, with appropriate aggregation to protect customer privacy. The PAs are also working on providing measure level information on Mass Save Data for 2016-2018. These important new enhancements, which are directly responsive to specific Councilor requests, are under development by the PAs. The PAs remain willing to engage in discussions and review other requests for data and/or enhancements to Mass Save Data, understanding the shared goals of transparency, cost-effectiveness, and protection of confidential information. The PAs have also updated the plan narrative to accurately reference the status of the EEAC stakeholder process, including the Department's December 2014 decision and different stakeholder views during the EEAC process. Finally, the PAs will also carefully review and follow up on any directives of the Department of Public Utilities on the database matters currently pending before it.	VII.C and related appendices.
	Major Overarching Comments		
16.	The Draft Plan describes in detail the existing programs already established and underway, but provides little specificity regarding changes or enhancements proposed by the PAs to these programs for 2016 - 2018. The EEAC requires that the Revised Plan include additional detail and clarity regarding the program elements being newly introduced for the 2016 - 2018 timeframe, elements being continued from previous years, and elements the PAs propose to continue with specific improvements. The Council expects additional details in the Revised Plan including implementation strategies, budgets, and timelines for all substantial changes the PAs plan to introduce relative to the 2013 - 2015 Plan.	Please refer to the program specific recommendations below and program descriptions in the plan for additional detail. This 2016-2018 Plan builds on many successful and nationally emulated programs that the PAs have developed over years of implementing energy efficiency in the Commonwealth. The PAs seek continued innovation, but also seek to continue implementing successful strategies. The program specific materials detail many new innovations for 2016-2018, such as providing a streamlined customer experience, increased use of technology (and automation), leveraging and protecting the energy efficiency workforce, a single-point-of-contact experience for the multi-family customer, increased adoption of LEDs, continued review and expansion of upstream market models, encouragement of net-zero buildings, a renter initiative, enhanced services for moderate income customers, expanded segment-based delivery approaches, and many more. Like its predecessors, the 2016-2018 Plan includes multiple parts that taken together as an integrated whole describe the PAs' strategy for acquiring all cost-effective energy efficiency resources through a sustained effort. While detailed, a Three-Year Plan is a statewide strategic plan and not a detailed implementation guideline. A statewide strategic plan provides the PAs with the flexibility necessary to make implementation changes to meet changing circumstances in order to deliver on their Plan goals and satisfy the GCA.	II.D.1; III.E.3 (details Residential new and innovative); III.G.4. (Highlights C&I enhancements)

Submitted: September 23, 2015

	Resolution Language		PA Response	Plan Section
17.	The Draft Plan provides few firm commitments, specifics, or dates by which program enhancements and new initiatives will be introduced. Similarly there are only rarely descriptions of action plans or timeframes for deciding on and implementing the various options the PAs are exploring. Taken as a whole, the lack of specificity in the Draft Plan is such that the EEAC cannot, at this stage, determine whether it can support the programmatic changes the PAs propose. The EEAC requests that dates, milestones and additional detail for all changes to programs and initiatives be included in the Revised Plan.		See above response.	II.D.1
18.	The EEAC encourages more innovation by the PAs through pilots and/or demonstration projects, as well as through programmatic changes. The Council urges the PAs to take advantage of opportunities to introduce new approaches to advance the energy efficiency market further. In particular, the PAs have the opportunity to continue driving the light emitting diode (LED lighting) market and the related phase-out of compact fluorescent lightbulbs (CFLs), rather than simply reacting to current market trends as described in the Draft Plan.		The PAs actively seek innovation and consistently work on demonstration projects within different programs. The PAs have also included separate budgets for R&D and Demonstration Projects in both residential and C&I sectors. The PAs are committed to technology innovations, through the MTAC as well as through other PA-specific and statewide efforts. Many PAs have in-house staff of technical and engineering professionals with expertise in such areas as energy codes and standards, building energy simulation tools, lighting technology and controls, assessment of energy efficiency products, and product development, who are dedicated to new technology research and, in collaboration with their evaluation colleagues, savings verification. The PAs have driven the market in energy efficiency technologies, such as LEDs, and will seek increased penetration through award-winning marketing campaigns and national leadership. Additionally, the PA programs are tightly coordinated to ensure that innovations in technology and market dynamics are shared and leveraged.	III
19.	The EEAC recognizes that lighting baselines and certain building code provisions are changing in the coming years, and that these changes will affect the level of claimed savings. However, the EEAC remains confident that the PAs can deliver new and improved programs that continue to grow cost-effective and deeper savings by leveraging increasing customer awareness, reaching historically underserved sectors, and taking advantage of rapid changes in technologies such as lighting, controls, and heat pumps, aligned with decreasing capital and installation costs of these and other technologies.		The PAs engage in a collaborative and iterative planning process for setting savings goals, taking into account changes to baselines that affect the level of claimed savings, as well as innovations and new programming, evaluation studies, and performing a detailed review of market conditions. This Plan is designed as a strategic guiding document to provide the PAs with flexibility to make implementation changes to meet changing market conditions and other circumstances in order to deliver on their Plan goals and satisfy the GCA. 	Cross-Cutting			
20.	a.	The PAs, in coordination with the	The residential and C&I customer profile studies were designed to provide geographic	VII.C

Submitted: September 23, 2015

	Resolution Language		PA Response	Plan Section
		EEAC, should develop a methodology for reporting accurate program penetration and participation numbers that will be reported regularly to the EEAC. The EEAC appreciates the difficulty of reporting on upstream programs. As such, it is appropriate for the PAs to develop building-level tracking with zip-code level reporting for building level measures and to report on upstream programs at a measure level by PA territory.	information, program penetration and participation through the EM&V process. The draft *Residential Customer Profile Study* found that the PAs served 200,523 premises through their Residential and Low-Income offerings in 2013, which represents 7% of all premises in the state. This data does not include customers who may have participated in upstream programs or those who received a Home Energy Report through a behavioral initiative. Due to the difficulty of tracking unique customer program participation across PAs, and concerns with customer privacy, the EM&V process was the most appropriate means to gather this information. As discussed in more detail in the statewide database section, two separate databases have been developed to support the customer profile studies. The PAs plan to perform customer profile studies on an ongoing basis so that this type of information can be regularly tracked. Direct access by stakeholders to these databases is not possible because of the need for customer consent for access to sensitive customer account and usage information. The PAs will accept Council requests to query the data in these databases and will prioritize these requests based on the cost of providing answers, the purpose and benefit of the data query and the timing of the request relative to study cycles. For additional information, please see Section VII.C.4. The PAs are also planning to use the Mass Save Data (www.MassSaveData.com) platform to provide geographic information. The PAs are developing a geographic tab that will include electric and gas incentives, usage, and savings. The geographic tab will be populated from the EM&V databases used to support the customer profile studies. In order to protect customer privacy, the PAs must ensure that the data in the geographic tab is sufficiently aggregated to avoid reverse engineering. This tab is still under development and the PAs' aggregation standards are still under discussion. Nevertheless, the PAs expect that they will be able to display C&I data at the town level and are reviewing whether this data can be displayed at the zip code level for Boston. The PAs are waiting for the residential customer profile study to be finalized and will then explore if it is feasible to present data at the zip code level.	
21.	b.	The PAs should support products and practices that reduce winter and summer peak demand by taking the following actions:	The PAs will assess new technologies and demand reduction strategies as they become available and commercially viable. Additionally, the PAs will support products and practices that reduce winter and summer peak demand where appropriate and cost-effective.	III.H.3
22.	i.	Design, implement, and evaluate a demand reduction or demand response offering in each PA's service territory.	The PAs are committed to working together with the Council's consultants to develop alternative efforts focused on creating demand savings during the 2016-2018 Plan. The PAs are currently focused on strategy identification and quantification of demand savings values. To that the end, the PAs have engaged in an expanded AESC study to develop avoided costs during seasonal "super peaks". This is a first step towards identifying benefits and costs of alternative strategies, assessing customer response to alternative strategies, and leveraging smart grid investments.	III.H.3
23.	ii.	Detail the results of the PAs' ad hoc group that is exploring demand	See above.	

	Resolution Language		PA Response	Plan Section
		reduction strategies, including a description of subsequent actions to be taken, and a timeline for implementation of such strategies in the Revised Plan.		
24.	iii.	Collaborate with the EEAC consultants in investigating the potential impact on efficiency savings from a greater emphasis in program design on demand savings or peak demand savings, including reviewing whether changes to the cost-benefit screening tools are appropriate.	See above. This work is in progress but is unlikely to be completed prior to the statutory filing date for this Plan.	
25.	c.	The PAs should work with the Department of Energy Resources (DOER) to identify appropriate incentives in the Mass Save programs for renewable thermal technologies.	The PAs remain committed to working with the EEAC consultants to explore addressing renewable thermal savings in 2016-2018. PAs are seeking to better understand exactly what technologies are contemplated by Councilors and their applicability in a three-year energy efficiency plan under the GCA and whether implementation of some of these efforts is better handled in other contexts or proceedings, such as grid modernization. In reviewing these matters, PAs will work with the Council's consultants to discuss and determine if there are cost-effective measures/strategies that can be appropriately delivered as energy efficiency measures, as opposed to renewable supply side measures, what funding sources are available, what energy savings and other quantifiable benefits can be claimed for incentivizing these measures, and what, if any, are the most promising potential technologies and, if applicable, choosing a set of them to prioritize. The PAs also suggest that any additional efforts beyond ongoing energy efficiency efforts should be supported with an appropriate performance incentive to better align PA and public policy interests as has been done with traditional energy efficiency efforts.	
26.	i.	DOER and the PAs shall jointly develop a methodology to claim savings associated with the installation of renewable thermal equipment and fully account for savings where appropriate associated with the reduction in use of the prior fuel source.	See above	
27.	ii.	The PAs should provide rebates and incentives for renewable thermal	See above	

	Resolution Language		PA Response	Plan Section
		technologies, where deemed appropriate and cost-effective at the sector level pursuant to the above methodology, not later than Q3 2016.		
28.	iii.	The PAs should continue to coordinate with the Massachusetts Clean Energy Center and DOER to provide information to customers and promote coordinated rebates and incentives for renewable thermal technologies.	The PAs will continue working with the CEC and cross-promoting incentives where there is overlap with PA programs, as appropriate. PAs can work to direct customers to the CEC website for CEC offerings related to renewable thermal technologies.	
	C&I Recommendations			
	A. Segment Specific Approaches			
29.	The Draft Plan includes several examples of existing segment - specific approaches such as coordination with municipalities, and it is clear that these are an important part of the PAs' C&I strategies. a. The PAs should provide more specifics about segment - specific approaches in the Revised Plan, including:		The Plan provides an expanded discussion of segment-specific approaches, including a visual representation of the drivers, barriers and metrics the PAs take into consideration, along with information about purchasing behavior and procurement practices, supply chain dynamics and past efficiency investment patterns, when developing a customized strategic approach to a variety of high-priority C&I customer segments, as identified by the Council and/or the PAs. These factors underpin the PAs choices regarding a wide range of design and implementation elements such as product/technology offerings, incentive levels and structure, marketing and messaging mix, channel selection and engagement, staffing, etc.	
30.	i..	Which segments will be and are being served with segment - specific approaches, and the timeframes and strategies for introducing new approaches.	See table referenced above and accompanying narrative discussion, as well as a chart on the immediately following page entitled *"Current & Planned Segment-based Approaches"*, which illustrates the customer segmented approaches that are deployed by the PAs now, or are in active development for deployment in the 2016-2018 Plan period.	
31.	ii.	The PAs' forthcoming on - line application and energy conservation measure portal.	A full discussion of both can be found in a subsection entitled *"More Tools for Customer Engagement"* within the C&I Retrofit section of the Plan.	
32.	iii.	How the PAs are leveraging industry, professional and Councilor	A section in the Plan entitled *"Mechanisms for Program Collaboration, Continuous Improvement, Incorporating Emerging Technologies, and Sharing and Incorporating Best Practices Information"* contains an explanation, along with examples, of the PA's current and future efforts	

Submitted: September 23, 2015

	Resolution Language		PA Response	Plan Section
		associations and networks.	to leverage relationships with a wide variety of important stakeholders including peer PAs around the country, professional and industry organizations and associations, etc. all of which are extremely important resources upon which the PAs rely for information, program performance feedback, ideas for program enhancements, improved delivery and marketing approaches, and other learnings.	
33.	iv.	More details and timeframes on staff and vendor training to better communicate with customers the value proposition of energy efficiency, address concerns, and stimulate interest in moving forward with recommendations.	The Plan contains a subsection entitled *"Education and Training for Customers, Trade Allies, and PA Staff and Contractors"* within the C&I Retrofit section. This section provides a full discussion of the variety of ways in which the PAs already offer regular specialized training sessions for all their trade allies, other energy professionals who support or participate in the programs, and for their own program and technical staff as well. Common formats include webinars and live presentations at multiple sites around the service territory, including on site at vendor facilities. In addition, every year the PAs sponsor and participate in hundreds of training or educational events around the Commonwealth to reach and influence all the parties who own, manage, or operate and staff buildings in Massachusetts. Some of these events provide customers with a broad exposure to a number of energy-savings technologies and service providers, such as the annual PA-sponsored Vendor Open Houses, while others are more focused and specialized, such as presentations to business associations, chambers of commerce, and meetings of local ASHRAE and IES chapters.	
34.	v.	How the PAs are addressing demand and peak load reduction through segment-specific approaches.	Each Plan initiative with potential to reduce demand while reducing consumption is now described in the Plan with language that notes the dual potential. In addition, the PAs will be exploring the potential to adapt elements of the C*alifornia Advanced Lighting Controls Training Program* (CALCTP) to Massachusetts. (See full discussion under the above-referenced training section.) CALCTP provides electrical contractors and electricians with training and a certification in Advanced Lighting Controls (ALC). The curriculum covers the proper programming, testing, installation, commissioning and maintenance of advanced lighting control systems, including dimmers, occupancy sensors, photo-sensors, relay modules and communication-based control devices. The PAs view this model has having the potential to capture significant KW as well as KWh savings. Additionally, the PAs plan to continue advancing new "smart" technologies and energy efficiency measures that directly or indirectly impact demand and peak load reduction in a cost effective manner.	
35.	vi.	How the PAs are addressing the topic of statewide consistency and best practice sharing for segment - specific approaches	The C&I Management Committee (C&IMC) serves as the ongoing venue for sharing individual PA innovations in program design, marketing, and delivery. The C&IMC regularly reviews its processes and operations in order to continuously optimize the balance between innovation and consistency and will continue these efforts throughout 2016-2018. For example, the PAs respond to the variations of local markets and market conditions through experimentation in program design, product promotion, or a unique focus on distinct customer segments of local importance. This localized testing allows concepts that might have statewide applicability to be tested and evaluated in a limited low-risk/low-cost environment, with the results then shared and scaled up statewide as appropriate and practicable. In addition, the PAs have a variety of other mechanisms to ensure that a robust process to identify and screen candidate technologies is maintained. Full discussions can be found in the	

Submitted: September 23, 2015

	Resolution Language		PA Response	Plan Section
			sections entitled *"Mechanisms for Program Collaboration, Continuous Improvement, Incorporating Emerging Technologies, and Sharing and Incorporating Best Practices Information"* and *"The Massachusetts Technology Assessment Committee (MTAC)."*	
36.	vii.	More information about targeted communication materials for sectors as well as improvements to the Mass Save website to provide these materials.	The Plan includes an expanded discussion of PA plans to reorganize and refresh the Mass Save® website to better direct customers to information specific to their needs in their business segment. As referenced in the Plan, the new design will focus less on technologies and programs and more on customers and their end uses along with available services. It will also feature new materials directed to specific segments and their needs. In addition, the redesign will also provide improved organization, navigation, and more customer-oriented language.	
37.	b.	The EEAC requests that the PAs report regularly on progress and innovations with respect to how the PAs are implementing segment specific approaches. The PAs should propose a format and schedule in the Revised Plan for these less formal updates.	The PAs will continue to report on segment-specific approaches, either as part of annual EM&V studies (primarily the C&I Customer Profile Report), or on a one-off basis to the Council as a whole, or to individual members as has been the practice for a number of years. Also, the PAs have discussed various approaches to providing more frequent and transparent communication to the Council regarding a variety of C&I related efforts and initiatives, including segment-specific approaches, and will work with the DOER early in the plan period to develop a process for enabling that to happen.	
38.	c.	Healthcare - The PAs shall provide information about how recommendations from the joint PA/EEAC Consultant Healthcare Best Practices study, or other segment strategy, will be implemented, including commitments to specific timelines for adoption.	As referenced in the section entitled *"Segments of Special Interest/Large Customers*", the Plan describes how the PAs invest significant staff and third party resources, as well as financial incentives, to serving the highest use customers, which are heavily represented by hospitals. The Health Care Best Practices studies was directed by the EEAC Consultants, and despite its methodological shortcomings, largely confirmed that the PAs' approaches to serving these customers constituted best practices – support for comprehensive audits, use of MOUs, providing educational support for facility managers, collaboration with industry organizations and associations, etc. For quite some time these have been, and will continue to be, foundational elements in the PAs approach to serving this strategically critical segment of customers.	
39.	d.	Mid - Size Customers - The PAs shall provide a timeline and details for new mid - size customer strategies.	All of the PAs have developed streamlined approaches to encourage comprehensiveness in the new construction/major renovation market for smaller and mid-sized buildings, a segment that accounts for 95% of the US non-residential building stock. National Grid and Cape Light Compact use the Advanced Buildings ("AB") approach in this market and Eversource has developed its own approach using engineering assumptions, building modeling, and an analysis approach that are very similar to those used by NBI. Under both models, the customer receives a set of recommendations that guides them to a more comprehensive approach to their building project without the necessity of a complex and often expensive modeling process. For existing Mid-Size Customers, the often cited *Mid-size Customer Needs Assessment* which looked at a single program year has been followed by the *2013 Customer Profile Study* which looks at customer trends longitudinally and largely shows Mid-size Customers are equitably served. The PAs have identified sections in the Plan that will specifically impact Mid-size	

Submitted: September 23, 2015

		Resolution Language	PA Response	Plan Section
			customers. See the sections entitled "*Highlights of 2016-2018 Enhancements*" and "*Further Market Segment Delivery*". To this end, the PAs plan to continue offering program services and initiatives, through various delivery mechanisms, which will provide mid-sized customers a diverse portfolio of cost effective energy efficiency strategies to further participation in these programs.	
40.	e.	Non - Profits - The PAs shall provide a timeline and details of strategic outreach, for serving non - profits beyond what is included in the Draft Plan.	In a section entitled *"Commercial Non-Profits",* the Plan describes how, drawing on delivery models from other programs and initiatives such as multi-family and the residential home energy services effort, as well as experiences of other PAs around the country, National Grid is developing a prototype approach for serving a particular subset of non-profit commercial customers – houses of worship. That prototype will be developed and tested within National Grid's service territory using a phased approach over a number of months. The results of that effort will be analyzed and shared, as are all such efforts, with the other PAs. This will provide the basis for a collective determination as to whether such an approach could successfully be extended and adopted statewide. The plan is to have this prototype launched before the start of the Three-Year Plan and learnings developed and reviewed with other PAs once sufficient data exist upon which to draw reasonable conclusions and inferences, likely within 6-9 months of launch. Also, the reexamination of the Small Business initiative will include a review of how effectively it currently provides services to non-profits, as many, if not most, non-profits access the programs through the Small Business Core Initiative pathway.	
41.	f.	Commercial Real Estate (CRE) - The CRE sections were not included in the Draft Plan. The EEAC requests that the PAs develop a CRE section of the Plan, informed by the findings of the CRE Working Group before August 1st, if not sooner. i. This section should include the following information:	A section entitled *"Further Engage the Commercial Real Estate Sector"* has been included in the Plan document. This section details the PA response to each of the recommendations contained in the report of the Commercial Real Estate Working Group. The discussion also incorporates similar findings from a study of the CRE market in the Pacific Northwest that was issued at about the same time as the CRE Working Group report. The PAs also note that during 2016-2018 NYSERDA will develop and conduct a set of studies of efficiency packages in key CRE building types and market segments. The objective of these pilots will be to acquire building data for analysis and to conduct M&V studies to provide insights into the actual performance of these packages. Results will be used to produce case studies that will be shared with the efficiency industry. Also in 2016-2018, NYSERDA will partner with large portfolio owners in key building segments (CRE, medical centers, colleges/universities, etc.) and providers of various Real Time Energy Management (RTEM) service providers to conduct a set of replicable pilots using a variety of these tools that monitor data and use analytics to identify where, when, and how energy is being used in a building. NYSERDA will acquire building data for analysis and will conduct M&V and persistence studies "to provide insights into the technical/operational underpinnings of RTEM and to develop credible models and case studies to support a clear value proposition for owners of similar buildings." The PAs will discuss with NYSERDA management the potential for collaboration in these test areas, and potentially others as well. These discussions will be led by National Grid, as the PA whose operations span both jurisdictions. At a minimum, the PAs own test designs can be informed by NYSERDA experience.	

Submitted: September 23, 2015

	Resolution Language		PA Response	Plan Section
42.	1.	Plans for evaluating sub‐metering for the CRE sector, including whether it will be considered as part of PAs' offerings, and a date by which that determination will be made or implementation will occur.	A section of the Plan entitled "Further Engage the Commercial Real Estate Sector" provides great detail about PA plans for working with CRE customers. Additionally, the Plan notes that, as has long been the case, submetering is incorporated into MOU agreements when, in the judgment of the principals, it will help identify and prioritize opportunities at the outset of the relationship and it will lead to customer action; that is, lead to savings. Submetering is also integral to the EM&V process, particularly when attribution and verification of behavior-based savings must be established. To the extent that CRE customers engage in MOU related agreements, the above would apply. While it is important to recognize that submeters in and of themselves do not produce savings, the PAs have and will continue to use submetering as a tool to support their "Pay for Performance" offering in which customers are rewarded for actual gas and/or electric usage reductions relative to a pre-established baseline which is determined by the prior installation of submeters.	
43.	2.	An assessment of all recommendations for CRE from the EEAC's March resolution, and a specific response to each.	See above.	
	B. Continuous Technology Improvement			
44.	The PAs did not propose in the Draft Plan any pilot programs, as the EEAC recommended in March, but note that they will undertake a "consolidated research and development ('R&D') effort to (a) support the work of the Massachusetts Technology Assessment Committee (MTAC), and (b) pursue technologies of interest in order to remain at the top of the 'innovation curve.'" However, there is little detail on how this work will be undertaken. New for the Draft Plan is the PA inclusion of a budget line item for "C&I R&D and Demonstration". The Revised Plan should include:		The Plan contains a section entitled *"Mechanisms for Program Collaboration, Continuous Improvement, Incorporating Emerging Technologies, and Sharing and Incorporating Best Practices Information"* which discusses in detail how the PAs identify and vet new technologies and new delivery approaches. Among the areas discussed are: in-house R&D (particularly among the PAs with multi-state operations); outcomes from partnerships with MOU Customers; and cooperative relationships with other program administrators or other regional efforts. There is also a full discussion of how the Massachusetts Technology Assessment Committee (MTAC) operates to identify and qualify technologies.	
45.	a.	More details about the scope and operation of R&D projects, including work performed at the MTAC and PA innovations outside the MTAC.	See above.	
46.	b.	Commitment to implement	See above.	

	Resolution Language		PA Response	Plan Section
		demonstration projects that advance innovation, especially as it relates to products that reflect rapid innovations in the marketplace, are of high customer interest, and/or have dependence on the customer for persistent savings.		
47.	c.	Regular updates to the EEAC on R&D and demonstration projects. The PAs should propose a format and schedule for these less formal updates in the Revised Plan.	The PAs have committed to provide quarterly status updates to internal stakeholders such as the C&I and Residential Management Committees as well as the Energy Efficiency Advisory Council along with semiannual updates to other external stakeholders. Documentation of recently reviewed technologies is always posted on the Mass Save® website at: http://www.masssave.com/en/professionals/business-opportunities/assessment-of-new-efficiency-technologies.	
	C. C&I Reporting			
48.	The PA Draft Plan has included more initiatives in the C&I programs, largely in line with the Council recommendations. These initiatives will have their own goals and budgets associated with them and will be part of the regular PA tracking data. In the Revised Plan, the PAs should:		The PAs share the Council's desire for increased transparency and the Plan has separated out elements of the programs for budget/planning/reporting purposes. Within the New Construction Program, the PAs created a Core Initiative for "New Buildings & Major Renovations" and another for "Initial Purchase & End of Useful Life" thereby increasing the granularity with which the Program, and its component elements, will be tracked during the course of the 2016-2018 Plan period.	
49.	a.	Establish a three‐year Combined Heat and Power (CHP) goal (not necessarily as a separate initiative in C&I Retrofit) and track/report on this CHP‐specific goal as part of the PAs' annual reports to the EEAC/Department.	After careful consideration, the PAs have decided not to separately plan, establish goals and budgets, and report on CHP. CHP results are, by nature of the complexity, relative risk, and long lead times of projects, highly variable and exhibit large fluctuations year to year, usually due to both the size and unpredictability of individual projects. It should be noted, however, that CHP measure level information is available in the electric PAs' BCR screening models, which are made available with the annual reports to the EEAC/Department and with the Plan.	
50.	b.	Consider adding an Upstream Products break‐out for New Construction that includes products beyond lighting, such as water heaters.	Given the relative infancy of the upstream delivery model as it relates to products other than lighting, the PAs do not believe it is a significant driver of overall C&I savings and or expenditures which would make it worthy of a separate Program and/or Core Initiative. However, during these early stages in their lifecycle, just as has previously been done very successfully with lighting, the PAs will be tracking the progress of any new upstream offerings on a nearly continuous basis, working collaboratively across PAs as well as with the PAs' contracted third party program implementation vendors. As with lighting, during these relatively early stages, evaluation studies are often undertaken and can provide valuable and comprehensive insights about progress to date and associated learnings. Should the Council so	

Submitted: September 23, 2015

	Resolution Language		PA Response	Plan Section
			desire, they could review the findings of these studies, which are found on the Council's website, or could ask for, and the PAs would provide, a high level summary, of such progress.	
51.	c.	Commit to continuing to report annually on C&I segment - specific approaches (e.g. CRE, healthcare, mid - size, industrial, etc.).	The PAs will continue to report on segment-specific approaches, either as part of annual EM&V studies (primarily the C&I Customer Profile Report), or on a one-off basis to the Council as a whole or individual member as has been the practice for a number of years.	
52.	d.	Increase goals for LED lighting, and C&I Retrofit in accordance with the results of the key drivers analysis.	The PAs have included in their goals significant increases in lighting in general and LED lighting specifically. In order to achieve these higher savings, the PA recognize that LED lighting technology offerings require careful positioning through the various program delivery mechanisms to maximize program impact, achieve savings goals and meet both short and long term customer energy savings requirements.	
53.	e.	Commit to semi - annual reporting to the EEAC on LED streetlight conversions.	As municipal budgeting and decision making is relatively slow paced, the conversion of streetlights to LED is likely to take place over quite a number of years – it has at times taken multiple years for a single community to move from consideration to installation. The PAs will collaborate with the DOER early in the Plan period to develop an appropriate structure and timeline for providing updates regarding progress in conversion of streetlights to LED.	
	D. C&I Updates			
54.	The PAs deliver significant energy savings and benefits through the programs through hard work and innovation. Updates from the PAs help inform the EEAC of these efforts and innovations. In the March 31, 2015 resolution, the EEAC asked for regular PA updates on a number of topics. For some topics, like the CHP potential analysis, these requests will require formal reports. Other areas, like the updates on sector - specific approaches or small business program innovations, will not necessarily require regular formal written reports. For topics not needing a formal written report, the EEAC would like the PAs to commit to a less formal reporting method to keep the Council informed of these and other efforts through means such as presentations to the EEAC or periodic (quarterly) PA C&I webinars. The PAs should propose a format and schedule for these updates in the Revised Plan. The Council thinks these less formal program		The PAs have discussed various approaches to providing more frequent and transparent communication to the Council regarding a variety of C&I related efforts and initiatives. The PAs agree that focused reporting on mutually-agreed topics can be very beneficial to increase Council understanding of program specifics, and will work with the DOER early in the plan period to develop a process for enabling that to happen. Alternative communication vehicles, such as webinars or workshops, might be useful approaches that would respect the time and logistical constraints of all parties.	

Submitted: September 23, 2015

	Resolution Language		PA Response	Plan Section
	updates will also provide checkpoints for the PAs to share program success.			
	E. Retro-Commissioning, Building Controls, and Sub-metering			
55.	The Draft Plan notes that the PAs will align the PAs' retro‐commissioning (RCx) programs with the recommendations from the "Retro‐commissioning Best Practices Study" completed by the PAs and the EEAC Consultants. Existing building operator training programs are discussed, but no new training programs are proposed. The Draft Plan does not address benchmarking in the context of commissioning or legacy controls. In the Revised Plan, the PAs should:		See below.	
56.	a.	Address issues of persistence of savings from RCx projects. Monitoring‐based commissioning can increase and ensure persistence of savings and should be further explored and demonstrated.	The PAs will continue to support and facilitate the implementation of RCx strategies, building systems optimization, and advanced controls operations wherever appropriate and consistent with energy efficiency program guidelines. To this end, the PAs will proactively implement the recommendations of the recently completed Retro-Commissioning Best Practice Study to streamline the RCx offerings and to achieve greater implementation of these strategies. For example, the PAs have already tested some of the RCx Best Practices recommendations by developing and implementing customized approaches to providing targeted RCx services to hospitals with a similar approach for labs currently in development. In addition, the PAs are committed to developing a common tool for RCx measures and expanding training for RCx for providers.	
57.	b.	Address how legacy controls will be included in the PAs' retrofit and RCx programs.	The PAs will continue to implement cost-effective energy efficiency measures and strategies consistent with program guidelines. As energy efficiency savings opportunities to existing advance building systems controls are identified through the retrofit program, or a component of that program such as RCx, the PAs plan to support measures in accordance with program guidelines and practices.	
58.	c.	Address how the use of benchmarking, sub‐metering and pre/post metering will be integrated into programs.	The PAs will continue to implement Energy Star® Benchmarking and will fully consider implementing additional cost effective benchmarking strategies on a case by case basis. Pre- and Post-metering has been integrated in the programs for the past several years, typically utilized during the consideration of complex projects and for the verification of energy savings. Sub-metering and pre and post metering devices alone do not result in energy savings. Whenever practical and cost effective, the PAs will continue to consider the use of appropriate pre/post metering, and sub-metering devices included in energy efficiency projects or strategies that lead to cost effective and quantifiable energy savings that are consistent with program guidelines and practices.	

	Resolution Language		PA Response	Plan Section
59.	d.	Commit to a strategy that expands building operator training programs, beyond the Draft Plan and traditional Building Operator Certification (BOC) offerings, including soliciting input from customers.	The Plan includes a greatly expanded discussion of the training opportunities currently provided by the PAs, as well options that will be considered and assessed during the coming plan period. Included are examples of local organizations and customer trade groups with which the PAs have regularly partnered and collaborated in the past, and expect to continue to do so in the future, to deliver educational and training content that fits the unique energy concerns of their members and constituencies. The Plan also discusses significant updates to the BOC training modules made by the BOC sponsors in recent years. Almost 40% of the content has been updated or replaced since 2013. The new curriculum focuses on low-cost opportunities to improve energy performance, building scoping and tune up, retro-commissioning, high performance HVAC systems, energy diagnostics using data loggers and BAS, selling efficiency projects, occupant engagement, and water conservation. Additional new BOC products include a continuing education webinar series to help BOC graduates maintain their certification; one day MOC events provided in partnership with sponsoring PAs for BOC graduates in their service areas; and a blended, online Level I course offering a mix of classroom and online training. The Plan also discusses several other new educational offerings that the PAs are considering.	
60.	e.	Commit to specific program enhancements and timelines for adoption of best practices identified in the RCx Best Practices Study.	The RCx subsection specifically addresses each of the five recommendations from the Best Practices Study report.	
61.	f.	Commit to increasing the availability of qualified RCx providers.	In discussions with program managers at identified “best practices” RCx programs, the PAs learned that no special effort was required to develop the supply of qualified RCx providers to meet program demands. Given consistent and clear direction as to program requirements and outcome expectations, and a commitment to funding availability, the local markets responded in a timely manner to take advantage of the business opportunity. As a result, there is no need to commit to increasing the availability of qualified RCx providers.	
	F. Behavioral and Engagement			
62.	The PAs note that they engage in Strategic Energy Management (SEM) in the context of existing programs and will consider expanding SEM offerings by engaging with early SEM adopters from the Pacific Northwest. The Draft Plan contains little information about behavioral programs and does not commit to deliver reports on either SEM or behavioral programs as requested by the Council. The PAs should include		The concept of Strategic Energy Management is fluid and evolving, and can encompass a number of interconnected and mutually reinforcing activities. A common definition of SEM is that it is “a comprehensive set of business practices that establish energy management as a standard operating procedure”. While there are different variations in SEM programs, they all focus on business practice change - shifting how organizations get things done, improving their capacity to reduce energy waste, and reducing energy intensity throughout the entire organization. The PAs plan to support behavior type initiatives that lead to cost effective, quantifiable, and persistent energy savings. To this end, the PA offerings may vary by service territory to support	

	Resolution Language		PA Response	Plan Section
	the following information in the Revised Plan:		customer energy efficiency efforts within that service territory.	
63.	a.	Commitment to assess cost effectiveness of SEM projects in line with the EEAC March 31, 2015 Resolution and, if deemed cost - effective at the sector level, a commitment to develop and evaluate an SEM demonstration project.	When considering expanding SEM efforts, much as with retro-commissioning, it will be critical for the success of recruitment efforts to understand what individual customer characteristics or categories of customers can be identified that will identify them as those who are most likely to see a value proposition in SEM. As the PAs consider SEM expansion opportunities (both in number and in kind) they will integrate the growing body of knowledge from their own local MOU/SEMP experiences and engage with SEM early adopter jurisdictions and their allies (such as the Pacific Northwest and the Northwest Industrial Strategic Energy Management Collaborative), and incorporate the results of their research activities and field experience.	
64.	b.	More detail on behavior approaches outside of memoranda of understanding (MOUs) and on whether and how savings are claimed from customer behavior changes.	See above.	
65.	c.	More detail on direct load control and methods for how the PAs could engage customers in demand response.	Efforts such as direct load control, and demand response more generally, are being, and will continue to be, considered by a collaborative working group comprised of the PAs and the Council consultants.	
66.	d.	Commitment to using the Consortium for Energy Efficiency (CEE) Minimum Elements document as a reference when discussing SEM programs, in order to ensure a common understanding of what is included.	See above.	
67.	e.	Commitment to implement and evaluate behavioral demonstration projects for small and medium C&I customers.	See above.	
	G. Small Business			

	Resolution Language		PA Response	Plan Section
68.	The Council appreciates the PAs' commitment to the Small Business program. The Draft Plan addresses a number of Council recommendations including realizing deeper savings, expanding gas measures, and expanded sector‐specific approaches. The PAs intend to make program enhancements though a series of incremental improvements. Using building analytics is under consideration by the PAs and web‐based customer engagement portals will be implemented by the PAs. The PAs should include the following information in the Revised Plan:		The PAs are very committed to serving Small Business customers through diverse offerings and delivery mechanisms available in the energy efficiency programs, particularly through the Small Business Core Initiative, and have included a detailed description of their on-going efforts and future plans for advancing that program to meet the customer's ever changing energy efficiency requirements, thereby improving upon their long-standing success with this important and large subset of C&I customers. As the Plan describes, he PAs have already embarked on an aggressive effort to test a wide range of potential improvements the results of which, once collected and synthesized, could form the basis of future improvements. Until such time as this process is complete, it is unclear and inappropriate to speculate whether improvements will be implemented incrementally, in phases, comprehensively, or at all.	
69.	a.	Specific commitments to program enhancements for the Small Business program, and a timeline for these enhancements. Some of the enhancements the EEAC thinks are important include: expanding offerings for gas measures, more comprehensive marketing/outreach/awareness programs, and more customized approaches for Small Business customers (by size and segment).	The *Small Business Core Initiative* subsection discusses the variety of tests which will be undertaken to explore concepts or approaches which show potential to expand the variety of gas measures available, reach more customers and/or hard to reach customers, as well more customized approaches for Small Business customers.	
70.	b.	A timeline for evaluating potential and cost effectiveness of building analytics and portals for small business customers (EEAC Councilors discussed a Q3 2016 deadline).	See above.	
71.	c.	An action plan, including timelines, for using the data collected by online portals to analyze and benchmark energy use to effectively target small businesses.	By its very nature, the Three Year Plan is not an operational or implementation- focused document and thus is not an appropriate vehicle in which to include an action plan. Instead, the PAs have described in great detail their on-going efforts and future plans to improve upon their already industry-leading efforts to effectively serve the energy efficiency needs of small business customers in the Commonwealth.	
	H. Combined Heat and Power			

Submitted: September 23, 2015

	Resolution Language		PA Response	Plan Section
72.	The PA Commitment to CHP is clear and the PAs largely incorporated the Council's recommendations. The PAs should include the following information in the Revised Plan:		See below.	
73.	a.	A firm commitment to complete the CHP potential report and implement findings including:	The PAs have included a lengthy description of CHP in their Plan and plan to aggressively target CHP opportunities during the 2016-2018 period, including a commitment to increase education and outreach as well as a commitment to commission a best practices review of CHP programs nationally and a reassessment of CHP opportunities in Massachusetts. While sharing the Council's commitment to excellence with regard to CHP delivery and the undertaking of research to enhance performance, the PAs do not feel it appropriate to adopt a specific time line for reporting on CHP activities or the results of any related research.	
74.	i..	Deliverable dates for a best practices review and potential study (EEAC suggested end of 2016)	The PAs are not planning to impose artificial deadlines or require additional reporting that would risk diverting the focus from providing customers with the highest quality information and greatest access to efficiency opportunities, a strategic commitment shared by both the PAs and the Council.	
75.	ii.	Specific mention of pre‐packaged and third party CHP options	The PA's CHP Guidebook, referenced in the Plan, identifies the many alternatives available to customers considering CHP and discusses key considerations for customers or third parties to achieve the appropriate, cost-effective CHP plants.	
76.	b.	A clear CHP goal and a schedule for annual reporting on the progress toward the three‐year goal, even if this is not a separate initiative outside of C&I Retrofit.	See C(a) above.	
77.	c.	Higher goals for CHP, in accordance with the results of the key drivers analysis.	Since the April 30th draft, the PAs have increased the savings contribution to goal expected to come from CHP. It is important to recognize that increased goals adds plan risk and uncertainty, as CHP savings are dependent on a relatively small number of large projects with relatively lost cost of savings which are difficult to replace at a comparable cost. Substitute savings will almost always be higher cost.	
	I. LED Streetlights			
78.	LED Streetlights represent a significant source of savings in the Commonwealth. The Draft Plan notes success with streetlight retrofits by Cape Light Compact and other PAs. However the Draft Plan does not commit to any innovations around streetlights, or to the EEAC‐requested goal of retrofitting the majority of utility owned streetlights		See below.	

	Resolution Language		PA Response	Plan Section
	and all municipal owned streetlights by 2018. The PAs should include the following information in the Revised Plan:			
79.	a.	An action plan for stimulating rapid conversion for municipally - owned street lights; for example:	The PAs remain committed to providing their municipal customers with the most up-to-date street lighting technology, including both lighting and controls. Local conditions and priorities of the local governing body in each unique city or town will control the rate at which the conversion can be accomplished.	
80.	i.	Cape Light Compact managed a joint conversion process for all of its municipalities, providing technical assistance and project management through the entire process.	See above.	
81.	ii.	Upstream or bulk purchase pricing for municipalities.	See above.	
82.	b.	A strategy and timeline to retrofit the majority of utility - owned street lights to LEDs within this Plan's timeframe (including a timeframe and commitment for filing of an appropriate tariff for utility-owned LED streetlights at the Department). The EEAC intends to support such a tariff at the Department, to aid in removing this barrier for the PAs.	The PAs are also committed to supporting the conversion of utility-owned streetlights to LED technology once the electric utilities in the state have developed, filed, and had approved the necessary tariffs. The PAs have identified a viable pathway to address an energy efficiency incentive structure that addresses utility owned streetlights conversion to LED technology and the manner by which it may be applied in the energy efficiency project implementation process.	
83.	c.	Higher savings goals attributable to LED streetlights in accordance with the results of the key drivers analysis.	The PAs savings goals do assume higher than previously planned savings to be derived from LED lighting in general, including street lighting, in part as a result of the key drivers analysis. LED streetlighting savings that are achievable is limited to the number of customer owned systems that have not yet converted to LED technology, which varies by PA.	
	J. Zero Net Energy (ZNE) Ready Buildings			
84.	In the Draft Plan, the PAs propose to establish a basis of technical knowledge and expertise, and a framework for program support for ZNE ready buildings. However there is no timeline or commitment to implement a Zero Net Energy		The PAs will continue to provide, as they have historically, technical and modeling assistance and incentives for all the efficiency measures towards Net Zero Ready that are cost-effective through the Whole Building Path of the New Construction Program. This path is explicitly designed for the purpose of promoting high performance buildings with lower energy use intensities (EUIs) and ongoing operational costs than code compliant buildings and is specifically	

		Resolution Language	PA Response	Plan Section
	Buildings (ZNEB) program. The PAs should commit to assessing a ZNE ready building tier and include a timeline for a new construction offering in the Revised Plan.		motivated through the programs using a performance based incentive basis (i.e., greater savings beyond code compliance the greater the incentive). Indeed, the PAs view a Net Zero Ready (NZR) Building as the ultimate expression of this path – driving the energy use intensity of the building to the lowest practical and cost-effective level before considering renewables. The PAs will also help customers with the necessary coordination with the Clean Energy Center in order to qualify for renewables incentives and inform them of the interconnection process to move the final step to Net Zero. However, the PAs underscore the importance of weighing NZE efforts in the context of overall savings potential and efforts to reduce greenhouse gas emissions in the Commonwealth. If the recent uptake of this concept serves as a guide, the actual number of market-based and cost-effective non-residential Net Zero buildings constructed in the Commonwealth over the coming three years is likely to be very, very small, and those that are undertaken are likely to be very modest in size. However, a somewhat larger cohort may be interested in pursuing Near Net Zero, or highly efficient, status. Energy Efficiency program support is but one area necessary to implement a NZE vision in the Commonwealth. It will take policy support, code support, grid integration, and more for Massachusetts to realize a NZE future and the PAs will continue to contribute where practical.	
	K. Delivered Fuels and Thermal Efficiency			
85.		There is no mention of the PAs' marketing comprehensive assessments to non - gas C&I customers. The PAs should include the following information in the Revised Plan:	While detailed, a Three-Year Plan is meant to serve as a statewide strategic plan and not an implementation or operational plan. A statewide strategic plan provides the PAs with the flexibility necessary to make implementation changes to meet changing circumstances based on evolving market dynamics in order to deliver on their Plan goals and satisfy the requirements and objectives of the Green Communities Act. The PAs have been and remain actively engaged in the RCS regulatory process. PAs have planned for treatment of oil heated multi-family properties, but await further development of the current RCS regulations. The PAs will continue to follow the regulatory process and when C&I tariff customers are eligible we will promote delivered fuel opportunities. The PAs will continue to consider cost effective C&I custom measures which save at least one utility-delivered fuel whether through a delivered fuel or renewable thermal equipment.	
86.	a.	A strategic plan for marketing, in-print, online, and in-person, a non-gas customer's ability to self-fund the thermal portion of a comprehensive energy assessment using a PA auditor.	See above.	
87.	b.	A timeline for assessing any barriers	See above.	

Submitted: September 23, 2015

	Resolution Language		PA Response	Plan Section
		or limitations to implementing the strategic plan, and a commitment to work with the EEAC to seek ways to address any barriers/limitations.		
	Residential Recommendations			
	A. New Initiatives			
88.	*Moderate Income Initiative* - The EEAC supports the Draft Plan proposals to develop a new moderate income offering within the Home Energy Services (HES) core initiative and the PAs' proposal to initially focus on households earning 61-80% of state median income (SMI). This initial offering should be developed further into an initiative to attract new participants to the HES and multi-family retrofit programs, as well as support follow-through of existing customers with deeper savings opportunities. Therefore, the Revised Plan should include:		The PAs are including a moderate income offer in the 2016-2018 Plan, with deployment in Q1 2016. Additional details of the program's design have been included in the Whole House residential program description under the Home Energy Services Initiative. As the moderate income offer is implemented, PAs will closely monitor, test, and refine. PAs have worked with the LEAN network to develop a triage system to examine cases of buildings which may not achieve a majority of units under 60% SMI, but do achieve a majority of units under 80% SMI, to determine if these can be enrolled through the LI Multi-family Initiative.	III.E.4.c (Detail within New Enhancements and Core Initiative Design sections)
89.	a.	Detail on the proposed scope of measures and program marketing plan, including plans to leverage partnerships with community groups, possible points of entry, and qualification for eligible customers.	The moderate income offer is an opportunity to be "qualified" for an increased incentive(s) when income is a barrier. The initial enhanced incentive is planned for insulation, covering 90% of costs up to $3000. PAs continue to evaluate enhancements to measures, including enhancements that may target moderate income customers. The moderate income offer is specifically designed to be offered when opportunities for deeper savings have been identified and recommendations have been made. This ensures that the additional administrative costs, including income verification, are tied tightly to actionable savings opportunities. This approach maximizes cost-effective savings and ensures equal access for all moderate income customers. It also allows HES to use cost-effective marketing techniques to drive customers to the initiative, preserve the Mass Save® brand awareness, and leverage the current penetration success of the Home Energy Assessment (HEA) channel. HES vendors will be given program collateral and support to enable them to have conversations with HEA participants who have identified savings opportunities. Vendors will provide these customers with further direction on how to submit for income verification. Customers who have completed income verification prior to assessment through the low-income program, will be triaged into HES for an HEA, and the income verification completed by the low-income agency will go with the customer into the HES program.	Detail in HES Initiative, Residential Whole House program section.

	Resolution Language		PA Response	Plan Section
			PAs remain enthusiastic about the ideas discussed in workshops regarding existing municipal efforts and local community organizations that currently serve this target market of moderate income customers. PAs have noted in the Plan their commitment to learn more and to leverage opportunities to use such connections to increase access for moderate income customers to Mass Save® incentives, with an emphasis on increasing installations. These opportunities and relationships are inherently service-area based and are evolving, with different implementation opportunities available for each PA.	
90.	b.	Detail about the customers in this income range, including number and proportion of residential customers in the 61-80% SMI in each PA territory and the number of those customers that the PAs expect to serve.	Based upon data from previous evaluation work for Efficient Neighborhoods+® (EN+), the population of residential customers that own and live in 1-4 family homes is estimated to be less than 10% statewide with some variation by PA service territory. Please note that renters have been identified as a separate target market. During implementation, PAs will monitor participation, the impact on budgets, and cost of savings, and will seek to understand the extent to which the offer successfully secures additional savings from a population who may not be currently participating due to financial barriers.	
91.	c.	Commitment to provide and incorporate, as appropriate, lessons learned from the Efficient Neighborhoods +® (EN+) evaluation and other pilots, demonstrations, or applicable programs by Q1 2016.	The PAs are committed to incorporating lessons learned from the EN+ evaluation and other pilots, demonstrations, and applicable programs and program evaluations by Q1 2016. Preliminary lessons learned from EN+ and other applicable programs were taken into account when designing the moderate income offer. The EN+ evaluation demonstrated that a proxy method of geographic targeting, paired with targeted outreach, has a very high cost per opportunity secured. The PAs designed the moderate income process with a more targeted enrollment process. The moderate income offer appears as a result of the HEA, with income verification. This puts more program dollars directly to work benefiting customers and securing identified opportunities.	
92.	d.	Commitment to assess by Q2 2017 the potential for serving customers at 81-100% and 101- 120% of state median income as part of an expanded moderate income offering.	The PAs will be closely monitoring the rollout of the moderate income offer and will assess impacts, both positive and negative, providing regular updates at EEAC meetings, as information is available (and to the extent updates are requested and placed on the meeting agenda).	
93.	*Renter Specific Initiative* - The EEAC supports the PAs' inclusion of a renter-specific initiative in the Draft Plan that recognizes a large and relatively underserved customer base. In order for the EEAC to fully comment on and understand this initiative, the PAs should include the following clarifying details in the Revised Plan:		The PAs are including a renter-specific visit as an enhancement of the HES core initiative.	III.E.4.c (Detail within New Enhancements and Core Initiative Design sections)
94.	a.	The implementation strategy and	By Q1 2016 the HES renter visit will be available to all HES customers. The renter visit is an	

Submitted: September 23, 2015

	Resolution Language		PA Response	Plan Section
		schedule for the renter-specific offering, providing dates, milestones, and a date in 2016 by which the offering will be available to qualified HES and multi-family customers. The PAs should provide details on program marketing, including plans to leverage partnerships with community groups.	enhancement of the HES core initiative available to 1-4 unit buildings on a single property. The PAs will maintain a single call to action through the statewide phone line. PAs are planning to update the on-line audit tool to include a renter scenario to support both renters and landlords enrolling in the HES program. PAs, as appropriate, will work with existing community resources, such as Renew Boston, to ensure that trusted community allies that serve high populations of renters are aware of the program and offer specialized materials for landlords. Customers will continue to be screened at the time of intake. If it is determined that a customer would be best served with a renter visit they will be scheduled for this, rather than a full HEA. PAs plan to offer a Whole Building incentive for 2-4 unit buildings, modeled on the Renew Boston Whole Building incentive, as extra support to engage landlords.	
95.	b.	The PAs' proposed engagement strategy to ensure immediate benefits to renters, with a plan for securing landlord buy-in and follow-through with whole-house/building measures.	At the time of intake, PAs plan to request contact information for landlords for additional follow-up. The potential adjustments to the on-line audit tool would ideally allow renters to share information about their landlord and other interested tenants in the same building. The renter visit will include the installation of no-cost instant-savings measures as listed below. The renter visit will also include a refrigerator screening, high-level visual inspection of possible weatherization opportunities, and review the heating system for potential rebates. The customer will also receive materials noting deeper measures that could be installed with landlord approval. PAs plan to develop marketing materials specifically tailored to renters. The Energy Specialist will attempt to collect the landlord information for follow-up (if not already received during intake). The Energy Specialist will leave door hangers on other renter units, noting the benefits of the visit and encouraging the other tenants to call. The Lead Vendor will then send follow-up information to landlords, including information on the Whole Building incentive.	
96.	c.	The savings measures that will be offered to renters and how such measures compare to the measures currently provided under the HES and multi-family retrofit initiatives.	No-cost instant savings measures for renters will parallel the HES gas and electric instant savings measures, including: • High efficiency lighting (LEDs & CFLs) • Low-flow showerheads • Faucet aerators • Smart strips • Programmable or wireless-enabled thermostats, if applicable and allowed by the landlord As mentioned, PAs plan to develop marketing materials tailored to renters. As the effort evolves	

	Resolution Language		PA Response	Plan Section
			PAs will continue to explore other potential renter-specific rebates.	
	B. Whole House Program			
97.	a.	A commitment to household-level tracking of all non-upstream measures, where technically feasible.	The term "household-level tracking" has not been defined. To the extent this term is synonymous with customer or account level tracking, disclosure of this information would require written customer consent. For a discussion of customer privacy issues, please see the statewide database section (VII.C); the PAs' April 2, 2014 Comments in Appendix [x]; An Act Establishing the Massachusetts Residential Conservation Service, Chapter 465, Acts of 1980 ("No person shall disclose the name of a customer or the contents of an energy audit report prepared for such customer to any person other than the customer, a subsequent purchaser of the audited building, the utility serving such customer, the secretary of energy resources, or their designees, unless the customer or subsequent purchaser waives his right to confidentiality with respect to such information"). Furthermore, customer privacy and data access issues are the subject of a pending docket with the Department: D.P.U. 14-141. Notwithstanding customer privacy concerns, tracking data at the customer level across programs and PAs at the zip code level is not technically feasible. Due to integrated gas and electric audits, which PAs believe customers greatly prefer, measures recommended by one PA may be installed by another, and the installation cannot be tracked in a cost-efficient manner from audit directly to customer. The residential and C&I customer profile studies were designed to provide geographic information on customers through the EM&V process. Finally, careful consideration of the purpose, costs and benefits of collecting and reporting this additional data, which may not increase savings or assist the PAs in meeting their goals, is necessary before spending customer funds. While providing details at the individual customer or account level is not technically or economically feasible, the HES Activity tab on Mass Save Data provides information about how customers are utilizing the programs. The HES tab shows a breakdown of measure-specific information, including the total number of Home Energy Assessments performed, quantity of bulbs installed, and the number of unique customers who received weatherization measures. In addition, the PAs are working on providing measure level information on Mass Save Data for 2016-2018 and expect to display quantity, total incentives, savings, and total benefits by measure.	
98.	i.	Include a proposal, with dates and milestones, for linking rebates and incentives provided to the same household across programs and PAs, together with a plan for reporting this whole house coordinated information at a zip-code level.	See above response.	

	Resolution Language		PA Response	Plan Section
99.	b.	Dates for: completion of the extensive review of the HES program, development of a plan for implementation of identified opportunities, and a report back to Council.	The plan references a "review of customer experience to identify opportunities for increased streamlining, simplifying and better targeting time and content of customer information to maximize the opportunity to influence customers taking action." Considerable work is currently in process with outside expert consultants to adjust the collateral materials provided to HES participants. The PAs are not planning to impose artificial deadlines or require additional reporting that would risk diverting the focus from providing customers with the highest quality information and greatest access to efficiency opportunities, a strategic commitment shared by both the PAs and the Council.	
100.	c.	Details, dates, and milestones regarding improvement of the integrated "one-stop shop" customer experience, including providing customers with both Mass Save and non-Mass Save incentive/rebate information, regardless of heating fuel source, consistent with the proposed Residential Conservation Services (RCS) regulations.	As discussed above, PAs are committed to continuous improvement of the customer experience. The current design and implementation of the initiative features a one-stop-shop approach and provides comprehensive information to customers on Mass Save® opportunities. The HES and LI single family initiatives serve all customers regardless of fuel type. The Multi-family and LI Multi-family initiatives are preparing to transition to a parallel approach when RCS regulations are final. The Mass Save® website has become a critical focal point in the comprehensive marketing program, providing a consolidated one-stop shop for residents and businesses to learn about energy efficiency offerings and opportunities. The Mass Save® website and strategies that drive customers to it will continue to be refined to ensure the highest quality customer experience. A majority of residential customers are aware of the website, and 30 percent of those surveyed report using it more than once in the past year. The Mass Save® assessment materials link customers to a federal website with updated information on tax credits and additional incentives. If the Commonwealth would like to provide a link to a URL that is updated on a regular basis and encompasses all available state incentives, the PAs would be pleased to link to that as well. The HEAT Loan initiative enabled over 11,000 loans in 2014, including financing for several fuel blind measures and provides another avenue for customers to access cross-initiative incentive opportunities.	
101.	d.	Details of the expected oil and propane savings by PA, based on an analysis of their service territory.	The current versions of the BCR models include measures for serving oil and propane customers. The April versions of the electric models are available on the EEAC website, and the PAs expect that the September versions will be added shortly after September 18th.	
102.	e.	Commitment to collaborating with DOER and the EEAC consultants to identify the actions and implementation steps needed to provide customers with an asset-based "home energy scorecard", including cost estimates for each	The deployment of the online assessment tool speaks to the ongoing commitment of PAs to reach out broadly and provide an effective and creative entry point for customers. PAs thoroughly researched tools to provide customers with clear insight on their energy use, including conducting an RFQ process to identify the best in class technology. The online assessment provides customers with a no–cost home energy scorecard tied directly to customer-specific, actionable Mass Save® energy efficiency opportunities, based on the resident's unique circumstances, all from the comfort of the customer's keyboard and at their	

Submitted: September 23, 2015

	Resolution Language		PA Response	Plan Section
		step.	leisure. Each user can be tracked and followed up with, regardless of whether they move on to an HEA or are better suited for another Mass Save® opportunity. The existing online assessment tool and resulting scorecard, provides a cost-effective, customer-centric approach, and already addresses the Council's interest in ensuring that customers have access to actionable home energy scorecards. PAs will continue to monitor DOE's ongoing research in neighboring states on alternative scorecards. Several PAs serve territories beyond Massachusetts where ongoing DOE research and program testing of scorecards is being conducted. These PAs will bring what they learn elsewhere to their Massachusetts customers and partner PAs as applicable. Currently the alternative models under review increase administrative overhead without connecting to energy savings.	
103.	f.	Strategies (including continuation of existing strategies) tailored to specific customer groups or segments, such as targeted approaches, technical assistance, or offerings (e.g., homes undergoing remodeling work, high energy users, and customers using electric resistance heat).	Each program and initiative description includes a description of the target market and a section detailing marketing strategies and targeted approaches for the targeted market. PAs have and will continue to segment and target market to customers with high energy use and electric resistance heat to support their adoption of energy savings offers. As discussed under behavior, high energy users are a primary target for the Home Energy Report. The Home Energy Report frequently promotes Residential core initiatives and is a valuable tool to spark participation from customers who have been identified through behavioral program efforts as high energy users. The deployment of the on-line assessment tool also allows PAs to learn more about customers, prior to a home visit, and connects customers to offerings targeted to their needs. The success of the Mass Save Facebook and other social media platforms has further supported PAs ability to target message to key consumer groups as well as leverage seasonal and other factors influencing customer interest and readiness to engage on specific energy efficiency opportunities.	
104.	g.	A description of efforts to ensure equitable treatment of Home Performance Contractors (HPCs) compared to lead vendors, including 3rd party quality control inspections and regular opportunities to engage and present to the Residential Management Committee (RMC).	Over 7,000 companies/contractors interact with MA energy efficiency initiatives through a multitude of participation paths (direct contract, open market rebate submittals, contracted to lead vendors, etc.). The approximately 20 Home Performance Contractors (HPCs) play an important role in the HES initiative and are therefore engaged through several channels including direct interaction with PAs through the BPWG, quarterly meetings, and an elected EEAC member. In fact, the Best Practices Working Group (BPWG) was established as an official conduit for formal feedback to the PAs for HPCs and IICs participating in the HES Initiative. A minimum of one RMC representative always attends the BPWG meetings. Through the BPWG meetings the RMC has effectively been made aware of HPC concerns. Based on the April Council recommendation, PAs reviewed the current composition of the BPWG and determined that it currently provides a higher representation of HPCs as a proportion of participating contractors statewide. HPCs hold 30% of the contractor seats while representing	III.E.4.c (Detail within Delivery Mechanism section)

	Resolution Language		PA Response	Plan Section
			approximately 18% of the contractors in the HES core initiative. The BPWG remains a critical and equal forum for interaction. The PAs have agreed to also participate in a new Contractor Performance and Engagement Forum to be convened by the DOER (not in replacement of or in lieu of the ongoing BPWG), which will review topics of relevance to the residential energy efficiency contractor community and the PAs. Topics may include how residential program contractors can be most effectively engaged in the programs, optimization of contractor performance, and suggestions from the contractor community for enhancements and improvements. This Contractor Performance and Engagement Forum will be convened by the DOER and will be an advisory forum and not an adjudicatory, regulatory, or dispute resolution body. Both lead vendors and HPCs are subject to 3rd party quality control (QC) inspections by a vendor competitively procured by the PAs. The QC vendor and program evaluations also provide valuable, external information and feedback to the PAs on HES successes, its vendors and subcontractors, and identifies areas of possible improvement.	
	C. HEAT Loans and Financing			
105.	a.	Strategy, dates, and milestones to assess how moderate income customers are currently served and could be better served by the HEAT Loan program, including assessment of the cost and effectiveness of a loan loss reserve, taking due account for the economic vulnerability of some customers.	Data presented at the Residential Workshops demonstrated that 87% of loans are approved. At this time, a loan loss reserve is not being considered. The Mass Save® HEAT Loan initiative is the most successful initiative of its kind in the nation, growing from 532 loans in 2006 to over 11,000 loans in 2014 (annual). Since inception, the Mass Save® HEAT Loan has made over $250 million available to thousands of homeowners implementing home energy efficiency improvements. With over $250 million financed (residential) - more than other leading states, <u>combined</u>- the Mass Save® HEAT Loan initiative has the largest volume of loans. It also has the broadest lender participation, with over 60 local banks and credit unions across the Commonwealth offering this product. Since 2011, the initiative has incorporated a broad FICO score acceptance, well into the sub-prime category. Approximately 45% of households taking the HEAT Loan in 2014 had incomes between $40,000 and $80,000, and banks indicate that income is not a major barrier for HEAT loan approval (detail found on page 229 of the DRAFT 2016-2018 Plan). The current HEAT Loan developed, deployed, and offered to customers by the PAs, in conjunction with the Massachusetts Bankers Association and Credit Unions, has low costs to the Programs, a very attractive interest rate, no credit enhancements, and no loan administrative costs passed back to PAs. Lenders bear the principal risks. PAs will continue this successful program working closely with our partners in the lending community who are best positioned to offer advice on loan application and approval processes. All customers of electric PAs receive HEAT Loan collateral with an indication of applicable measure opportunities identified in their home. Gas PAs that have municipal electric companies within their territories will offer the HEAT Loan to natural gas and municipal electric customers as	

Submitted: September 23, 2015

	Resolution Language		PA Response	Plan Section
			well. In this way, all customers that pay into the funds are able to access the HEAT Loan. This universal access and common 0% interest rate has tremendous marketing and brand value for energy efficiency and the PAs' energy efficiency programs. The Mass Save® HEAT Loan is a major success story. The PAs have given the Council's recommendation serious attention. At this time the current structure, including the single 0% interest rate, is working well, both in terms of costs to administer and results in broadly serving the Massachusetts market place by leveraging the expertise and capital of the existing lending community. Similarly it does not appear at this time that there is reasonable justification for a loan loss reserve given the programs current success in serving moderate income customers and current broad FICO score acceptance. The PAs will continue their efforts to identify the nature of barriers for different customer segments, which may be related to accessing capital, and will explore financing products/solutions to address them. The PAs will also continue to review the cost to administer the HEAT Loan offer and seek out efficiencies and cost savings.	
106.	b.	A date by which the PAs will finalize additional measures to be financed through the HEAT loan, including those currently funded through DOER's Expanded HEAT Loan Program.	Two of the "additional measures" offered under the DOER expanded program are grant offers, not financing, and are therefore not appropriate to add to the HEAT Loan. PAs would consider allowing the highly successful HEAT Loan process to be leveraged by DOER and other partners for additional energy measures where the partner entity provides the supporting funding. However, PAs cannot commit to add measures that are not clearly consistent with current efficiency program savings goals and aligned with efficiency program incentives.	
	D. Multifamily Retrofit			
107.	a.	Provide detail on the PAs' proposed single point of contact and commit to assessing what changes are necessary to integrate commercial and residential rate codes into a whole building approach.	Under the enhanced program design, customers will have a designated project point of contact ("PPC"). The PPC will be the designated agent or lead vendor identified by the PA responsible for the efficiency measures for the primary heating fuel. For example, if the primary heating fuel for the building is natural gas, the gas PA will designate the PPC who is responsible for providing the customer with a seamless project-level experience. Conversely, if the primary heating fuel is electric, (and as the proposed RCS regulations would allow oil and other fuels), the electric PA will designate the PPC who is responsible for providing the customer with a seamless project-level experience. The PPC is envisioned to be responsible for managing the full program delivery path once assigned to a project, coordinating efficient delivery of applicable measures. The plan is for the PPC to be responsible for clearly tracking all measures and incentives by meter type, i.e. residential and commercial meters, electric, and gas, at each stage from initial assessment through final reporting and billing. PAs have already identified and broken out for tracking measures both by meter type (Commercial/Residential) and fuel type (Gas/Electric) in the planning documents.	III.E.4.b (Detail within New Enhancements and Core Initiative Design sections)

Submitted: September 23, 2015

	Resolution Language		PA Response	Plan Section
108.	b.	Commit to developing and providing targeted offerings to different segments of the multifamily building market.	PAs will continue to deploy segmentation strategies in all programs. The Whole Building approach utilized in the Multi-Family Initiative already allows tailoring based on the unique characteristics of the building, such as mixed use, construction type, and variations in ownership and occupancy.	
109.	c.	Provide plans for improving the integration of efficiency into refinancing events, such as through a proposed partnership with the state's housing finance agencies or commercial lending institutions.	The PAs are engaged in ongoing discussions with the State's housing finance agencies. The PAs will not be providing plans or other details as part of the three-year plan. This is not a program, or even an implementation detail, but a conversation between PAs and their customers about optimal ways and potential partnerships to provide energy efficiency services.	
110.	d.	Commit to providing multi-family customers with user-friendly benchmarking tools to track unit-level energy usage and comparisons against peers.	The PAs currently offer, and will continue to offer, support for Multi-Family properties to benchmark their properties through the EPA Benchmarking tool (Portfolio Manager). The link to this nationally recognized tool is included on the website page(s) associated with the Multi-Family Retrofit core initiative. EPA Portfolio Manager is a free tool available to all property owners that represents a gold standard for benchmarking. The PAs have supported data upload through the Green Button Initiative and have extensively coordinated with disclosure efforts such as the Boston Energy Reporting and Disclosure Ordinance to support customers' ease of access to benchmarking and compliance with reporting requirements. It should be noted there are no savings associated with benchmarking itself. Unit-level energy usage is not a common element of multi-family benchmarking. The PAs behavioral program does serve multi-family units and provides those units with unit-level energy information and comparison against peers (i.e. other multi-family units).	
111.	e.	Implement a pay-for-performance demonstration program.	The Multi-Family Initiative already includes a comprehensive Energy Action Plan with incentive levels based on the extent of energy savings (i.e. performance). Customers choosing higher performance options or more/all measures will achieve high performance and the highest available incentive. In addition, PAs offer building-operator training to support customers in maintaining their efficiency gains through proper operations and maintenance.	
	E. Behavior			
112.	a.	Commit to expand behavior program participation and include dates and milestones to implement this expansion. PAs not implementing behavior programs should document why these measures are not cost-effective and why the PA is not partnering with other PAs that are	The request to expand participation in behavioral programs fails to acknowledge critical elements of behavioral program design and evaluation. The current behavioral program design and evaluation are based upon the highest industry standard, specifically, the SEE Action Evaluation, Measurement, and Verification (EM&V) of Residential Behavior-Based Energy Efficiency Programs: Issues and Recommendations (https://www4.eere.energy.gov/seeaction/system/files/documents/emv_behaviorbased_eeprograms.pdf.) Based on this standard, PAs are maintaining the planning assumptions for projected participation and initiative savings.	

		Resolution Language	PA Response	Plan Section
		implementing behavior programs.	Behavioral program savings per household are very small. Program design must therefore include a very large control group to clearly pick up the signal of savings. Program design must also include a buffer for participant attrition, i.e. you must leave some customers available to fill in for customers who opt-out of the program. This is necessary just to maintain current levels of savings but further limits the number of customers who can be assigned to the treatment group. If the program "steals" participants from the control group to add to treatment group (i.e. expand treatment participants), we risk losing statistical precision on savings estimates and possibly not conforming to industry best practices. In addition, there is not a direct relationship between increasing the size of the program and increasing the amount of savings (i.e. you cannot increase the program size by 10% and expect a 10% increase in savings). The treatment group, by design, includes the highest kWh/therm users first, as they are most likely to save more per household. As customers with lower usage per household are added to the treatment group we will begin to see lower absolute savings per household. Because the cost to treat each customer remains constant but we would secure less savings per customer, program cost effectiveness would decline.	
	F. New Construction			
113.	a.	By Q4 2016, commit to working with the EEAC consultants to explore how to claim savings for renewable energy systems in the cost/benefit analysis.	The PAs remain committed to working with the EEAC consultants to explore addressing renewable thermal savings in 2016-2018. PAs are seeking to better understand exactly what technologies are contemplated by Councilors and their applicability in a three-year energy efficiency plan under the GCA and whether implementation of some of these efforts is better handled in other contexts or proceedings, such as grid modernization. In reviewing these matters, PAs will work with the consultants to discuss and determine if there are cost-effective measures/strategies that are appropriately delivered as energy efficiency measures, as opposed to renewable supply side measures, what funding sources are available, what energy savings and other quantifiable benefits can be claimed for incentivizing these measures, and what, if any, are the most promising potential technologies and, if applicable, choosing a set of them to prioritize.	
114.	b.	Add a performance path for multi-family housing.	A performance path for the multi-family high rise program will be implemented in 2016. PAs are currently reviewing several modeling products to achieve this goal.	
115.	c.	Implement a renewable-ready requirement in the highest two performance tiers and the top prescriptive tier.	For 2016-2018 the PAs are exploring a "Path to Zero" option for the top tiers of the performance path. The enhancement would recognize new construction home builders for achieving both a high energy efficiency standard as well as the incorporation of renewable energy building features. Key components of the "Path to Zero" option would likely include renewable-ready requirements and key energy efficiency measures. Proposed PA Zero Net Energy education and marketing will communicate how builders can use the RNC initiative and the "Path to Zero" enhancement to reach net zero or net zero ready.	
116.	d.	By Q4 2016, commit to working with the EEAC consultants to assess the	In late 2017, PAs will assess how the Zero Net Energy Builder trainings and "Path to Zero" options are affecting Zero Net Energy residential building practices in Massachusetts. PAs will	

	Resolution Language		PA Response	Plan Section
		impact of creating a ZNE incentive top performance tier and report findings to the Council. Use findings to inform implementation of a ZNE top performance tier.	make adjustments to the new construction initiative, if necessary, to continue driving the market toward Zero Net Energy residential new construction.	
	G. Renewable Thermal			
117.	a.	The PAs should actively collaborate with DOER on the development and implementation of RCS guidelines, and by Q4 2016, update and maintain the cost-benefit screening tools for renewable thermal technologies.	The PAs have been and remain actively engaged in the RCS regulatory process. PAs have planned for treatment of oil heated multi-family properties, but await movement on the current RCS regulations. PAs continue to work with EEAC consultants and request pertinent updates, to date no updates have been provided. The PAs will continue to update and maintain screening tools for all qualifying measures.	
	H. Products Program			
118.	*Lighting* - The EEAC supports the commitment in the Draft Plan to phase out incentives for specialty CFLs by 2016. However, the Draft Plan does not fully address the Council's recommendations on LEDs and appears to use inconsistent and overly conservative volume and cost projections for 2016-2018.		Since the April Draft, the PAs have revised volumes and incentives per bulb, as referenced in conversation with the Consultants.	
119.	a.	Increase savings projections to reflect a growing market share of LEDs and increasing sales volumes for retail lighting.	The PAs have revised LED/CFL volumes. The PAs are committed to using the best data available for projection.	
120.	b.	Commit to quarterly reporting to the EEAC on progress of LEDs during Plan implementation.	The PAs will share updates at regular EEAC meetings when new information is available and requested.	
121.	*Heating and Hot Water* - The PAs did not propose residential upstream incentives for hot water heaters in the Draft Plan, although this is being implemented for C&I customers. The Council recognizes that the PAs need to understand the market potential for this incentive and the effects			

Submitted: September 23, 2015

	Resolution Language		PA Response	Plan Section
	of implementing an upstream program on savings.			
122.	a.	Include an assessment of implementing upstream incentives for residential tankless water heaters and other potential HVAC measures and report back to the Council by Q3 2016.	With pending evaluations in the 2016-2018 Plan, the PAs are still awaiting the best information to adjust their initiatives. As mentioned in a past EEAC meeting by the EEAC EM&V Consultants, there could be some impacts that will need to be addressed. The residential group will assess potential savings impacts of DHW measures moving upstream. The PAs will watch the implementation of upstream incentives in C&I and evaluation results as part of this assessment.	
	Low-Income Recommendations			
123.	The EEAC acknowledges the establishment of the income guideline for Low Income programs at 60% of state median income (SMI) in the Green Communities Act, and the PAs' inclusion of a moderate income offering within the residential Whole House programs in the Draft Plan. The Council recognizes the need for flexibility in programs that serve buildings with high tenant turnover or families living on the margin of eligibility in the Low Income programs. In addition, the Council recognizes the variety of organizations that hold nonprofit status and that some of those organizations own buildings that serve low income populations and may have opportunities for energy savings. The Revised Plan should commit to:			
124.	a.	Explore ways to flexibly serve low‐income multi‐family buildings with at least 50% of residents earning up to 80% SMI.	The PAs have established a process to work with LEAN to identify and flexibly serve buildings with a majority of residents at or under 80% (SMI) residents. The PAs and LEAN will be addressing these situations on a case-by-case basis.	
125.	b.	Explore alternative incentives or service approaches for non‐profit organizations that primarily serve low income customers.	PAs and LEAN will work together to explore providing alternate funding or enhanced incentives to certain non-profit organizations that primarily service low-income customers where appropriate. PAs and LEAN have discussed this group of customers, noting that it is not likely a large group, and have determine that they will review these situations on a case-by-case basis. Each PA will provide LEAN with a point of contact; when a customer is identified, the PA and LEAN will review the situation and determine an appropriate solution for that customer.	

I. **<u>Council's Resolution of October 26, 2015</u>**

Massachusetts Energy Efficiency Advisory Council Resolution Regarding the 2016-2018 Massachusetts Joint Statewide Three-Year Electric and Gas Energy Efficiency Investment Plan

October 26, 2015

BE IT RESOLVED THAT

The Members of the Energy Efficiency Advisory Council ("Council") present the following comments on the draft 2016-2018 Massachusetts Joint Statewide Three-Year Electric and Gas Energy Efficiency Investment Plan ("Statewide Plan") submitted to the Council on October 23rd, 2015, and the individual plans ("Individual Plans") prepared by each of Program Administrators ("PAs") for submission to the Department of Public Utilities ("DPU") as required by the Green Communities Act of 2008 ("GCA"). Under the GCA, the Council is charged with reviewing the PAs Statewide Plan and submitting its approval and comments to the DPU and the PAs. The Council recognizes and commends the PAs on the significant achievements made during the first two Statewide Plans, in particular the economic and energy benefits that nation-leading comprehensive energy efficiency programs have delivered to the ratepayers of Massachusetts. The 2016-2018 Statewide Plan recognizes energy efficiency as a resource, setting nation-leading savings levels for both electric (2.93% of retail sales) and gas (1.24% of retail sales). The proposed plan also ensures continued growth of energy efficiency in the Commonwealth with year over year increases in annual and lifetime savings goals for both electric and gas. These goal levels represent a significant increase from the 2013-2015 Three Year Plan, including a 15% increase in electric (2.55% of retail sales) and a 10% increase in gas (1.13% of retail sales).[1]

In developing its input on this Statewide Plan, the Council undertook a comprehensive engagement process to solicit and discuss input for the development of the 2016-2018 plans, starting with creating an engagement plan in Q3 2014. The Council held a special meeting for public comments in January 2015. Following that, the Council held seven topical workshops in February and March, led by the Department of Energy Resources ("DOER") that featured extensive and in-depth discussion between Councilors, PAs and the EEAC Consultants. The workshops and public comments informed the Council's March 31st, 2015 resolution regarding the Statewide Plan and culminated in specific programmatic recommendations from the Councilors[2].

The PAs submitted a draft of the Statewide Plan on April 30, 2015. Some of the recommendations from the Council were included in the plan but the consensus of the Council was that the savings goal levels proposed were too low, there were program details missing, and the projected cost per unit of savings was too high. The Council held another special meeting for public comments in May as well as two facilitated workshops in June to develop comments on the draft Statewide Plan. These efforts informed the July 21st, 2015 EEAC resolution to the DPU[3].

---

[1] These goal levels also represent a significant increase from the PA's April draft Statewide Plan, while reducing the cost to achieve; annual electric goals increased 17% while the cost per unit of savings decreased 13%, and annual gas goals increased 15% while the cost per unit of savings decreased 6%.
[2] Briefing Documents, presentations, and meeting summaries from the workshops are available at ma-eeac.org
[3] http://ma-eeac.org/wordpress/wp-content/uploads/Final-EEAC-July-Resolution-7-21-15.pdf

In July through September of 2015, the DOER, the Executive Office of Energy and Environmental Affairs ("EEA"), and the Attorney General's Office ("AGO") met to discuss and explore common agreement of the 2016-2018 goals and budgets with the PAs. These goals were incorporated into the September 23rd draft plan which was presented to the Council. Through September and October the Council provided additional input on the draft Plan, culminating in this resolution.

Overall Plan Comments

The Council appreciates the significant efforts the PAs have invested in the development of the Statewide Plan to address the priorities of the Council and stakeholders. We recognize and appreciate the significant contributions of PA staff, Council consultants, Councilors, the Low-Income Energy Affordability Network ("LEAN"), and stakeholders in preparing these energy efficiency plans. The development of the 2016-2018 Statewide Plan reflects significant collaboration across PAs and among members of the Council, DOER, EEA and the AGO.

These comments present the judgment and determination of the Council based on its review of the draft of the Statewide Plan, which was submitted by the PAs on October 23rd, 2015:

- The Council has reviewed the Statewide Plan that the PAs submitted to the EEAC on October 23rd, 2015. We approve and support the 2016 – 2018 Statewide Plan, as these savings levels represent record levels of energy efficiency savings in the United States and continue Massachusetts on a path to achieving all cost effective energy efficiency.[4]
- We confirm that the Statewide Plan[5] includes ambitious energy savings goals, sensible program budgets, and substantial benefits to Massachusetts consumers as required by the GCA, and highlights a continued commitment to innovation and technology, demand/peak reduction efforts, and contractor engagement. The programs and strategies in the Statewide Plan represent a significant opportunity to maximize the benefits of energy efficiency for the Commonwealth over the next three years, and represent an increasing commitment to gas and electric savings through energy efficiency.
- We expect the Individual PA Plans will remain fully consistent with the Statewide Plan. Specifically, the energy savings levels and budgets in the Statewide Plan, and reflected in the electric and gas Terms Sheet should be reflected fully in the Individual Plans.
- While the current savings, budgets, and benefits proposed in the Statewide Plan are appropriate, there exists significant variation in the plan details among individual PAs. The Council urges the PAs to continue their joint planning and best practices efforts, with the goal of achieving programmatic consistency and equivalency while fostering creativity and providing equitable service for customers across the Commonwealth.
- We recognize the opportunity for energy efficiency to reduce energy usage at times of peak demand and mitigate energy and capacity prices. We support the establishment of a Demand Savings Group with participation from interested and qualified Councilors and

[4] This approval is provided there are not unexpected or contrary data or details that appear in later PA submissions. In approving this resolution, the Council also acknowledges the right of the DOER, the Attorney General, and any other member of the Council to participate in the proceedings before the DPU.
[5] http://ma-eeac.org/plans-updates/

other stakeholders, to address opportunities to reduce peak demand in an expeditious way.

- We recognize that performance incentives are an integral part of the planning and implementation of the energy efficiency programs. We accept, consistent with DPU Guideline 3.6, the performance incentives set forth in the Statewide Plan, including the performance incentive pool (emphasizing the maximum performance incentive pool at the design level shall be $118 million, comprised of $100 million for electric programs and $18 million for gas programs).
- We believe that the costs to implement and operate energy efficiency programs should be kept as low as possible, while achieving the objectives and requirements of the GCA. We appreciate the willingness of the PAs to project reduced costs to achieve savings and plan for sensible program budgets consistent with the Council's priorities as defined in the Council's July 21st Resolution. Achieving ambitious energy savings at sensible program costs will provide significant and lasting benefits to ratepayers, businesses, and the Commonwealth.
- We expect that the PAs will use competitive procurement whenever possible to obtain the highest quality, lowest cost service providers in the implementation of the Statewide Plan.
- We recognize that minimizing bill impacts on customers is an essential consideration. The approach in the Statewide Plan to be filed on October 30th, 2015 pursues ambitious savings goals at sensible program costs, and indicate that most PAs' customer bill impacts are expected to result in moderately low incremental cost compared to prior years. The Council and PAs will continue working together to ensure that savings are being delivered cost-efficiently, including maintaining a keen eye on program costs.
- The Council and PAs will continue to work collaboratively throughout the three-year roll-out of the Individual Plans, as directed by the GCA, through continued quarterly reports and specific updates in regular meetings that focus on topics to be determined by the Council. We expect the PAs to analyze new lessons learned, develop adjustments, and put them into practice.

On a statewide basis, the October 23rd, 2015 Statewide Plan reflects the highest levels of efficiency savings goals, as well as close PA attention to Council recommendations from the July 21st resolution, and inclusion of many specific recommendations. We appreciate that these elements are reflected in the plan including:

- A renter-specific initiative to be rolled out in Q1 2016, including semi-annual PA reports to the EEAC that will include timely rental visit metrics including participation levels and conversion rates by renters and their landlords by PA, and qualitative information on any barriers encountered and plans to address them.
- A moderate income initiative beginning in Q1 2016, including semi-annual PA reports to the EEAC on participation rates by PA.
- PAs will continue to work with the Commonwealth's housing financing agencies and LEAN (with mutual expectations and deliverables) to develop and implement enhanced approaches to leverage multi-family refinancing events to maximize retrofit potential.

The parties will specifically consider performance-based retrofit products. The PAs will present the results of these efforts and specific proposals derived from them by the close of Q1 2016.

- More detail about the PA's Massachusetts Technology Assessment Committee (MTAC), and semi-annual updates to the Council on progress reviewing and implementing new technologies into programs.
- A clear commitment to Combined Heat and Power (CHP) installations, and tracking CHP project savings and expenditures (subject to customer confidentiality requirements) against PA's CHP Plan projections in semi-annual presentations to the EEAC and in data sets provided on Mass Save Data.
- Regular and specific updates to the Council on C&I program progress and penetration (including segment specific approaches - especially for challenging subsectors such as small and mid-size commercial, small hospitals, non-profits, and multifamily - measures such as street lighting and LED costs and conversion, and innovations such as strategic energy management) through semi-annual presentations to the EEAC. The PAs will collaborate with DOER by the end of 2015 to consider how best to present this information (e.g., potential use of roundtables, webinars, etc.) and to develop a schedule for updates on specific topics.

However, data tracking and reporting issues have yet to be satisfactorily resolved by the Mass Save Data website. We recommend that the DPU continue to investigate the need for greater state-wide data transparency and reporting by the PAs through its open proceeding D.P.U. 14-141 *Response of the Department of Public Utilities to Data Privacy and Data Security Issues Related to the Statewide Energy Efficiency Database*.

The PAs have recently provided the Technical Reference Manual (TRM), 2016-2018 Plan Version, which provides the important supporting details for the savings included in the Statewide Plan. The Statewide Plan commits that an online Technical Reference Library (TRL) will be available in 2016. Since the Council has not had an opportunity to review the TRM and subsequent TRL, the Council reserves its rights to complete a review of these documents and provide comments to the DPU as appropriate.

Accordingly, the Members of the Energy Efficiency Advisory Council in recognition of the aforementioned reasons, respectfully request the Commissioners of the Department of Public Utilities to approve the 2016-2018 Massachusetts Joint Statewide Three-Year Electric and Gas Energy Efficiency Investment Plan and the Individual Plans of the electric and natural gas companies and municipal aggregators, to the degree that the Individual Plans are fully consistent with the Statewide Plan. We further request that said approval consider, embrace and reflect the comments that we articulate above.

TETCO	Texas Eastern Transmission
TGP	Tennessee Gas Pipeline
VOM	Variable Operating and Maintenance Costs
WTI	West Texas Intermediate

Chapter 1: Executive Summary

This 2015 Avoided-Energy-Supply-Component Study ("AESC 2015," or "the Study") provides projections of marginal energy supply costs that will be avoided due to reductions in the use of electricity, natural gas, and other fuels resulting from energy efficiency programs offered to customers throughout New England. All reductions in use referred to in the Study are measured at the customer meter, unless noted otherwise.

AESC 2015 provides estimates of avoided costs for program administrators throughout New England to support their internal decision-making and regulatory filings for energy efficiency program cost-effectiveness analyses. The AESC 2015 project team understands that, ultimately, the relevant regulatory agencies in each state specify the categories of avoided costs that program administrators in their states are expected to use in their regulatory filings, and approve the values used for each category of avoided cost.

In order to determine the value of efficiency programs, AESC 2015 provides projections of avoided costs of electricity in each New England state for a hypothetical future, the "Base Case," in which no new energy efficiency programs are implemented in New England from 2016 onward. The Base Case avoided costs should not be interpreted as projections of, or proxies for, the market prices of natural gas, electricity, or other fuels in New England at any future point in time, for the following two reasons. First, the projections are for a hypothetical future without new energy efficiency measures and thus do not reflect the actual market conditions and prices likely to prevail in New England in an actual future with significant amounts of new efficiency measures. Second, the Study is providing projections of the avoided costs of energy in the long term. The actual market prices of energy at any future point in time will vary above and below their long-run avoided costs due to the various factors that affect short-term market prices.

AESC 2015 provides a fresh assessment of avoided electricity and natural gas costs from a new team using a model that simulates the operation of the New England wholesale energy and capacity markets in an iterative, integrated manner. On a 15 year levelized basis AESC 2015 estimates direct avoided retail electric costs on the order of 11 cents/kWh and direct avoided gas costs at utility city-gates in the order of $6.00 to $8.00/MMBtu depending on location and gas end-use.

The AESC 2015 estimates of direct avoided electricity and gas costs are similar to the corresponding AESC 2013 estimates. Certain AESC 2015 projections differ from those in AESC 2013 due to differences in market conditions that have occurred since AESC 2013 was completed, differences in certain assumptions regarding future market conditions and differences in analytical approaches. Key changes are:

- Increases in the quantity of shale gas production available at low marginal production costs, resulting in somewhat lower projections of avoided gas supply costs and lower avoided costs for electric energy;
- Assumed addition of a total of 1 Bcf/day of new pipeline capacity through November 2018;
- Earlier retirement of Brayton Point (2017 versus 2020) and higher costs for new fossil fueled generating capacity additions, leading to higher estimates of avoided costs for electric capacity;
- Higher Renewable Energy Credit (REC) prices due to the lower projection of wholesale energy market prices;
- Lower estimates of electricity demand reduction induced price effects ("DRIPE") from reductions in electricity use due to lower estimates of the size of those DRIPE effects and to shorter projections of the duration of those effects; and
- Lower estimates of natural gas and cross-fuel DRIPE from reductions in natural gas consumption due to lower estimates of gas supply elasticity and differences in analytical approach

The Study provides detailed projections of avoided costs by year for an initial 15-year period, 2016 through 2030, and extrapolates values for another 15 years, from 2031 through 2045.[1] All values are reported in 2015 dollars ("2015$") unless noted otherwise. For ease of reporting and comparison with AESC 2013, many results are expressed as levelized values over 15 years.[2] The AESC 2013 levelized results are calculated using the real discount rate of 2.43 percent, solely for illustrative purposes.[3]

1.1 Background to Study

AESC 2015 was sponsored by a group of electric utilities, gas utilities, and other efficiency program administrators (collectively, "program administrators" or "PAs"). The sponsors, along with non-utility parties and their consultants, formed an AESC 2015 Study Group to oversee the design and execution of the report.

The Study sponsors include: Cape Light Compact, Liberty Utilities, National Grid USA, New Hampshire Electric Co-op, Columbia Gas of Massachusetts, Eversource Energy (Connecticut Light and Power, NSTAR Electric & Gas Company, Western Massachusetts Electric Company, Public Service Company of New Hampshire, and Yankee Gas), Unitil (Fitchburg Gas and Electric Light Company, Unitil Energy Systems,

[1] Escalation rates for extrapolation are based on compound annual growth rates specific to the value stream and are noted throughout the report.

[2] 15-year levelization periods of 2014-2028 for AESC 2013 and 2016 to 2030 for AESC 2015. AESC 2013 used a real discount rate of 1.36 percent.

[3] The AESC 2015 real discount rate is a projection of the rate for a ten-year U.S. Treasury Bond developed from *An Update to the Budget and Economic Outlook: 2014 to 2024*, Congressional Budget Office, August 2014 and the Energy Information Administration (EIA) Annual Energy Outlook 2014 (AEO 2014), as detailed in Appendix E.

Inc., and Northern Utilities), United Illuminating Holding (United Illuminating, Berkshire Gas Company, Southern Connecticut Gas and Connecticut Natural Gas), Efficiency Maine, and the State of Vermont. The non-sponsoring parties represented in the Study Group include: Connecticut Department of Energy and Environmental Protection, Connecticut Energy Efficiency Board, Massachusetts Energy Efficiency Advisory Council, , Massachusetts Department of Public Utilities, Massachusetts Department of Energy Resources, Massachusetts Attorney General, Massachusetts Low-Income Energy Affordability Network (LEAN), Acadia Center, New Hampshire Public Utilities Commission, Rhode Island Division of Public Utilities and Carriers and Rhode Island Energy Efficiency and Resource Management Council.

The AESC 2015 Study Group specified the scope of services, selected the Tabors Caramanis Rudkevich ("TCR") project team, and monitored progress of the study. As instructed by the Study Group, the TCR team developed seven distinct forecast components which, are reported in Chapters 2 through 7 of this report (See Exhibit 1-1).

For each component, the TCR project team presented its methodologies, assumptions, and analytical results in draft deliverables for each of the subtasks specified by the Study Group. The TCR team reviewed each draft deliverable with the Study Group in conference calls. The relationships between the sections of this report, the forecast components, and the subtask deliverables are presented in Exhibit 1-1.

Exhibit 1-1. Relationship of Chapters to Forecast Components and Subtasks

Chapter/Appendix	Forecast Component	Subtasks
Chapter 2 – Avoided Natural Gas Costs	1	2A, 3A
Chapter 3 – Avoided Costs of Fuel Oil and Other Fuels	2, 5	2B, 3B, 2E, 3E
Chapter 4 – Embedded and Non-Embedded Environmental Costs	6	2F, 3F
Chapter 5 – Avoided Electricity Costs	3, 4	2C, 3C , 2D, 3D
Chapter 6 – Sensitivity Analyses	N/A	4B
Chapter 7 – Demand Reduction Induced Price Effects	7	2G, 3G
Appendix A – Usage Instructions	N/A	4C
Appendix G – Survey of Transmission and Distribution Capacity Values	N/A	4A
Appendix E – Common Financial Parameters	N/A	1

This report was prepared by a project team assembled and led by TCR. Rick Hornby managed the project. Dr. Benjamin Schlesinger and Dr. John Neri of Benjamin Schlesinger and Associates ("BSA") led the development of forecasts of natural gas and fuel oil supply costs as well as of gas demand reduction induced price suppression (gas DRIPE). Dr. Alex Rudkevich developed the forecasts of wholesale electric energy and capacity costs as well as of electricity DRIPE effects. Scott Englander of Longwood Energy Group led the analysis of Renewable Portfolio Standard ("RPS") requirements and compliance costs as well as of environmental costs avoided by reductions in energy use. Dr. Richard Tabors served as senior advisor.

1.2 Avoided Costs of Electricity

Initiatives that enable retail customers to reduce their peak electricity use ("demand") and/or their annual electricity use ("energy") have a number of key monetary and environmental benefits. Major categories of benefits include:

- Avoided costs due to reductions in quantities of resources required to meet electric demand and annual energy. Electric capacity costs are avoided due to a reduction in the annual quantity of electric capacity that load serving entities ("LSEs") will have to acquire from the Forward Capacity Market ("FCM") to ensure an adequate quantity of generation during hours of peak demand. Electric energy costs are avoided due to a reduction in the annual quantity of electric energy that LSEs will have to acquire. These avoided costs include a reduction in the cost of renewable energy incurred to comply with the applicable RPS.[4] Non-embedded environmental costs are avoided due to a reduction in the quantity of electric energy generated. (A non-embedded environmental cost is the cost of an environmental impact associated with the use of a product or service, such as electricity, that is not reflected in the price of that product.) AESC 2015 uses the long-term abatement cost of carbon dioxide emissions as a proxy for this value.
- Local transmission and distribution ("T&D") infrastructure costs are avoided due to delays in the timing and/or reductions in the size of new projects that have to be built, resulting from the reduction in electric energy that has to be delivered. AESC 2015 surveyed participating sponsors for recent values.
- Reductions in the quantities of capacity and energy that have to be acquired from wholesale energy and capacity markets may cause prices in those markets to decline relative to Base Case levels for a period of time. AESC 2015 refers to the reduction or mitigation of market prices due to reductions in demand for electric capacity and electric energy as "capacity DRIPE" and "energy DRIPE," respectively. In addition, reductions in annual retail electricity use will cause a reduction in gas consumption for electric generation, which is expected to have a price suppression effect on gas production and basis prices, which we refer to as electric own-fuel and cross-fuel DRIPE. (Reductions in annual retail gas use also have a price suppression effect on gas production and basis prices, which we refer to as gas fuel and cross-fuel DRIPE).

AESC 2015 developed estimates of the following major components of avoided electricity costs:

- **Avoided retail capacity.** Avoided retail capacity costs for the AESC 2015 Base Case consist of revenue from demand reductions bid into the FCM and the value of generating capacity avoided by demand reductions that are not bid into the FCM. Projected annual FCM prices are higher than in AESC 2013, for example 15 year levelized costs are approximately 77% higher. This

[4] Electric energy is measured in kilowatt hours (kWh) or megawatt hours (MWh); electricity capacity is measured in kilowatts (kW) or megawatts (MW).

increase is primarily due to earlier retirements of existing capacity (e.g. Brayton Point) and higher costs of new capacity.

- **Avoided retail energy.** This is the largest component of avoided electricity costs. It consists of the wholesale electric energy price increased by an assumed risk premium of 9%. Levelized annual avoided energy costs under the AESC 2015 Base Case are approximately 13% lower than those in AESC 2013, depending on the pricing zone. The levelized annual wholesale electric energy costs are lower primarily due to projections of lower natural gas prices and somewhat lower projected costs for compliance with anticipated federal regulations of carbon emissions.
- **Avoided RPS compliance costs.** Energy efficiency reduces the load subject to RPS obligations, avoiding the associated cost of compliance. The cost of RPS compliance is driven by the prices of renewable energy certificates (RECs), which are the principle means of compliance. AESC 2015 REC prices are approximately 40% higher than AESC 2013 because of the lower 2015 projections of wholesale energy prices.
- **Avoided non-embedded CO_2 costs.** This is the cost of controlling CO_2 emissions, to the extent that cost is not reflected in electricity market prices. The AESC 2015 projections are approximately the same as AESC 2013.
- **Electricity DRIPE.** This is the value of the reduction in capacity and energy market prices expected from reductions in electric energy use. AESC 2015 is projecting no electric capacity DRIPE and a smaller amount of electric energy DRIPE. The lower estimates are due to differences in projections of market conditions and differences in analytical approach. These are summarized in Section 1.4 and discussed in detail in Sections 6.10 and 7.2.

The relative magnitude of each component for the Summer On-Peak costing period is illustrated in Exhibit 1-2 for an efficiency measure with a 55-percent load factor implemented in the West Central Massachusetts zone ("WCMA").

Exhibit 1-2. Illustration of Avoided Electricity Cost Components, AESC 2015 vs. AESC 2013 (WCMA Zone, Summer On-Peak, 15-Year Levelized Results, 2015$)

Illustration of Avoided Electricity Cost Components, AESC 2015 BASE vs. AESC 2013 (WCMA Zone, Summer On-Peak, 15 Year Levelized Results, 2015$)

	AESC 2013 in 2013$	AESC 2013 in 2015$ [1]	AESC 2015 BASE	AESC 2015 BASE Relative to AESC 2013	
	cents/kWh	cents/kWh	cents/kWh	cents/kWh	% Difference
Avoided Retail Capacity Costs [2,3,4]	2.01	2.08	2.91	0.83	40%
Avoided Retail Energy Cost [5, 6, 7]	6.98	7.22	6.29	-0.93	-13%
Avoided Renewable Energy Credit [5, 6, 8]	0.66	0.69	0.96	0.27	39%
Capacity and Energy Subtotal	**9.65**	**9.99**	**10.15**	**0.17**	**2%**
CO_2 Non-Embedded	4.33	4.48	4.48	0.00	0%
Capacity DRIPE	0.69	0.71	0.00	-0.71	-100%
Intrastate Energy, Own Fuel and Cross-Fuel DRIPE	2.84	2.94	1.08	-1.86	-63%
DRIPE Subtotal	**3.53**	**3.65**	**1.08**	-2.57	-70%
Total	**17.51**	**18.12**	**15.71**	-2.41	-13%

Notes

1. AESC 2013 values levelized (2014-2028); escalated to 2015$ at		**1.035**
2. Assumes load factor of		**55%**
3. Avoided Cost of Capacity purchases ($/kW-year)	AESC 2013 (2013)	**$ 96.55**
	AESC 2015 (2015)	**$ 140.10**
4. Adjusted for 8% distribution losses and 17% reserve margin		
5. Retail Adjustment = Avoided Wholesale Cost * (1 + risk premium)		
6. Risk premium		**9%**
7. Avoided Energy Cost 2015$/MWh		**$ 57.68**
8. AESC 2015 REC (cents/kWh) pre-adjustment		**$ 0.88**

For this costing location and period, AESC 2015 is projecting total avoided costs from direct reductions in energy and capacity of 10 cents per kWh. This amount is approximately 2 percent higher than the corresponding AESC 2013 total.

The total of all components—i.e., the avoided cost of energy and capacity reductions (10 cents per kWh), plus energy and capacity DRIPE, plus non-embedded CO_2 costs—is 16 cents per kWh. This total is 13 percent lower than the corresponding AESC 2013 total.

1.2.1 Avoided Electric Capacity Costs

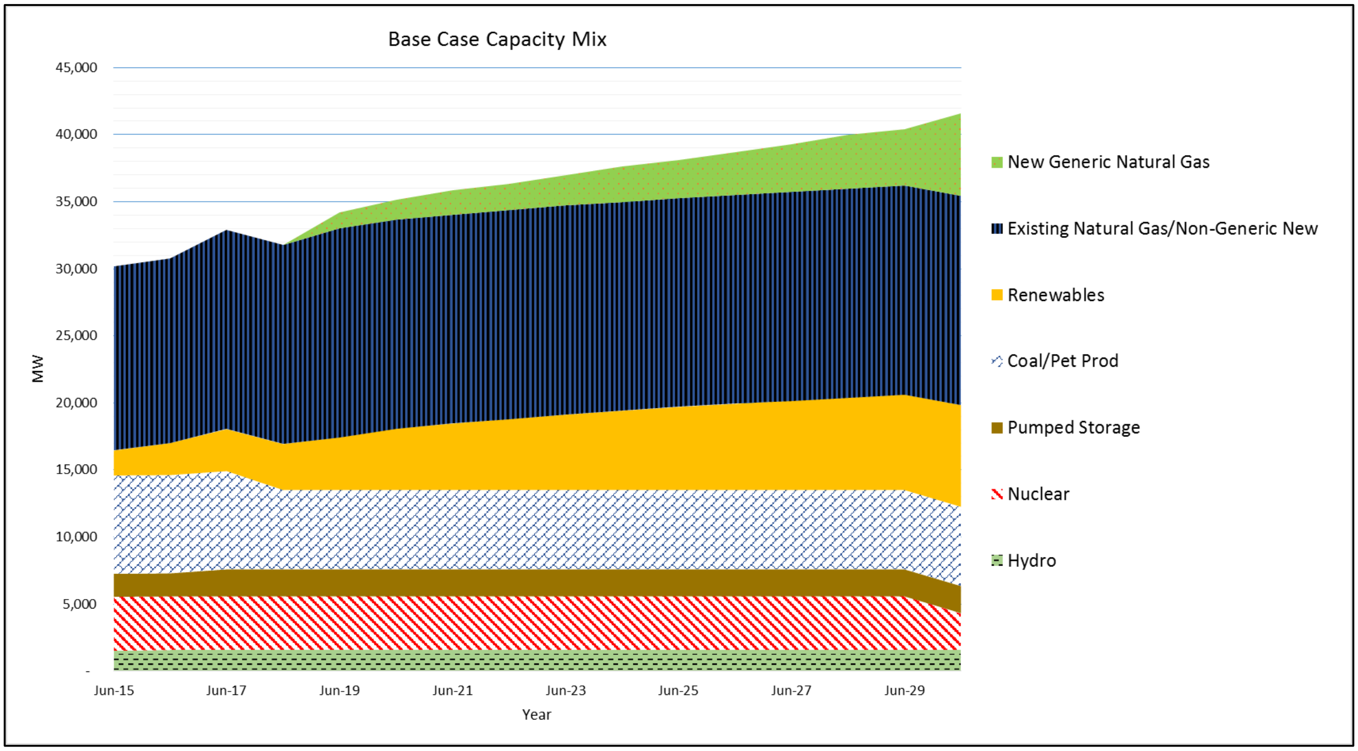
Avoided electric capacity costs are an estimate of the value of a load reduction by retail customers during hours of system peak demand.[5] The major input to this calculation is the wholesale forward capacity price to load (in dollars per kilowatt-month), which is set for a capacity year (June–May) roughly three years before the start of the capacity year. To develop an avoided cost at the meter, the wholesale electric capacity price is first increased by the reserve margin requirements forecasted for the year, then increased by eight percent to reflect ISO-New England's (ISO-NE's) estimate of distribution losses.

The major drivers of the avoided wholesale capacity price are system peak demand, capacity resources, and the detailed ISO-NE rules governing the auction. ISO-NE rules specify which resources are allowed to bid in the auction, how the resources' capacity values are computed, and what range of prices each resource category is allowed to bid. The load-resource balance is determined by load growth, retirements of existing capacity, addition of new capacity from resources to comply with RPS requirements, imports, exports, and new, non-RPS capacity additions.

As indicated in Exhibit 1-3, AESC 2013 projects that new capacity, other than RPS-related renewable resources, will have to be added starting in the 2018/2019 power year (The ISO-NE power year is June through May). This change is driven primarily by earlier projected retirements of certain existing fossil units.

[5] The benefit arises from two sources: the reduction of load at the system annual peak hour and the capacity credit attributed to energy-efficiency programs (called "passive demand response" in the ISO-NE forward capacity mechanism), measured as the average load reduction of the on-peak hours in high-load months or the hours with loads over 95 percent of forecast peak.

Exhibit 1-3. AESC 2015 Capacity Requirements vs. Resources (Base Case), MW



The AESC 2015 Base Case estimate of levelized capacity prices is approximately 40 percent higher than the estimate from AESC 2013 on a 15-year levelized basis... The higher values are primarily due to earlier retirements of existing generating units and more expensive capacity additions.

The actual amount of wholesale avoided electric capacity costs that a reduction in demand will avoid depends on the approach that the program administrator (PA) responsible for that reduction takes towards bidding it into the FCM. PAs will achieve the maximum avoided cost by bidding the entire anticipated kW reduction from measures in a given year into the FCA for that power year. PAs have to submit those bids when the FCA is held, However, the FCA for a given power year is held approximately three years in advance of the applicable power year. Some expected load reductions may not be bid into the first FCA for which the reduction would be effective, due to uncertainty about future program funding and energy savings.[6]

[6] PAs also avoid capacity costs from kW reductions that are not bid into FCAs, since those kW reductions lower actual demand, and ISO-NE eventually reflects those lower demands when setting the maximum demand to be met in future FCAs and the allocation of capacity requirements to load. However, the total amount of avoided capacity costs is lower because of the time lag—up to four years—between the year in which the kW reduction first causes a lower actual peak demand and the year in which ISO-NE translates that kW reduction into a reduction in the total demand for which capacity has to be acquired in an FCA. Since the load reduction in one year will affect the allocation of capacity responsibility in the next year, the PA's customers experience a one-year delay in realized savings that are not bid into the auctions at all.

1.2.2 Avoided Electric Energy Costs

Avoided electric energy costs at the customer meter consist of the wholesale electric energy price plus the REC cost plus a wholesale risk premium. Exhibit 1-4 presents the projected mix of generation underlying our projection of electric energy prices.

The AESC 2015 Base Case is projecting generation from natural gas to be the dominant source of electric energy over the study period. Renewable generation is projected to increase over time in compliance with RPS requirements. Generation from nuclear is projected to remain flat until year 2029 and then decline based on the assumption of Seabrook retiring in March 2030. Coal generation is projected to decline substantially by 2020 as unit retire.

Exhibit 1-4. AESC 2015 Base case Generation Mix (GWh)

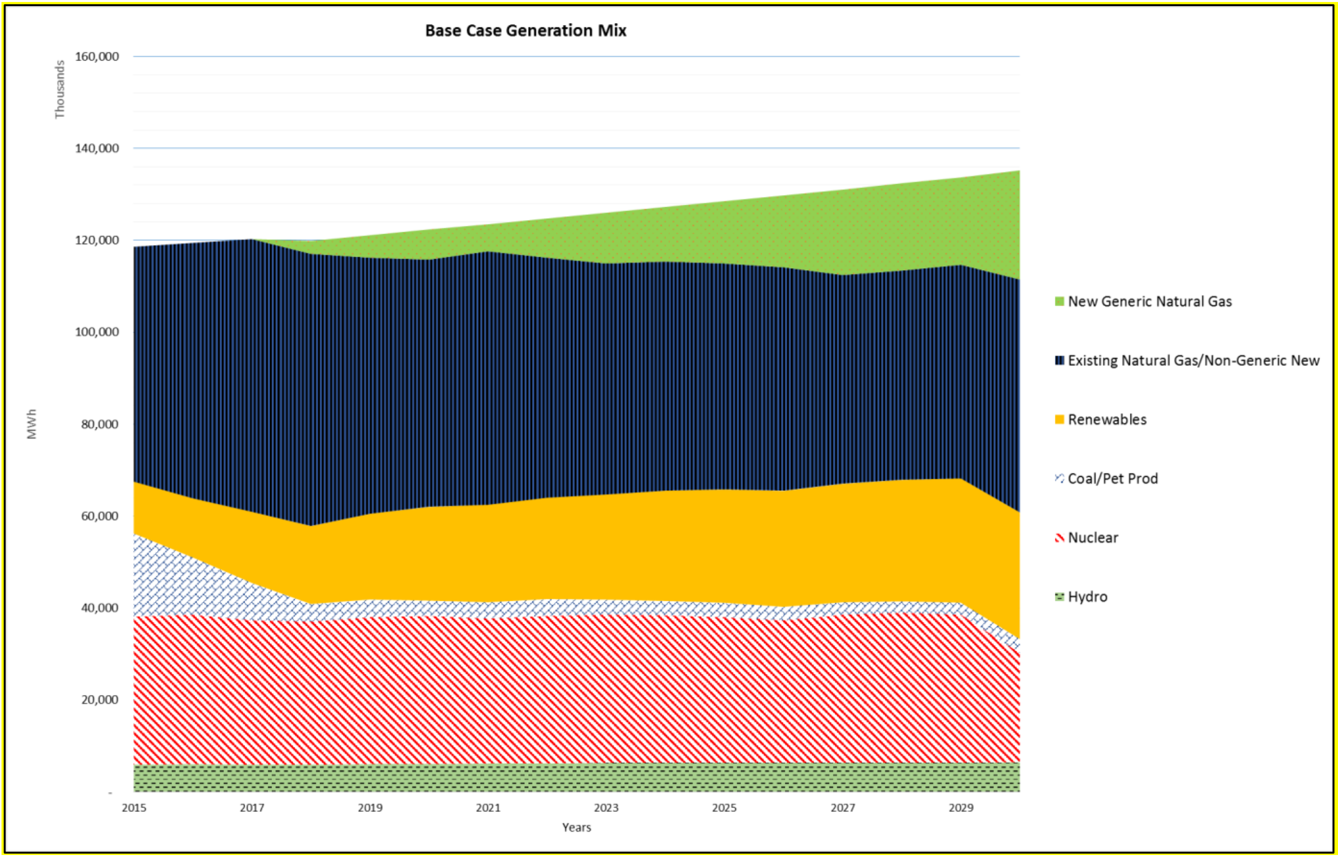


Exhibit 1-5 presents the AESC 2015 electric energy prices for the West Central Massachusetts zone for all hours compared to energy prices from AESC 2013. This WCMA price also represents the ISO-NE Control Area price, which is within this zone. On a 15 year levelized basis (2016-2030), the AESC 2015 annual all-hours price is $56.58/MWH (2015$), compared to the equivalent value of $61.95/MWh from AESC 2013, representing a reduction of 8.7 percent. The lower estimate for AESC 2015 is primarily due to a lower estimate of wholesale natural gas prices in New England and of CO_2 emission compliance costs.

Exhibit 1-5. AESC 2015 vs. AESC 2013 – All-Hours Prices for West-Central Massachusetts (2015$/kWh)

	Winter Peak Energy	Winter Off-Peak Energy	Summer Peak Energy	Summer Off-Peak Energy	Annual All-Hours Energy
AESC 2015 (2016-2030)	$62.10	$56.82	$57.68	$45.04	$56.58
AESC 2013 (2014 - 2028)	$66.64	$58.78	$66.03	$53.33	$61.95
% Difference	-6.8%	-3.3%	-12.6%	-15.6%	-8.7%

Notes:
All prices expressed in 2015$ per MWh.
Discount Rate 1.36% for AESC 2013, 2.43% for AESC 2015

Exhibit 1-6 presents the resulting 15-year levelized avoided electric energy costs for AESC 2015 by zone, after adding in the relevant REC costs and wholesale risk premiums. This exhibit also provides the corresponding estimates from AESC 2013 by zone.

Exhibit 1-6. Avoided Electric Energy Costs, AESC 2015 vs. AESC 2013 (15-year levelized, 2015$)

Avoided Electric Energy Costs, AESC 2015 versus AESC 2013 (15 year levelized 2015$)
Avoided Electric Energy Costs AESC 2015 and AESC 2013

		Winter On Peak Energy	Winter Off-Peak Energy	Summer On Peak Energy	Summer Off-Peak Energy

1.2.3 Embedded and Non-Embedded Environmental Costs

Some environmental costs associated with electricity use are "embedded" in our estimates of avoided energy costs, and others are not. The costs that are embedded are incorporated in the pCA model used to generate wholesale energy prices for AESC 2015.

For AESC 2015, we anticipate that the "non-embedded carbon costs" will continue to be the dominant non-embedded environmental cost associated with marginal electricity generation in New England.

Based on our review of the most current research on marginal abatement and carbon capture and sequestration ("CCS") costs, and our experience and judgment on the topic, we believe that it continues to be reasonable to use the AESC 2013 CO_2 marginal abatement cost of $100 per short ton.

1.3 Avoided Natural Gas Costs

Initiatives that enable retail customers to reduce their natural gas use also have a number of benefits. The benefits from those reductions include some or all of the following avoided costs:

- Avoided gas supply costs due to a reduction in the annual quantity of gas that has to be produced;
- Avoided pipeline costs due to a reduction in the quantity of gas that has to be delivered; and
- Avoided local distribution infrastructure costs due to delays in the timing and/or reductions in the size of new projects that have to be built resulting from the reduction in gas that has to be delivered.

Detailed results of our analysis are presented in Appendix C, Avoided Natural Gas Cost Results. A summary of results is presented below.

1.3.1 Wholesale Natural Gas Supply Costs

AESC 2015 assumes that the Marcellus/Utica shale will be the primary source of gas supply to New England. However, because a dominant liquid hub has yet to develop for that production area the forecast of wholesale natural gas commodity prices in New England is derived from projected gas prices at the Henry Hub. There are far more forecast and trading data available for Henry Hub than for the Marcellus/Utica area, a situation we expect will change over time.

The AESC 2015 Base Case estimate of Henry Hub prices is $ 5.18/MMBtu (2015$) on a 15-year levelized basis for the period 2016 to 2030. This is approximately 7 percent lower than the 15-year levelized price from the AESC 2013 Base Case for a similar time period.[7]

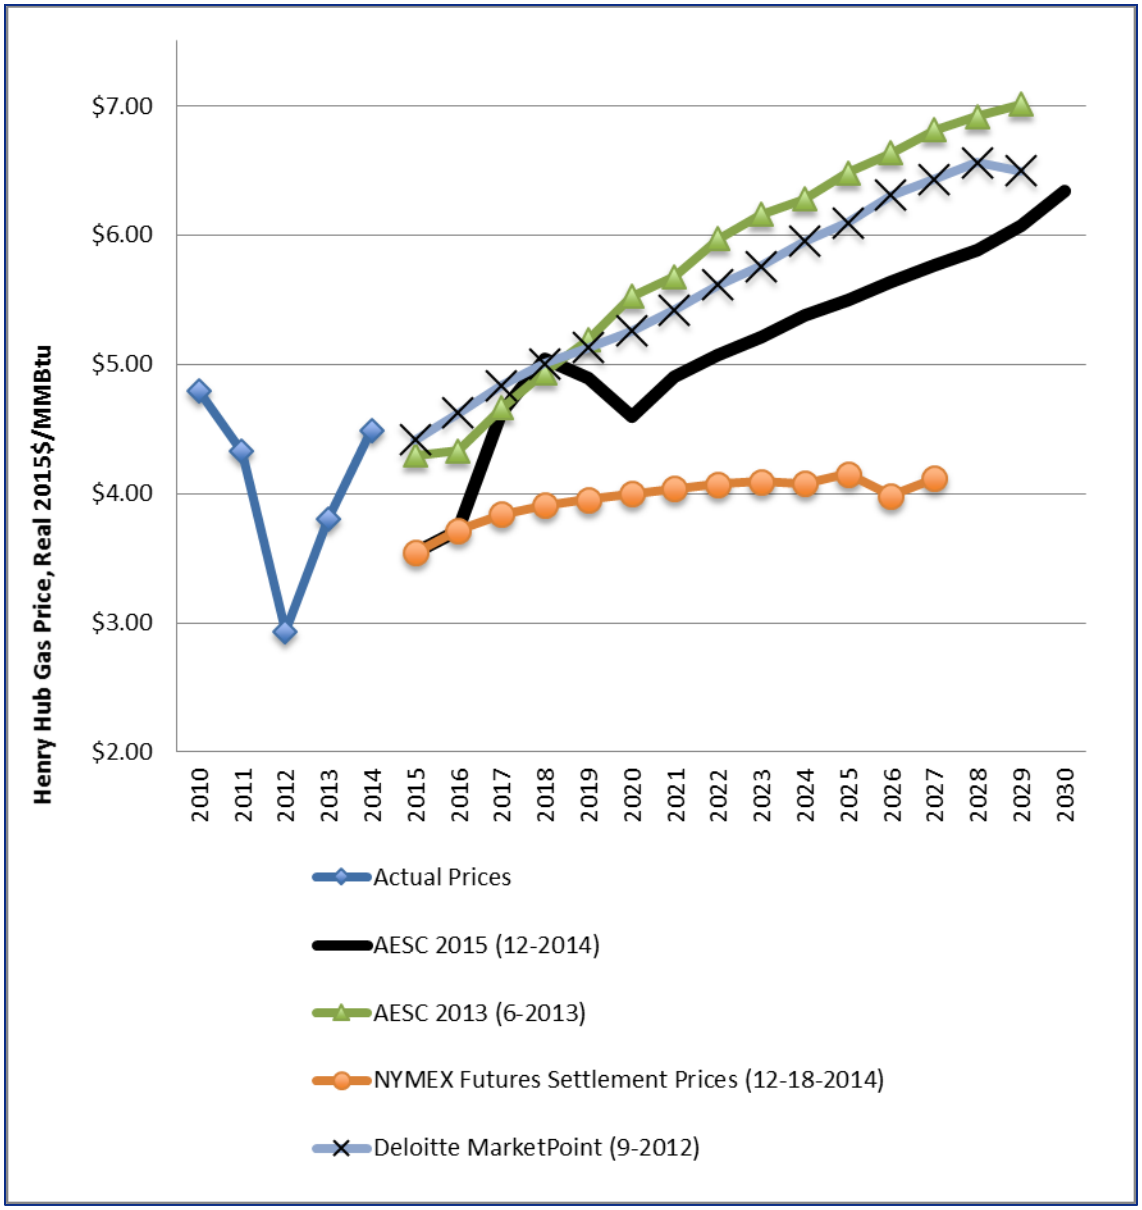
The AESC 2015 Base Case Henry Hub estimate is composed of NYMEX futures prices (as of December 18, 2014) through December 2016, and on a forecast derived from the Reference Case forecast from the Energy Information Administration's ("EIA's") Annual Energy Outlook ("AEO") 2014 for 2017 through 2030. The near-term forecast is based on NYMEX futures because they are an indication of the market's estimate of prices for the future months for which trading volumes are significant.[8] For the remaining period, the forecast is based on an AEO long-term forecast because it captures the market fundamentals that will drive those prices (i.e., demand, supply, competition among fuels) and because its underlying inputs and model algorithms are public.

Exhibit 1-8. Actual and Projected Henry Hub Prices (2015$/MMBtu) illustrates the difference between the AESC 2015 and AESC 2013 Henry Hub prices.

[7] The 15-year levelized (2014-2028) AESC 2013 Base Case in 2015$ is $5.56/ MMBtu, i.e.., 5.37/MMBtu (2013$) * 1.035).

[8] The NYMEX futures used to prepare prior AESC studies have proven to be higher than actual Henry Hub prices, indicating that price expectations of the gas industry are not always accurate.

Exhibit 1-8. Actual and Projected Henry Hub Prices (2015$/MMBtu)



This Exhibit indicates the downward trend in long-term forecasts of Henry Hub gas price forecasts since AESC 2013 was completed. Long-term gas price forecasts have been declining for several reasons. Actual gas prices have remained low. Expectations that gas supply will decline due to severe shale gas production decline rates have not materialized, nor have fears of significant production cost increases associated with the need to comply with tighter environmental regulations. Finally, and perhaps most importantly, drilling productivity has increased beyond expectations and drilling programs have become far more efficient, and time- and cost-effective.

1.3.2 Avoided Wholesale Gas Costs in New England

AESC 2015 developed a forecast of the avoided wholesale cost of gas in New England based on an analysis of the market fundamentals expected to drive that cost over the study period, using much the same general approach as the AESC 2013 Study. Specifically, the forecast of the avoided cost of gas supply begins with primary sources serving New England, and then forecasts avoided cost of gas delivery from primary sources to gas users in New England. The difference between the wholesale market price of gas at one delivery point and another delivery point is referred to as a gas price basis differential, or simply “basis.” AESC 2015 developed the avoided wholesale cost of gas in New England as the avoided cost at the Henry Hub plus the basis between the Henry Hub and New England.

In addition to developing a projection of the cost of gas from the Henry Hub and the Marcellus/Utica shale, the TCR team examined other key market fundamentals that will affect the avoided cost of gas in New England including projected demand for gas for electric generation and for retail end-uses, the projected quantity of imports of gas from Atlantic Canada and of LNG, and the projected level of pipeline capacity to deliver gas from the Marcellus/Utica shales into New England. (The projected demand for gas in New England for electric generation will be driven by numerous factors, including the long run projected price of fuel oil relative to the price of natural gas, and the level of financial penalties ISO-NE may impose on generating units which fail to meet their capacity performance obligations).

1.3.3 Avoided Natural Gas Costs by End Use

The avoided cost of gas at a retail customer’s meter has two components: (1) the avoided cost of gas delivered to the local distribution company (“LDC”), and (2) the avoided cost of delivering gas on the LDC system (the “retail margin”). AESC 2015 presents these avoided gas costs without an avoided retail margin and with an avoided retail margin, as the ability to avoid the retail margin varies by LDC.

The AESC 2015 avoided cost estimates are summarized in Exhibit 1-9 and Exhibit 1-10. These exhibits also compare the AESC 2013 results to the corresponding values from AESC 2013. Vermont requested AESC 2015 to provide avoided costs for a different set of costing periods.

Exhibit 1-9. Comparison of Avoided Gas Costs by End-Use Assuming No Avoidable Retail Margin, AESC 2015 vs. AESC 2013 (15-year levelized, 2015$/MMBtu except where indicated as 2013$/MMBtu)

	RESIDENTIAL				COMMERCIAL & INDUSTRIAL			ALL RETAIL END USES

Vermont				
AESC 2013 (2013$)	$ 389.03	$ 20.68	$ 8.68	$ 6.32
AESC 2013 (b)	$ 402.76	$ 21.41	$ 8.98	$ 6.54
AESC 2015	$ 523.08	$ 21.83	$ 7.51	$ 6.19
2013 to 2015 change	30%	2%	-16%	-5%

Factor to convert 2013$ to 2015$ 1.0353

Note: AESC 2013 levelized costs for 15 years 2014 - 2028 at a discount rate of 1.36%.
AESC 2015 levelized costs for 15 years 2016 - 2030 at a discount rate of 2.43%.

This set of AESC 2015 avoided natural gas cost estimates for Southern and Northern New England are generally lower than the AESC 2013 estimates, primarily due to the difference between the AESC 2015 projection of gas prices at Henry Hub and the AESC 2013 projection. The estimates for VT are also generally lower, except for the design day costs, which are higher due to a higher projection of Vermont Gas System (VGS) marginal transmission costs.

Exhibit 1-10. Comparison of Avoided Gas Costs by End-Use Assuming Some Avoidable Retail Margin, AESC 2015 vs. AESC 2013 (15-year levelized, 2015$/MMBtu except where indicated as 2013$/MMBtu)

	RESIDENTIAL				COMMERCIAL & INDUSTRIAL			ALL
	Non Heating	Hot Water	Heating	All	Non Heating	Heating	All	RETAIL END USES

AESC 2013 (b)	6.76	8.32	9.68	9.23	7.29	8.70	8.14	8.46
AESC 2015	6.52	8.86	9.64	9.15	7.11	8.61	8.01	6.88
2013 to 2015 change	-4%	6%	0%	-1%	-3%	-1%	-2%	-19%

Factor to convert 2013$ to 2015$ 1.0353

Note: AESC 2013 levelized costs for 15 years 2014 - 2028 at a discount rate of 1.36%.
AESC 2015 levelized costs for 15 years 2016 - 2030 at a discount rate of 2.43%.

This set of avoided natural gas cost estimates are also generally lower than the AESC 2013 estimates, again principally due to the lower projected gas price at Henry Hub. The exception is residential water heating, whose avoided margin was underestimated in AESC 2013.

1.4 Demand Reduction Induced Price Effects (DRIPE)

DRIPE refers to the reduction in wholesale market prices for energy and/or capacity expected from reductions in the quantities of energy and/or capacity required from those markets during a given period due to the impact of efficiency and/or demand response programs. Thus, DRIPE is a measure of the value of efficiency received by all retail customers during a given period in the form of expected reductions in wholesale prices.

DRIPE effects are typically very small when expressed in terms of their impact on wholesale market prices, i.e., reductions of a fraction of a percent. However, DRIPE effects may be material when expressed in absolute dollar terms, e.g., a small reduction in wholesale electric energy price multiplied by the quantity of electric energy purchased for all consumers at the wholesale market price, or at prices / rates tied to the wholesale price.

The value of DRIPE is a function of (i) the projected size of the impact on market prices, (ii) the projected duration of that price effect, and (iii) the quantity of energy purchased at prices tied to the wholesale market price during the duration of the price effect.

AESC 2015 estimated three broad categories of DRIPE:

- **Electric efficiency direct DRIPE:** The value of reductions in retail electricity use resulting from reductions in wholesale electric energy and capacity prices from the operation of those wholesale markets.

- **Natural gas efficiency direct and cross-fuel DRIPE:** The value of reductions in retail gas use from reductions in wholesale gas supply prices and reductions in basis to New England. Gas efficiency cross-fuel DRIPE is the value of the reductions in those prices in terms of reducing the fuel cost of gas-fired electric generating units, and through them wholesale electric energy prices.

- **Electric efficiency fuel-related and cross-fuel DRIPE:** The value of reductions in retail electricity use from reductions in wholesale gas supply prices and reductions in basis to New England. The reductions in those prices reduces the fuel cost of gas-fired electric generating units, and through them wholesale electric energy prices. Electric efficiency cross-fuel DRIPE is the value of the reductions in the wholesale gas supply price to retail gas users.

Exhibit 1-11 provides a high level overview of the AESC 2015 estimates of electricity and natural gas DRIPE.

Exhibit 1-11. DRIPE Overview

Reduction in Retail Load	Cost Component Affected	DRIPE Category
Electricity	Electric Energy Prices	Own-price (energy DRIPE)
Natural Gas	Gas Production Cost	Own-price (gas Supply DRIPE)
	Gas Production Cost	Cross-fuel (gas to electric)
	Basis to New England	Cross-fuel (gas to electric)
Electricity	Gas Production Cost	Own-price (gas Supply DRIPE)
	Basis to New England	Own- price (basis DRIPE)
	Gas Production Cost	Cross - fuel (electric to gas)

The AESC 2015 electric efficiency direct DRIPE results are lower than the corresponding AESC 2013 DRIPE results because AESC 2015 is projecting electricity DRIPE to be smaller in size and shorter in duration. The differences between the two studies are due to differences in analytical approach and in projected market conditions.

The AESC 2015 natural gas efficiency direct and cross-fuel DRIPE results, and electric efficiency fuel-related and cross-fuel DRIPE results are lower than the corresponding AESC 2013 DRIPE results primarily because of a lower estimate of basis due to a different analytical approach.

1.4.1 Analytical Approach to Estimate Electricity DRIPE

AESC 2015 estimated the size and duration of electricity DRIPE in New England, both capacity and energy, using a differential approach based on direct simulations of projected market conditions and resulting projected market prices under several different cases. AESC 2015 used a BAU Case, described in Chapter 6, as the reference point against which it measured the size and duration of DRIPE effects under each of the other cases. The other cases are the BASE Case, described in Chapter 5, and state-specific DRIPE Cases for each New England state, described in Chapter 7. The different approach is the analytical approach most commonly used to estimate DRIPE. AESC 2013 estimated the size of DRIPE using regression analyses and estimated the duration of DRIPE based on qualitative estimates.

1.4.2 Size of Electricity DRIPE.

AESC 2015 is projecting a capacity price DRIPE effect of zero. In the short term ISO New England (ISO-NE) has already set capacity prices through the 2018 power year. In the long term, as discussed in Section 6.10, AESC 2015 models future ISO-NE auctions to avoid acquiring surplus capacity and presumes that the cost characteristics of the new gas CT and CC units that will be setting the capacity market price are essentially the same.

AESC 2015 is projecting smaller energy DRIPE effects than AESC 2013 over the period January 2015 through May 2018. AESC 2015 projects the energy market prices under the BAU case and each state-specific DRIPE case by simulating the formation of energy prices based on the energy supply curve and the ISO-NE unit commitment process. The formation of energy prices under those cases, and hence the size of the resulting energy DRIPE is largely driven by the AESC 2015 assumptions' regarding the supply curve and unit commitment process.

The supply curve dampens energy DRIPE because the section of the curve that sets energy prices on most days is essentially flat, as described in Section 6.10. The unit commitment process dampens energy DRIPE because ISO-NE makes its decisions regarding which units to commit to serving load based on its projection of load for 24 hours, not for just one hour, as described in Chapter 5. Because of those two factors, AESC 2015 did not find a simple linear relationship between the energy load in a given hour and the load in that hour. Instead, AESC 2015 has demonstrated that the relationship between energy prices and loads in a given hour, is affected by load throughout the day, fuel prices on the day and unit availability on the day.

There will be days on which actual conditions will differ from the ISO NE forecast conditions due to unanticipated market conditions, e.g., an unexpected outage, oversupply or unexpectedly high or low demand. It is not clear that energy DRIPE effects would occur under those types of unexpected market conditions, i.e., when the market did not operate exactly as planned ("perfect markets" or according to perfect foresight). Many factors can cause unexpected market conditions, and one would have to identify and analyze those factors in order to determine if load reductions from energy efficiency would have any effect on prices under those conditions. In other words, to estimate the energy DRIPE effect of efficiency reductions on a day when actual conditions are materially different from forecast conditions, one must know the specific cause of the difference. It is also important to note that energy efficiency is a long-term, passive demand resource. As such, its load reduction profile is very different from that of Active Demand Resources, which provide reductions only at the time of and only in response to unexpected market conditions.

1.4.3 Duration of Electricity DRIPE

AESC 2015 is projecting electricity DRIPE effects to be shorter in duration than AESC 2013, ending after two and a half years (June 2018) rather than eight years. The differences in estimates of duration are due to differences in projection of market conditions and in analytical approach. AESC 2015 projects that ISO-NE will begin adding gas-fired capacity in all zones starting in the 2018/19 power year, approximately three years earlier than ASESC 2013. Also, AESC 2015 developed its projections of capacity and energy DRIPE from 2018 onward directly using simulation modeling of the energy market.

1.5 Avoided Cost of Fuel Oil and Other Fuels

Some electric and gas efficiency programs enable retail customers to reduce their use of energy sources other than electricity or natural gas. The benefits associated with reducing the use of "other fuels"—such as fuel oil, propane, kerosene, biofuel, and wood—include avoided fuel supply costs. For petroleum-related fuels, the major driver of these avoided costs are forecast crude oil prices.

The avoided costs of fuel oil and other fuels are used primarily by administrators of electric energy efficiency programs. Detailed results are presented in Appendix D, Avoided Costs of Other Fuels.

Exhibit 1-12 summarizes the prices projected by AESC 2015 and AESC 2013 for fuel oil and other fuels.

Exhibit 1-12. Comparison of AESC 2015 and AESC 2013 Fuel Oil and Other Fuel Prices (15-year levelized, 2015$)

Sector	Residential						Commercial	
Fuel	No. 2 Distillate	Propane	Kerosene	BioFuel	Cord Wood	Wood Pellets	No. 2 Distillate	No. 6 Residual (low sulfur)
AESC 2015 Levelized Values (2015$/MMBtu); 2016-2030	$ 19.20	$ 18.35	$ 20.94	$ 18.68	$ 6.80	$ 7.74	$18.70	$16.47
AESC 2013 Levelized Values (2015$/MMBtu); 2014-2028	$ 28.89	$ 29.16	$ 31.73	$ 30.35	$ 10.47	$ 17.45	$ 27.78	$ 16.80
AESC 2015 vs AESC 2013, % higher (lower)	-33.5%	-37.1%	-34.0%	-38.5%	-35.0%	-55.6%	-32.7%	-1.9%

The projected AESC 2013 prices for these fuels are generally lower than those from AESC 2013, primarily due to a fundamentally lower forecast of underlying crude oil prices. On a 15-year levelized basis, the AESC 2015 values range from 32 percent to 55 percent lower than the AESC 2013 projections, except for residual.

Chapter 2: Avoided Natural Gas Costs

This Chapter presents the AESC 2015 projections of avoided natural gas costs to power plants and to retail gas customers in New England. It describes the major economic and technical assumptions underpinning the major component of those projections, i.e., the avoided costs of gas production, the avoided cost of delivering gas from production areas to wholesale buyers in New England, and the avoided costs of distributing gas to retail end-users.

2.1 Overview of New England Gas Market

In order to place our forecast of wholesale natural gas prices for New England in context we begin with an overview of demand for natural gas in New England by major consuming sector as well as the physical supply of gas to the region.

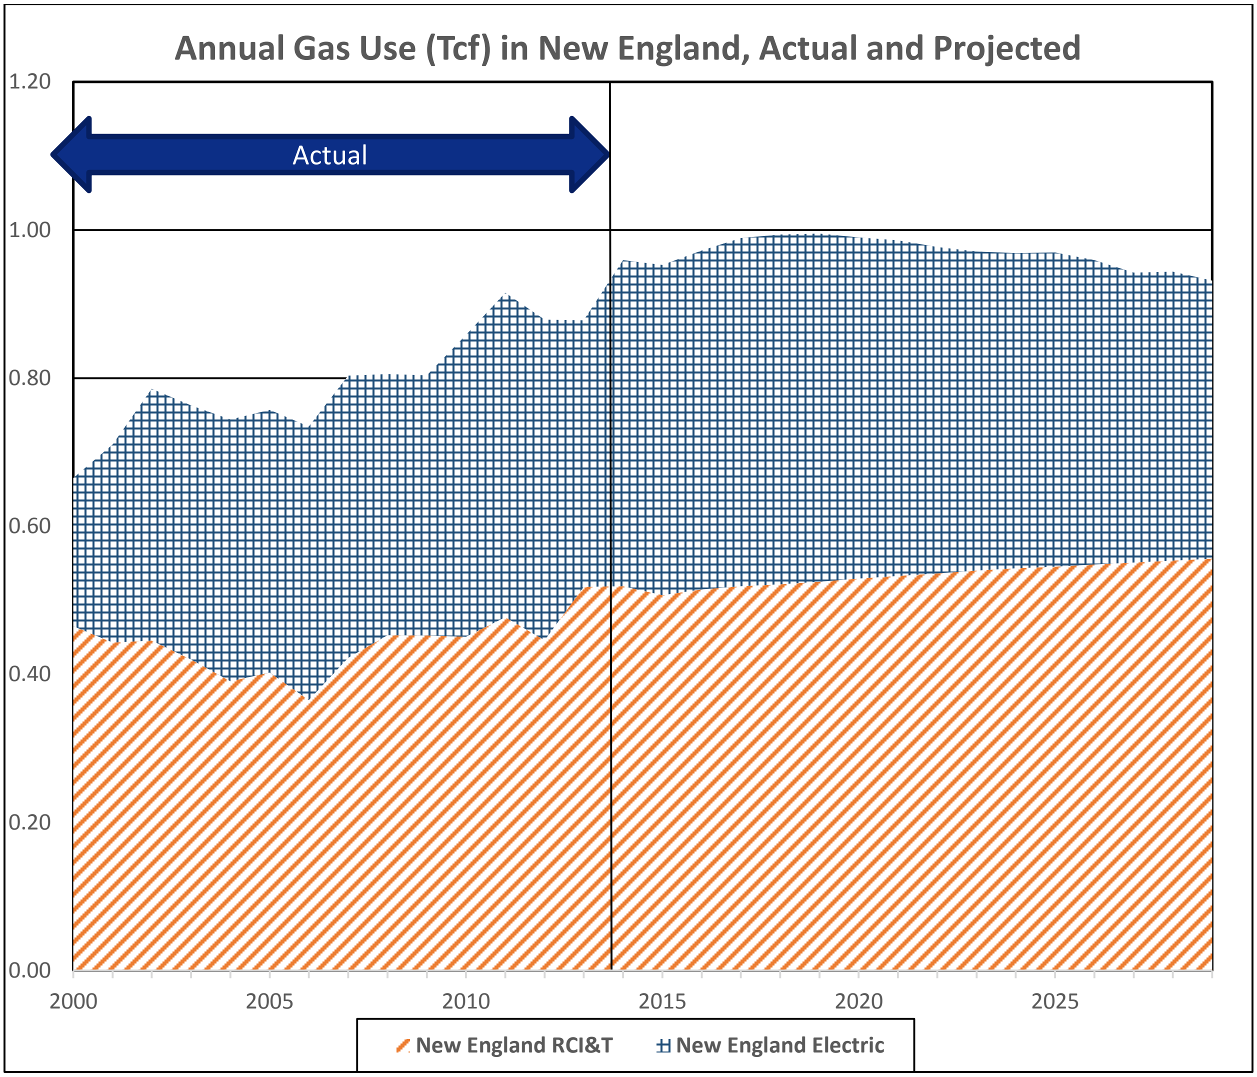
2.1.1 Demand for Gas in New England

Total gas use in New England is currently about 1 trillion cubic feet per year (EIA 2014). The market for that gas can be grouped into two distinct categories. The first category is natural gas purchased for direct use by, or on behalf of, very large end-users in the electric-generation, industrial, commercial, and institutional sectors. The second category is gas purchased by local distribution companies (LDCs) for re-sale to retail customers in the residential, commercial, and industrial (RC&I) sectors. The annual quantity of gas use in each category, actual and projected is presented in Exhibit 2-1.

The annual quantity of natural gas purchased for direct use by very large end-users, primarily for electric generation, has increased dramatically since the 1990s. That demand today accounts for roughly half of the annual gas consumption in New England. In its 2014 Annual Energy Outlook (AEO 2014), the Energy Information Administration (EIA) forecast annual gas use for electric generation in New England to remain relatively constant between 2014 and 2028 in most cases.[9]

[9] AEO 2014, Table: Energy Consumption by Sector and Source, New England, Reference case and High Oil & Gas Resource Case.

Exhibit 2-1. Actual and Projected Annual Gas Use in New England (Tcf)



The annual quantity of gas purchased by LDCs for resale to residential, commercial and industrial customers has been relatively stable since the 1990s. The AEO 2014 Reference Case projects gas use in those sectors to grow at about 0.39% per year between 2014 and 2028.[10] There is a strong interest in expanding retail use of gas in New England by extending existing distribution systems to provide consumers in under-served areas greater access to natural gas service. However, experience from other jurisdictions indicates that increasing retail gas use in this manner typically takes a number of years. For example, growth of retail natural gas use in Nova Scotia and New Brunswick has been gradual following

[10] The AEO 2014 High Resource Case projects gas use in those sectors to grow at 0.57% per year over that period.

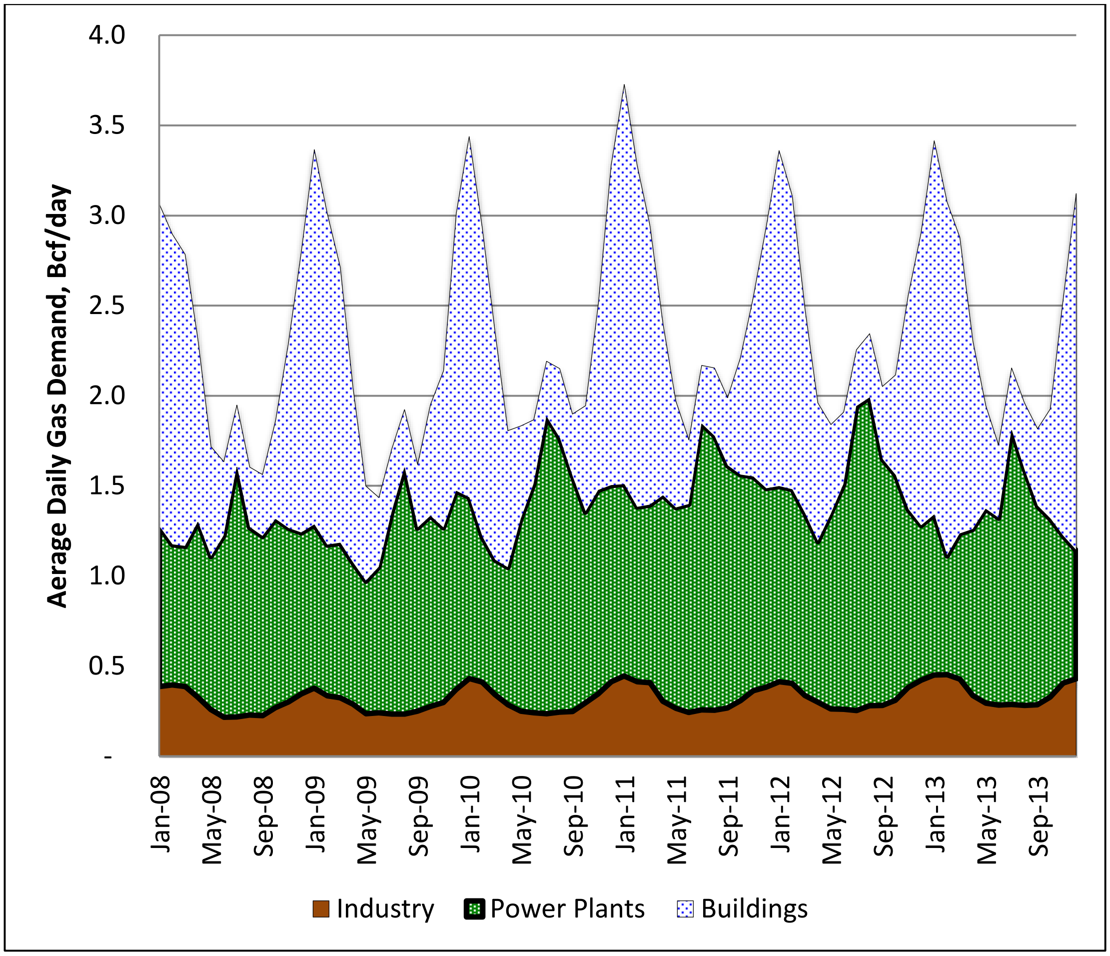
completion more than a decade ago of the large-scale M&NP; the same was the case in California following major expansions of gas pipeline capacity from Western Canada.[11]

The demand for wholesale gas in New England in all sectors varies substantially by season, and in some cases, from month by month within each season. The quantity of gas for direct use varies by month, with the greatest use occurring in summer months. In contrast, the greatest gas use by retail customers occurs in winter months since the dominant end-use is heating. As a result, LDCs have a much greater seasonal swing in gas load during the course of a year. For example, an LDC's gas load in January or February can be five times its load in July or August. Because of these large swings in gas load, LDCs acquire a portion of their winter requirements during the summer, store it in underground facilities outside of New England, and withdraw it during the winter when needed. In addition, LDCs use liquefied natural gas (LNG) and propane stored in New England to meet a portion of their peak requirements on the coldest days of the winter.

The variation in gas use by month in New England in 2008-2013 is illustrated in Exhibit 2-2.

[11] Source: Statistics Canada, California Energy Commission; pipelines refer to 0.55 Bcf/day M&NP (Canadian portion) completed in 1999 and 0.2 Bcf/day PG&E Line 401 expansion in 2002.

Exhibit 2-2. Monthly Gas Use in New England (January 2008 through December 2013)



Source: EIA.

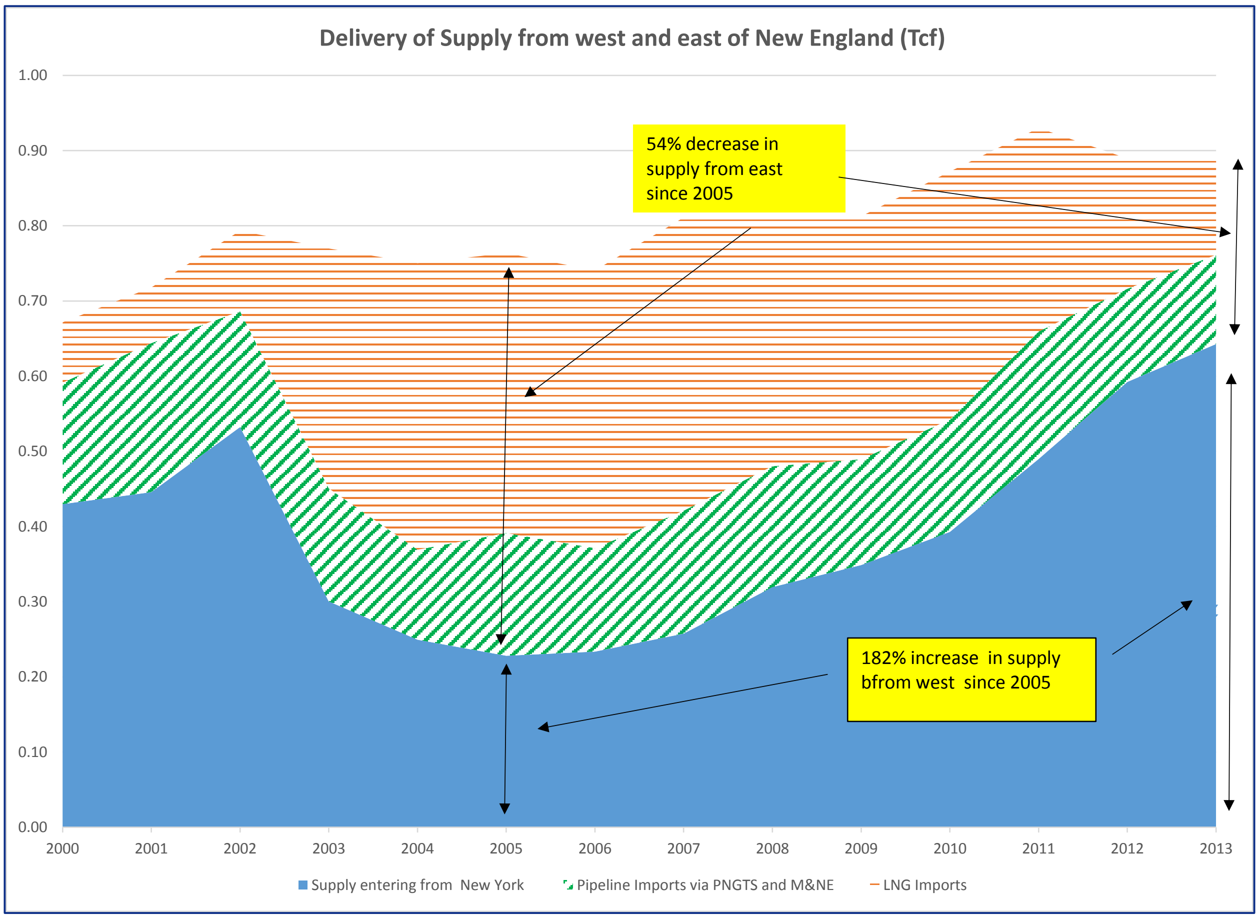
2.2 Supply of Wholesale Gas in New England

The natural gas used in New England is acquired from gas producing areas located outside New England and delivered to the region. Most of the gas consumed in New England is delivered by pipeline from producing areas in Appalachia, with smaller amounts from the U.S. Southwest, Western Canada, and Eastern Canada. Liquefied natural gas (LNG) is delivered by ship from LNG-exporting countries, principally Trinidad and Tobago in recent years.

Adequate delivery capacity from producing areas to New England, and within New England, is essential to ensure a firm supply of natural gas to, and within, the region. During the past two winters wholesale market prices spiked dramatically, to approximately $17/MMBtu in February 2012 and $25/MMBtu in February of 2013, and some gas-fired generating units were unable to operate due to inadequate gas supply. That experience highlights the need for additional delivery capacity within New England and, equally important, the need for additional delivery capacity to bring gas from producing areas west of New England, principally from the Marcellus/Utica fields, into New England in winter months.

That need for additional pipeline capacity to deliver gas from Marcellus/Utica to New England has been driven in part by the sharp decline in gas deliveries into eastern New England. Those gas deliveries are imports from Atlantic Canada and Quebec delivered into Maine, and LNG delivered into Massachusetts. Those imports have declined sharply, especially since 2011. As, indicated in Exhibit 2-3, the combined annual supply from those sources has declined over 50% since their peak in 2005. As we will discuss in 2.10, we do not expect supplies from those two sources to increase materially over the study period. In contrast, supply delivered from other producing areas into western points of the regional grid has increased over 180% since 2005.

Exhibit 2-3. Annual Gas Supply to New England



Source: TCR, from EIA data.

The following key features of the natural gas industry market structure, particularly the pipeline sector, help explain the lack of adequate delivery capacity to bring gas from producing areas west of New England in winter months.

- First, interstate pipelines, such as Algonquin Gas Transmission (AGT) and TGP which serve New England, are not allowed to sell gas; instead, they provide transportation and storage services to their customers ("shippers") under prescribed terms and conditions ("tariffs") under rate schedules approved by the FERC. Shippers acquire this capacity under long-term contracts of 10-20 years with the pipelines. Most pipelines serving the U.S. northeast, including New England, are fully subscribed, i.e., all of their capacity is spoken for (contracted) by shippers under firm transportation contracts guaranteeing shipment of gas up to the maximum amount in the contract, except for events of force majeure.

- Second, existing firm contract holders ("firm shippers") may release their capacity rights – much like sub-letting realty - in secondary markets in which firm capacity rights are acquired by other shippers. In this way, pipeline capacity rights are available in a flexible array of durations, some as short as a day or less (e.g., for power generation needs), and along various paths. But during times when gas demand is high, the firm shippers, many of whom are gas distribution utilities that must serve their retail customers, typically do not release their capacity.
- Third, FERC generally will not allow interstate pipelines to build new capacity unless they have lined up shippers who are prepared to enter long-term contracts for that new capacity. The major reason why there has been and continues to be, a shortage of pipeline capacity to deliver gas to power plants in New England, particularly in winter months, is the reluctance of those power plants to enter long-term contracts for firm capacity on those pipelines.

2.2.1 Pipelines delivering gas to, and within, New England

The physical pipeline system through which gas is delivered to New England is illustrated in Exhibit 2-4. Pipelines deliver gas directly to a number of electric generating units and very large customers, and indirectly through deliveries to LDCs which, in turn, distribute that gas to retail customers. A more extensive discussion of the New England gas industry and gas supply is published by the Northeast Gas Association (NGA 2013).

Exhibit 2-4. Natural Gas Pipelines Serving New England

Source: State of Connecticut, Joint Natural Gas Infrastructure Expansion Plan, 2014.

Deliveries into western New England

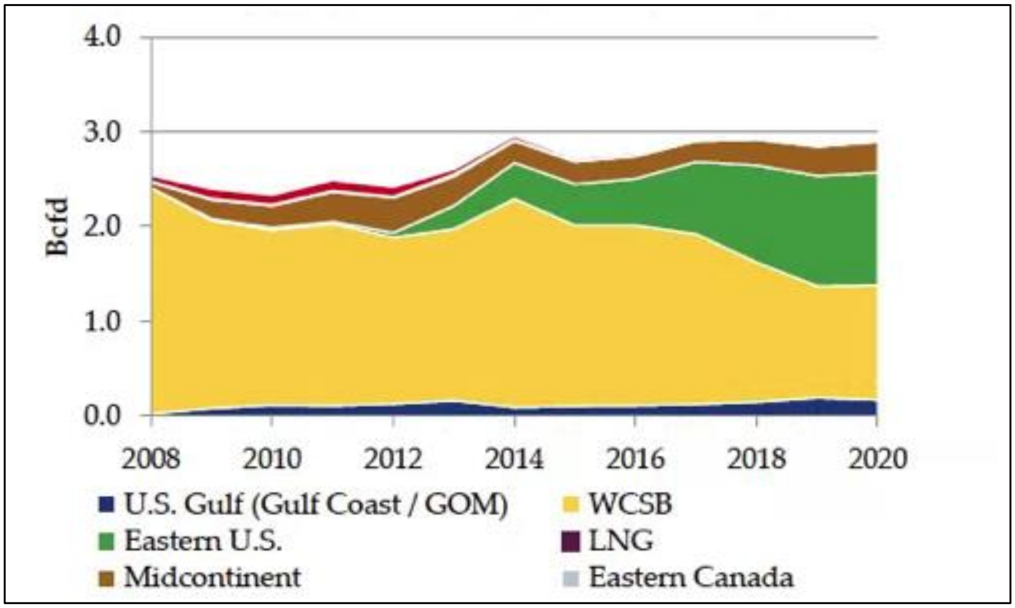
Two pipelines directly from the Marcellus/Utica shale region – Tennessee Gas Pipeline (TGP) and Algonquin Gas Transmission (AGT, an effective extension of Spectra's Texas Eastern Transmission system, or "Tetco") – deliver the majority of gas consumed in New England. TGP delivers primarily into Massachusetts, New Hampshire and Maine while AGT delivers primarily into Connecticut, Rhode Island, and Massachusetts.

The Iroquois Gas Pipeline delivers gas into Connecticut, which it receives from TGP in New York State and from the TransCanada pipeline in Quebec, Canada.

Deliveries from TCPL. The Portland Natural Gas Transmission System (PNGTS) receives gas from the TransQuebec and Maritimes Pipeline (TQM), which is an extension within Quebec of the TransCanada Pipeline (TCPL). The point of receipt is at the international border at Pittsburg, New Hampshire. PNGTS also receives gas from New Brunswick, Canada, via the Maritimes and Northeast Pipeline (M&NP), which moves gas from the international border at Eastport, Maine to an interconnection in, Maine. PNGTS, M&NP and Granite State Pipeline all then connect Westbrook, Maine with Tennessee Gas Pipeline (TGP) at an interconnection in Haverhill, Mass. The segment of between Westbrook, ME and Haverhill, MA consists of shared facilities jointly owned and operated by PNGTS, M&P and Granite State Pipeline. Gas deliveries to Vermont continue to be entirely from Canada, via TCPL, at an interconnection with Vermont Gas at the international border in Highgate Springs, VT.

An increasingly substantial portion of gas flowing from TCPL into Northern New England via PNGTS, into Connecticut from the Iroquois Gas Pipeline, and into Vermont Gas emanates from the Marcellus/Utica shale region. As shown in Exhibit 2-5, gas supplies into Ontario from the Eastern U.S. gas are increasingly replacing supplies from the WCSB – 'Eastern U.S.' in the exhibit refers to the Marcellus/Utica shale region, which has become the marginal source of gas supply on TCPL's eastern section because of its low price and ample volumes.

Exhibit 2-5. Gas Supply Mix in Ontario



Source: Navigant 2014 Mid-Year Outlook, from Ontario Energy Board, 2014 Natural Gas Market Review, Navigant Consulting, Inc., December 2014, page 37.

EIA data on pipeline gas imports and exports substantiate the Ontario analysis. They show that Niagara has turned into an export point carrying increasing volumes of pipeline gas from the Marcellus/Utica region into Ontario, while diminishing volumes are entering Canada from the St. Clair, Michigan, interconnection that formerly carried WCSB gas back into Canada via the Great Lakes Transmission Pipeline, a part of TCPL.

Deliveries into Eastern New England

The Maritimes & Northeast Pipeline (M&NP) and Portland Natural Gas Transmission System (PNGTS) systems deliver gas into Maine, Massachusetts, and New Hampshire. Those pipelines ultimately deliver into the TGP system at the interconnection in Dracut, Massachusetts and into Algonquin via the Hubline project from Beverly to Weymouth, Massachusetts (see the potion of Algonquin located offshore northeastern Massachusetts in Exhibit 2-4). M&NP delivers gas from the Canaport LNG receiving/regasification import terminal in New Brunswick, Canada, and from offshore Nova Scotia. PNGTS receives gas from the TransQuebec & Maritimes Pipeline (TQM) in Quebec, Canada. As noted earlier, an increasingly substantial portion of gas flowing on PNGTS emanates from the Marcellus/Utica shale region as TQM receives all of its gas supplies from TCPL in Ontario.

LNG imports are delivered into the regional grid from three LNG facilities in New England - Distrigas in Everett, Massachusetts, the Northeast Gateway facility completed in 2008 offshore Cape Ann, Massachusetts and the Neptune LNG facility completed in 2010 off the coast of Gloucester. The Distrigas facility, which has operated continuously since 1971, delivers gas into the Tennessee Gas Pipeline, the Algonquin Gas Pipeline, the Boston Gas component of National Grid (formerly KeySpan) system, the Mystic Electric Generating Station Units 8 & 9, and sends LNG by truck to LDC storage tanks throughout the region. The Northeast Gateway and Neptune facilities deliver gas into the Algonquin Gas Pipeline via the Hubline. Since 2010, both the Northeast Gateway and the Neptune facilities have been generally inactive.

2.3 Natural Gas Production Cost Assumptions

This section presents the assumptions underlying our projections of gas prices at the Henry Hub and in the Marcellus and Utica shale gas producing regions, as well as Henry Hub price forecasts.

AESC 2015 recognizes that the Marcellus/Utica shale will be the primary source of gas supply to New England throughout most of the planning horizon, but there is as yet an insufficiently reliable history of pricing data in the Marcellus/Utica region. In addition, no clearly dominant price reference point has yet emerged in that region as of year-end-2014, most likely because its production growth has been so quick. As a result, AESC 2015 relies, as part of its forecast model of the avoided cost of gas in New England, upon a projection of gas prices at Henry Hub, where economic and gas pricing data remain unparalleled.

The major demand and supply factors expected to drive the price of gas over the study period include:

- Gas resources, reserves, production and the technologies that underlie each of these,
- The general availability, upstream of and apart from New England, of ample gas pipeline transportation capacity, and the consequently widespread impacts of low-priced shale gas throughout North American markets, but for New England,
- Regional, national and, increasingly, international economic activity,
- Advances in technologies for gas production, transportation and use, e.g., notably in the past decade, respectively, horizontal drilling, advanced LNG systems, and high-efficiency gas-fired electricity generation using combined-cycle combustion turbines (CCGTs),
- Price elasticity of natural gas in each use and cross-elasticity with oil, electricity and other competing fuels, and
- Infrastructure expansion, including pipeline and storage capacity.

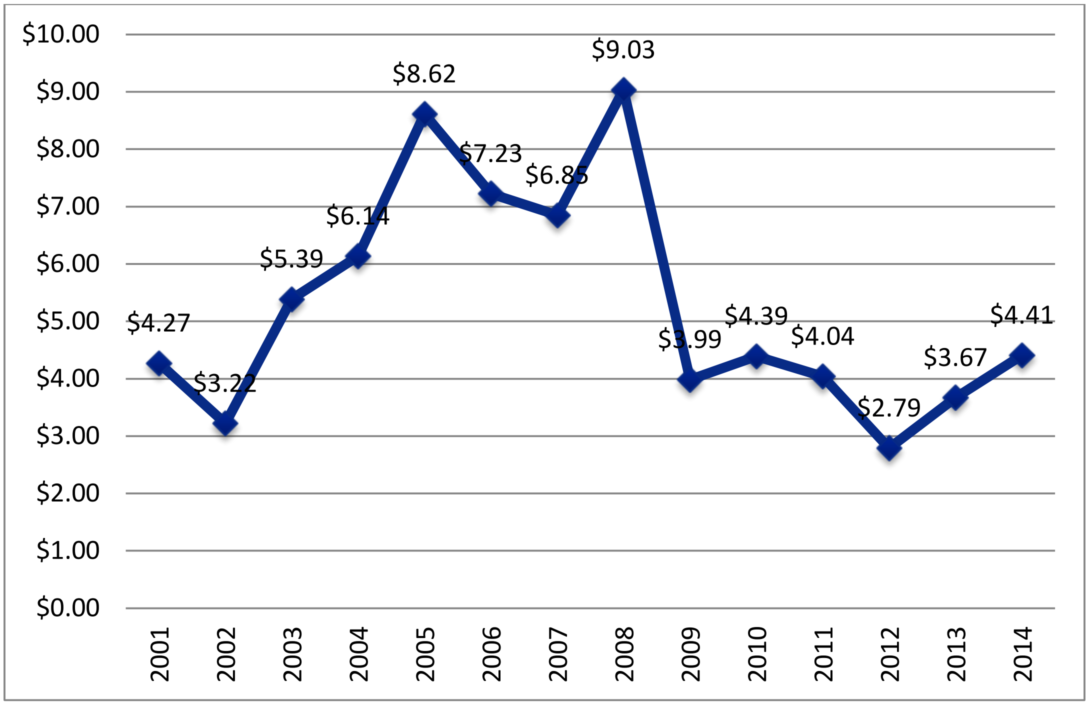
2.3.1 Major drivers of Natural Gas Production Costs over the past 30 years

For the past three decades, market forces of supply and demand have set prices for natural gas delivered into pipelines from producing areas throughout the U.S. and Canada.[12]

1980s-1990s (low conventional gas price era). Pressure from low-priced spot gas transformed U.S., then Canadian markets. The old-era pipeline-producer sales and purchase agreements (SPAs) were bought out, restructured, and otherwise disappeared, while spot and other negotiated gas markets surged to dominate the industry. By 1993, pipeline gas had disappeared from the market, and gas prices remained low in North America for nearly a decade. During this period, NYMEX launched its gas futures contract, which became their second most traded contract, after crude oil. A large number of gas-fired power plants began construction as well, including numerous cogeneration and combined-cycle plants in New England, buoyed by low gas prices and growing confidence in the now unregulated gas commodity markets. Most of the gas trading mechanisms described above evolved in the 1980s-to-2000 period as well, all within an environment of low gas prices.

[12] Decontrol of U.S. natural gas prices at the wellhead took effect initially under the Natural Gas Policy Act of 1978 (PL 95-621) in mid-1983, and was later codified under the Natural Gas Wellhead Decontrol Act of 1989 (PL 101-60).

Exhibit 2-6. Average Annual Henry Hub Gas Prices since 2000 ($/MMBtu)



2000-2008 (second era of gas shortages). Rising gas demand for electricity generation throughout the U.S. forced higher gas prices and contributed to a series of price spikes that restored a general expectation of gas shortages. During this period, annual average Henry Hub prices rose from $4.00 per MMBtu up to range of $7.00 to $9.00 per MMBtu as indicated in Exhibit 2-6. During this period, delivered gas prices at times exceeded delivered fuel oil prices in New England, and seemed in national markets to track crude oil closely, as indicated in the actual monthly spot prices plotted in Exhibit 2-7. North America undertook a second wave of LNG import terminal construction, completing nine of them, including the Canaport terminal in New Brunswick that feeds LNG directly into New England via the Brunswick Pipeline and Maritime & Northeast Pipeline (M&NP). Also, Brent crude and WTI were closely correlated in this era.

2009-2020s and possibly beyond (the "shale revolution"). Widespread and quickly rising gas production from shale has obliterated the shortages mentality, and gas markets became quickly saturated, and then overwhelmed.[13] As illustrated in Exhibit 2-7 any price relationship that had existed between Henry Hub gas and crude oil completely disappeared, whether WTI or Brent. Henry Hub prices sunk to the $3.00-$4.00 per MMBtu range, where they remain at year end 2014. Familiar basis relationships around the North American continent have been upended, especially with increased – and still increasing – gas production from the Marcellus/Utica shales. Henry Hub, which since 1990 has spoken for the North

[13] The U.S. oil-versus-gas drilling rig count remains at about 4:1, according to data issued by Baker Hughes.

American continental gas market, is weakening as a price reference point, especially for pricing of gas in the regions between it and the Atlantic Ocean, including New England.

Exhibit 2-7. Monthly Prices of Natural Gas and Crude Oil – Actuals and Futures, 2001-2020

2.3.2 The "Shale Revolution"

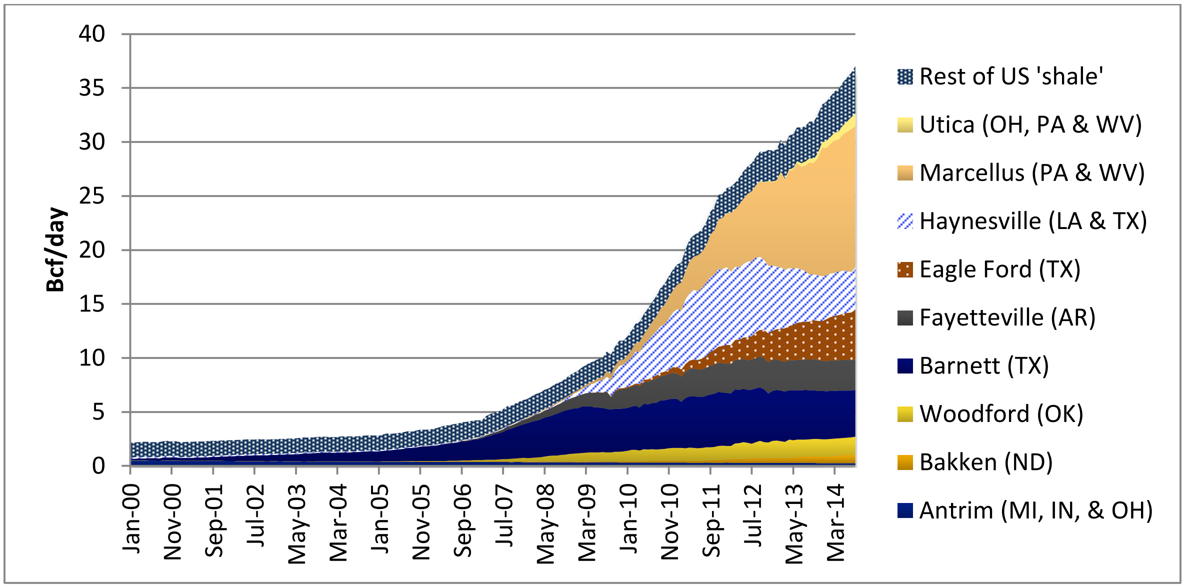
The so-called "Shale Revolution" that has been underway since the latter part of the previous decade refers to an unprecedented rise in gas production, and more recently, oil production as well, extracted from shale and other source rock beneath the earth's surface.

It is an overarching assumption of this forecast that the "Shale Revolution" can no longer be viewed as a temporary, fleeting phenomenon but is here to stay, at least over most of the life of this forecast (herein, the "planning horizon"). Recent increases in US gas production from shale are shown in Exhibit 2-8. As the exhibit makes clear, production increases have taken place over a short period of time, accelerating in the past half-decade from a relatively low base of activity. As recently as seven years ago, in January 2008, for example, natural gas produced from shale in the US had only just surpassed 6 Bcf/day, or about 10% of US gas production in 2008. In contrast, by year-end 2013, shale gas production was meeting 40.6% of US natural gas requirements (see Exhibit 2-9), a proportion that had risen to 43.2% by August 2014, and seemed likely to surpass 50% in 2015 or 2016.[14] All the while, total US gas

[14] Based on EIA data and forecasts, op.cite.

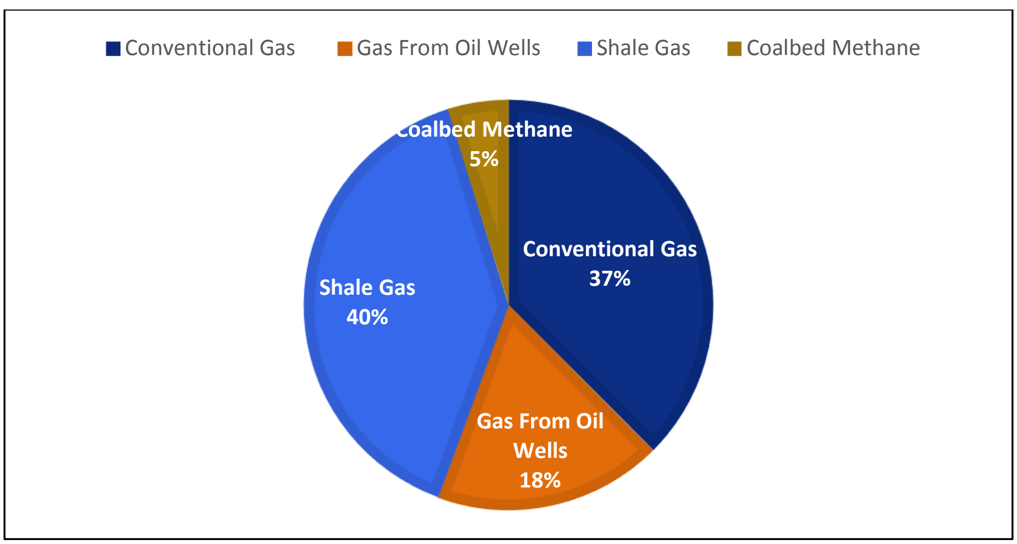
production has been rising, although not as quickly as production from shale, indicating that conventional resources are being crowded out to an extent by low-cost shale gas.

Exhibit 2-8. Increase in U.S. Natural Gas Production from Shale Fields, Monthly through August 2014



Source: EIA Administrator Adam Sieminski, in presentation before the US-Canada Energy Summit, Chicago, IL, October 17, 2014; compiled from state administrative data collected by Drilling Info Inc. Data are through August 2014 and represent EIA's official tight oil & shale gas estimates, but are not survey data. State abbreviations indicate primary state(s).

Exhibit 2-9. Derivation of U.S. Natural Gas Supplies, 2013



Source: EIA 2014, Natural Gas Gross Withdrawals and Production Volumes in 2013 (http://www.eia.gov/dnav/ng/ng_prod_sum_dcu_NUS_a.htm).

As shown in Exhibit 2-10, the Marcellus and Utica shales have proved to be especially productive. Together, these fields supplied about 20% of the entire US gas market at year-end 2014 – and a far higher percentage of the New England market – this from de minimus production levels only a half-decade earlier.[15] Averaging approximately 18.4 Bcf/day by February 2014 and rising by more than 0.3 Bcf/day per month,[16] the Marcellus/Utica shales have increased to the point where they are physically supplying nearly all of the gas requirements in the U.S. Northeast and New England, apart from imported LNG into New England.

A number of reasons are cited by Kuuskraa (2014) to explain why shale gas and oil production has evolved so quickly – these largely relate to improving drilling technologies and rig efficiencies, and also the presence of traded gas markets with open access on interstate pipelines:

- Improving well performance – longer well laterals, increasing number of fracturing stages, widespread availability of accurate well log data enabling reduction in the percentage of "dry holes" down to nearly zero
- Major efforts to reduce costs – increasing rig efficiencies, reduced well stimulation costs, reduced set-up and production timing
- Production of associated gas from "tight oil" plays – break-even costs of associated natural gas from "tight oil" are low to negative
- Steady introduction of new gas plays to counter resource depletion.[17]

The foregoing improvements in gas production have taken place within an environment of extensive field knowledge and experience gained from decades of drilling activity in conventional gas and oil plays located within the same regions as the major shale plays.

[15] EIA Drilling Productivity Report for Key Tight Oil and Shale Gas Regions ("EIA Drilling Productivity Report"), February 2015: 16,550 MMcf/day and 1,854 MMcf/day, respectively for Marcellus and Utica shales (see http://www.eia.gov/petroleum/drilling/#tabs-summary-2); and EIA Natural Gas Gross Withdrawals and Production, 2,674,827 MMcf in September 2014 (http://www.eia.gov/dnav/ng/ng_prod_sum_dcu_NUS_m.htm).

Note these volumes update even some very contemporary publications and articles relying on earlier or inaccurate data, e.g., article in Nature Magazine, "Natural gas: The fracking fallacy," by Mason Inman, 03 December 2014, where Marcellus Shale is depicted as peaking in 2020 at about 12-13 Bcf/day (120-130 Bcf/year) in 2020, despite current production cited earlier in this note, as reported by EIA, of 18.4 Bcf/day, including the adjacent Utica shales. See, further, December 2014 responses to the Nature Magazine article by EIA and the University of Texas, Bureau of Economic Geology (http://www.eia.gov).

[16] EIA Drilling Productivity Report, January 2015, as above.

[17] Vello Kuuskraa, President, Advanced Resources International, Inc. (ARI), in presentation before the Electric Power Research Institute (EPRI) 33rd Annual Fuel & Planning Seminar, Washington, DC, November 12, 2014.

Exhibit 2-10. U.S. Shale Gas Production and Rate of Increase at Year-End 2014

Region	February 2015 Gas Production, Bcf/d	Monthly Change at January 2015 MMcf/d	Monthly Change at January 2015, %
Marcellus/Utica	18.4	+305	1.7%
Eagle Ford	7.5	+97	1.3%
Haynesville	7.0	+69	1.0%

Bakken	1.5	+27	1.8%
Total	45.4	+613	1.4%

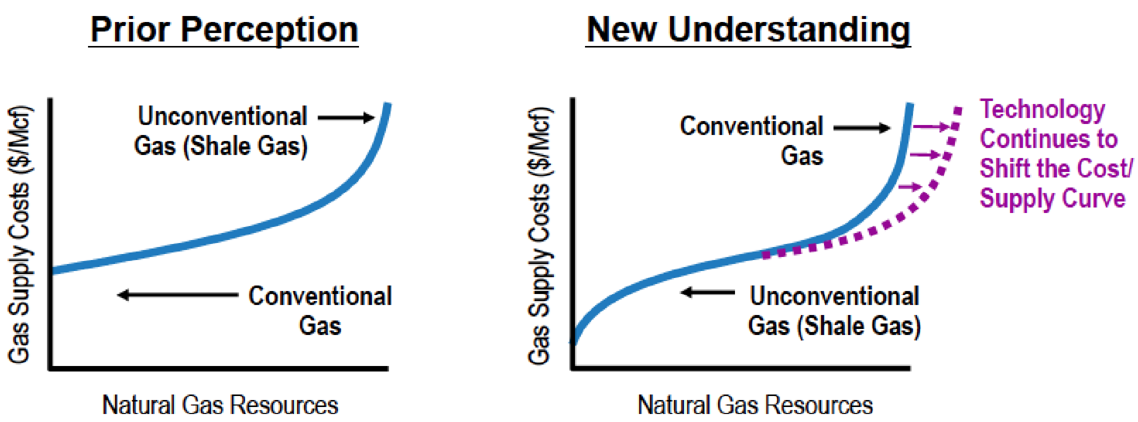
Source: EIA, Drilling Productivity Report, January 2015.

Natural gas production from the Marcellus/Utica shales has benefited greatly from its ability to access an extensive existing pipeline grid. This gas has generally been able to travel to where it is consumed on a "non-firm" basis, and gas sales take place within flexible, liquid, efficient spot gas markets. The one major exception has been pipeline capacity to the Northeast and New England during winter months. The lack of adequate firm pipeline capacity to deliver gas from the Marcellus/Utica shales to those regions has caused the wholesale market price of gas in New England to skyrocket during the past two winters, and in the Northeast last winter.

Kuuskraa (2014) goes on to explain that, under past perceptions, conventional gas and oil was cheaper to produce than unconventional resources such as shale, tight sands, tight oil, and the like, which require well stimulation techniques of one kind or another. In Exhibit 2-11, he makes the point that conventional gas used to occupy the lower left-hand portion of the overall US price-quantity gas supply curve, while unconventional resources occupied the upper right-hand portion. In other words, gas from ordinary downward-only (vertical, un-stimulated) gas wells was cheap to drill and produce, despite a number of finding risks like imperfect success rates. On the other hand, the nation's vast unconventional gas and oil resources have long been documented, but they were deemed too expensive to produce because well stimulation would be required at high cost (as was believed at the time).[18]

As Kuuskraa points out: "Today, unconventional gas (particularly high quality, liquids-rich shale gas) forms the low-cost portion of the natural gas cost/supply curve."[19]

Exhibit 2-11. Illustrative Price-Quantity Curve for Overall U.S. Natural Gas Supply



Source: Kuuskraa, 2014, before EPRI (see Footnote 6).

In summary to this discussion, the AESC 2015 forecast of avoided gas costs in New England has as its overarching assumption that shale gas is here to stay as a dominant component of U.S. gas supplies, comprising at least 50% of the nation's gas supply through the planning horizon.[20] Even despite lowered energy price expectations, shale gas will continue to depress underlying North American natural gas prices for at least two decades (see discussion below), will replace other supplies of gas as well as fuel oil and coal, and will obviate otherwise inevitable LNG imports.

2.4 The Marcellus and Utica Shales

The Marcellus/Utica shale field has become the nation's largest gas producing field, with no exceptions. Centered in Pennsylvania, Ohio and West Virginia, the Marcellus and Utica shales (herein, Marcellus/Utica) are estimated to hold one of the largest gas fields discovered in the history of the global industry, i.e., about 410 trillion cubic feet (Tcf) of undeveloped technically recoverable gas. For perspective, the Marcellus/Utica is estimated to hold about twice the recoverable gas resources of Alaska's North Slope. Improving technology and field practices tailored to the Marcellus/Utica have

[18] For example, see EIA and Gas Research Institute reports, and legislative history of the Natural Gas Policy Act of 1978.

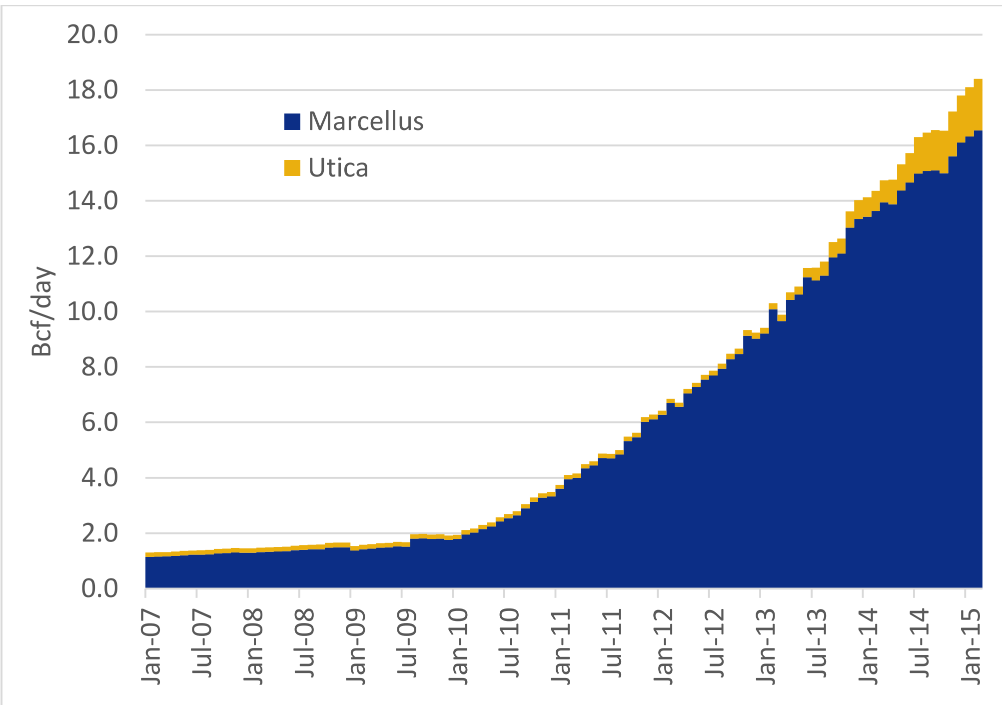
[19] Ibid. Kuuskraa before EPRI, November 2014.

[20] Discussion of health and safety impacts of the major shale production technique, hydraulic fracturing combined with horizontal drilling, may be found in later portions of this chapter.

enabled this gas to be produced at lower costs than most other gas plays in the US, including other shale fields.

Even though it is now already producing more than twice as much gas as any other field in the U.S., shale or otherwise, Marcellus/Utica production is continuing to increase (see Exhibit 2-12). Gas production has been rising by about 1 Bcf/day every three months since 2011, and is likely in our view to reach an average daily production range of about 20-25 Bcf/day by 2020. By contrast, Alaska's proposed North Slope gas pipeline was to have delivered from 4 Bcf/day to 7 Bcf/day of gas, depending upon various pipeline configurations that have been offered in the past nearly four and one half decades since North Slope oil and gas was discovered in 1968.

Exhibit 2-12. Marcellus/Utica Shale Gas Production Growth, Million cf/day



Source: EIA Drilling Productivity Report, January 2015.

As a result of unexpectedly major volumes of natural gas produced in the Marcellus/Utica, a number of gas pipeline flows have been reversed in the U.S. in order to transport gas out of the Marcellus/Utica shale to Chicago, Central Canada, and even to Louisiana and Texas.

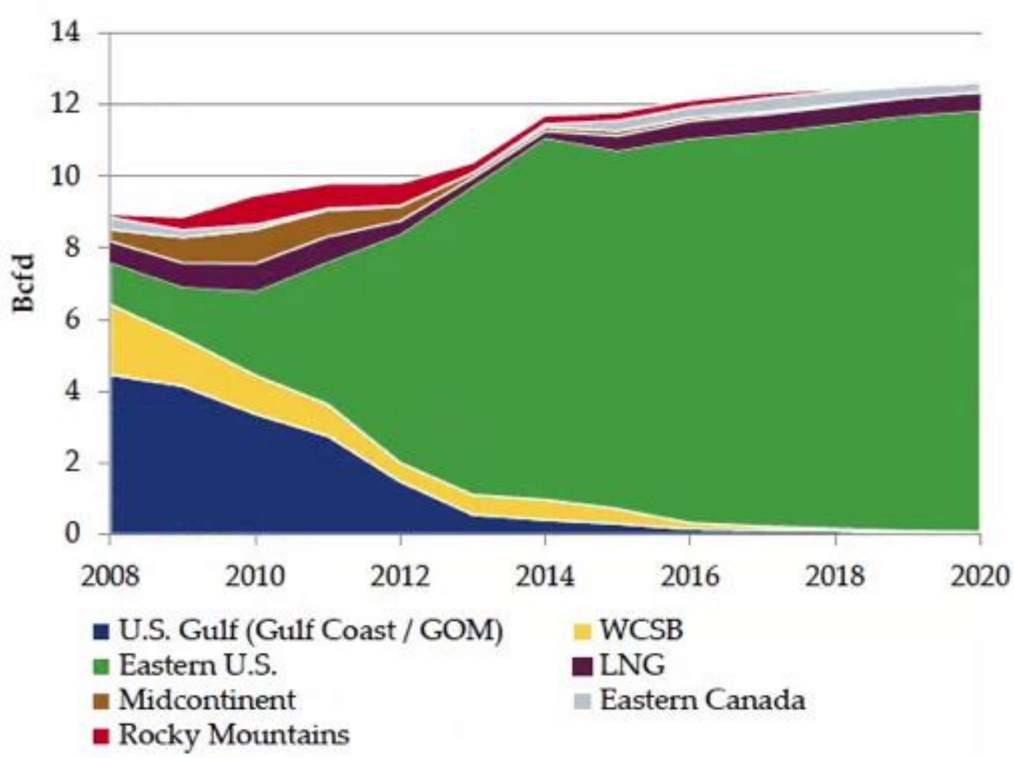
The foregoing developments are having important spillover effects on New England's gas supply sources:

- First, Marcellus/Utica gas is largely displacing New England's traditional gas supplies from U.S. southwestern producing areas including Louisiana and Texas.

- At the same time, as described above, the international gas import point at Niagara through which Canadian gas has for thirty years entered New York State, bound in part for New England, was recently reversed and Marcellus/Utica gas is currently flowing into Central and Eastern Canadian markets. This gas is increasingly displacing gas produced in the Western Canadian Sedimentary Basin (WCSB) which, for decades, supplied essentially all of this region's gas requirements via the TransCanada pipeline system mainline.
- Thus, since Central and Eastern Canada is increasingly consuming Marcellus/Utica gas instead of WCSB gas as shown in Exhibit 2-5, most of New England's gas supplies from Canada, e.g., via the Iroquois and Portland Natural Gas pipelines, is actually Marcellus/Utica gas as well – and all of it is on the margin. In other words, whether New England wholesale buyers move gas on the Algonquin or Tennessee Gas pipelines from New York State, or they import pipeline gas from Central Canada (Ontario and Quebec), they are in reality acquiring gas mostly from the Marcellus/Utica producing region.

AESC 2015 assumes that production from the Marcellus/Utica shales will continue to increase and to supply an increasing portion of the New England market over time, eventually supplying almost the entire pipeline (i.e., non-LNG) market through the following two decades, and then largely beyond then through the end of the planning horizon (see Exhibit 2-13, from OEB/Navigant 2014)

Exhibit 2-13. Sources of Gas Supply in the U.S. Northeast Region, Including New England



Source: 2014 Mid-Year Outlook, from Ontario Energy Board, 2014 Natural Gas Market Review, Navigant Consulting, Inc., December 2014, page 36.

In addition, as was assumed in the AESC 2013 forecast of avoided gas costs, AESC 2015 anticipates that New England will continue to rely on imported LNG to help meet its winter peak gas demand requirements for a limited number of days.

2.5 Long-Run Avoided Cost of Gas Supply

The AESC 2015 Base Case and High Gas Case forecasts from January 2017 onward rely on Henry Hub gas price projections contained in the Energy Information Administration's Annual Energy Outlook (AEO) 2014 Reference Case.[21] The AESC 2015 Low Gas Case sensitivity forecast relies on the AEO 2014 High Oil and Gas Resource Case (HRC). These forecasts were selected based upon our review of the AEO 2014 suite of forecasts, as well as on runs of the World Gas Model housed at Deloitte and at the James A. Baker III Institute for Public Policy at Rice University (Baker-WGM), current futures market prices of gas and basis, and insights from other research agencies and consulting firms**.**

Unlike AESC 2013, AESC 2015 does not adjust AEO 2014 forecasts for marginal well economics or compliance with anticipated tighter regulation of fracturing, as no such corrections are needed. This decision is based upon the reviews described above, on our understanding that these factors have been internalized in EIA's contemporary rounds of AEO forecasts, and on recent data.

2.5.1 Reliance on AEO 2014 Reference Case

EIA's annual domestic energy forecasting process involves an annual cycle consisting of analysis activity conducted internally and through use of contractors. The process takes place largely during the summer preceding the date of (and release of) AEO forecasts, thus the bulk of work in preparing the AEO 2014 Reference Case took place predominantly during Summer 2013. The EIA's analysis involves preparing and testing necessary updates to, and changes in the National Energy Modeling System (NEMS), including numerous runs and reruns of the updated model. Throughout this process, a series of peer reviews are conducted with industry experts and stakeholders. This series of activities normally intensifies during the summer and fall preceding EIA's issuance of the early release of its Reference Case, normally in mid-December. The AEO 2015 preparation cycle has been delayed to accommodate the more than 50% decline in crude oil prices that took place in the latter half of 2014, as well as other recent developments.

In the High Oil and Gas Resource Case (HRC), the EIA makes a number of assumptions about the unconventional gas and oil resource base that, together, expand recoverable gas volumes well beyond

[21] The AESC 2015 High Gas Case Henry Hub price is the AEO 2014 Reference Case plus 15%, which reflects the minimum increase in gas prices in the AEO 2014 Low Oil and Gas Resource Case over the AEO 2014 Reference Case.

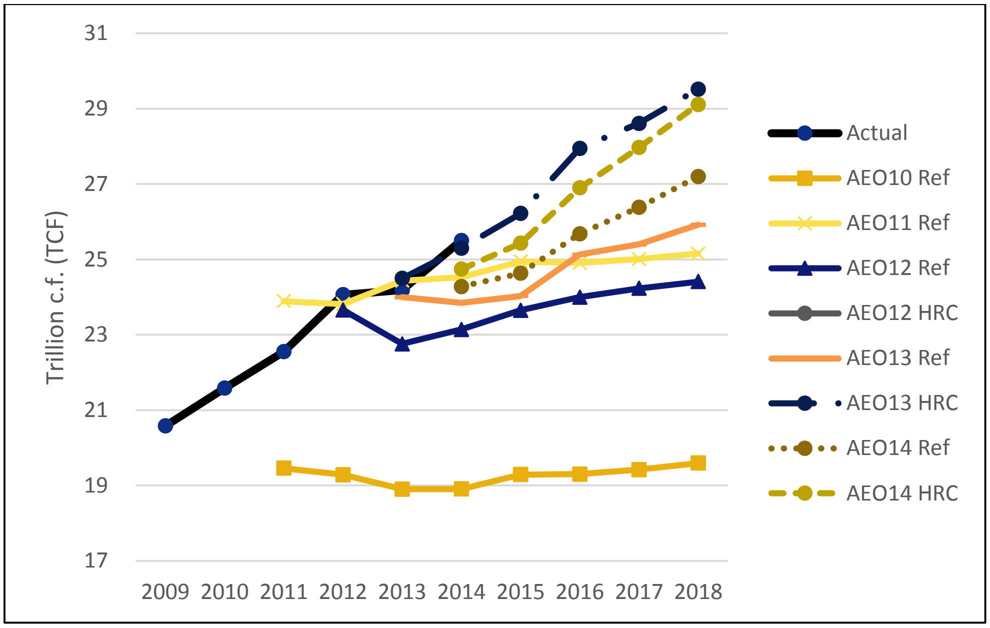
those assumed in the Reference Case. The HRC makes no other changes to the AEO Reference Case assumptions, e.g., contains no differences in assumptions concerning existing drilling laws and regulations, macro-economic conditions, or about other fuels. [22] Importantly, the HRC assumes that the estimated ultimate recovery (EUR) of shale and tight sands gas is 50% higher than in the Reference Case and the number of wells left to be drilled is 100% higher. In the AEO 2013 and AEO 2014 versions, the HRC forecasts project significantly lower gas prices than the corresponding Reference Cases.

In our analysis, the HRC series has been a closer predictor of the growth in shale gas production than has the Reference Case series. As shown in Exhibit 2-14, AEO Reference Cases in recent years have been consistently low in their projections of U.S. dry gas production, while the HRC series has come closer to reality. The situation with respect to AEO forecasts of gas prices has not been as clear as it has been with volumes however. For example, we note that, in some years, AEO Reference Cases have come closer to forecasting actual gas prices than the HRC cases. As shown in Exhibit 2-14, the EIA forecasts that appear to have come closest to projecting actual prices have been the AEO 2013 Reference Case – which was the driving forecast in the AESC 2013 report – and the AEO 2014 HRC.[23]

[22] The EIA defines the HRC as follows: "Estimated ultimate recovery per shale gas, tight gas, and tight oil well is SO% higher and well spacing is 50%lower (or the number of wells left to be drilled is 100% higher) than in the Reference case. In addition, tight oil resources are added to reflect new plays or the expansion of known tight oil plays and the estimated ultimate recovery for tight and shale wells is increased 1% per year to reflect additional technological improvement. Also includes kerogen development, tight oil resources in Alaska, and 50% higher undiscovered resources in lower 48 offshore and Alaska than in the Reference case." See, for example: http://www.eia.gov/oiaf/aeo/tablebrowser/.

[23] Note that, through the late 2020s, the AEO 2013 Reference Case and the AEO 2014 High Oil & Gas Resource Case are almost identical in terms of their projected Henry Hub gas price; after that, these diverge, as the AEO 2014 High Oil & Gas Resource Case decreases to meet NYMEX market general expectations.

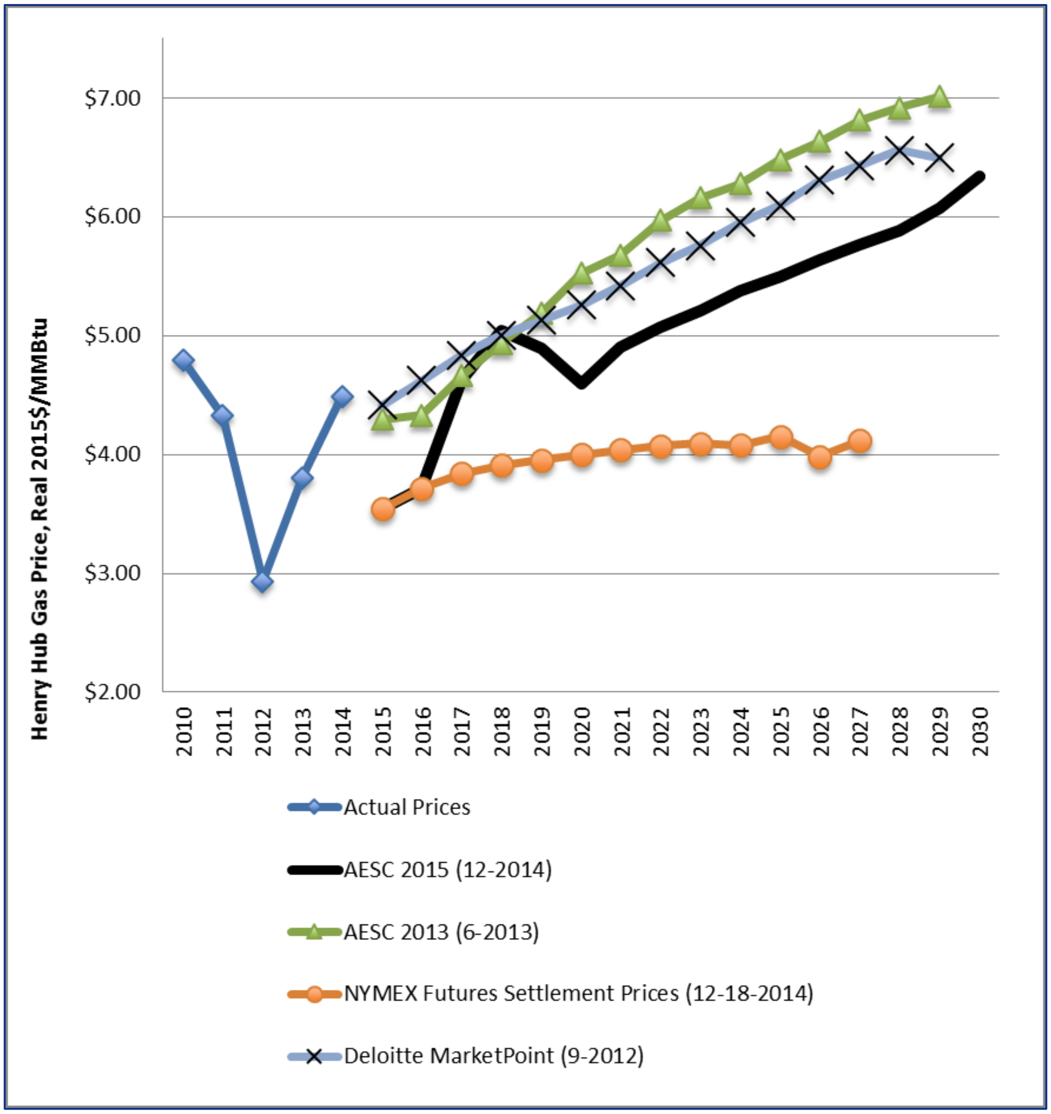
Exhibit 2-14. Comparison of U.S. Gas Production Forecasts in Recent AEO Forecasts vs. Actual Gas Production



Consequently, AESC 2015 opts on the conservative side and derives its Henry Hub gas price assumptions largely from the AEO 2014 Reference Case. It must be pointed out, however, that no statistical proof could substantiate selection of any particular case in a meaningful way on the basis of price, in light of the wide risks and uncertainties confounding all Henry Hub gas price forecasts at a time when:

- Gas production is growing rapidly.
- Production is moving away from the traditional southwestern producing regions, to the Marcellus/Utica region.
- Crude oil prices are highly unstable, having fallen almost suddenly by about 50% in the latter half of 2014.
- Coal competition with natural gas remains sharp.
- LNG exports are poised to begin in about a year, starting with initial exports of U.S. LNG from the Sabine Pass LNG terminal in November 2015.

Exhibit 2-15. Comparison of Annual HH Prices – Actuals, AEO Forecasts and December 2014 NYMEX Futures



In addition, as if the foregoing uncertainties were not great enough, around the time the AESC 2015 report was prepared, the EIA announced it intended to delay early release of its AEO 2015 Reference Case until March 2015.

2.5.2 Marginal Production Cost of Natural Gas from Shale

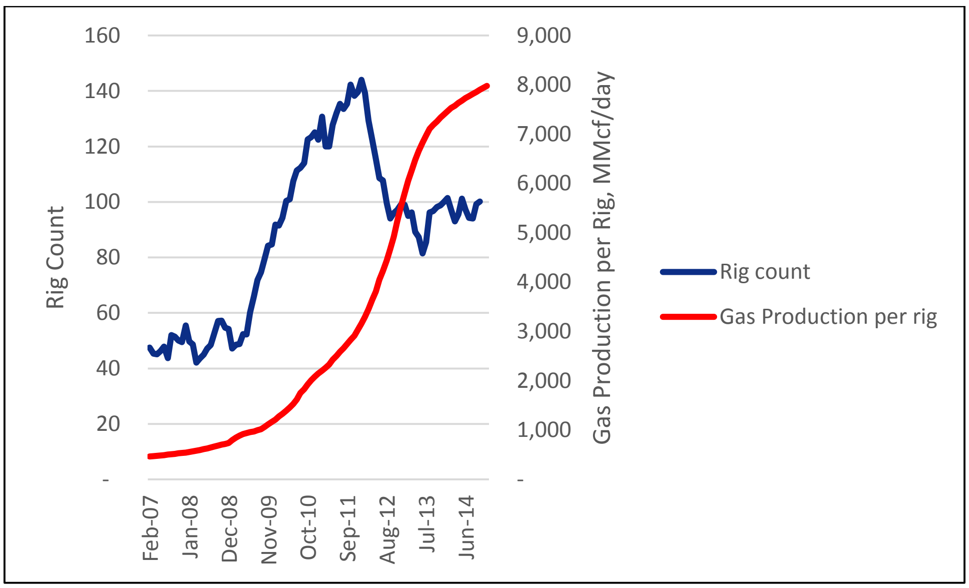
Since the AESC 2013 report was prepared and issued, EIA has expanded the data it provides that are related to the marginal cost of gas production from dry-gas prone and liquids-prone shale plays. In particular, data contained in EIA's new monthly publication, the Drilling Productivity Report (DPR), suggests considerable economies are evolving in production from each of these kinds of shale fields.

The DPR series was begun in October 2013 to address the paradox of rapidly rising gas production per well, and rising gas production overall, in the Marcellus despite a sharply falling rig count in 2011-2012.

Analysts of U.S. shale gas activities had long assumed that falling gas prices would result in a falling rig count, which would then, in turn, quickly reduce gas production. Fundamental reasons for accepting this sequence – and its reverse: rising prices lead to rising rig counts, which lead to more gas production – include the relatively small scale of individual shale well drilling operations and their steeply production decline rates on an individual basis. In addition, the speed with which rigs can be moved, deployed and removed have been a factor. But the key missing element in understanding why and how shale gas production could grow so rapidly has been the increase in rig productivity, i.e., production of gas per drilling rig, per unit of time, brought about by improved technology, tighter operating practices, and increased drilling efficiency.

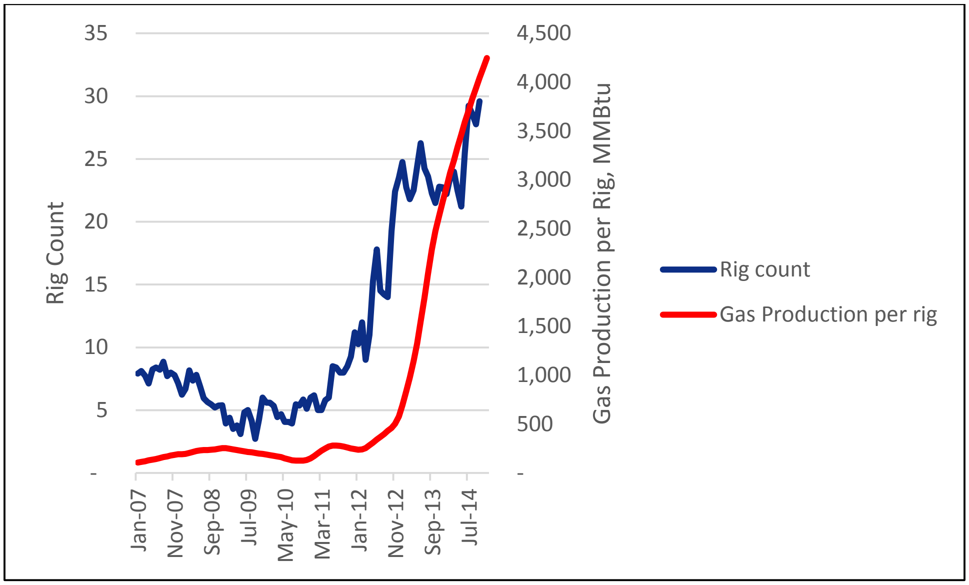
The dramatic growth in drilling productivity in the Marcellus and Utica regions, shown in Exhibit 2-16 and Exhibit 2-17, explains why production is rising despite the declining rig count.

Exhibit 2-16 Rig Count vs. Rig Productivity: Marcellus Shale



Source: EIA Drilling Productivity Report, November 2014.

Exhibit 2-17 Rig Count vs. Rig Productivity: Utica Shale



The increases in gas production shown in those two exhibits have been realized in other shale formations as well, and are echoed in rising oil production statistics as well as for gas. Unlike a "learning curve" in the usual sense, these advances are more a reflection of technological, management and operating improvements that have been tailored to each producing field.

Inclusion of rising rig productivity has been a major, necessary correction to U.S. gas price forecasts. In particular, we understand that the current version of EIA's NEMS model is taking the foregoing kinds of drilling productivity improvements into consideration in development of the AEO 2015 forecast. The NEMS Model contains an Oil & Gas Module, which is used to project gas production based on costs of developing resources in each U.S. gas-producing region. NEMS' Oil & Gas Module anticipates continued improvements in rig and program efficiencies as drilling moves beyond core areas in each shale field.

In its comprehensive documentation report, EIA summarizes its approach in the following general statement:

> The general methodology relies on a detailed economic analysis of potential projects in known crude oil and natural gas fields, enhanced oil recovery projects, developing natural gas plays, and undiscovered crude oil and natural gas resources. The projects that are economically viable are developed subject to the availability of resource development constraints which simulate the existing and expected infrastructure of the oil and gas industries. The economic production from the developed projects is aggregated to the regional and the national levels. (EIA 2011)

In its 2013 methodology update, which describes methodology underlying the AEO 2014 cases, the EIA indicates that the Oil & Gas Module contains production cost data in all categories, much like a group of natural gas supply curves. A gas supply curve refers to a price-quantity curve that contains the marginal cost of producing additional volumes of gas from that field or play covered in that curve. A gas supply curve in this manner is implicit in each of the 85 gas-producing fields listed in its AEO 2014 assumptions report, which includes ten subfields of the Marcellus, Utica, Devonian and other nearby shales. In each case, the EIA's estimate includes production costs for marginal wells throughout the entire unproved technically recoverable tight/shale oil and gas resources, by play. The EIA's gas supply methodology, therefore, embeds the costs of producing each component of the resource, sequenced by rising costs – starting with the low-cost core interior, through the next higher cost fields in the area, and on to the higher marginal cost portions, then the highest cost components.

As a consequence, therefore, there is no longer any reason to add or subtract any special factors to adjust EIA's forecasts for marginal well economics – these are embedded in EIA's supply analyses underpinning the AEO suite of forecasts, including each component of the Marcellus/Utica shales.

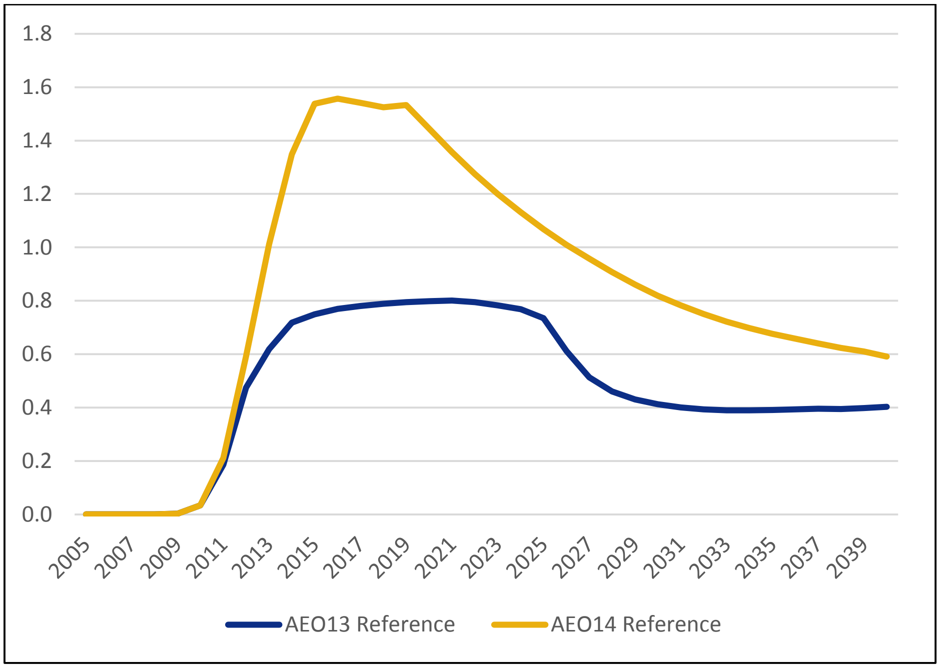
2.5.3 Inherent Limitations in AEO Reference Cases

Despite its widespread usefulness and acceptance, AEO Reference Case forecasts are necessarily bound to reflect law and regulations in effect at the time of the forecast.[24] In addition to assumptions about the economy, assumptions concerning technology and the extent of recoverable oil and gas resources in the Reference Case are consistent with understandings that are in existence or viewed as most likely, at the time the analysis is prepared, e.g., summer and autumn of each year for the following year's forecast. As discussed above, considerable uncertainties surround any energy forecast, let alone one produced amidst the aggressive pace of change taking place in the U.S. oil and gas industry in all respects. As a consequence, EIA's numerous sensitivity cases – particularly the High Oil and Gas Resource Case ("HRC") – take on particular significance.

[24] In the AEO 2014 Reference Case, real GDP grows at an average annual rate of 2.4% from 2012 to 2040. Crude oil prices are projected to rise to about $141/barrel (2012 dollars) in 2040. Note that the AESC 2015 forecast includes a downward adjustment to oil price projections in AEO 2014 Reference Case, as described in the accompanying section on fuel oil avoided cost assumptions, methodology and forecasts.

For example, contrast the analysis of tight oil production in the Eagle Ford by Dana Van Wagener (Wagener, EIA April 2014) with the most recent edition of EIA's Drilling Productivity Report shown in Exhibit 2-18. These differences demonstrate how difficult it is to project rising production and falling costs of shale resource development at a time of when both features – production volumes and production costs – are changing rapidly.

Exhibit 2-18. Eagle Ford Crude Oil Production in the Reference Case, 2005-40 (million bbl/day)



Source: Wagener, EIA April 2014; see preceding footnote.

As Wagener demonstrates (see Exhibit 4 2), the AEO 2013 Reference Case projected the Eagle Ford crude oil production would level off at less than 800,000 barrels per day for about a decade; then, the AEO 2014 Reference Case projected the Eagle Ford would level off at just over 1.5 million barrels per day. Timely EIA data indicate the Eagle Ford is currently producing 1.7 million barrels per day as of December 2014. Similar under-estimates of shale oil and gas production in EIA's reference cases are numerous – especially for gas production from the Marcellus/Utica shales.

The foregoing argues convincingly for caution in the use of the AESC 2015 forecast of avoided gas costs in New England because this forecast relies extensively on the AEO 2014 Reference Case.

2.5.4 Summary of Forecasting Issues in AESC 2015

The AESC 2015 Base Case and High Case forecasts rely on the AEO 2014 Reference Case (High Case is a 15% upward price adjustment from the AEO Reference Case),while the AESC 2015 low gas Case relies on the AEO 2014 High Oil & Gas Resource Case (HRC). Over the past several years the AEO HRC series have more closely tracked the pace of gas production increases in the recent past than have the Reference

Cases. AEO Reference Case forecasts prior to and including AEO 2014 have tended to underestimate production from shale gas and, in some cases, over-estimate wellhead prices from those plays.

Crude oil prices decreased by 50% in a matter of months during the second half of 2014. As described in Chapter 3), experienced analysts advise that prices may fall even lower amidst a gathering price war. But like prior price wars, peace is likely to 'break out' as most OPEC member budgets (and some non-OPEC budgets as well, e.g., the Russian Federation) strain to the breaking point, forcing cooperative action.[25] If domestic crude oil prices were to remain in the $60-$70 per barrel range for the next five years, drilling activity in some strongly crude-prone, high-cost plays may decrease markedly, e.g., the Bakken, Niobrara and Canadian oil sands regions, as these areas generally do not have the benefit of natural gas sales to help offset lower crude prices. Likewise, drilling in the liquids-rich Eagle Ford and Utica plays will not fall of as greatly because of their prolific gas production and excellent market access. Drilling in the Marcellus Shale may also be affected, but to a lesser extent, as the Marcellus is a dry gas play, thus it is not clear that low oil prices will have a material impact on production from that field.

With regard to LNG exports, AESC 2015 agrees with AESC 2013 assessment of the gas price impact of LNG exports. The only significant new study issued since then was EIA's report of October 2014,[26] which corroborates the conclusions in AESC 2013, namely, that the consumer price effects of LNG exports will be modest. But in any event, lower crude oil prices may reduce expected LNG exports from the U.S. because global natural gas prices are typically linked under long-term contracts to crude oil prices. This is the case in a number of likely receiving markets for LNG from the U.S., including Japan, South Korea, Central Europe, parts of Western Europe, and elsewhere. As global oil prices fall, therefore, global gas market prices beyond North America fall as well, and the economic margin tightens, reducing the gap between U.S. gas prices (plus liquefaction and shipping) and other gas prices internationally. Medlock, Hartley (Rice/Baker Institute) and others have argued that high costs of liquefaction and transportation of US gas to these markets would make some LNG exports uneconomic depending on how low world crude prices fall.27

2.6 Incremental Gas Production Costs Related to Compliance with Emerging Hydraulic Fracturing/Horizontal Drilling Regulations

Analysts have identified a number of potential sources of additional costs gas producers might incur in the future in order to comply with existing, impending or potential regulations governing hydraulic

[25] See, for example, Verleger (October 2014) and others in current discussions. Verleger sees little risk to the Marcellus as crude prices fall briefly, potentially to as low as $35 or $40 per barrel, but then recovery to the $60 to $70 range.

[26] EIA, "Effect of Increased Levels of Liquefied Natural Gas Exports on U.S. Energy Markets," October 29, 2014.

[27] See, for example, Kenneth B. Medlock, "A Discussion of US LNG Exports in an International Context," Center for Energy Studies, James A Baker III Institute for Public Policy Adjunct Professor, Department of Economics Rice University, January 11, 2013 presentation before the National Capital Area Chapter of the U.S. Association for Energy Economics.

fracturing/horizontal drilling.[28] These potential sources of additional costs primarily involve water and wastewater treatment and disposal regulations, regulations governing the handling and/or elimination of toxic materials, and the need to reduce greenhouse gas (GHG) emissions and the wellhead and in the gas pipeline and distribution grid. AESC 2015 assumes that the long-term AEO 2014 Reference Case gas market forecast adequately reflects these potential additional costs, for the reasons discussed below.

2.6.1 Water and Wastewater Treatment and Disposal

In most basins, gas-bearing shale seams are located far beneath groundwater basins, e.g., shale seams are at depths ranging from 6,000 to 12,000 feet, while groundwater basins are typically at bottom depths of no more than 2,000 or 2,500 feet. Non-porous bedrock separates the two layers, i.e., shale seams are below even deep groundwater aquifers, thus preventing material from one layer from mixing into the other. Sealed drill-pipes routinely traverse aquifers to avoid direct contact with groundwater, although occasional instances of groundwater contamination caused by ruptured drill-pipe have been reported. Moreover, naturally occurring fractures or fissures in the bedrock may inadvertently provide transport channels among strata. In relatively rare instances where transport through the bedrock has been available, fracking pressures were suspected of driving native hydrocarbons from shale seams up into groundwater aquifers.

During the early years of the shale revolution, reports of benzene and other drinking water contamination near shale gas fracking operations prompted environmental regulators to restrict shale-drilling operations in some locations until a better understanding of the processes at work could be gained. In one celebrated case, New York City's water supply, which is derived from aquifers beneath five counties in the eastern fringe of the Marcellus Basin and transported through tunnels in the bedrock, was deemed sufficiently threatened to necessitate suspension of shale gas drilling operations in all five counties, and ultimately throughout the State.

In response to these concerns, the US Environmental Protection Agency (EPA) commenced an in-depth analysis of the foregoing issues with the goal of determining if the agency needs to regulate shale gas drilling operations under the U.S. Safe Water Drinking Act. In one widely-reported instance, a driller in Wyoming (Encana) conducted hydraulic fracturing (herein, "fracking") operations into shallow shale seams located quite near the aquifer, with the predictable result that groundwater became

[28] The AESC 2013 Forecast added to its gas price forecast a "fracturing best practices upward adjustment" rising to $.54 per MMBtu by 2021 and remaining at that amount through the planning horizon. However, despite its useful review of literature available at the time, this report offered no source documenting any such estimate, apart from an unreferenced 2010 report by the consulting firm of Tudor, Pickering. Any such 4-5 year old estimate would necessarily predate the rise in shale gas production in the US, particularly in the somewhat more recent Marcellus or Utica basins, and could not comprehend drilling improvements and efficiencies since then.

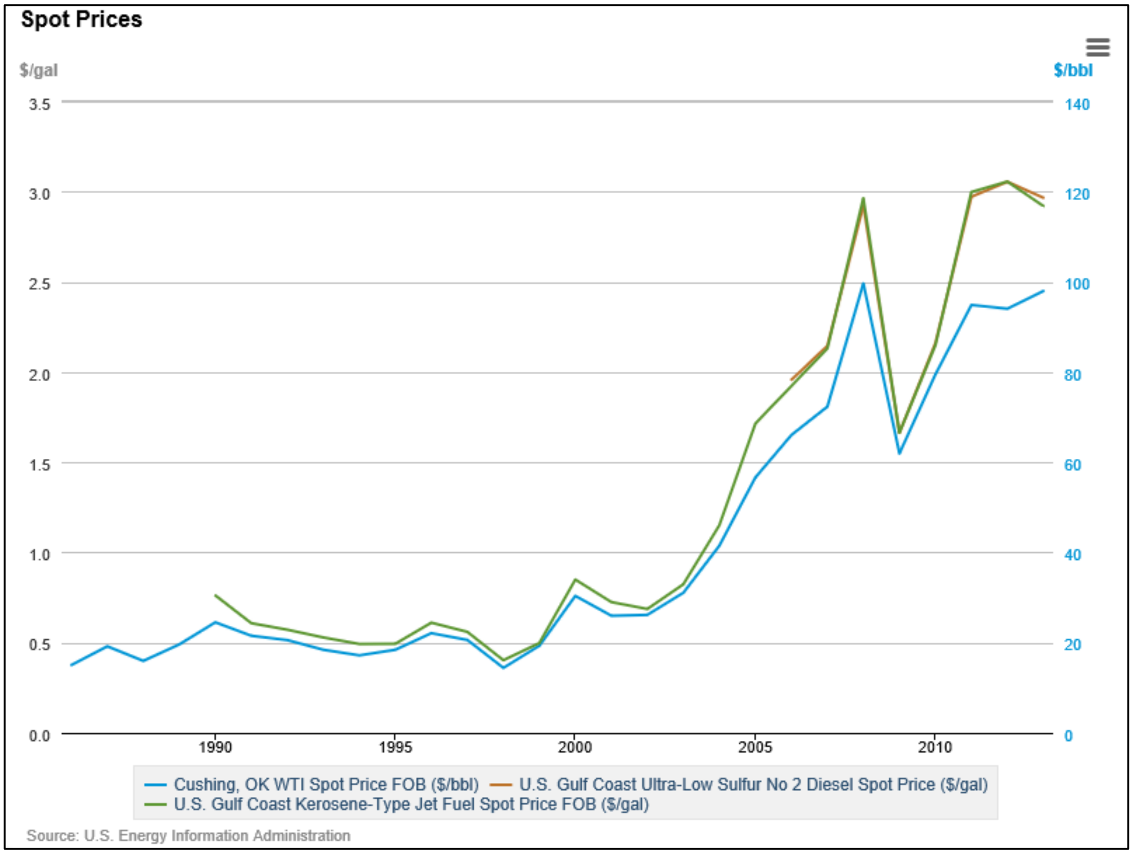
contaminated with materials contained in fracking waters and shale-borne substances. The EPA's report termed the incident exceptional.[29]

Fracking fluids consist largely of water and sand (as a propping agent), although some drillers also use a variety of other substances, including 1-2 percent concentrations of biocides, gels, and organic substances to improve performance. Some of the fluids injected into shale seams in fracking operations re-emerge in return water from wells under fairly high pressures ("flowback"). Flowback consists of much the same materials that went into the well, plus various other solids, hydrocarbons, and other materials resident within the shale seam. If not fully recycled, flowback is effectively an industrial effluent that must be treated and disposed of properly.

Before the price of liquids increased to very high values in 2011-2012 (as shown in Exhibit 2-19), flow-back in some drilling operations was handled in ways that contributed to wasting valuable liquid materials: some flow-back was spread on land away from aquifers to prevent leaching into groundwater, some was disposed of in adjacent waterways, and some was trucked off-site to public wastewater treatment plants for disposal to the extent of available capacity. The sheer volumes of flowback wastewaters, together with reported instances of impermissible wastewater disposal practices, excessive truck traffic, and the like, prompted regulators to examine shale gas operations more closely to ensure compliance with the U.S. Clean Water Act and other federal, state and local laws. More recently, as producers turned sharply to liquids-prone shale plays – particularly the Eagle Ford, Bakken, and others in relatively arid regions – they have been required to recycle flowback waters with greater frequency and intensity in order to maximize recovery of condensates, including benzene and other valuable liquids, and to use local water supplies more efficiently. In so doing, producers have also effectively minimized pathways to the groundwater associated with improper disposal of flowback wastewaters.

[29] Jim Martin, Region 8 Administrator, U.S. Environmental Protection Agency (EPA),before U.S. House of Representatives Committee on Science, Space, and Technology, Subcommittee on Energy and the Environment, Hearing on Ground Water Research at Pavillion, Wyoming, February 1, 2012, "It should be noted that fracturing in Pavillion is taking place in and below the drinking water aquifer and in close proximity to drinking water wells – production conditions different from those in many other areas of the country." (Martin testimony, page 4)

Exhibit 2-19. Crude Oil and Selected Petroleum Product Prices in Markets Adjacent to U.S. Southwestern Shale Regions



In summary, gas drilling operations have radically changed since the onset of the shale revolution, when many of the initial concerns surrounding "fracking" became voiced. Pennsylvania, Ohio, and other Marcellus/Utica states have tightened regulation, while gas prices have remained low all the while.

2.6.2 Methane Leakage

Methane, a greenhouse gas (GHG) that is the primary component of natural gas, is understood to be a far more powerful GHG than carbon dioxide, exceeding the strength of CO_2 in this respect by factors variously estimated to be 20-25 over a 100 year cycle.[30]

Overall, the present status of knowledge about natural gas and methane as a GHG was summarized in a working paper issued in 2013 by the World Resources Institute,[31] as follows:

[30] Steffen Jenner and Alberto J. Lamadrid, "Shale gas vs. coal: Policy implications from environmental impact comparisons of shale gas, conventional gas, and coal on air, water, and land in the United States," Energy Policy 53 (2013) 442-453.

[31] James Bradbury, Michael Obeiter, Laura Draucker, Wen Wang, and Amanda Stevens, "Clearing the Air: Reducing Upstream Greenhouse Gas Emissions from U.S. Natural Gas Systems," World Resources Institute, Working Paper, April 2013.

> 1. Fugitive methane emissions from natural gas systems represent a significant source of global warming pollution in the U.S. Reductions in methane emissions are urgently needed as part of the broader effort to slow the rate of global temperature rise.
>
> 2. Cutting methane leakage rates from natural gas systems to less than 1 percent of total production would ensure that the climate impacts of natural gas are lower than coal or diesel fuel over any time horizon. This goal can be achieved by reducing emissions by one-half to two-thirds below current levels through the widespread use of proven, cost-effective technologies.
>
> 3. Fugitive methane emissions occur at every stage of the natural gas life cycle; however, the total amount of leakage is unclear. More comprehensive and current direct emissions measurements are needed from this regionally diverse and rapidly expanding energy sector.
>
> 4. Recent standards from the Environmental Protection Agency (EPA) will substantially reduce leakage from natural gas systems, but to help slow the rate of global warming and improve air quality, further action by states and EPA should directly address fugitive methane from new and existing wells and equipment.
>
> 5. Federal rules building on existing Clean Air Act (CAA) authorities could provide an appropriate framework for reducing upstream methane emissions. This approach accounts for input by affected industries, while allowing flexibility for states to implement rules according to unique local circumstances. (Bradbury et al, 2013)

In response to increased gas drilling and a wide variety of methane emission estimates from numerous sources, the EPA issued on April 17, 2012, New Source Performance Standards (NSPS) governing GHG emissions from oil and gas drilling and producing activities. Under the rule, shale well drilling operations are required to use "reduced emissions" or "green completion" equipment to capture gas and condensate that comes up with hydraulic fracturing flowback, preventing their release into the air and making the valuable hydrocarbons available to the producer for sale. During a transition period that was scheduled to end on January 1, 2015, producers had the option to flare, although green well completions are preferred for multiple reasons.

- They provide the same reduction in Volatile organic compounds (VOCs) as flaring. But while flaring allows the emission of smog-forming nitrogen oxides, green well completions do not.
- By capturing a valuable resource rather than wasting it, green well completions make that resource available for sale or use by the producing company. According to the EPA, green well completions were already used on about 50 percent of wells at the time the draft rule was issued.

EPA estimates the total annualized engineering costs of the final NSPS will be $170 million. When estimated revenues from additional natural gas and condensate recovery are included, the annualized engineering costs of the final NSPS are estimated to be -$15 million, assuming a wellhead natural gas price of $4/thousand cubic feet (Mcf) and condensate price of $70/barrel (measured in 2008 dollars).[32] Industry sources also report a reduction in the cost of gas associated with green completions. In this respect, the WRI authors went on to conclude: "Fortunately, most strategies for reducing venting and leaks from U.S. natural gas systems are cost-effective, with payback periods of three years or less." (Bradbury et al, 2013).

In summary, recent EIA Annual Energy Outlooks take into consideration the relevant regulatory and other structural components needed to forecast avoided costs of gas in New England. In particular, the TCR team is unaware of any credible research or analysis published subsequent to AESC 2013 that supports its assumption that AEO forecasts are not accurately reflecting the cost of compliance with environmental and greenhouse gas regulations governing shale gas production. On the contrary, the EPA has projected positive economics associated with its requirement for green completions as a means of controlling and reducing GHG emissions from shale gas well drilling operations. In addition, actual gas production experience in 2013 and 2014 has been dispositive in this regard.

2.7 Uncertainty and Risk in Projecting Wholesale Gas Market Prices

As noted earlier, the major factors driving gas demand and supply, and hence wholesale gas market prices, include:

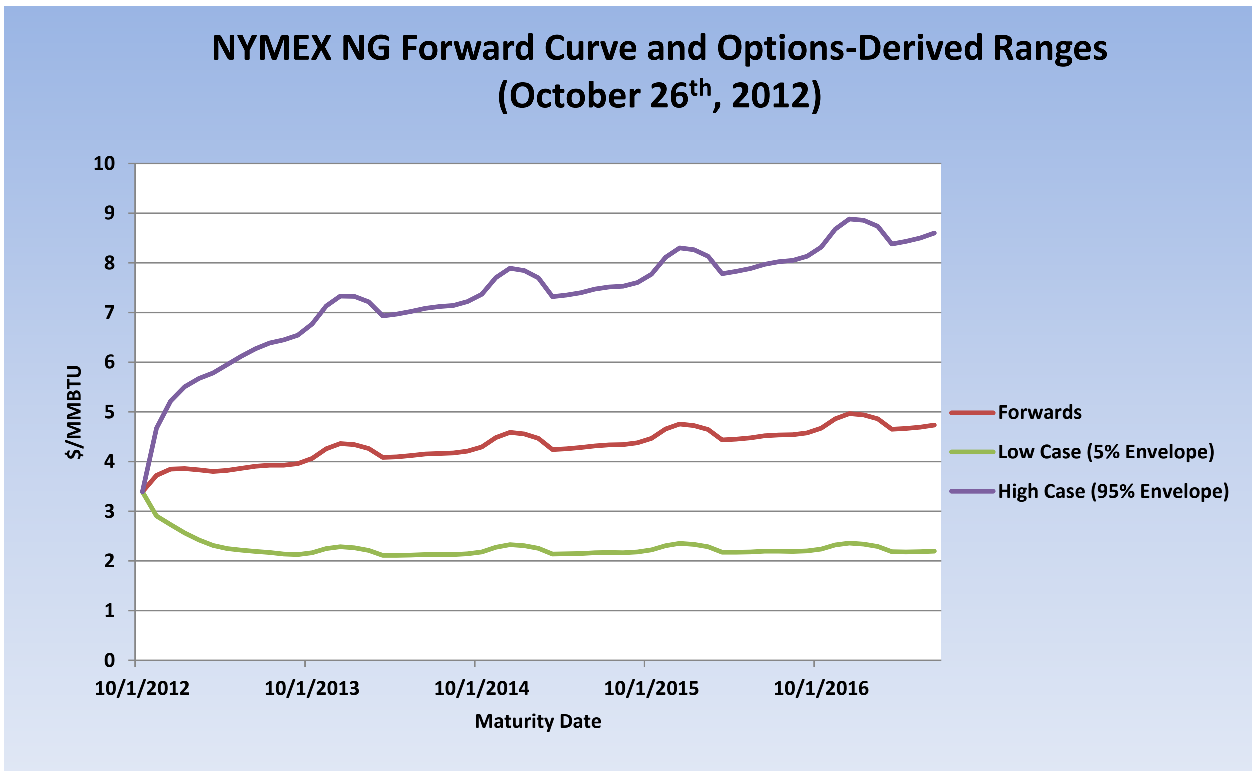
- Gas resources, reserves, production and the technologies that underlie each of these
- The availability of gas transportation via two million miles of gas pipelines and distribution mains in North America
- Regional, national and, increasingly, international economic activity
- Advances in technologies for gas production, transportation and use, e.g., notably in the past decade, respectively, horizontal drilling, advanced LNG systems, and high-efficiency gas-fired electricity generation using combined-cycle combustion turbines (CCGTs)
- Price elasticity of natural gas in each use and cross-elasticity with oil, electricity and other competing fuels
- Infrastructure expansion, including pipeline and storage capacity

[32] U.S. Environmental Protection Agency, Regulatory Impact Analysis, Final New Source Performance Standards and Amendments to the National Emissions Standards for Hazardous Air Pollutants for the Oil and Natural Gas Industry., Office of Air and Radiation, Office of Air Quality Planning and Standards, April 2012.

Variations in forecasts based upon those assumptions is inevitable due to the uncertainty associated with projecting future values of those driving factors.

Sensitivity analyses around the range of natural gas commodity economics is the best way to assess risks inherent in the forecast, and will be included in the AESC 2015 report. Stibolt (Galway Group, 2012) and other analysts comment widely on the risks in forecasting gas market prices, observing that the 90% confidence interval may be as high as the range of $3 to $8 per MMBtu.[33] While these levels of risk are prevalent in most energy forecasts over the past few decades, AESC 2015 captures the uncertainties by choice of High and Low Cases that are more closely articulated to actual market assumptions that the kind of wide range Stibolt (2012) and other have been able to compute from analysis of gas options market prices.

Exhibit 2-20. Range of Implied Risk in Natural Gas Prices



Source: Robert D. Stibolt, "Perspectives on World Natural Gas Markets," Galway Group, L.P., in presentation before the 31st USAEE/IAEE North American Conference, Austin, TX, November 6, 2012.

[33] Robert D. Stibolt, "Perspectives on World Natural Gas Markets," before the IAEE-USAEE Energy Conference, Austin, TX, November 2012. Analysis of implied volatility based on NYMEX natural gas option prices.

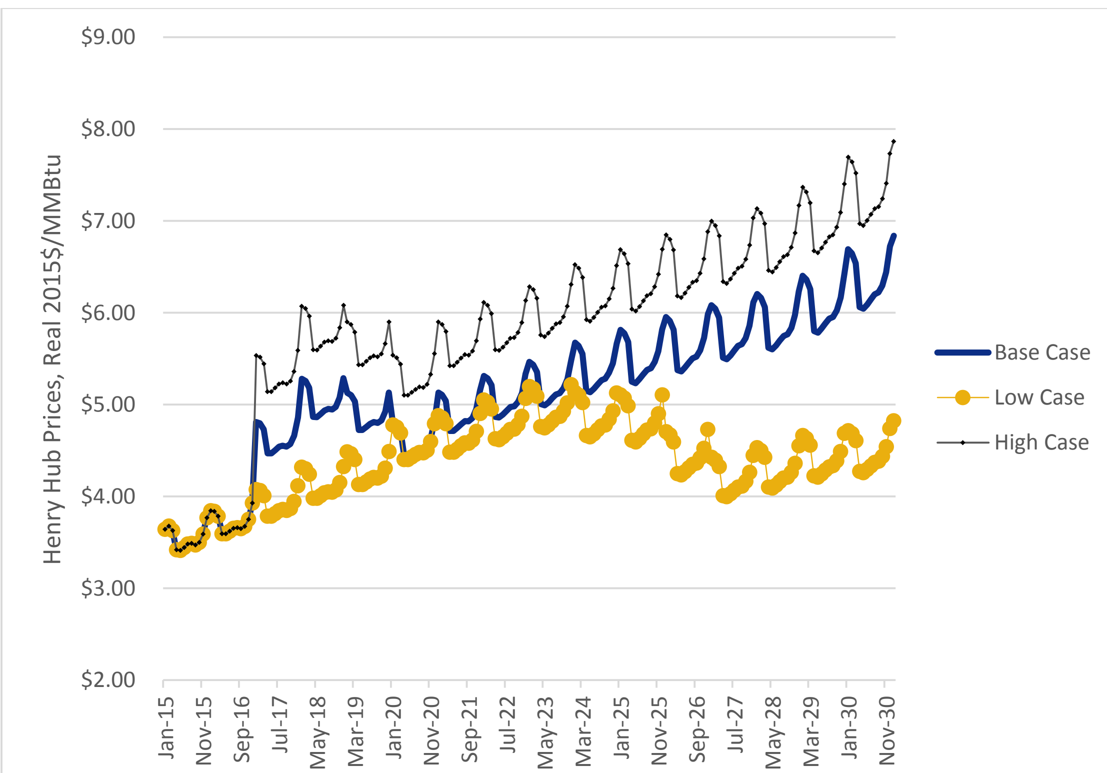
2.8 Gas Price Volatility and/or Uncertainty of Gas Prices

Volatility is a measure of the randomness of variations in prices over time as affected by short-term factors such as extreme temperatures, hurricanes, supply systems disruptions, etc. It is not a measure of the underlying trend in the price over the long-term. AESC 2015 forecasts of natural gas production prices under base, high, and low cases provide projections of expected average natural-gas prices in any month of any year. Actual gas prices are quite volatile and in any future month, week, or day may vary considerably around the expected annual average prices forecast in each of those three cases. Consistent with prior AESC studies, we do not forecast the actual monthly or weekly prices that would reflect historical price volatility primarily because we are forecasting prices used to evaluate avoided costs in the long term.

2.9 AESC 2015 Forecast of Gas Prices Henry Hub

The AESC 2015 forecast of gas prices at Henry Hub for the three cases shown in Exhibit 2-21 was developed as described below.

Exhibit 2-21. AESC 2014 Forecast of Monthly Henry Hub Gas Prices, 2015$/MMBtu



2.9.1 Base Case Forecast of Henry Hub Gas Prices

In developing the AESC 2015 Base Case Henry Hub price forecast, the TCR Team considered a number of available forecasts, as discussed above. The Base Case Henry Hub price forecast relies on the AEO 2014

Reference Case annual Henry Hub price forecast to 2031 and NYMEX monthly Henry Hub futures settlement prices to 2027 at December 18, 2014, as follows:

a. For the months from January 2015 to December 2016, AESC 2015 monthly Henry Hub prices equal NYMEX monthly Henry Hub futures, as above (converted to real 2015$).

b. For the months from January 2017 to January 2031, AESC 2015 equals AEO 2014 Reference Case annual Henry Hub price forecast, converted to real 2015$, and restated to monthly prices.

c. From January 2017 through December 2027, annual AEO 2014 Reference Case Henry Hub prices were converted to monthly prices using monthly variations in NYMEX Henry Hub futures prices throughout.

d. From January 2028 to January 2031, annual AEO 2014 Reference Case Henry Hub prices were converted to monthly prices using monthly variations in NYMEX Henry Hub futures prices during 2027.

e. For all remaining months to December 2045, Henry Hub prices are extrapolated from the above forecast for 2027-2030.

The foregoing procedure resulted in the AESC 2015 Base Case projection of monthly gas prices at Henry Hub from January 2015 through January 2031.

Comparison to other Forecasts of Annual Henry Hub Prices

Exhibit 2-22 compares the AESC 2015 Base Case projections of Henry Hub prices (i.e., the AEO 2014 Reference Case), with NYMEX as of December 18, 2014 and public forecasts from other sources reported in AEO 2014. The AESC 2015 Base Case forecast for 2025 is higher than the NYMEX value and the average of the public forecasts from AEO 2014.

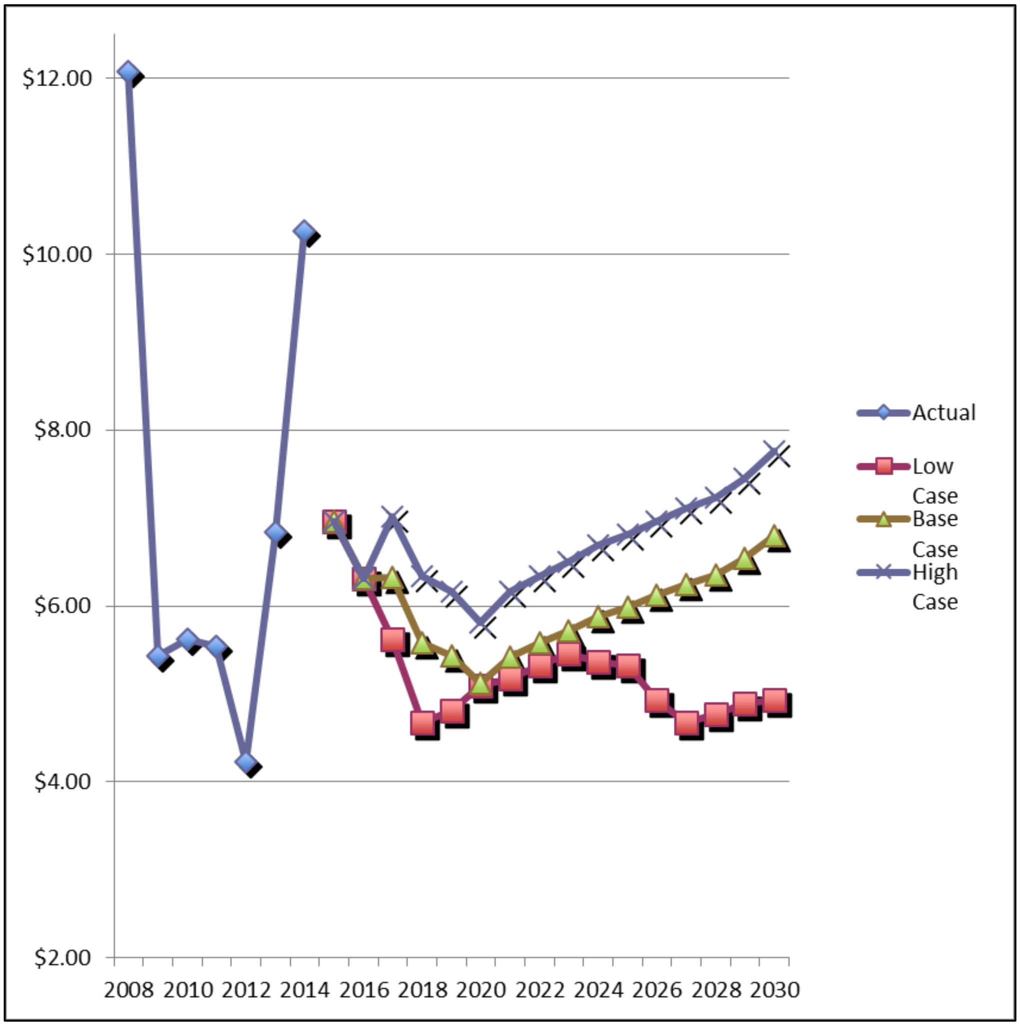
Exhibit 2-22. Comparison of Projections of Annual Henry Hub Prices (2015$/MMBtu)

		Henry Hub $2015/MMBtu		
		2015	**2025**	**2035**
NYMEX	NYMEX 12/18/2014	3.54	4.07	NA
Non-AEO Forecasts	IHSGI	NA	4.12	4.65
	EVA	NA	5.98	6.79
	ICF	NA	5.72	7.24
	BP	NA	0.00	0.00
		0.00	0.00	0.00
	Average Non-AEO Forecast	#DIV/0!	5.27	6.23
AEO	AEO 2014 Reference Case	3.93	5.50	7.27
AESC 2015	AESC 2015 Base Case	3.55	5.50	NA

2.9.2 Low and High Price Case Forecasts of Henry Hub Gas Prices

The AESC 2015 Low and High Cases reflect differing assumptions about the factors driving the national gas supply market. In the High Case, the AEO 2014 Reference Case Henry Hub gas price forecast is increased by 15%; in the Low Case, the AEO 2014 High Oil & Gas Resource (HRC) is substituted altogether for the Reference Case, and converted to monthly prices based on the same variations in NYMEX Henry Hub gas futures prices, as described above. Exhibit 2-23 compares all three AESC 2014 forecasts of avoided gas costs in New England, showing annual average prices.

Exhibit 2-23. AESC 2015 Avoided Gas Cost Forecasts - Base, High and Low Cases for Annual Wholesale Customers on Algonquin (2015$ per MMBtu)



The procedure employed to develop the AESC 2015 High Price Case forecast of monthly Henry Hub gas prices is identical to the foregoing, except we increase each of the forecast Henry Hub prices in the AEO 2014 Reference Case forecast by 15%. This level of increase is based on our judgment. It is less than the average 20% increase under the AEO 2014 Low Oil & Gas Resource Case because we believe the AEO

2014 Reference Case already is, if anything, on the high side. Thus, choosing a 15% increase for the AESC 2015 High Case is, in our judgment, a very high price case.

2.10 Wholesale Gas Costs in New England

AESC 2015 includes a forecast of the avoided wholesale cost of gas in New England based on an analysis of the market fundamentals expected to drive that cost over the study period. In addition to the projected cost of gas at Henry Hub, therefore, those fundamentals include the projected demand for gas in New England for electric generation and for retail end-uses, the projected quantity of imports of gas from Atlantic Canada and of LNG, production in the Marcellus/Utica shale regions, and the projected level of pipeline capacity that will be available to deliver gas from the Marcellus/Utica shales into New England throughout the planning horizon. (The projected demand for gas in New England for electric generation will be driven by numerous factors, including the long run projected price of fuel oil relative to the price of natural gas, and the level of financial penalties ISO-NE may impose on generating units which fail to meet their capacity performance obligations.)

Regional gas pricing in New England, and elsewhere east of the Mississippi is adapting to reflect the increasing role of Marcellus/Utica shale gas production, as described earlier in this chapter. In this section, we review the way wholesale natural gas market mechanisms operate in the U.S. as they affect New England, and then review basic assumptions about how they will function and what factors will drive gas prices going forward through the planning horizon of this report.

In essence, the way the gas market works is that competing suppliers and buyers in New England and elsewhere negotiate and establish gas prices for each day, or for the month ahead, at hubs in spot markets. They take into consideration information about hub prices, geography, service differentiation, weather, pipeline capacity availability, expected electricity and other gas demands, and other factors. As production and demand changes take place, the nexus of gas demand and supply can vary greatly from point to point throughout the gas pipeline grid over days, seasons, and decades. The flexibility and depth of hub-based spot markets has been, and will continue to be a significant enabling factor in the continued development and rise of shale gas production, which is often variable on a day-to-day basis.

In the following sections, we review assumptions about commercial mechanisms, price drivers, and pipeline capacity as they affect future avoided costs of gas to power plants and LDCs.

2.11 Factors Driving Wholesale Avoided Costs in New England

Forecasting avoided gas costs in New England necessarily involves determination of future prices of gas from the marginal source of gas production, pipeline rates to New England gas receipt points and basis to New England pricing points. Our assumptions concerning these elements are discussed in this section.

2.11.1 Pipeline Rates to New England

As discussed above, shippers on Algonquin, TGP and other pipelines pay for gas transportation services according to rate schedules contained in each pipeline's tariff. Pipeline rates are generally set on a cost of service basis and approved by the FERC (by state regulatory commissions and boards in the case of LDCs) following rate proceedings involving shippers and numerous other interested parties. Some pipelines have sought to charge market-based rates to their shippers, i.e., basis, but the FERC has to date not generally approved such formulations.

Rates paid for pipeline transportation services depend on the class of shipper:

- Firm shippers pay demand charges that are fixed, effectively pipeline capacity reservation charges, plus commodity and fuel charges that are variable, i.e., vary with the volume of gas that is shipped. Under current rate design principles, fixed charges recover nearly all the pipelines' costs of service.
- Non-firm (interruptible, general, and numerous other categories) pay variable charges only, although such rates are also designed to recover costs (i.e., they are greater than the variable charges paid by firm shippers).

Firm shippers on New England's gas pipelines include LDCs, and some electric power plants and gas marketing companies.

As in prior years' AESC reports, the AESC 2015 forecast assumes power plants bid into the New England pool based on the spot market value of gas, i.e., on the local spot price. During winter months, therefore, spot prices in New England are historically quite high as demand for house heating is at its highest and available pipeline capacity must be supplemented with gas in storage in the form of liquefied natural gas (LNG), with imported LNG, and propane-air, as discussed in earlier sections of this report. During other months, when pipeline capacity is available, high-cost LNG is not needed, demand is relatively low, and prices fall to levels just above supply hub prices, i.e., Marcellus/Utica regional hub prices plus pipeline fuel charges (typically only a few percent of supply region prices).

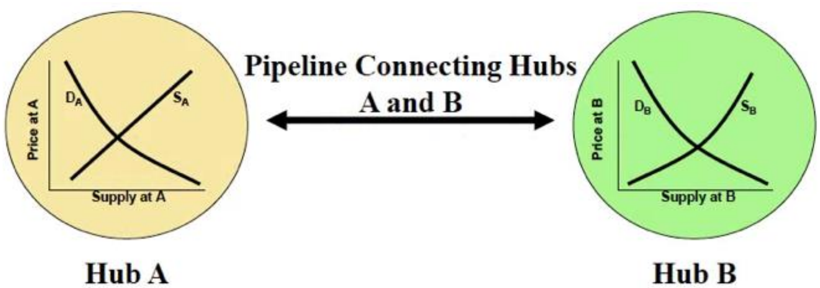
As a result of the foregoing, actual pipeline rates only partly or indirectly drive difference in market prices between gas supply regions and consuming regions. This point is key in New England, and is elaborated on below.

2.11.2 Gas Price Basis Differentials to New England

As discussed in section 3, liquid hubs are defined as those where trading volumes, numbers of participants, choices of supplies and demands, and market depth are all sufficient to establish fair commodity market prices that are set by the forces of supply and demand. Examples in the U.S. gas industry include Henry Hub, Texas Eastern M-3 (Tetco M-3), and many others including, in New England, Algonquin Citygates and Tennessee Zone 6 (Dracut). The defining characteristic of a gas hub (or pricing point) is the immediate or short-term availability of liquid markets, i.e., to the buyers, a number of alternative supplies and suppliers of natural gas, and, to the sellers, a number of alternative demands and buyers of gas. Hence, the forces of supply and demand are able to establish an immediate market clearing price at every point in time, or every day, depending on how much trading is conducted. Conditions for a successfully functioning hub include continual supply-demand imbalances, large and small, and the freedom for parties to transact at will to reconcile these imbalances. Thus, as pointed out above, there is always a buyer for gas supplies, and likewise, there is always a seller of gas – thus market clearing prices are able to establish on an economic basis (i.e., the price that balances supply and demand), even if such prices change from time to time in response to changing supply-demand balances and imbalances, even within a day's trading at major gas hubs.

Gas price basis differentials, sometimes shortened to "basis," refer to the difference between the price of gas at one liquid hub and another, each defined in the foregoing sense. As shown in Exhibit 2-24, illustrative hubs A and B are each liquid pricing points, in other words, the interaction of gas supply and demand at each hub (shown in the diagram as price-quantity curves at each hub) determine clearing prices in spot or short-term markets. This takes place independently of transportation rates on one or another pipeline, even a pipeline that may connect the two hubs.

Exhibit 2-24. Illustration of Basis Differentials in the U.S. Gas Industry



For example, in Exhibit 2-24, Hub A might be Texas Eastern Zone M-3 ("Tetco M-3") and Hub B might be Algonquin Citygates ("AGTCG"), both liquid gas hubs. The Algonquin pipeline's route of transportation connects Lambertville, NJ (within Tetco M-3) with a number of gas utilities in New England, whose receipt points are located at what are known as "city gates" for each LDC, i.e., points where Algonquin delivers gas to the LDC. Even though Algonquin's firm rate is approximately \$.23 per MMBtu to transport gas along its length from Lambertville to LDC city gates in New England, that does not force AGTCG versus Tetco M-3 basis to equal \$.23 because gas supply and demand are setting the instant price at each point. Sometimes basis is worth more than the pipeline's rate, e.g., in winter peaks, and sometimes it is worth less than the rate, e.g., in mild weather. Indeed, AGTCG-Tetco M-3 basis is rarely exactly (or even close to) Algonquin's filed rate.

It should be noted that most points of gas commerce are <u>not</u> actually located at hubs. For example, the meter of hundreds of gas-fired power plants, thousands of individual apartment complexes and large commercial establishment – these kinds of locations rarely would constitute hubs because they have no physical alternative source of gas supply. All their gas comes from one place, namely, the other side of the meter and typically, from only one vendor – thus none of the above hub-like supply-demand commercial mechanisms described above are possible.

Indeed, whole regions may fall into this category, if they are entirely dependent on the neighboring region for all or most of their gas supply. The entire six-state New England region was for many years in such a situation – all of its gas supplies crossed the New York State or Canadian border; New England was literally at the end of the line (the pipeline). Following completion of pipeline infrastructure from elsewhere – the Iroquois, M&NP, and Portland (PNGTS) pipelines, AGTCG finally became a pricing point, where supply and demand established the price of gas, and whose price became reported in trade press. At that point, New England basis became a relevant commodity – i.e., the price of gas at AGTCG minus, for example, Henry Hub. Until then, gas prices in New England were set by an outside liquid hub, e.g., Henry Hub, Transco Zone 6 New York, or AECO in Alberta, and then buyers would directly add on the pipeline's or pipelines' transportation rates, much as the price of gas supplied to a university or office building in Houston equals the nearby liquid hub price, plus the LDC's distribution rate.

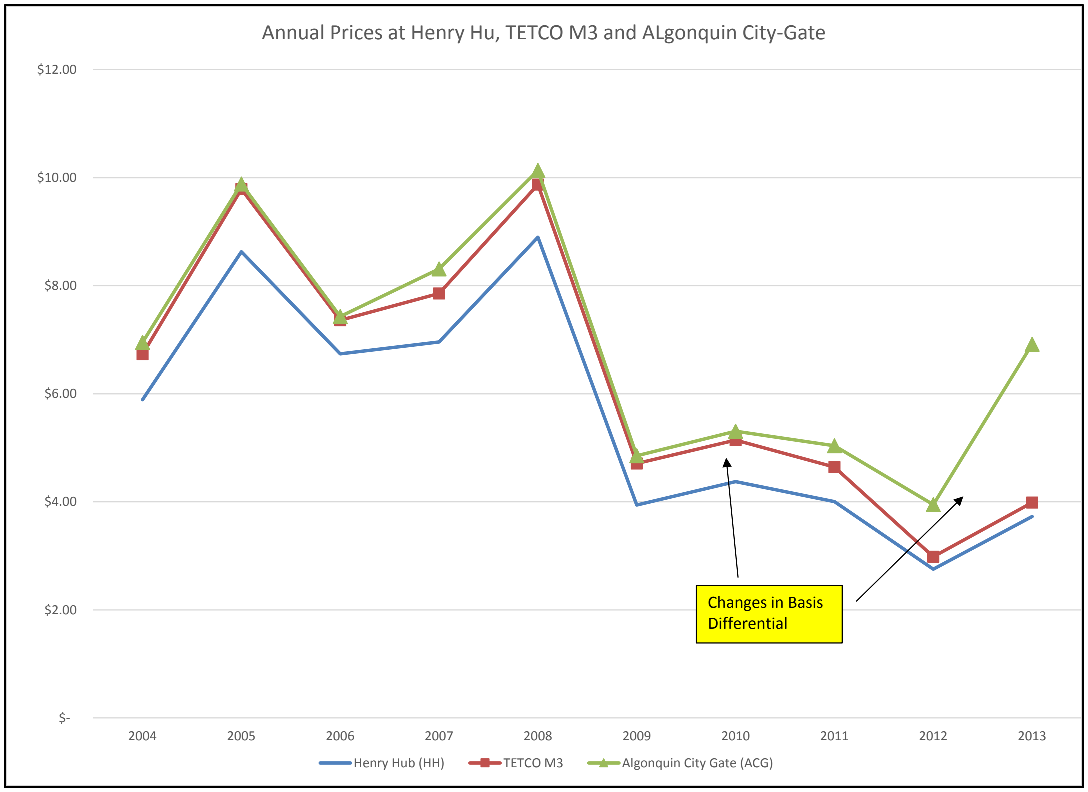
The point is that sometimes and for some buyers in New England, New England basis sets the price of gas locally, and sometimes it does not – therefore, basis is important to understand and forecast, as well as pipeline rates.

More recently, a major question in forecasting gas markets in New England is: relative to which hub, representing which producing region, should basis in New England be measured? We expect production from Marcellus/Utica will drive gas supply costs in New England, but it is not clear which Marcellus/Utica hub will be most prominent in setting gas prices in New England. There are presently several gas hubs and pricing points in the Marcellus/Utica region, including Tetco M-3, which is highly liquid, as well as Leidy (on the Transco Pipeline), Dominion South Point, and others. Only a thorough study of liquidity, outside the scope of this report, and time, will determine if another hub as prominent as Henry Hub is likely to emerge, and which one it will be.[34]

The change in basis between average annual wholesale prices in New England, the Marcellus/Utica area, and Henry Hub over the past 10 years is illustrated in **Exhibit** 2-25. Wholesale prices in New England are represented by the Algonquin city-gate in the exhibit, while the annual average price of gas from the Marcellus/Utica shale region is represented by the Tetco M-3 hub. From 2004 through 2010, basis between New England and Henry Hub and Tetco M-3 and Henry Hub were each quite stable, at approximately $0.88 and $1.08 on average respectively. Since 2011 prices those basis differentials have changed, with Tetco M-3 prices declining more than Henry Hub prices and prices in New England increasing.

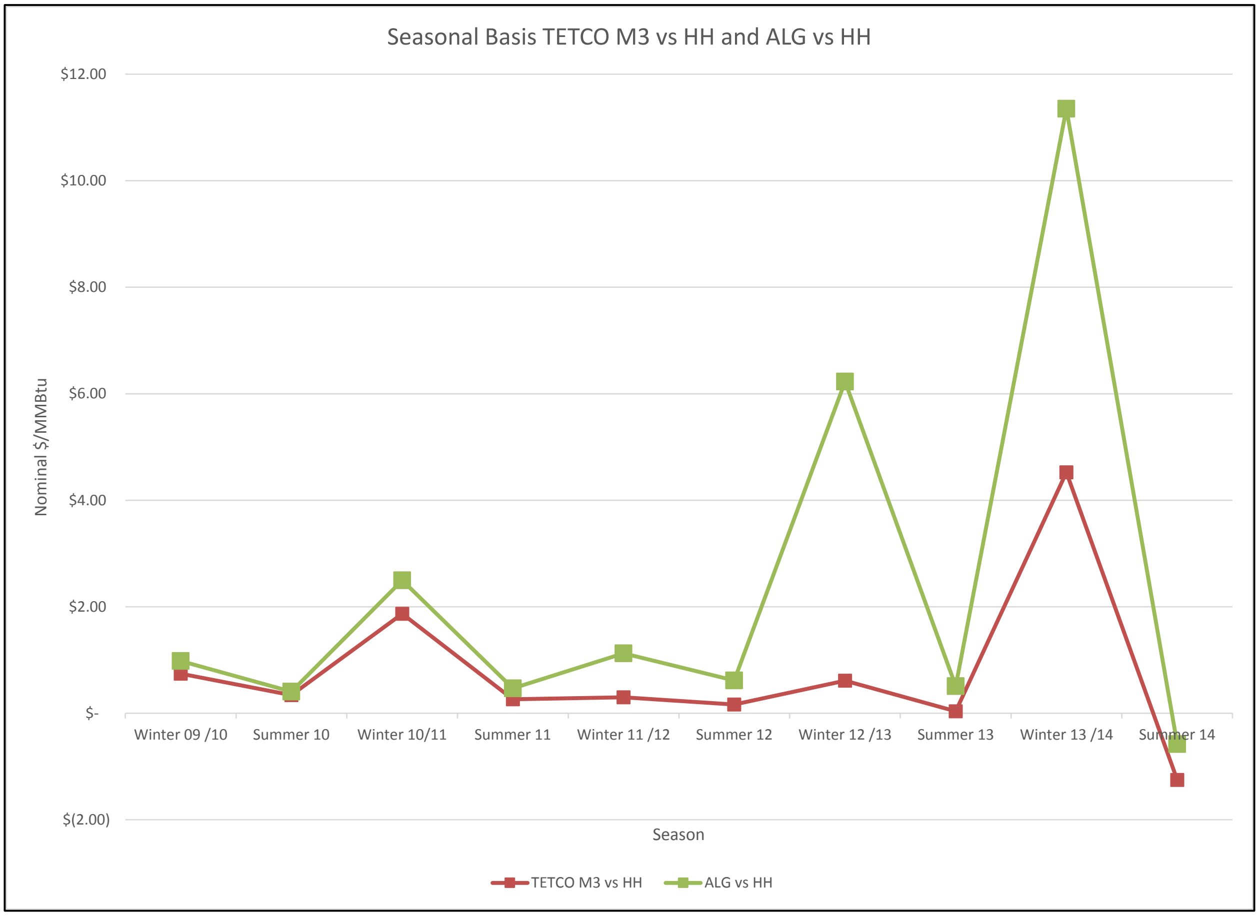
[34] Henry Hub was largely unheard of outside the local industry, and gas prices there were neither surveyed nor reported by gas trade press until 1989, just after NYMEX announced in its CFTC filing that Henry Hub was selected as the point of physical deliveries in its forthcoming gas futures contract.

Exhibit 2-25. Annual Average Prices, Henry Hub, TETCO M3 and Algonquin City Gate, 2004 – 2013 ($/MMBtu)



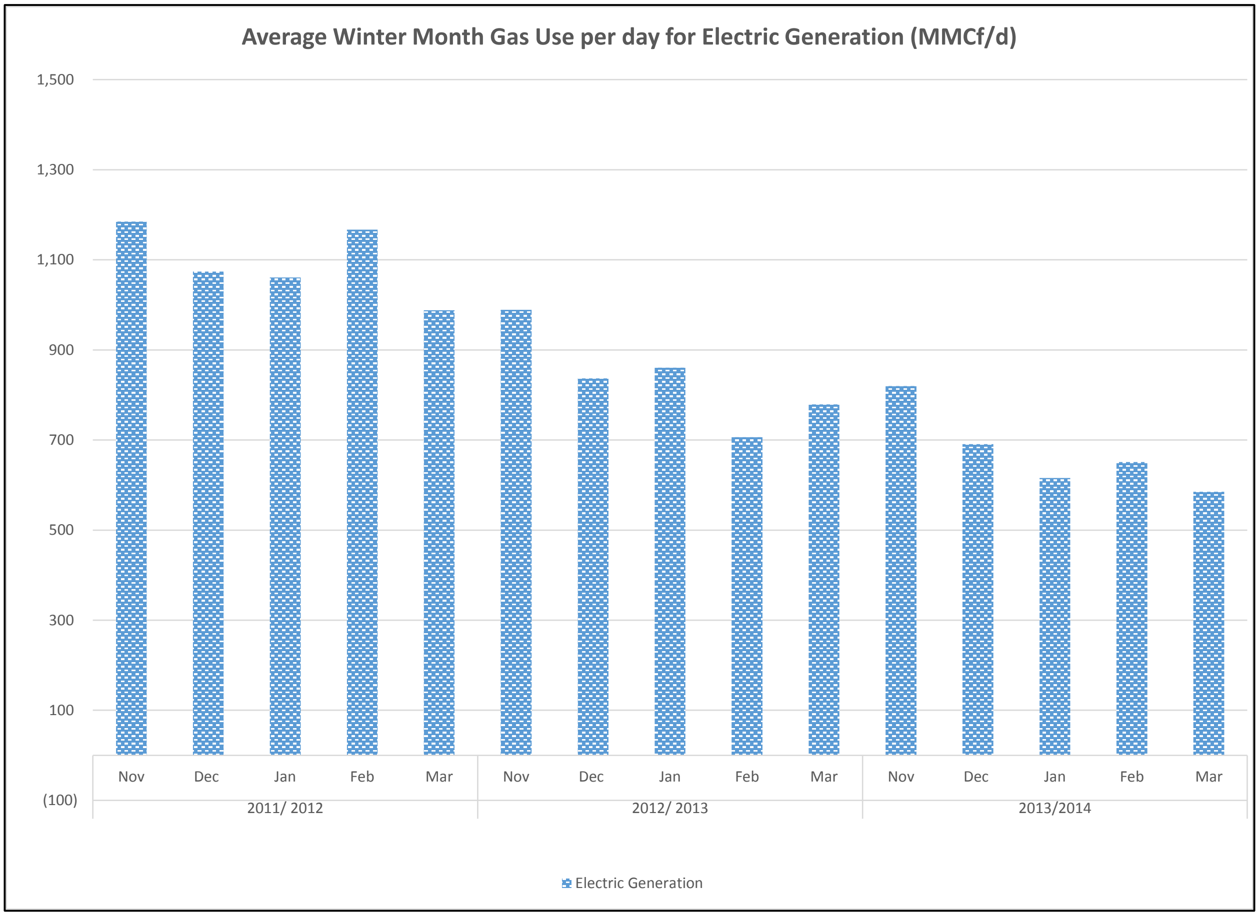
These recent changes in basis are more evident, and dramatic, when viewed by season. Those differentials, plotted in Exhibit 2-26, illustrate the "basis blowouts" which New England experienced in the winters of 2012/2013 and 2013/2014.

Exhibit 2-26. Seasonal Basis to HH



The "basis blowouts" which New England experienced in the winters of 2012/2013 and 2013/2014 do not appear to be caused by a dramatic increase in gas use for electric generation in those two winters relative to prior winters. As indicated in Exhibit 2-27, gas use for electric generation in the winter months of November through March in those two winters was less than in the winter of 2011/2012, when there was no basis blow out. Instead, as discussed earlier, the basis blowout in the past two winters appears to have been driven by the sharp decline in gas deliveries into eastern New England and the corresponding dramatic increase in the supply that had to be delivered into western New England from Marcellus/Utica and other producing areas west of New England.

Exhibit 2-27. Average Gas Use per Day for Electric Generation in Winter Months (MMcf/day)



2.12 Pipeline Capacity Delivering Gas to, and in, New England

One of the major factors driving the basis differential between wholesale gas prices at market hubs in New England and the Marcellus/Utica is the lack of adequate pipeline capacity to deliver gas from producing areas into New England in winter months. In order to develop the AESC 2015 forecast of basis in New England over the study period, we reviewed the projects proposing to add pipeline capacity between the Marcellus/Utica region and New England, as well as to add pipeline capacity within New England.

At the present time, there are five gas pipeline systems that deliver gas into New England. These are listed in Exhibit 2-28 together with their firm contracted capacities serving New England.

Exhibit 2-28. Existing Gas Pipelines in New England, November 2014

Pipeline System	Firm Contracted Capacity Serving New England (Bcf/d)	Enters New England From:	Major Upstream Gas Supplies
Pipelines primarily receiving gas in western New England			
Algonquin	1.1	New York State	Marcellus/Utica
Kinder Morgan/Tennessee (TGP)	1.3	New York State	Marcellus/Utica, U.S. Southeast
Iroquois Gas Transmission	0.2	New York State	Western Canadian Sedimentary Basin (WCSB), Marcellus/Utica
Sub-total	**2.6**		
Pipelines primarily receiving gas in eastern New England			
Maritime & Northeast Pipeline (M&NP)	0.9	New Brunswick, Canada	Sable Island, Canaport LNG import terminal
Portland Natural Gas Transmission System (PNGTS)	0.2	Quebec (P.Q.), Canada	Western Canadian Sedimentary Basin (WCSB); Marcellus/Utica
Sub-total	**1.1**		
Total	**3.7**		

Source: ICF, "Assessment of New England's Natural Gas Pipeline Capacity to Satisfy Short and Near-Term Electric Generation Needs: Phase II"," ISO New England, December 16, 2013, Exhibit 2-3, pg. 12.

The total capacity of the existing gas pipelines serving New England is approximately 3.7 Bcf/day, as seen in Exhibit 2-28. (Note that this total does not include the aggregate 2.2 Bcf/d capacity of the Distrigas LNG terminal plus gas utility peak shaving facilities.[35]). Of that total, approximately 2.6 Bcf/day of pipeline capacity is available to deliver gas received from west of New England. In contrast, maximum average gas use per day in January and February for both residential, commercial and industrial load and electric generation has been approximately 3.3 Bcf/day. Thus, if the region wanted the ability to acquire all of its maximum winter month average daily supply from west of New England, it would need another 0.5 Bcf/day of capacity delivering into western New England. (Note emphasis, because maximum gas use per day is much higher when based on gas utility "design day" requirements and electric industry peak winter day demand.) [36]

2.12.1 Proposed Gas Pipeline Expansions in New England

Numerous pipeline capacity expansions have been proposed to deliver added gas supplies to LDCs and power plants in New England. These are listed in Exhibit 2-29. The total pipeline infrastructure that would be added in New England for all of these proposed projects, if completed, would be within the range of 2.3 Bcf/day to 5.4 Bcf/day.

[35] ICF, "Assessment of New England's Natural Gas Pipeline Capacity to Satisfy Short and Near-Term Electric Generation Needs: Phase II"," ISO New England, December 16, 2013, Exhibit 2-3, pg. 12.

Exhibit 2-29. Proposed Gas Pipeline Capacity Expansions To, and Within, New England

Pipelines primarily receiving gas in western New England				
Project	**Capacity, Bcf/day**	**Planned in-service**	**Status as of December 2014**	**Shippers**
Tennessee – Connecticut Expansion	0.072	16-Nov	Precedent Agreements executed; FERC filing anticipated by EOY 2014.	Connecticut Natural Gas; Southern Connecticut Gas, Yankee Gas
Algonquin Incremental Market ("AIM")	0.342	16-Nov	FERC Filing in February 2014; Draft EIA issued on 8/8/14.	LDC affiliates of UIL, NU, National Grid, Nisource; Cities of Norwich and Middleborough, MA
PNGTS – Continent-to-Coast ("C2C")	0.165	16-Nov	Open Season closed 1/2014, since extended due to uncertainty over availability of upstream capacity.	None announced to date
Spectra – Atlantic Bridge	0.100 to 0.600	17-Nov	In negotiations	Unitil Corp.
Spectra & Northern Utilities – Access Northeast	1	18-Nov	Announced 9/14. Solicitation of interest held fall 2014	None announced to date
Kinder Morgan/Tennessee – Northeast Energy Direct	0.600 to 2.200	18-Nov	Precedent Agreements executed for 0.5 Bcf/day, others In negotiation; Pre-Filed to the FERC in July 2014.	Various New England LDCs (approx. 500 MMcf/day as of 11/2014)

Source: New England Gas Association (NEGA, November 2014).

In addition to the projects listed in Exhibit 2-29, and in some cases to support their operations, gas pipeline capacity upstream (to the west) of New England must be increased (NEGA, 2014). For example, Cabot Oil & Gas and Williams are developing the 120-mile Constitution Pipeline, to extend from Susquehanna County, PA, to the IGTS and TGP systems in Schoharie County, N.Y. The sponsors of that pipeline plan to have it in operation for the 2015-2016 winter (proposed capacity is 650 MMcf/day, and Cabot and Southwestern Energy are announced shippers). The Constitution Pipeline could help serve gas demands in New England, New York, and Central Canada. This and other proposed "upstream" pipeline projects are listed in Exhibit 2-30.

Exhibit 2-30. Proposed New Pipeline Capacity Upstream of New England

Project	Capacity, Bcf/day	Planned in-service	Status as of December 2014	Shippers
Cabot/Williams Constitution Pipeline	0.65	Late 2015	Authorized by FERC 12/2/14	Extend from Susquehanna County, PA to the Iroquois Gas and Tennessee Gas pipeline systems in Schoharie, N.Y.
Iroquois Gas - Wright Interconnect Project (WIP)	0.65	2015	Authorized by FERC 12/2/14	Enable delivery of 0.65Bcf/d from Constitution Pipeline into Iroquois and Tennessee.
Tennessee - Niagara Expansion	0.158	Nov. 2015	Filed with FERC Feb. 2014	Designed to provide transportation from Marcellus Shale to TGP's interconnect with TCPL in Niagara, N.Y.
Iroquois Gas - South-to-North Project	0.3	Nov. 2016	Open season Dec. 2013 – Jan. 2014	Reverse flow on Iroquois from Iroquois' existing interconnects with Dominion Transmission in Canajoharie, NY and Algonquin Gas Transmission in Brookfield, CT, as well as the proposed Constitution Pipeline in Wright, NY.

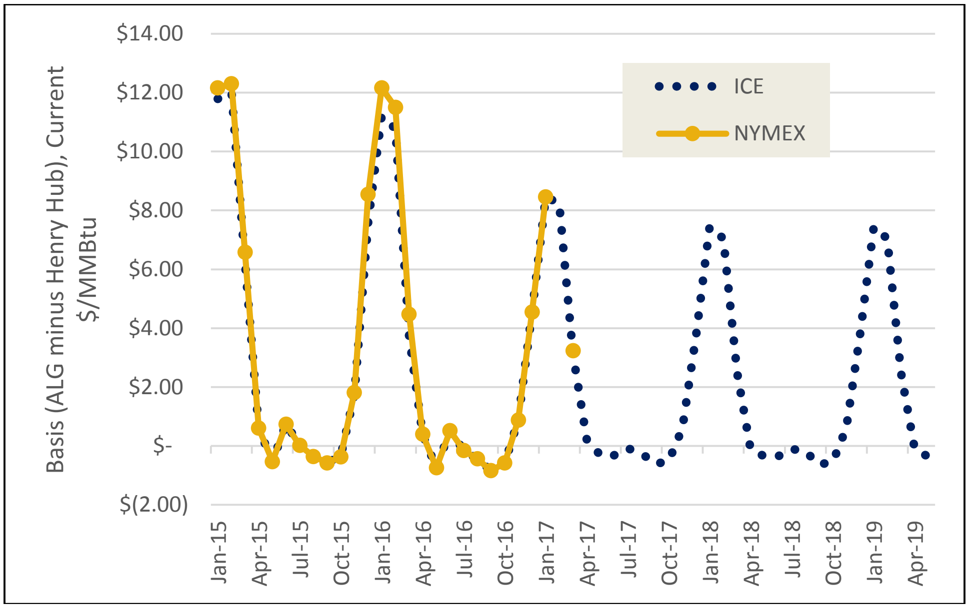
2.12.2 Projection of Basis Differentials to New England.

AESC 2015 projected the basis between Algonquin Citygates and Henry Hub ("ALG HH basis") using different methods for three different segments of the study period. Those three segments are January 2015 through October 2017, November 2017 through October 2019, and November 2019 onward.

January 2015 through October 2017

AESC 2015 projected ALG-HH basis through October 17 based on an average of NYMEX and ICE basis futures as of December 15, 2014 presented in Exhibit 2-31. Small differences between settlement prices for ALG-HH basis on each exchange indicate some liquidity exists in these contracts. The marked rise in ALG-HH basis futures during winter months is consistent with past behavior, but not necessarily a valid forecast. AESC 2015 relied on these futures for the near-term months when trading volumes are the highest. Basis futures, like any futures, represent the market for a commodity (ALG-HH basis in this case), i.e., the nexus of traders' views on this value. The decrease in winter basis spikes (less intensive "blow-outs" starting Winter 2016-2017) suggests that the market is anticipating some degree of future gas pipeline construction into the New England region. For hub pricing purposes, deliveries to PNGTS and Vermont Gas are equated to TGP based on current market directions.

Exhibit 2-31. Algonquin Citygates Basis Futures, ICE and NYMEX, $/MMBtu Relative to Henry Hub



November 2017 through October 2019

AESC 2015 basis projections for the period November 2017 through October 2019 assume that additional pipeline capacity will be added to serve the New England market in November 2017 and November 2018 respectively:[37] The assumed capacity additions are the Tennessee-Connecticut Expansion, the Algonquin Incremental Market (AIM) expansion, and the portion of the Kinder Morgan/Tennessee Northeast Energy Direct expansion to which LDCs have agreed to subscribe and are likely to subscribe, in our judgment. Thus, AESC 2015 anticipates that proposed pipeline expansions for which shippers have entered into binding precedent agreements will be built, plus about 10 percent. In all, as indicated in Exhibit 2-32, AESC 2015 assumes that approximately 1 Bcf/day of new pipeline capacity will enter service in New England during this period.

[37] *Source: Exhibit 4-6 in Task 2A Gas Assumptions, 12-15-2014 v2).*

Exhibit 2-32. Anticipated Gas Pipeline Capacity Expansions to New England

Project	Capacity, MMcf/day	Rationale
Tennessee-Connecticut Expansion	72	Subscribed.
Algonquin Incremental Market (AIM)	342	Subscribed.
Kinder Morgan/Tennessee – Northeast Energy Direct	600	500,000 MMBtu per day of the offered capacity range has been subscribed; an additional volume of at least 100,000 MMBtu per day of subscription is anticipated.
Other capacity		As economical (see below)
Total	Approx. 1,000	Approx. total subscribed.

AESC 2015 projects that the addition of approximately 1 Bcf/day of pipeline capacity will reduce New England basis in peak months significantly, indeed, to 30% below the ALG-HH basis levels anticipated by traders as reflected in futures prices for this period, as of December 14, 2014 (which were shown in Exhibit 2-31).

After November 2017, when we assume the AIM and Tennessee Connecticut Expansion together add 0.4 Bcf/day, AESC 2015 projects a 46% drop in peak month basis relative to the 2016/2017 winter. After November 2018, when we assume the Northeast Energy Direct project or its equivalent adds another 0.6 Bcf/day in November 2018, AESC 2015 projects peak winter month basis to drop by another 44%. These capacity additions are not expected to have nearly as great an impact on basis in off-peak months. In all, AESC 2015 assumes the capacity additions, shown in Exhibit 2-32, will restore New England winter basis to levels more consistent with earlier, pre-blow-out winters.

AESC 2015 projects Tennessee Zone 6 HH basis to be slightly lower than ALG HH basis and Iroquois HH basis to be lower than Tennessee's. These projections are supported by basis data[38] and by the fact that the Tennessee and Iroquois pipelines each receive Marcellus/Utica gas along a more direct and less costly route than the Texas Eastern-Algonquin combination. In addition, Iroquois predominantly serves the more competitive New York Metropolitan area, thus will not sustain the higher basis levels characteristic of Algonquin.

AESC 2015 assumes that gas utilities will use most, if not all, of the additional pipeline capacity available to them to meet load growth on their systems, thereby not increasing the ability of gas fired generators

[38] Platts IFGMR monthly Market Center Spot Gas Prices.

to acquire gas from Marcellus/Utica during winter months. In particular, we reasonably anticipate that, once gas utilities in MA, CT and ME acquire additional capacity they will “build out” their systems in order to grow their load by adding more customers because they have indicated their intent to do so by entering into binding Precedent Agreements for new pipeline capacity.

AESC 2015 is projecting the addition of 1 Bcf/day of pipeline capacity will reduce basis in peak months based on its assumption gas fired generators will be able to use a portion of that additional pipeline capacity for several years. That assumption, in turn, rests upon an assumption that it will take several years before growth in retail gas use will require New England gas utilities to use one hundred percent of their entitlements to this additional capacity. The latter assumption rests on the following high-level comparison of projected average peak winter month demand in New England, excluding VT,[39] and projected capacity able to deliver gas from Marcellus/Utica during winter months. We prepared that comparison based on the following:

An estimate the capacity available to deliver gas from Marcellus into New England each year from 2011 through 2023. This estimate assumes that by 2015 Marcellus Gas will be able to flow into the PNGTS system from TCPL. (See for example, December 2014 report by Navigant for Ontario that discusses increasing supply of Marcellus gas flowing into Ontario and then eastward on the TCPL system). We focus on capacity available to deliver gas from Marcellus into New England because of the dramatic decline in supply from LNG imports to New England and from production from eastern Canada delivered via MN&P.

Compare that estimate to projected load under two different Growth Cases, the AEO 2014 Reference Case forecast for New England and a higher growth case based on public projections from CT[40] and ME respectively.

Calculate average gas use/day by gas utilities and by electric generators in the peak winter months of December, January and February for the winter of 2011/2012. We use 2011/2012 data because those months had close to normal Heating Degree Days per data for the NGRID system.

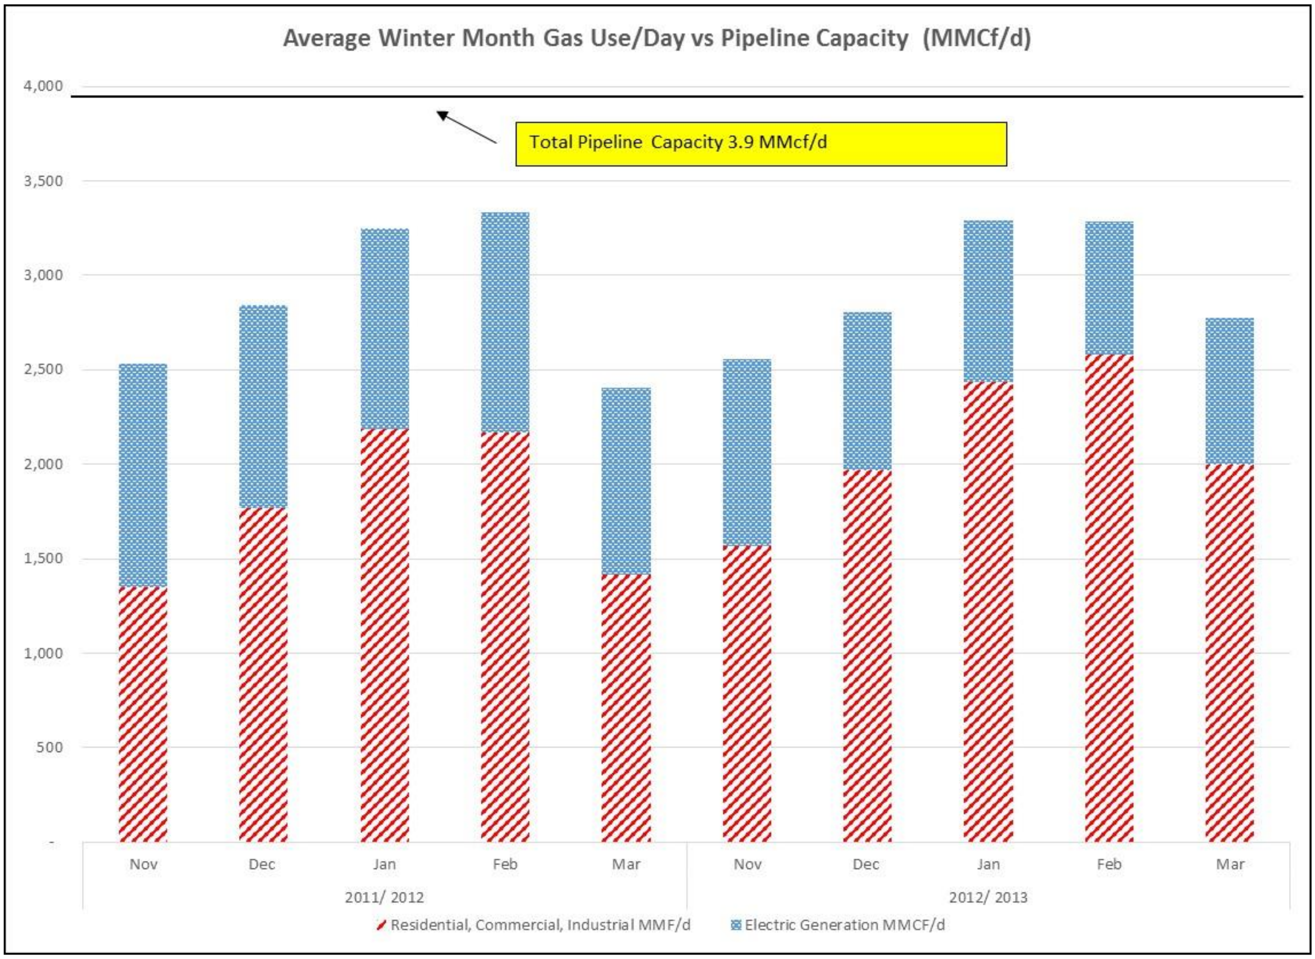
a. Project average gas use/day by gas utilities and by electric generators in the peak winter months for each of the two load growth cases. The projection assumes average gas use/day in those 3 months growths at the same rate as annual gas use.
b. Compare the average gas use /day to the estimate of capacity available to deliver gas from Marcellus into New England each year.

[39] VT is excluded because it is not connected to the rest of the New England pipeline grid. It acquires all of its supply via TCPL.

[40] Connecticut’s Gas Local Distribution Companies Joint Natural Gas Infrastructure Expansion Plan, June 14, 2013. http://www.dpuc.state.ct.us/DEEPEnergy.nsf/c6c6d525f7cdd1168525797d0047c5bf/4539e0715c01bd9a85257b8d005af2a/$FILE/Gas%20Expansion%20Plan%20vFINAL.pdf

As discussed earlier, and indicated in Exhibit 2-33, the spikes in basis in the winter of 2012/2013 was not due to insufficient total pipeline capacity serving New England. Instead, it was due to insufficient pipeline capacity able to deliver gas from west of New England.

Exhibit 2-33. Average Winter Month Gas use per Day vs. Pipeline Capacity



Our comparisons, presented in Exhibit 2-34 and Exhibit 2-35 indicate that under either load growth projection it does not appear that gas utilities will use 100% of the additional new pipeline capacity capable of delivering gas from west of New England on average during the three peak winter months for many years. Instead, it appears that a significant portion of the additional new capacity will be available to deliver gas for electric generation.

Exhibit 2-34. AEO 2014 Reference Case Load Forecast

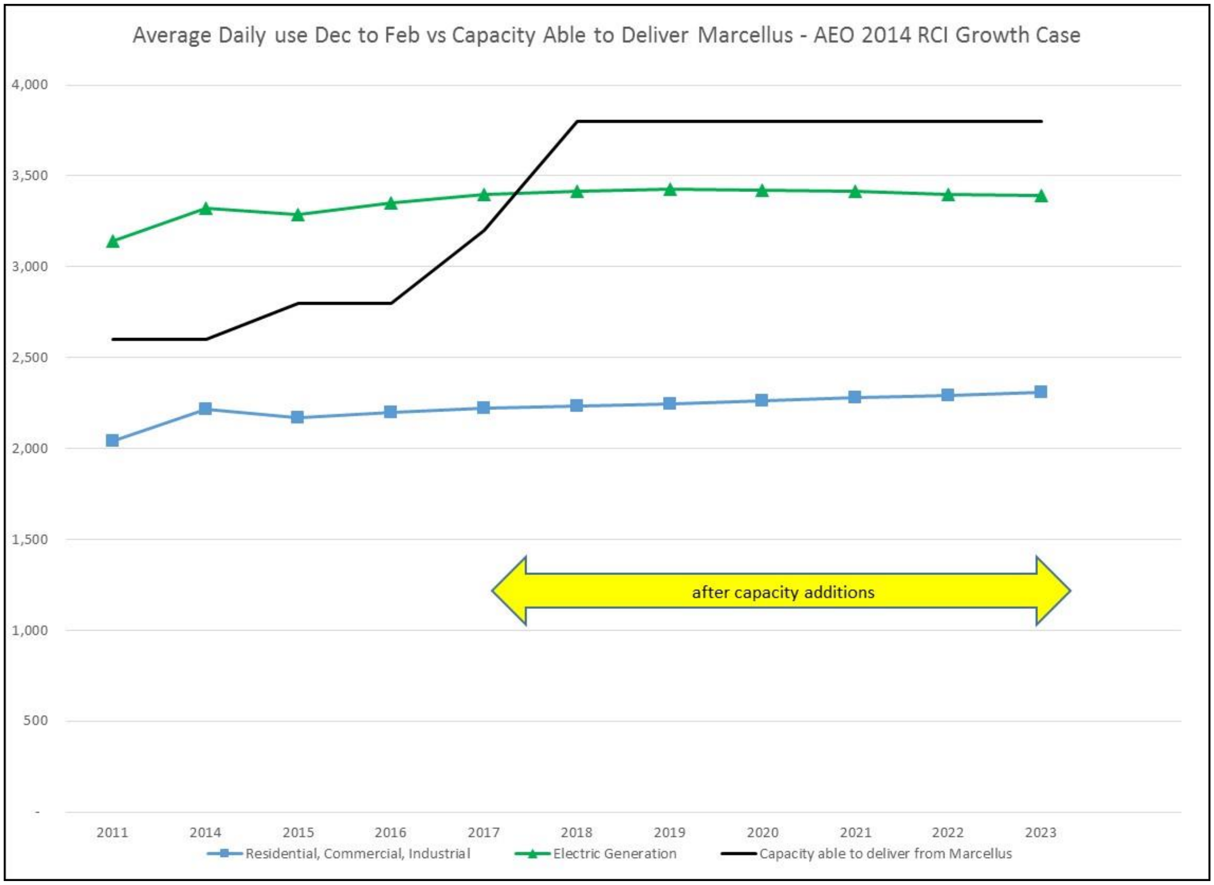


Exhibit 2-35. High Gas Utility Load Forecast

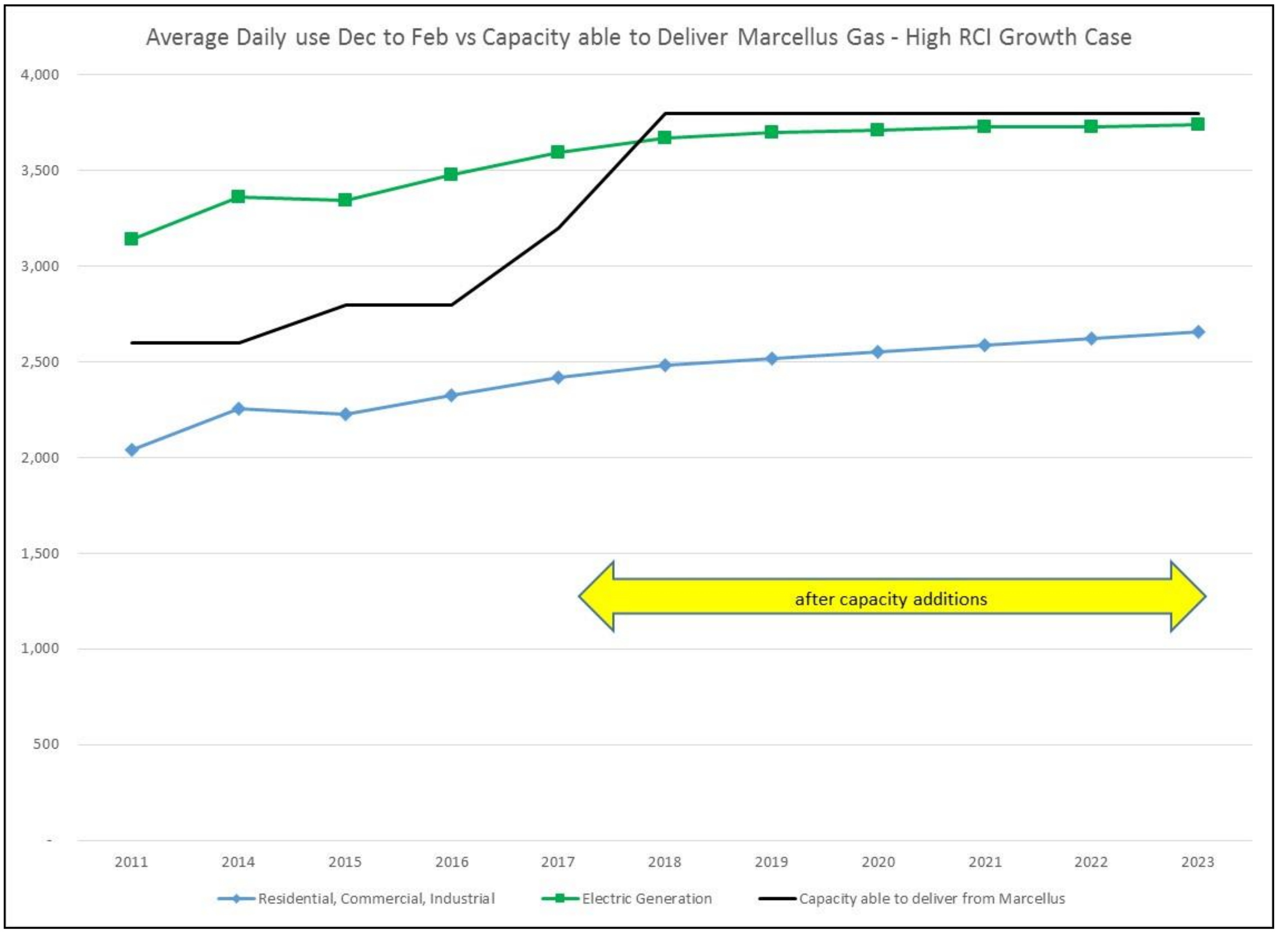

Instead, even with high gas utility load growth, it appears the addition of 1 Bcf/day of capacity by November 2018 would significantly increase the quantity of pipeline capacity available to deliver gas for electric generation on average during the three peak winter months.

It is reasonable to assume that up to 1 Bcf/day of capacity will be added within that timeframe based upon the number of projects competing to add pipeline capacity into New England, as listed in Exhibit 2-29, and the visibly high peak-period gas prices experienced in New England. This assumption is consistent with the discussion of New England market conditions for capacity and supply presented in the CT gas utilities' infrastructure expansion plan, pages 88 to 91.[41]

November 2019 onward

From 2020-2031, ALG, Tennessee and Iroquois HH basis remain at lower levels as above, inflated in nominal dollars in the Base Case to reflect the 0.4% annual average demand increase inherent in the

[41] ibid.

AEO 2014 Reference Case. In other words, real ALG-HH basis and Tennessee Henry Hub basis are both expected to decline in the 2020s because low gas demand, increasing efficiency of peak gas consumption, and increasingly mild weather will all act to prevent – on average – basis blow-outs.

2.13 Avoided Natural Gas Costs by End Use

2.13.1 Introduction and Summary

The avoided cost of gas at a retail customer's meter has two components: (1) the avoided cost of gas delivered to the local distribution company (LDC) and (2) the avoided cost of delivering gas on the LDC system (the "retail margin"). Natural gas avoided costs are presented with and without the retail margin.

AESC 2015 developed avoided natural gas cost estimates for three regions: Southern New England (Connecticut, Rhode Island, and Massachusetts), Northern New England (New Hampshire and Maine), and Vermont. Exhibit 2-36 provides the fifteen year levelized estimates assuming no avoided distribution margin, with comparisons to the corresponding values from AESC 2013. VT requested that AESC 2015 calculate its avoided costs for a different set of costing periods.

Exhibit 2-36. Comparison of Avoided Gas Costs by End-Use Assuming No Avoidable Retail Margin, AESC 2015 vs. AESC 2013 (15-year levelized, 2015$/MMBtu except where indicated as 2013$/MMBtu)

	RESIDENTIAL				COMMERCIAL & INDUSTRIAL			ALL
	Non Heating	Hot Water	Heating	All	Non Heating	Heating	All	RETAIL END USES
Southern New England (CT, MA, RI)								
AESC 2013 (2013$)	6.08	6.57	6.73	6.60	6.26	6.58	6.44	6.53
AESC 2013 (b)	6.29	6.80	6.97	6.83	6.48	6.81	6.66	6.76
AESC 2015	6.00	6.53	6.70	6.56	6.20	6.54	6.39	6.48
2013 to 2015 change	-5%	-4%	-4%	-4%	-4%	-4%	-4%	-4%
Northern New England (ME, NH)								
AESC 2013 (2013$)	6.03	7.53	8.02	7.62	6.58	7.54	7.12	7.39
AESC 2013 (b)	6.24	7.80	8.30	7.89	6.82	7.81	7.37	7.65
AESC 2015	6.00	7.69	8.25	7.80	6.63	7.71	7.24	7.54
2013 to 2015 change	-4%	-1%	-1%	-1%	-3%	-1%	-2%	-1%

	Design day	**Peak Days**	**Remainin g winter**	**Shoulder / summer**
Vermont				
AESC 2013 (2013$)	$ 389.03	$ 20.68	$ 8.68	$ 6.32
AESC 2013 (b)	$ 402.76	$ 21.41	$ 8.98	$ 6.54
AESC 2015	$ 523.08	$ 21.83	$ 7.51	$ 6.19
2013 to 2015 change	30%	2%	-16%	-5%

Factor to convert 2013$ to 2015$ 1.0353

Note: AESC 2013 levelized costs for 15 years 2014 - 2028 at a discount rate of 1.36%.
AESC 2015 levelized costs for 15 years 2016 - 2030 at a discount rate of 2.43%.

This set of AESC 2015 avoided natural gas cost estimates for Southern and Northern New England are generally lower than the AESC 2013 estimates, primarily due to the difference between the AESC 2015 projection of gas prices at Henry Hub and the AESC 2013 projection. The estimates for VT are also generally lower, except for the design day costs, which are higher due to a higher projection of Vermont Gas System (VGS) marginal transmission costs.

Exhibit 2-37 provides the fifteen year levelized estimates assuming some level of avoided distribution margin for Southern and Northern New England, again with comparisons to the corresponding values from AESC 2013. The exhibit does not include a comparison for VT because of its use of different costing periods and different end use load shapes.

Exhibit 2-37. Comparison of Avoided Gas Costs by End-Use Assuming Some Avoidable Retail Margin, AESC 2013 vs. AESC 2011 (15-year levelized, 2013$/MMBtu except where indicated as 2011$/MMBtu)

Note: AESC 2013 levelized costs for 15 years 2014 - 2028 at a discount rate of 1.36%.
AESC 2015 levelized costs for 15 years 2016 - 2030 at a discount rate of 2.43%.

2.13.2 Retail End Use Load Shapes

The shape of the retail gas load has a major impact on the cost of natural gas supplied and thus the avoided natural gas costs. End uses of natural gas at the retail level are distinguished by two major types of end-use, heating related load which is driven by temperature and has a low annual load factor and non-heating load which tends to have a flat shape and hence a relatively high load factor. AESC 2015 bases its analyses on a representative utility with a heating load accounting for 70 percent of its total annual load and a non-heating load accounting for the remaining 30 percent. (Residential sector water heating has a load shape that is approximately 75 percent temperature related and 25 percent non-temperature related.

The level of gas use by month for each major type of end-use is shown in table and chart form below. Exhibit 2-38 shows the percentage of annual load in each month for heating and non-heating loads respectively. Exhibit 2-39 plots those loads by month. (This load data is from data provided by National Grid (MA) for AESC 2011 and is consistent with load data Study Group utilities provided for AESC 2015. It will be updated as necessary based on data utilities provide for AESC 2015.)

Exhibit 2-38. Percentage of Annual Load in Each Month for Heating and Non-Heating Loads

Load Type		APR	MAY	JUN	JUL	AUG	SEP	OCT	NOV	DEC	JAN	FEB	MAR
Non-Heating	(a)	8.33%	8.33%	8.33%	8.33%	8.33%	8.33%	8.33%	8.34%	8.34%	8.34%	8.34%	8.33%

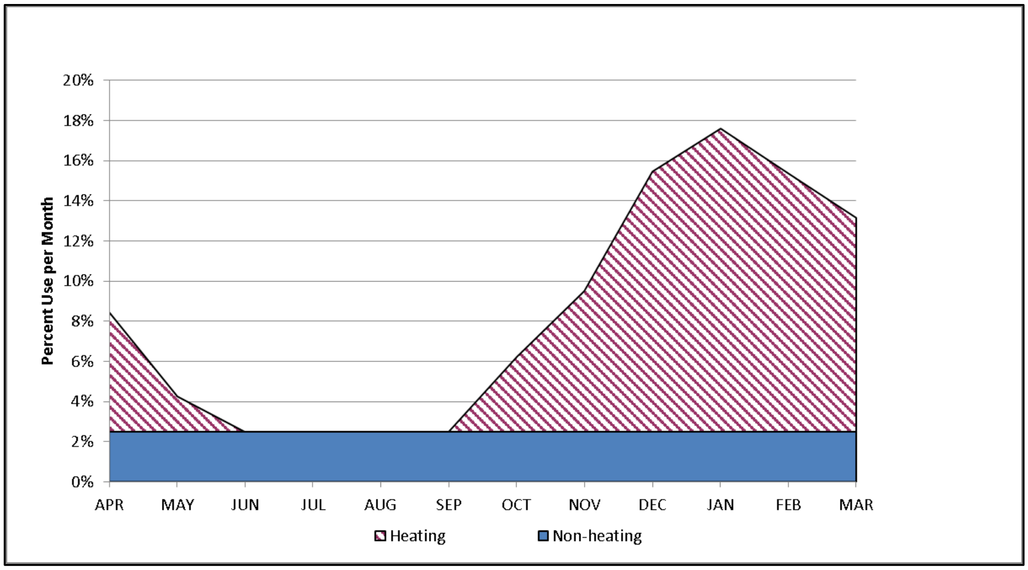
(a) Constant load all year; rounding altered in the winter months to maintain 100% use for the year.
(b) Distribution of the heating (low load factor) load among the months of the year based on data provided by National Grid (MA).
(c) Weighted average for each month at 70% heating load shape and 30% non-heating load shape.

Exhibit 2-39. Chart of Annual Load in Each month for Heating and Non-Heating Loads

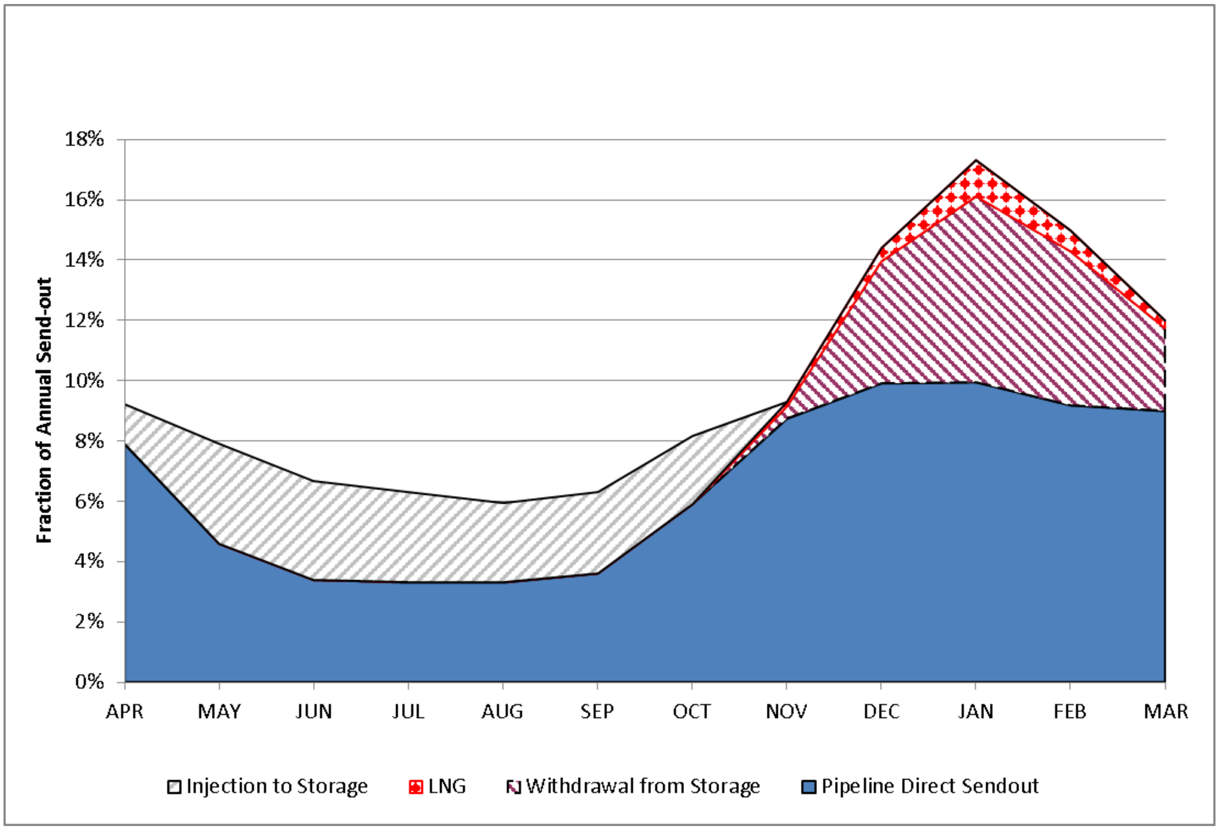


Because of the size of the gas load during the winter (defined as November through March in the gas industry) relative to the summer, and because the variation in daily load during winter months due to variation in daily temperatures, LDCs develop a portfolio of supplies in order to provide reliable service at reasonable cost over time. These portfolios comprise three major categories of delivery and storage resources: long-haul pipeline transportation, underground storage, and LNG or propane facilities. AESC 2015 calculates the avoided cost of gas delivered into the distribution system of a representative New England local distribution company from the avoided cost of each resource in each month and the relative quantity of each resource that an LDC uses in each month.

As illustrated in Exhibit 2-40, LDCs use their long-haul pipeline transportation to supply load directly in each month of the year. In addition, in summer months LDCs use a portion of that pipeline transportation capacity to deliver gas from producing areas for injection into underground storage, and sometimes for liquefaction and injection into LNG tanks. In winter months LDCs meet customer load with gas delivered by pipeline directly from producing areas and from underground storage.

LDCs use gas from LNG and propane facilities delivered directly into their distribution systems to meet daily peaking and seasonal requirements during the months of heaviest load, mostly December through February.[42]

Exhibit 2-40. Sendout from Resources by Month.



2.13.3 Avoided Costs of Representative Gas Supply Resources

New England LDCs use three basic supply resources to meet the requirements of their customers. These resources are (1) gas delivered directly from producing areas via long-haul pipelines, (2) gas withdrawn from underground storage facilities (most of which are located in Pennsylvania) and delivered by pipeline, and (3) gas stored as liquefied natural gas and/or propane in tanks located in the LDC service territories throughout New England.

Except for Vermont AESC 2015 used a representative New England LDC to determine the fraction of customer requirements met from each resource each month and the fraction of storage refill in each of

[42] The data underlying the representative LDC sendout by source is data from LDCs used in AESC 2011. It will be updated as necessary based on data utilities provide for AESC 2015.

the summer months, April through October. Vermont has only one LDC, VGS, and a somewhat different supply mix. AESC 2015 calculates the avoided costs for VGS in a separate section using the characteristics of VGS.

Our analysis assumes that LDCs have optimized the mix of supply sources and thus long-term energy efficiency. The characteristics of a representative New England LDC we use in our analysis are shown in Exhibit 2-41 below. That exhibit presents the numerical data presented earlier in Exhibit 2-40 as a graphical representation.

Exhibit 2-41. Sendout Characteristics of Representative LDC

For each gas supply resource we identify the costs of acquiring the resource and the cost of delivering that resource to the LDC.

- For long-haul pipeline deliveries the cost components are: (a) gas purchase costs, (b) the FT service demand rate, and (c) the variable transportation cost. The variable transportation cost includes the variable transportation commodity rate charged by the pipeline, and the cost of gas retained by the pipeline for compressor fuel use and "lost and unaccounted for" gas.

- For deliveries from off-system underground storage resources, which include firm transportation service from the storage to the LDC, the cost components are: (a) the cost of gas purchased for injection, (b) the fixed storage and transportation service charges, and (c) the variable storage and transportation service charges, which includes the storage and transportation fuel costs.

- For on-system peaking resources, we assume there is only a variable cost component. In the case of LNG peaking, which is the predominant type of on-system peaking for LDCs in Southern New England and Northern New England, the variable cost is the purchased gas cost and the cost of gas consumed for liquefaction and vaporization. For propane-based peaking, which is the only type of on-system peaking in Vermont, the variable cost is assumed to be the propane price.

Gas Purchase Cost and Resource Service Cost Assumptions

For this avoided-cost analysis we assume that the marginal gas purchase cost is the monthly price of gas at the Henry Hub. We draw those from our forecast of monthly Henry Hub prices.

As in AESC 2013, we assume that the marginal source of gas to New England LDCs from the Henry Hub is transportation and storage on either of the Tennessee Gas Pipeline (TGP), for LDCs in Northern and Central New England, or the route of Texas Eastern Transmission (TETCO) and Algonquin Gas Transmission (AGT), for LDCs in Southern New England. AESC 2015 developed its projected costs of marginal supply resources for Southern and Northern New England by updating the AESC 2013 projections to reflect the AESC 2015 forecast of Henry Hub prices.

AESC 2015 developed its projected costs of marginal supply resources for Vermont in consultation with staff of VGS. AESC 2015 identified, and developed the marginal costs for, four resources corresponding to the VGS supply resources and the four Vermont four costing periods. The four resources are baseload supply from Dawn via TCPL, storage withdrawals from Dawn storage via TCPL, propane peak shaving and new pipeline capacity, both upstream of and on VGS. Exhibit 2-42 shows the projected costs by year for each of those resources.

Exhibit 2-42. Projected Costs of Marginal Gas Supply Resources in Vermont (2015$/MMBtu)

VT	Delivered Cost of Marginal Resource (2015$ per MMBtu)

2.14 Avoided Distribution Cost by Sector

The avoided cost for each end-use by sector is the sum of the avoided cost of the gas sent out by the LDC and the avoidable distribution cost, called the avoidable LDC margin, applicable from the citygate to the burner tip.

Estimates of the portion or amount of distribution cost that is avoidable due to reductions in gas use from efficiency measures vary by LDC. Some LDCs have estimated this amount as their incremental or marginal cost of distribution; that is, the change in cost of distribution incurred as demand for gas increases or decreases. The conclusion was that the incremental cost of distribution depends upon the load type and the customer sector. For low load factor or heating loads, more of the embedded cost for each sector is incremental or avoidable than for high load factor or non-heating loads. The incremental or avoidable cost is measured as a percent of the embedded costs. For AESC 2015, we measure the embedded cost as the difference between the city-gate price of gas in a state and the price charged each of the different retail customer types: residential, commercial/industrial, and all retail customers.[43] The embedded distribution cost for each of the two regions, Southern New England and Northern New England, were the weighted average distribution costs among the relevant states where the weighting is the volume of gas delivered to each sector in each state.

Exhibit 2-43 shows the estimated avoidable LDC margin percentage and avoidable costs, in 2013$ per MMBtu, by each of the end-use types and customer sectors for each region in New England.

Exhibit 2-43. Estimated Avoidable LDC Margins (2013$/MMBtu)

	LDC Average Retail Margin + City-Gate Cost (a)	Avoidable LDC Margin (a)		
		Non-heating (High Load Factor)	Heating (Low Load Factor)	All
		%	%	
Avoidable Margin (percent) (b)

Average City Gate Price	6.975			
Residential	7.709	0.62	1.62	1.57
Commercial & Industrial (e)	4.082	0.61	1.14	0.98
All Retail (f)	5.805			1.28
Northern New England (d)				
Average City Gate Price	8.454			
Residential	6.590	0.53	1.38	1.34
Commercial & Industrial (e)	3.198	0.48	0.90	0.77
All Retail (f)	3.676			0.81
Vermont				
Average City Gate Price	8.010			
Residential	9.087	0.73	1.91	1.85
Commercial & Industrial (e)	3.740	0.56	1.05	0.90
All Retail (f)	4.349			0.96

(a) Average of Margins among states for 2009-2013 weighted by the delivered volumes in each state.
(b) Based on LDC marginal cost studies from National Grid (MA).
(c) Southern New England is Massachusetts, Connecticut, and Rhode Island.
(d) Northern New England is New Hampshire and Maine.
(e) An average of the margins weighted by the commercial and industrial use delivered volumes.
(f) An average of residential, commercial and industrial margins weighted by associated volumes.

[43] The citygate gas prices and the prices charged to each retail customer sector are reported by the EIA for each state each year. In AESC 2015 the cost used is the average for 2009-2013, the most recent five years for which data is available.

Some LDCs assume they will not avoid any distribution costs due to reductions in gas use from efficiency measures. The avoided cost of gas by end-use for an LDC with no avoided distribution cost is their avoided cost of gas delivered to their citygate.

2.14.1 Total Avoided Gas Costs by End Use

Exhibit 2-44 through **Exhibit** 2-48 show the total avoided costs per year per MMBtu for the retail end-uses categorized by the end-use type and customer sector for Southern New England, Northern New England, and Vermont. The levelized avoided cost is the cost for which the present value at the real rate of return of 2.43 percent has the same present value as the estimated avoided costs for the 15-year period 2016 through 2030 at the same rate of return.

Exhibit 2-44 through Exhibit 2-46 present the avoided cost by end-use for utilities at which it is assumed that no LDC retail margin is avoidable.

2.14.2 Comparison of Avoided Retail Gas Costs with AESC 2013

Exhibit 2-49 and Exhibit 2-50 show the end-use avoided costs of gas use in AESC 2015 as compared to AESC 2013 assuming no avoided margin and some avoided margin respectively. The end-use avoided costs of gas use in AESC 2015 are generally less than estimated in AESC 2013 for all three regions in New England.

2.15 Avoided Natural Gas Capacity Costs

The AESC 2015 scope of work requires a recommendation as to whether a separate natural gas capacity value should be developed and introduced into program administrator benefit-cost models. The scope of work further requests, depending on the recommendation, an estimate of peak-day $/MMBtu (capacity value). This section provides that recommendation and also provides a projection of avoided peak-day costs.

AESC 2015 does not recommend development of a separate natural gas capacity value until the program administrators demonstrate a need to evaluate gas efficiency measures that reduce peak day sendout only, rather than reducing gas commodity use plus peak day sendout. This recommendation is based upon the same reasons discussed in prior AESC studies, in particular AESC 2011 pages 4-17 through 4-19. The primary reason is pragmatic, and arises from the key differences between the gas industry and the electric industry relative to the calculation of, and application of, avoided capacity costs as summarized below.

First, the electric industry has demand response measures which reduce peak demand in a few high use hours each year and thereby primarily avoid capacity costs. In contrast, the gas industry does not appear to have measures which reduce gas use solely on a peak day. (In this regard it is important to recognize that gas utilities acquire peaking resources to meet their “design day” requirements which is a needle peak demand on 1 day with exceptional colder-than-normal temperatures that occur perhaps only once in 30 years. They acquire a different set of winter season supply resources to meet their requirements in in each month of a colder-than-normal design winter).

Second, the avoided "capacity value" of gas efficiency programs that reduce gas use with different load profiles is embedded in the avoided costs by end-use that we have developed. The avoided capacity cost of efficiency measures that reduce gas used for heating end-uses consists of avoided pipeline capacity costs, avoided storage service capacity costs and avoided peaking resource capacity costs. All of those avoided capacity costs are included in the avoided cost of heating uses that we provided, and they reflect the load factor at which utilities use each of those sources of capacity. The same applies for efficiency measures that reduce gas use for residential water heating or for non-heating purposes.

To the extent some program administrators do want an avoided cost of peak day use, we provide projections in Exhibit 2-51 for Southern New England (SNE), Northern New England (NNE) and Vermont. These estimates are based upon the same resource assumptions as in AESC 2013, i.e., avoided on system LNG liquefaction and vaporization for SNE and NNE, and propane peaking in Vermont.

Exhibit 2-51. Avoided Cost of Peak Day Use

AVOIDED PEAK DAY COSTS
(2015$/Dekatherm)

	Southern New England (1)	Northern New England (1)	Vermont (2)
2015	$ 10.69	$ 10.69	$ 521.44
2016	$ 8.31	$ 8.31	$ 521.65
2017	$ 9.49	$ 9.49	$ 522.54
2018	$ 10.16	$ 10.16	$ 522.41
2019	$ 10.41	$ 10.41	$ 522.84
2020	$ 9.99	$ 9.99	$ 522.49
2021	$ 10.60	$ 10.60	$ 522.83
2022	$ 10.75	$ 10.75	$ 522.98
2023	$ 10.90	$ 10.90	$ 523.10
2024	$ 11.38	$ 11.38	$ 523.30
2025	$ 11.54	$ 11.54	$ 523.40
2026	$ 11.79	$ 11.79	$ 523.56
2027	$ 11.94	$ 11.94	$ 523.67
2028	$ 12.07	$ 12.07	$ 523.78
2029	$ 12.26	$ 12.26	$ 523.97
2030	$ 18.73	$ 18.73	$ 542.13

Notes
1 Avoided resource is on-system LNG liquefaction / vaporization
2 Avoided resource is on-system propane peaking

2.16 Assessment of Alternative Natural Gas Costing Periods

The Study Group asked TCR to analyze the avoided natural gas cost results and assess whether alternative costing period definitions may more accurately and reasonably reflect the seasonal and hourly variation of marginal energy costs in comparison to the definitions presented in Task 3A 1 of the scope of work. This section describes our analysis of alternative costing period definitions for natural gas costs, and our recommendations based on that analysis.

The key point from our analysis is that the current natural gas costing periods for the residential, commercial and industrial ("RC&I") sectors are fundamentally different from the current definitions of electric energy costing periods.

- Electric energy costing periods are currently defined in terms of the time period during which electric energy is used. Program administrators use the avoided electric energy costs for each time period to calculate the avoided cost of reductions in various types of electric energy end-use according to the shape of those reductions by time period.
- In contrast, natural gas costing periods for the RC&I sectors are currently defined in terms of the sector in which gas is used and the end-uses for which natural gas is used within that sector. As a result, the avoided natural gas costs resulting from the current natural gas costing periods reflect both the time period during which electric energy is used and the shape of the natural gas end-use.

Our analysis focuses on the costing periods for the residential, commercial and industrial ("RC&I") sectors for two reasons. First, our analysis did not find any problems with the natural gas costing periods used for electric generation. AESC 2015 and prior AESC studies estimate the average daily cost of natural gas for electric generation by month. That costing period and approach is reasonable for a long-term projection of avoided electric generation costs. Although the price of natural gas for electric generation varies by day within each month, in the long-term the daily prices in a given month are not materially different than the average price for that month. Second, the factors driving the avoided cost of gas for electric generation during a specific time period are different from those driving the avoided cost of gas for the RC&I sectors. The price of gas for electric generation is determined by the wholesale gas market in New England. In contrast, the avoided cost of gas for the RC&I sectors is determined by the wholesale gas market at production area hubs, such as the Henry Hub, plus the regulated costs of pipeline transportation, storage services and peaking facilities.

2.16.1 Current Natural Gas Costing Periods versus Electric Energy Costing Periods

The natural gas costing periods used in AESC 2015, and in prior AESC studies, are defined in terms of the sector in which gas is used and the end-uses for which natural gas is used within that sector. Task 3A1 defines the costing periods as:

a. Electric generation:
b. Commercial and industrial non-heating
c. Commercial and industrial heating

d. Residential heating

e. Residential water heating

f. Residential non-heating

g. All commercial and industrial

h. All residential

i. All retail end uses

In contrast, electric energy costing periods are currently defined in terms of the time period during which electric energy is used. Aggregate electric energy load, and electric energy prices, vary by season (winter, summer), by day of week (i.e. weekdays versus weekends), and by hour within weekdays (i.e. on-peak 7 am to 11 pm; off-peak 11 pm to 7 am). The electric energy costing periods used in AESC 2015, and in prior AESC studies, reflect those variations in load and price by time period. The four current electric energy costing periods are:

a. Winter (October – May), on-peak (weekdays 7 am to 11 pm)

b. Winter (October – May), off-peak (weekdays 11 pm to 7 am weekdays, weekends, and holidays)

c. Summer (June - September), on-peak (weekdays 7 am to 11 pm)

d. Summer (June - September), off-peak (weekdays 11 pm to 7 am, weekends, and holidays).

Natural gas load for the RC&I sectors in aggregate, and the costs of natural gas to serve that aggregate load, also vary by winter and summer. Winter in the gas industry is November through March (151 days) and summer is April through October (214 days). The cost of natural gas to serve that aggregate load varies by day during sub-periods within the winter, rather than by hour and by weekday versus weekend in the electric industry. Two commonly used sub-periods within the winter are peak days (i.e. top 10 coldest days) and shoulder days (i.e., remaining 141 days). For example, in this study Vermont Gas Systems has requested that we calculate avoided costs for four periods per year, i.e., a design day, 9 peak days, 80 shoulder days and 275 baseload days.

AESC 2015, and prior AESC studies, have developed annual avoided costs for the RC&I sectors in three steps, as illustrated in Exhibit 2-52. Step one is to identify the marginal resource used to supply load during the relevant gas industry costing period and the avoided cost of that resource. For example, the marginal resource in the 10 peak days may be a peaking service with a marginal cost of $8.62/MMbtu... Step two is to determine the portion of each RC&I end-use load that occurs in each gas industry costing period. For example, 2.7% of non-heating load may occur in the 10 peak days. Step three is to multiply the avoided cost in each costing period by the percentage load in that costing period, and add all the resulting costs by costing period to calculate the annual avoided cost for each end-use. For example, if .02 percent of residential heating load occurs during peak days and 99.9 percent occurs during shoulder days, the avoided cost of a reduction in residential heating load would be $6.60/MMBtu as illustrated in Exhibit 2-52.

Exhibit 2-52. Illustration of Avoided Costs by Sector and End-Use

Avoided Resource and Cost by Costing Period				Portion of Residential End-Use by Costing Period			Avoided Cost by Residential End-Use		
Costing Period	Days	% of year	Avoided Cost $/MMBtu	Non-heating load	Water heating load	Heating load	Non-heating load	Water heating load	Heating load
			a	b	c	d	e = a *b	e = a *c	e = a *d
Peak	10	2.7%	$ 8.62	2.7%	0.1%	0.2%	$ 0.24	$ 0.01	$ 0.02
Shoulder	141	38.6%	$ 6.60	38.6%	75.4%	99.8%	$ 2.55	$ 4.98	$ 6.59
Baseload	214	58.6%	$ 5.01	58.6%	24.5%	0.0%	$ 2.94	$ 1.23	$ -
Total	365	100.0%		100.0%	100.0%	100.0%	$ 5.72	$ 6.21	$ 6.60

Based on a review of gas utility filings and prior AESC studies, AESC 2015 recommends that Program Administrators consider changing the costing periods for natural gas in future AESC studies to three resource based costing periods – peak days (10), shoulder days (141) and baseload days (214). These costing periods would be methodologically consistent with those used to calculate avoided electric energy costs. Program administrators can then use the avoided gas costs for each time period to calculate the avoided cost of reductions in various types of gas end-use according to the shape of those reductions by time period.

In order to apply these resource based costing periods PAs would have to be able to determine the portion of each RC&I end-use load that occurs in each costing period. PAs should be able to obtain that load shape information from the gas utility supplying their service territory. Gas utilities typically have formulae for predicting gas use per customer by month for each major rate class. For example, a formula for residential heating use per customer might be zero base use per day + 0.012 Dth per heating degree day (HDD) while the formula for residential n0n-heating use per customer might be 0.04 Dth/day plus + zero Dth per HDD. PAs would use these formulae, plus the HDD per month, to project the load shape of each major end use.

Chapter 3: Avoided Costs of Fuel Oil and Other Fuels by Sector

3.1 Introduction

This draft deliverable presents our forecasts of avoided costs for petroleum products used in electric generation as well as in the residential, commercial, and industrial sectors in New England. All of these forecasts are driven by our forecast of crude oil prices. For the electricity generation sector, we forecast avoided costs of No. 2 (distillate) and No. 6 (residual). For the residential, commercial and industrial sectors we forecast avoided costs of those two grades and of propane. In addition, for the residential sector we also forecast avoided costs of other fuels used for heating purposes, specifically a biofuel blend (B20), kerosene, cordwood, and wood pellets.

The AESC 2015 forecasts for crude oil and petroleum fuels for electric generation are presented in Exhibit 3-1. Crude Oil and Fuel Prices for Electric Generation (2015$). The AESC 2015 forecasts for fuel oil and other fuels in the residential, commercial and industrial sectors are presented in Exhibit 3-2.

Exhibit 1 7 presents the AESC 2015 fifteen year levelized avoided costs for selected fuels in the residential and commercial sectors, as well as the comparable levelized costs from AESC 2013

3.2 Forecast of Crude Oil Prices

AESC 2015, like the AESC 2013 Study, recognizes that crude oil prices constitute the dominant component of petroleum product prices. The AESC 2015 forecast of crude oil prices begins with the forecast of crude oil (West Texas Intermediate or WTI) from the EIA AEO 2014 Reference case, which was prepared in the fall of 2013. Our analyses use prices of WTI for this comparison because it is reflects domestic markets, is actively traded, and its price in the past has been very close to that of the low-sulfur light crude used in EIA's Reference Case.

We then make a downward adjustment to the projected costs of crude and petroleum products to reflect changes in the outlook since AEO 2014 was prepared. That adjustment is based on our assessment of recent trends in U.S. oil production and the significant drop in oil prices in the last six months and revised outlook as reflected in current NYMEX futures prices.[44]

[44] AESC 2015 projections using NYMEX all rely on settlement prices as of December 18, 2014.

Exhibit 3-1. Crude Oil and Fuel Prices for Electric Generation (2015$)

Year		Crude Oil Prices				Electric Generation (1)

3.2.1 Increase in U.S. Tight Oil Production

Just as U.S. natural gas production increased steeply since 2009, so too has oil and liquids production. Since 2010, as documented in AESC 2013, drillers have been moving aggressively to shift their focus toward shale plays that have been more liquids-prone than dry-gas prone, e.g., preferring plays like the Eagle Ford, Permian, Bakken and Niobrara fields. These shifts have been motivated not only by high global oil prices, but also by the ready ability to sell and export co-produced natural gas liquids (and, more recently, condensates as well). In addition, producers have been able to improve cash flows by selling off by-product natural gas in shale fields where gas can be transported and stored using a base of existing infrastructure, e.g., especially in Texas, from the prolific Eagle Ford and Permian Basin oil-prone regions.

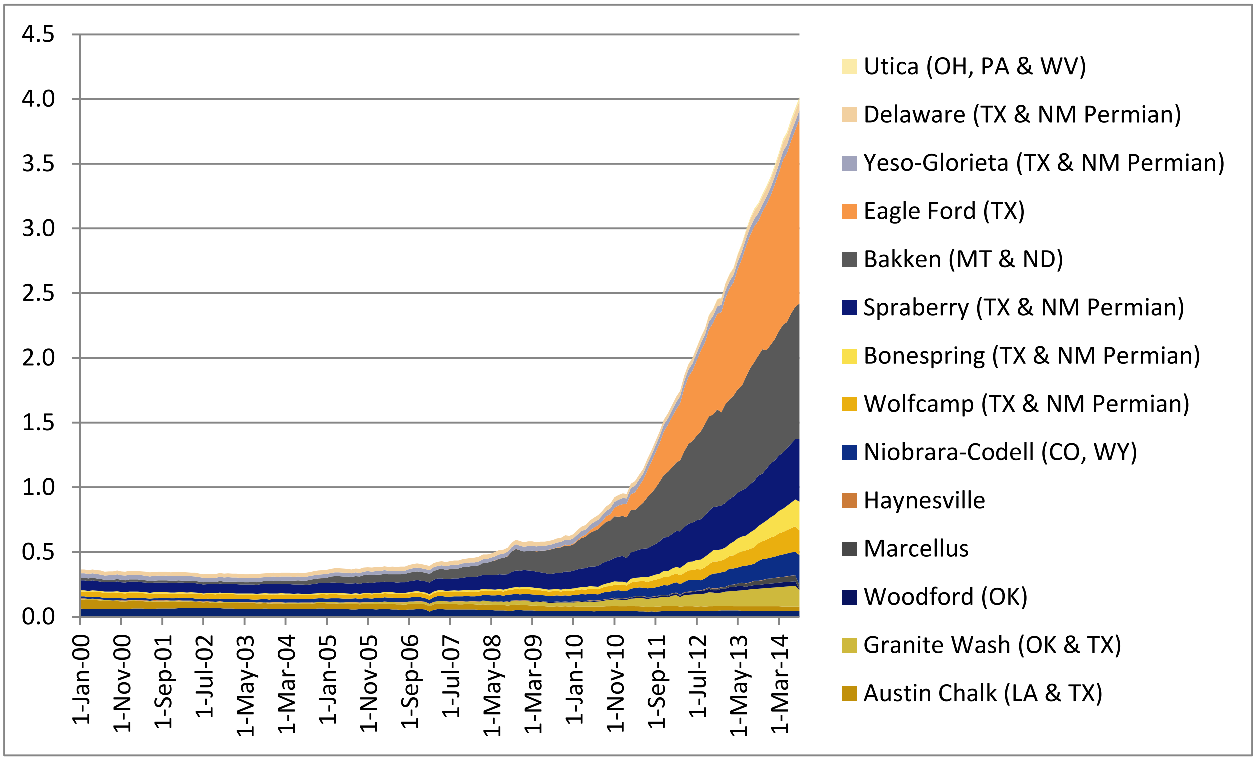
The resulting surge in production of oil and liquids is shown in

Exhibit 3-3. U.S. tight oil production[45] surpassed 4 million barrels per day (MBD) before the end of 2014, and appeared on its way to continue increasing in 2015, despite lower crude oil prices and a lower rig count.[46] U.S. tight oil production appears heading toward the 5-6 MBD range, as matters stood in December 2014.

[45] The term "tight oil" is loosely applied to a number of light crude oil and condensate liquids produced from shale wells.

[46] EIA, Today in Energy, "Despite lower crude oil prices, U.S. crude oil production expected to grow in 2015," January 2, 2015.

Exhibit 3-3. U.S. Monthly Tight Oil Production, by Field, million bbl/day



Source: EIA Administrator Adam Sieminski, in presentation before the US-Canada Energy Summit, Chicago, IL, October 17, 2014; compiled from state administrative data collected by DrillingInfo Inc. Data are through August 2014 and represent EIA's official tight oil & shale gas estimates, but are not survey data. State abbreviations indicate primary state(s).

Increased U.S .oil production since 2010 has, in turn, produced a corresponding and unexpected sharp decline in U.S. oil imports, thereby weakening global oil prices. Indeed, the decline in global crude oil prices that began in late summer 2014 has resulted in part from increased U.S. tight oil production, a linkage that has become clear since the AESC 2013 report. Moreover, global oil market participants observe the rate of U.S. oil production increases shown in

Exhibit 3-3 and, thereby, reasonably anticipate further reductions in U.S. oil importation.

At the same time U.S. oil production has been rising and oil imports have been declining, continuing economic weakness in Europe, Russia and the Asia Pacific region have contributed to relatively stagnant demand for petroleum products globally. In addition, structurally reduced oil demand in the U.S., hitherto the world's largest oil consumer, has resulted from increasingly stringent vehicle efficiency standards.[47] Thus, stagnant global oil demand and rising U.S. oil production have combined to weaken

[47] This includes tightening under both the Bush and Obama Administrations of U.S. Corporate Average Fuel Economy (CAFE) standards and corresponding penalties, as well as the DOE's Advanced Technology Vehicles Manufacturing (ATVM) loans which, again under both Administrations, have launched quantum improvements in hybrid and battery all-electric vehicle

global oil markets significantly – and both conditions are likely to persist into 2015. Eventually, cash-strapped OPEC countries will succeed in raising crude oil prices, although we do not expect OPEC will be able to restore crude prices to the levels seen from 2012 to 2014. Consequently, AESC 2015 projects levelized crude oil prices of $12.30 per MMBtu (2015$) over the next decade, as shown in Exhibit 3-1, which corresponds to a levelized price of $71.36 per barrel (2015$).

3.2.2 Impact of Lower Crude Oil prices in 2014

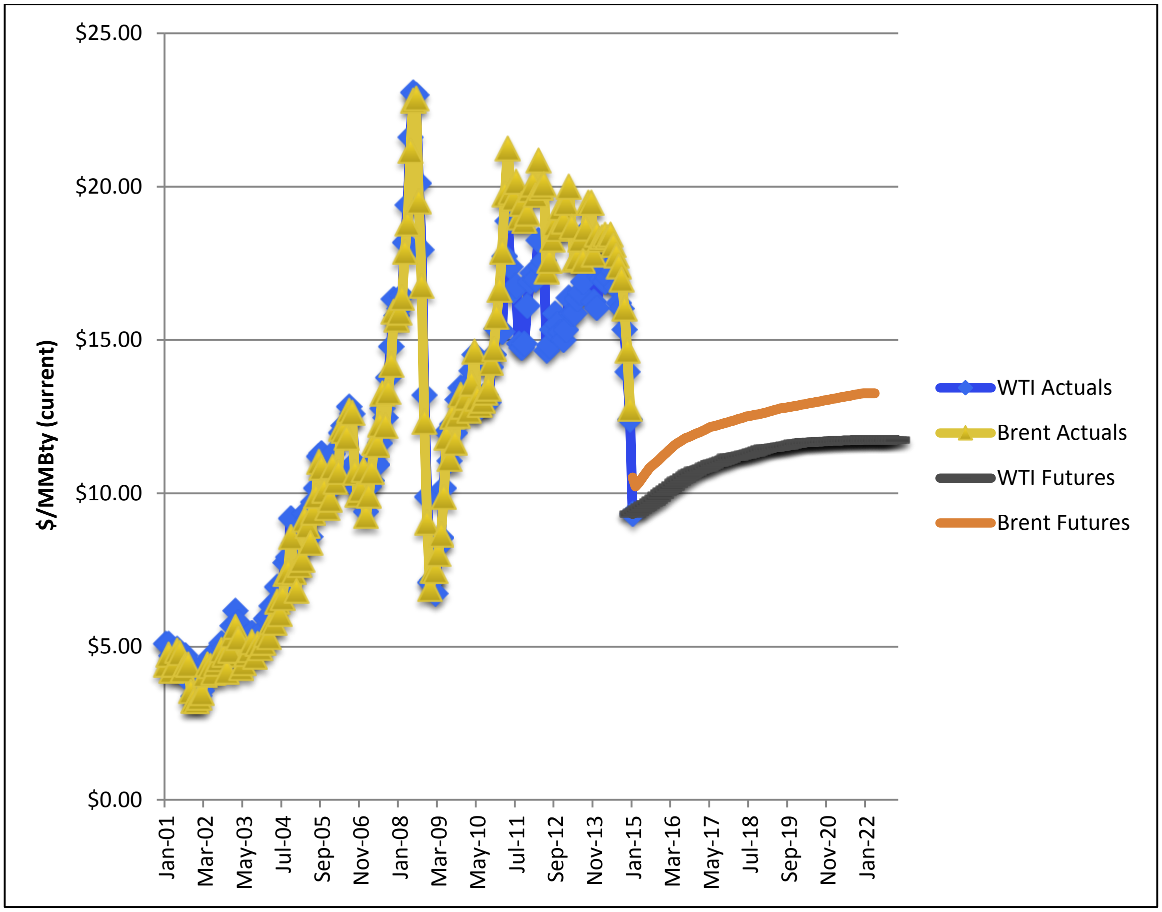
Following on the foregoing discussion of why crude oil price have fallen, analysts are currently debating a number of inter-related questions:

- Why, when, at what levels, and how many times will oil prices hit bottom?
- What will be the effects on U.S. tight oil production, and the U.S. economy?
- How will recent, less aggressive WTI crude forecasts play into future fuel oil prices for DFO and RFO, and competition with natural gas?

To appreciate the questions and think about the answers, one of the important distinctions in global crude prices is the difference between spot and futures (or forward) market prices. As demonstrated in Exhibit 3-4, global oil commodity futures markets anticipate that global and U.S. benchmark prices, respectively Brent and West Texas Intermediate (WTI), will for various reasons stabilize somewhat above current spot price levels. In general, crude markets anticipate somewhat recovered crude oil prices because of the rising need for cash on the part of some OPEC members, recovering demand, and increasing pressures to raise or at least stabilize prices.

technologies. See, for example, the EIA's discussion at http://www.eia.gov/todayinenergy/detail.cfm?id=7390 and the DOE's review at http://energy.gov/lpo/services/atvm-loan-program.

Exhibit 3-4. Monthly Prices of Natural Gas and Crude Oil – Actuals and Futures, 2001-2022



Source: CME-NYMEX, settlement prices at December 18, 2014; note figure plots past monthly spot prices for Henry Hub gas, WTI crude oil and Brent, as well as recent closing futures prices on CME-NYMEX for each of these same three commodities.

Even before global oil prices began to decline in 2014, U.S. tight oil producers were already aggressively moving to improve recovery and management technologies. Such drilling enhancements have reportedly reduced break-even points (BEP) and increasing per-barrel returns to producers.[48] No systematic, timely analyses of this effect are yet available in public literature, although early reports appear to suggest workable BEPs in the major tight oil-producing areas have variously fallen from crude oil prices of $50 per barrel to $70 per barrel, to as low as the $30 to $50 range.[49]

[48] In general, the break-even point is the point at which the discounted profit-to-investment ratio equals one, i.e., the net operating income over time of a project equals the sum of investments over time, taking into consideration the time value of money (Society of Petroleum Engineers, Petroleum Economics, see petrowiki.org/PEH%3APetroleum_Economics#cite_note-r9-8).

[49] Note October 2014 estimates of analysts at EIA, Morgan Stanley, GlobalData Ltd. cited in http://www.bloomberg.com/news/2014-10-14/u-s-shale-oil-output-growing-even-as-prices-drop-eia.html

Energy economist Phillip K. Verleger, a practicing oil market analyst for four decades, posits that, even if there is a repeat of the unbridled crude oil price collapse of 1989-1999, "…cash WTI decreases to $45 per barrel, while forward prices fall to around $72. Such declines would have important implications for North American crude production. [However] forward oil at $72 would probably provide sufficient incentive to maintain activity in the Bakken, Eagle Ford Shale, Julesburg, and Permian Basin shale."[50] Verleger wisely cautions that all such forecasts and analogies are fraught with risk.

In summary, we anticipate U.S. tight oil production will continue on a path to at least 5 MBD, and possibly as high as 8 MBD.[51] We anticipate this will force OPEC members finally to agree, perhaps in a series of meetings throughout the winter of 2014-2015, to reduced production quotas. Such agreement will, in turn, stabilize crude oil prices and avert a repeat of the 1998-1999 oil price war, or shorten (or prevent) a price war that might otherwise take place.

3.3 AESC 2015 WTI Forecast versus AEO 2014 Reference Case and December 2014 Futures Prices

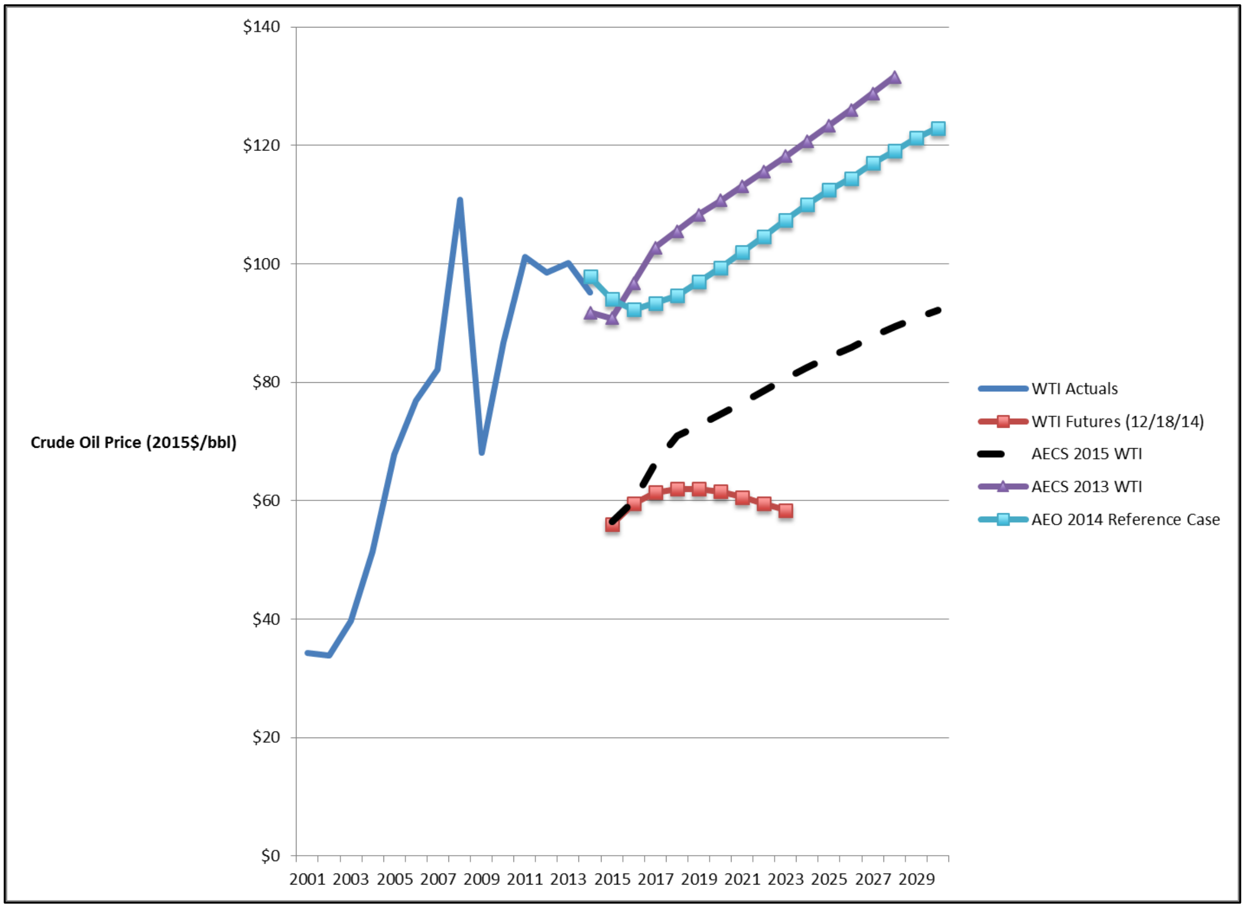
Our first step in developing a forecast of crude oil prices was to compare the EIA AEO 2014 Reference Case forecast of WTI prices with NYMEX futures prices for WTI as of December 18, 2014.

Just as in AESC 2013, this comparison revealed a significant difference between NYMEX futures for WTI in the medium to long term, and the AEO Reference Case forecast prices. That disparity is presented in **Exhibit** 3-5 which plots, in 2015 dollars per bbl, (1) actual WTI oil prices since 2001, (2) WTI futures through 2022, (3) AEO 2014 Reference Case forecasts, and (4) AESC 2013 and 2015 forecast prices through 2028 and 2030, respectively.

50 Phillip K. Verleger, "Notes at the Margin: Oil Price War 3.0," Vol XVIII, No. 42, October 13, 2014.

51 This range is consistent with the range of tight oil production increases in the AEO 2014 Reference Case and High Oil & Gas Resource Case, respectively.

Exhibit 3-5. WTI Crude Price History, Annual Average NYMEX Futures as of December 18, 2014, and AEO and AESC Forecasts (2015$ per bbl)



The exhibit shows that the AEO 2014 Reference Case projections of crude oil prices differ dramatically from NYMEX futures as of December 2014.

The AESC 2015 Base Case forecast of crude oil prices reflects an average 25% downward adjustment to the AEO 2014 Reference Case forecast to reflect changes in the oil market outlook since AEO 2014 was prepared. We make this level of adjustment in the crude oil and corresponding petroleum product price projections because we believe from our understanding of current and expected oil markets that forward oil prices throughout the AEO 2014 Reference Case are overstated by about 25% to 30%, hence an average 25% downward adjustment is conservative. AEO 2015 will not be released by EIA in time to include its oil market insights and forecast as price drivers for AESC 2015. Indeed, our understanding is that the early release of AEO 2015, previously scheduled for mid-December 2014 , has been held up for much these reasons, in particular, to afford EIA sufficient time to revise its crude oil and petroleum product price projections. We expect the AESC 2015 Base Case forecast of crude oil prices, to be generally consistent with oil market forecasts in the forthcoming AEO 2015 Reference Case.

With the foregoing in mind, the AESC 2015 forecast of WTI crude oil prices (the dashed line in **Exhibit** 3-5) begins in 2015 and 2016 with average annual NYMEX WTI crude settlement prices in each year, which, respectively equal 60% and 65% of the AEO 2014 Reference Case WTI crude oil price projections in these two years. During the long-term forecast years, 2018 through 2030, AESC 2015 crude prices equal 75% of the AEO 2014 Reference Case crude forecast, as described above. During 2017, the AESC 2015 price transitions to the long-term forecast level, equaling 72% of the AEO 2014 Reference Case WTI price forecast.

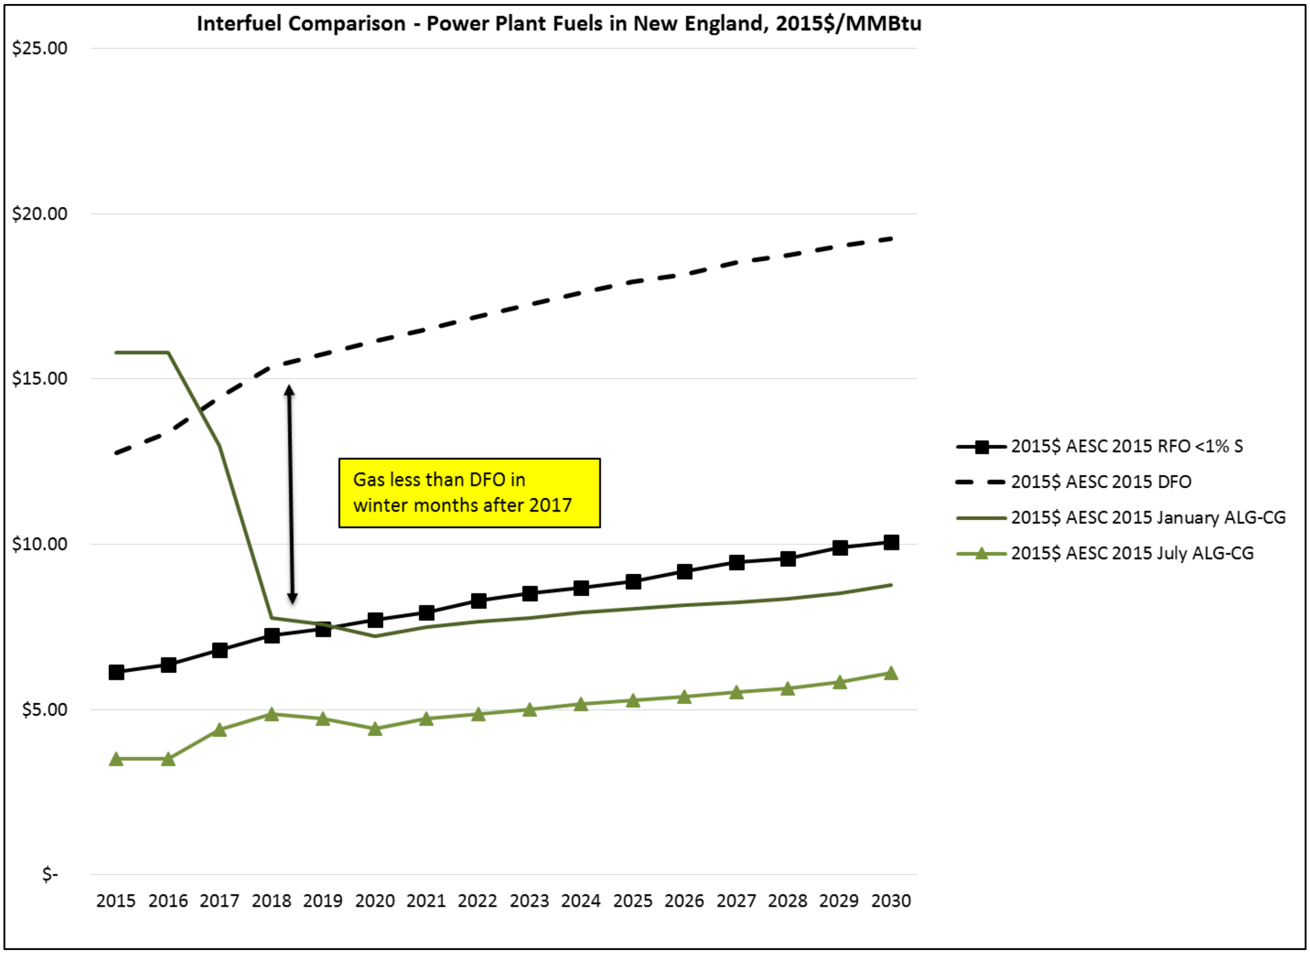
3.4 Avoided Costs of Fuel for Electric Generation

AESC 2015 provides forecasts of prices for distillate, residual, and coal for electricity generation in New England.

3.4.1 Forecast Prices of Distillate and Residual

AESC 2015 forecasts of distillate fuel oil (DFO) and residual fuel oil (RFO) for electric generation reflect the same level of discount from the corresponding AEO 2014 Reference Case projections for DFO and RFO to electricity generators in New England. As indicated in Exhibit 3-6, these projections indicate that DFO will be competitive with natural gas for electric generation in the winter months from 2015 through 2017. However, DFO is not projected to be competitive in the mid- to long-term, once additional pipeline capacity comes into service and natural gas basis to New England drops to levels seen prior to 2012.

Exhibit 3-6. Projected wholesale gas costs in New England vs. DFO and RFO



3.4.2 Forecast Prices of Coal

The AEO 2015 Reference Case assumes that coal in New England will remain unchanged in real term from the current levels. We consider this reasonable. The U.S. has substantial coal resources and coal prices have been relatively stable over a long time period without the volatility seen in oil and natural gas prices. While coal at the mine mouth is relatively cheap on an energy basis, it is expensive to transport and to burn. Coal is more expensive in New England because of the transportation costs, and represents a smaller fraction of annual electric generation in New England than most other parts of the U.S.

Coal demand is also unlikely to increase because of the age of existing coal-fired generation plants, various environmental concerns and anticipated retirements of coal-fired generation in many parts of the United States and specifically in New England. We use plant-specific actual coal prices as reported by SNL Energy for 2015. These coal prices in $/MMbtu are:

Brayton Point 1-3	$2.35
Bridgeport Harbor 3	$2.46
Merrimack 1-2	$4.04
Schiller 4&6	$3.81

3.5 Avoided Costs of Petroleum Prices in the Residential, Commercial, and Industrial Sectors

The AEO 2014 Reference Case provides forecasts of prices for distillate, residual fuel oil and propane in the residential, commercial, and industrial sectors in New England. The retail price of each fuel in each sector of a given state can be separated into two major components. The first component is the price of the underlying resource, crude oil. The second component is a margin, or the difference between the price of each fuel at the retail level and the crude oil price. The margin represents the aggregate unit costs of the refining process, distribution, and taxes attributed to the particular fuel by sector and state. As in AESC 2013, we developed our forecast of prices for fuels in each sector in two basic steps:

- First, we calculated the price margin implicit in the AEO 2013 forecast of the New England regional price for each fuel, expressed as a ratio to the crude oil price, and compared it to the historical price margin, calculated from historical price data.
- Second, we derived regional forecasts of New England prices for each fuel by multiplying our forecast of the crude oil price by the above product price ratios.

The AESC 2015 forecast of regional prices of petroleum and related products by sector is based on the following approaches:

- **No. 2 and 6 Fuel Oil:** The AEO 2015 Reference Case forecast of product prices for New England by sector were adjusted by the ratio of AESC 2015 crude oil forecast to AEO 2013 crude oil forecast.
- **No. 4 Oil:** We did not prepare a projection. No. 4 is a blend of distillate and residual and we had no data on the relative proportions of that blend.
- **B20:** The AEO 2015 forecast is based on the average ratio of B20 diesel and diesel prices in New England, as well as a review of data on bioheat available from heating oil dealer websites. We did not prepare a projection for B5 as that blend does not appear to have a material market share.

Since oil prices did not show meaningful variations by month or season, we did not develop monthly or seasonal price variations for petroleum products. Storage for petroleum products is relatively inexpensive and this also tends to smooth out variations in costs relative to market prices. For these reasons our forecast does not address volatility in the prices of these fuels.

3.5.1 Weighted Average Avoided Costs by Sector Based on Regional Prices

We developed weighted average costs of avoided petroleum-related fuels by sector by multiplying our projected regional prices for each fuel and sector by the relative quantities of each petroleum-related fuel that AEO 2015 projects will be used in that sector. The relative quantity of each petroleum-related fuel that AEO 2015 projects for each sector, expressed as percentages, will be presented in Appendix D. The resulting weighted average costs of avoided petroleum-related fuels by sector will also be presented in Appendix D.

3.5.2 Prices by State by Sector

To determine if there were material differences by state in the historical prices for any of these fuels in these sectors, we analyzed the actual prices by sector in each state from 1999 through 2012 using data from the EIA State Energy Data System (SEDS). This is the most complete and consistent source of state-level energy prices.

Given the uncertainty associated with future quantities of fuel use by state by sector, future policies on fuel taxes by state by sector, and other uncertainties, we concluded that no further precision would be obtained from an estimate of avoided petroleum-related fuel prices by sector by state.

3.6 Avoided Costs of Other Residential Fuels

AESC 2015 developed forecast avoided costs for propane, kerosene, cordwood and wood pellets.

- The avoided costs for propane are based on the AEO 2014 Reference case forecast and the AESC 2015 crude oil price forecast.
- The avoided costs for kerosene are based on AESC 2015 forecast of distillate in the residential sector and the historical average ratio between the price of kerosene and the price of distillate from EIA SEDS data.
- The avoided costs for cordwood and for wood pellets are based on AESC 2015 forecast of distillate in the residential sector, the historical average ratio between the price of cord wood and the price of distillate in the residential sector from EIA SEDS data, and the price of pellets versus of cord wood as reported by state agencies in Vermont, New Hampshire and Maine.

Exhibit 3-7 presents the AESC 2015 fifteen year levelized avoided costs for selected fuels in the residential and commercial sectors, as well as the comparable levelized costs from AESC 2013.

Exhibit 3-7. Avoided Costs of Retail Fuels (15 year Levelized, 2015$) - AESC 2015 vs. AESC 2013

Sector	Residential						Commercial	
Fuel	No. 2 Distillate	Propane	Kerosene	BioFuel	Cord Wood	Wood Pellets	No. 2 Distillate	No. 6 Residual (low sulfur)
AESC 2015 Levelized Values (2015$/MMBtu); 2016-2030	$ 19.20	$ 18.35	$ 20.94	$ 18.68	$ 6.80	$ 7.74	$18.70	$16.47
AESC 2013 Levelized Values (2015$/MMBtu); 2014-2028	$ 28.89	$ 29.16	$ 31.73	$ 30.35	$ 10.47	$ 17.45	$ 27.78	$ 16.80
AESC 2015 vs AESC 2013, % higher (lower)	-33.5%	-37.1%	-34.0%	-38.5%	-35.0%	-55.6%	-32.7%	-1.9%

Chapter 4: Embedded and Non-Embedded Environmental Costs

4.1 Introduction and Overview

This chapter discusses the values associated with mitigating the most significant airborne pollutants created by: 1) the combustion of natural gas, fuel oil, coal, and biomass for the purpose of electricity generation; and 2) the combustion of natural gas, fuel oil, wood, and kerosene for use in commercial, industrial, and residential sectors. These values, or environmental costs, have two components, referred to as "embedded" and "non-embedded" environmental costs.

Embedded environmental costs are environmental costs that are reflected in the market prices of fuels and/or of electric energy produced fuels. AESC 2015 embeds environmental costs explicitly as pollutant allowance prices which are in turn reflected in marginal electricity prices, i.e., avoided market costs. AESC 2015 also embeds environmental costs implicitly through its assumptions regarding the operating characteristics of generating units, and the characteristics of new units added to meet capacity. Those assumptions reflect the impact of environmental regulation on the investment and operating decisions by owners of generating units, e.g., to limit emissions through retrofits or to retire units.

Non -embedded environmental costs are environmental costs imposed on society by the use of these fuels, but not reflected in market prices.

This chapter discusses embedded and non-embedded environmental costs in five major sections:

- **Environmental Regulations: Embedded Costs:** This section identifies avoided costs associated with expected and existing NO_x, SO_2, and CO_2 regulations. These costs are embedded in the assumptions used by our electric market simulation model (pCA) to calculate avoided electric energy costs. Compared to the AESC 2013 assumptions, the AESC 2015 estimates for NO_x and CO_2 are lower by approximately 65% and 14% respectively. The estimate for SO_2 is essentially the same.
- **Non-Embedded Environmental Costs:** For AESC 2015, we anticipate that the non-embedded CO_2 cost will continue to be the dominant non-embedded environmental cost associated with marginal electricity generation in New England. This cost is not included in AESC 2015 avoided cost calculations for electric energy or other fuels. We provide recommendations for PAs to apply avoided non-embedded CO_2 costs in their evaluations of EE programs.
- **Value of Mitigating Significant Pollutants:** This section identifies and describes the most significant pollutants associated with electricity generation, end-use natural gas, and end-use fuel oil and other fuels. The section then provides the value associated with

mitigating those pollutants for end-use natural gas, fuel oil, and other fuels based on AESC 2015 NO_x, SO_2, and CO_2 emissions allowance prices per short ton (embedded costs), and the AESC 2015 recommended CO_2 (non-embedded) abatement cost. For end-use natural gas, fuel oil, and other fuels, the value of mitigating significant pollutants is non-embedded.

- **Discussion of Non-Embedded NO_x Costs:** This section addresses non-embedded NO_x costs, at the request of the Study Group, in order to increase awareness. Please note that we are *not* recommending that PAs use an additional non-embedded NO_x value beyond the embedded allowance prices discussed in this chapter. Instead, we recommend a methodology consistent with AESC 2013.
- **Compliance with State-Specific Climate Plans:** this section describes our review of state-specific regulations or climate plans that would directly impact the cost of electric generation over the study period.

Emissions from hydraulic fracturing are covered in Chapter 2.

4.2 Environmental Regulations: Embedded Costs

For all fuels, we estimate the embedded value associated with the mitigation of NO_x, SO_2, and CO_2 based on the allowance prices per short ton of emissions described and presented in this section. In addition, future environmental regulations will impact generator expenses, outages, and retirement decisions, which are inputs into our simulation model.

4.2.1 Cost of Complying with Existing and Expected SO_2, NO_x, and CO_2 Regulations

AESC 2015 applies the per-unit costs of complying with regulations governing the emissions of SO_2, NO_x and CO_2 in the pCA electricity market model simulations. pCA includes the unit costs associated with each of these emissions when calculating the generator offer prices used to make commitment and dispatch decisions. In this way, AESC 2015 projects market prices that reflect, or “embed,” the compliance costs for each type of emission, excluding mercury.

The per-unit compliance costs assumed for each pollutant are presented in Exhibit 4-1. NOx allowance prices have fallen considerably since AESC 2013, from approximately $28 per ton to approximately $10 per ton in AESC 2015. At $1.11 per ton, the 2015 SO_2 prices are little changed from the $0 AESC 2013 value. The 15-year levelized value of the embedded avoided cost of carbon compliance for AESC 2015 is 14 percent lower than AESC 2013 (2015$), i.e., $15.68/ton versus $20.42/ton. This decrease is primarily due to a slightly lower forecast of Regional Greenhouse Gas Initiative (RGGI) prices through 2020, reliance on year 2029 results from a regional CO_2 price forecast for 2021 onward based on a simulation of EPA’s proposed Clean Power Plan (CPP) and an assumed linear transition from the RGGI 2020 value to the 2029 CPP forecast value.

Exhibit 4-1. Emission Allowance Prices per Short Ton (Constant 2015$ and Nominal Dollars)

	NOx		SO2		CO2	
Year	2015$	Nominal	2015$	Nominal	2015$	Nominal
2015	10.00	10.00	1.11	1.11	6.28	6.28
2016	10.00	10.17	1.11	1.13	7.26	7.38
2017	10.00	10.16	1.11	1.15	7.87	8.15
2018	10.00	10.57	1.11	1.17	8.47	8.95
2019	10.00	10.78	1.11	1.19	9.32	10.05
2020	10.00	11.00	1.11	1.22	10.16	11.18
2021	10.00	11.22	1.11	1.24	12.54	14.07
2022	10.00	11.44	1.11	1.27	14.92	17.07
2023	10.00	11.67	1.11	1.29	17.30	20.18
2024	10.00	11.90	1.11	1.32	19.67	23.42
2025	10.00	12.13	1.11	1.34	22.05	26.74
2026	10.00	12.36	1.11	1.37	24.43	30.18
2027	10.00	12.59	1.11	1.39	26.80	33.74
2028	10.00	12.82	1.11	1.42	29.18	37.42
2029	10.00	13.07	1.11	1.45	31.56	41.23
2030	10.00	13.31	1.11	1.47	33.94	45.17

NO_x & SO_2 from SNL Financial. CO_2 (2015-2020) from RGGI Updated Model Rule Modeling. CO_2 (2029) from "Critical Mass: An SNL Energy Evaluation of Mass-based Compliance Under the EPA Clean Power Plan," SNL Energy. CO_2 (2021-2028): linear interpolation. CO_2 (2030): linear extrapolation.

NO_x and SO_2

The NO_x and SO_2 allowance prices are based on values provided by SNL Financial, which constitute the pCA default assumptions.[52] Since there is still considerable uncertainty about the longer term, we have kept NO_x and SO_2 prices level at constant 2015 dollar (2015$) values. For mercury, we assume no trading, and hence no allowance price.

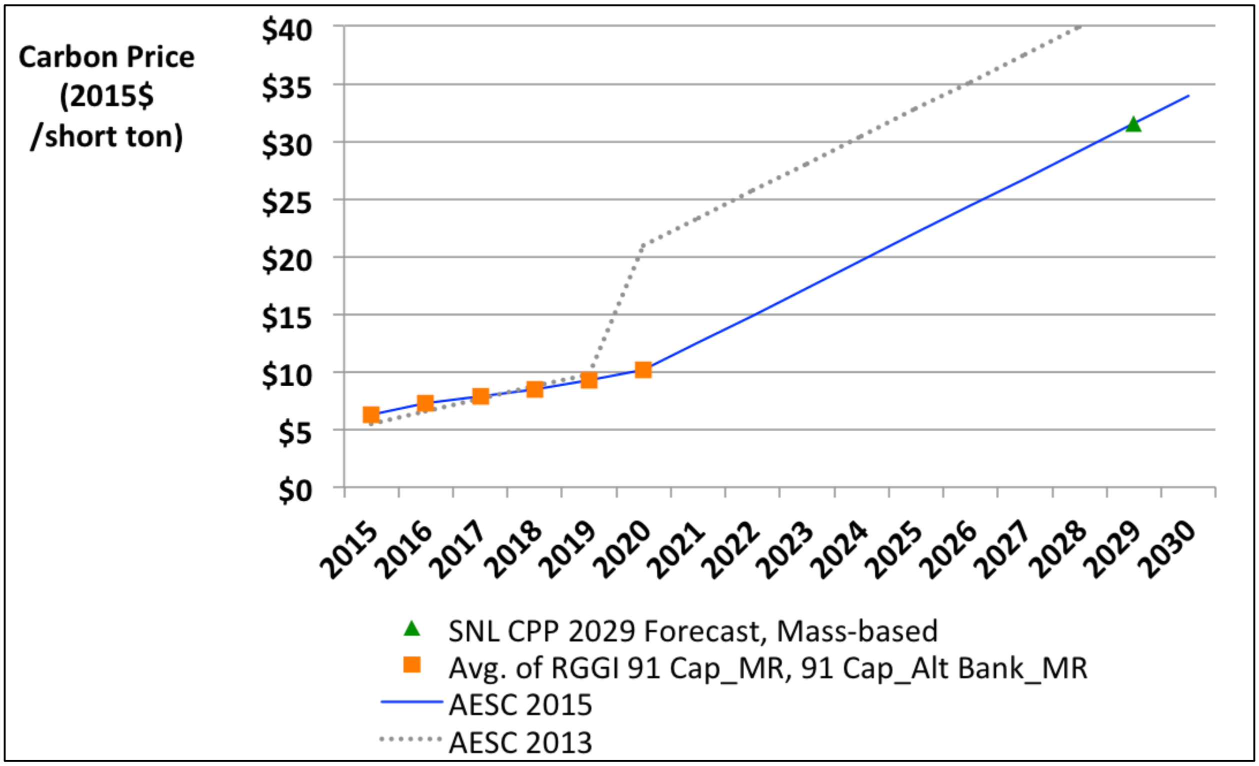
[52] The SNL values were found to be consistent with those in other sources, such as Megawatt Daily and Argus Air Daily.

CO_2

AESC 2015 assumes CO_2 regulation under the Regional Greenhouse Gas Initiative (RGGI) through 2020, and CO_2 regulation under EPA's proposed Clean Power Plan (CPP) between 2021 and 2030.

The AESC 2015 CO2 forecast is presented in Exhibit 4-2.

Exhibit 4-2 AESC 2015 Carbon Price Forecast



Our Base Case estimates of embedded CO_2 costs through 2020 are derived from RGGI allowance price forecasts through 2020. In February of 2012, the RGGI states agreed to reduce the 2014 CO_2 cap from 165 million to 91 million tons, a reduction of 45%. The cap would decline 2.5% each year from 2015 to 2020.[53] The RGGI states' analysis indicated that this would result in the allowance price rising to between approximately $4 and $6 per short ton (2010$) in 2014 and increasing to between approximately $8 and $10 per ton (2010$) in 2020, depending on the scenario. AESC 2015 uses annual prices that are the averages of those projected for the scenarios 91_Cap_Bank_MR and 91_Cap_AltBank_MR.[54]

[53] This annual reduction results in a 2020 cap value of 78.1 million short tons.

[54] RGGI IPM Analysis: Amended Model Rule, February 8, 2013, and associated IPM modeling results data. Available at: http://www.rggi.org/docs/ProgramReview/February11/. The average of the two scenarios modeled prices for 2014 (in current dollars) is very close to the RGGI December 3, 2014 auction price of $5.21.

Between 2020 and 2029, EPA has proposed that an interim standard would apply, which states or regions would be required to meet on average over the period.[55] Under the CPP as proposed, states or regions will have the option to comply with either an emissions rate-based standard, or its mass-based equivalent. Based on comments submitted by RGGI, and discussions with others following developments related to the regulations closely, we believe that compliance—at least in the RGGI states if not everywhere—is more likely to be implemented using mass-based standards, or mass-based equivalents of rate-based standards. SNL Energy has forecast allowance prices under CPP using AuroraXMP.[56] SNL modeled mass-based compliance under CPP for the RGGI region, without constraints representing the existing RGGI standards or potential extension of them. AESC uses SNL's 2029 (final CPP) value of $31 (2014$), with a linear interpolation between that and RGGI's 2020 value of $10.16 (2010$), extrapolating one year further to 2030.[57] The 2030 extrapolated value, incidentally, is approximately the same as the 2030 EPA modeled value under the rate-based standard.[58]

The sum of the CPP final (2029) goals for the RGGI states combined, in mass-equivalent terms, is 64 million short tons of CO2,[59] which is the level the RGGI cap would reach in 2028, were it to continue to decrease at the established 2014-2020 rate of 2.5% per year. Extending the 2.5% annual decrease in the RGGI cap results in a 2020-2029 average of 70 million short tons, as compared to a CPP interim standard for the RGGI states of 69 million short tons. Exhibit 4-3 shows a comparison of the RGGI cap and combined CPP goal.

[55] SNL does not present estimates for individual years during the interim period. As discussed below, it is expected that the EPA is likely to do away with or waive the interim goals.

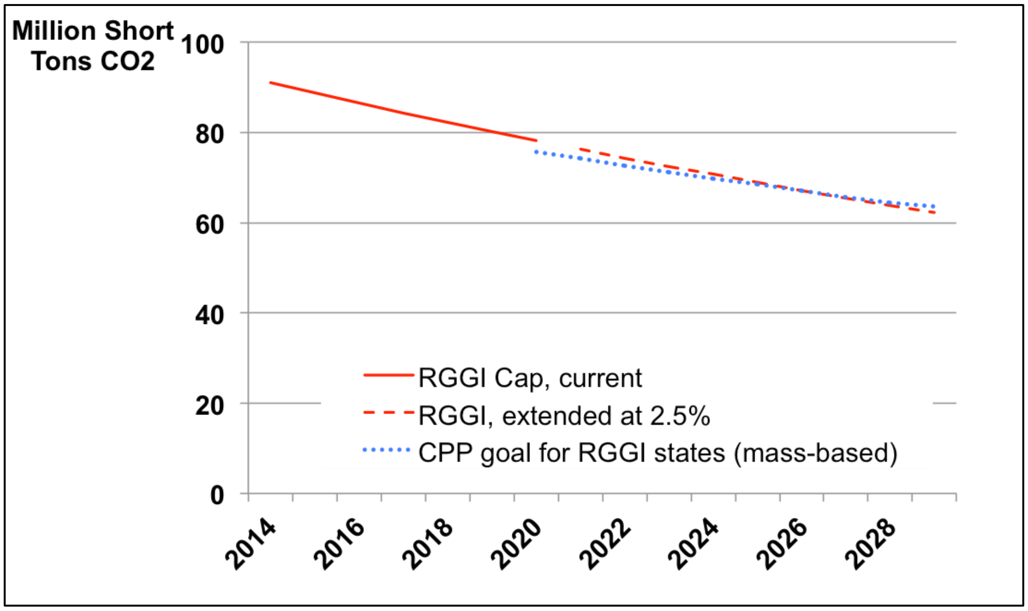
[56] "Critical Mass: An SNL Energy Evaluation of Mass-based Compliance under the EPA Clean Power Plan." A. Gelbaugh et. al, December 2014. http://www.slideshare.net/SNLFinancial/analysis-of-the-epas-clean-power-plan-on.

[57] EPA performed an analysis of example implementations of and compliance with CPP using the simulation tool IPM, developed by ICF, with five-year increments. The simulations were performed assuming compliance with the proposed state emissions rate standards, and assuming a given mix of compliance in each state using the four compliance "building blocks." Under mass-based standards, compliance costs are expected to be lower than under the equivalent rate-based standards.[57] For those reasons, and because we expect the RGGI states to elect to comply using a mass-based standard, we believe that EPA's modeled CO_2 shadow prices for a rate-based constraint are not appropriate for use as a CO_2 price trajectory in AESC.

[58] Based on EPA's IPM simulation results, CO2 shadow price for NPCC, Option 1, rate-based compliance ($34.27 in 2015$). Simulation results available at: http://www.epa.gov/airmarkets/powersectormodeling/docs/Option%201%20Regional.zip.

[59] Calculation based on data in the *Rate to Mass Translation Data File*. *See* U.S. Environmental Protection Agency website. Accessed December 2, 2014. Available at: http://www2.epa.gov/carbon-pollution-standards/clean-power-plan-proposed-rule-technical-documents#rate-to-mass. In this report, we focus on the proposed final CO_2 emissions standards to be achieved by 2030 under compliance "Option 1." The EPA also proposed alternative "Option 2" goals, which reflect emissions reductions that are less stringent but must be met earlier, with an interim goal set for 2020–2024 and a final goal for 2025.

Exhibit 4-3. Current and Extended RGGI Cap Compared to Sum of CPP Goals for RGGI States



Source: Based on RGGI data and data in the U.S. EPA Clean Power Plan Rate to Mass Translation Data File (see text).

4.2.2 Existing and Expected Regulations

This section summarizes the existing and expected environmental regulations that are incorporated into AESC 2015, and which are reflected in Exhibit 4-1, above.

CO2 - Regional Greenhouse Gas Initiative

The Regional Greenhouse Gas Initiative is a cap and trade greenhouse gas program for power plants in the northeastern United States. Current participant states include Connecticut, Delaware, Maine, Maryland, Massachusetts, New Hampshire, New York, Rhode Island, and Vermont. Pennsylvania, Québec, New Brunswick, and Ontario are official "observers" in the RGGI process. As of March 11, 2015, 27 RGGI auctions have occurred.

RGGI is designed to:

- Limit CO_2 emissions from power plants to 2009 levels for the period 2009 – 2013, followed by a 53 percent reduction below those levels by 2020.
- Allocate a minimum of 25 percent of allowances for consumer benefit and strategic energy purposes. Allowances allocated for consumer benefit will be auctioned and the proceeds of the auction used for consumer benefit and strategic energy purposes.

- Include certain offset provisions that increase flexibility to include opportunities outside the capped electricity generation sector.[60]

EPA Regulations—Greenhouse Gases

Greenhouse Gas Tailoring Rule

Under EPA's Greenhouse Gas Tailoring Rule, large sources of greenhouse gas emissions are subject to permitting requirements. For purposes of determining whether New Source Review applies, a "large source" is a new facility with emissions of at least 100,000 tons per year of carbon dioxide equivalent (CO_2e) or an existing facility that emits at least 100,000 tons per year CO_2e and is making modifications that would increase greenhouse gas emissions by at least 75,000 tons per year CO_2e. These sources are required to obtain permits under the New Source Review Prevention of Significant Deterioration program and therefore must install Best Available Control Technology (BACT) for greenhouse gases. In the case of a modification, to a facility that does not emit at least 100,000 tons per year CO_2e but will increase greenhouse gas emissions by 75,000 tons per year CO_2e, the BACT requirement only applies for GHG if the project triggers new source review for another criteria pollutant. Any new or existing source with emissions of 100,000 tons per year CO_2e or more must obtain a Title V operating permit.

On June 23, 2014, the U.S. Supreme Court confirmed the EPA's authority to regulate GHG emissions from new and modified stationary sources required to obtain pre-construction and operating permits for non-GHG air pollutants, but held that EPA may not require a source to obtain a pre-construction or operating permit solely on the basis of its potential GHG emissions. The decision upholds EPA's regulation of about 83 percent of stationary source GHG emissions under the PSD/Title V permitting process, because nearly all of these sources also emit significant amounts of criteria air pollutants.[61] In practice, this represents a modest change.

Greenhouse Gas New Source Performance Standards (GHG NSPS)

Under Section 111 of the Clean Air Act, EPA sets technology-based standards for new sources on a category-by-category basis. These standards are set based on the best demonstrated available technology (BDAT) and apply to all new sources built or modified following promulgation of the standard.

[60] *See* Regional Greenhouse Gas Initiative website. Accessed November 25, 2014. Available at: http://www.rggi.org/design/program-review. Our calculation of the 2020 reduction from the 165 million ton 2009 level is as follows: (165-91*(1-0.025)^6)/165 = 53%

[61] Jennings, et al., *Supreme Court rejects premise for GHG Tailoring Rule, but largely maintains EPA's authority to set GHG emission limits*, DLA Piper Climate Change Alert (June 26, 2014). Available at: https://www.dlapiper.com/en/us/insights/publications/2014/06/supreme-court-rejects-premise/

On March 27, 2012, EPA proposed[62] NSPS for greenhouse gas emissions from new electric generating units. The standard was set at 1,000 lb CO_2e/MWh, which is equivalent to the emission rate that a combined-cycle natural gas unit can achieve. The rule also allows a unit's emissions to be averaged over 30 years to achieve an annual average emission rate of 1,000 lb CO_2e/MWh. This option allows the phase-in of CCS within the first 10 years of operation. On January 8, 2014, EPA proposed to withdraw the 2012 proposed GHG NSPS, given that new proposed requirements based on different analyses from the original proposal would establish requirements that would differ significantly from the original proposal.[63]

In September 2013, EPA released a revised 111(b) rule, New Source Performance Standards for GHGs from new sources. The proposed standards for new power plants are the first uniform national limits on CO_2 emissions by new power plants. EPA is proposing separate standards for certain natural gas-fired stationary combustion turbines, fossil fuel-fired utility boilers, and integrated gasification combined cycle (IGCC) units. All standards are in pounds of CO_2 per megawatt-hour (lb CO_2/MWh gross).[64]

Fossil Fuel-Fired Utility Boilers and IGCC Units

EPA is proposing two limits for fossil fuel-fired utility boilers and IGCC units, depending on the compliance period that best suits the unit. These limits require capture of only a portion of the CO_2 from the new unit. These proposed limits are:

- 1,100 lb CO_2/MWh gross over a one-year period, or
- 1,000-1,050 lb CO_2/MWh gross over a seven-year period

Natural Gas-Fired Stationary Combustion Units

EPA is proposing two standards for natural gas-fired stationary combustion units, depending on size. The proposed limits are based on the performance of modern natural gas combined cycle (NGCC) units. These proposed limits are:

- 1,000 lb CO2/MWh gross for larger units (> 850 MMBtu/hr)
- 1,100 lb CO2/MWh gross for smaller units (≤ 850 MMBtu/hr)

[62] 77 Fed. Reg. 22392 (April 13, 2012).

[63] *See* U.S. Environmental Protection Agency website. Accessed December 2, 2014. Available at: http://www2.epa.gov/carbon-pollution-standards/2013-proposed-carbon-pollution-standard-new-power-plants

[64] *Ibid.*

On January 8, 2014, EPA issued a second NPRM on the proposal, and under an updated timeline announced late 2014, it intends to issue a final rule on Carbon Pollution Standards for New, Modified and Reconstructed Power Plants in summer of 2015.[65]

Almost no new coal plants are being proposed due to low gas prices, so the direct impact of Section 111(b) is currently modest. Nevertheless, the proposed rule is being litigated. It is thought that the principal purpose of challenges to Section 111(b) derives from the rule's role as a prerequisite for Section 111(d). Because Section 111(d) only applies to existing sources where there are standards of performance for new sources of the same type, invalidating Section 111(b) could also invalidate Section 111(d).[66]

Opponents question whether the proposed rule conforms to the Energy Policy Act of 2005 since the proposed rule relies on a "new technology," i.e., carbon capture and sequestration (CCS). It is unlikely for the current challenges to succeed, because the plaintiffs are seeking to stop the rulemaking while it is still underway. Future challenges are expected once the final rule is issued.

Clean Power Plan Proposed Rule

While New Source Performance Standards apply only to new facilities, Section 111(d) of the Clean Air Act requires states to develop plans for *existing* sources of any non-criteria pollutants (i.e., a pollutant for which there is no NAAQS) and non-hazardous air pollutant whenever EPA promulgates a standard for a new source. These plans are subject to EPA review and approval, similar to state implementation plans under the NAAQS program.

A draft 111(d) rule controlling GHGs from greenhouse gases existing sources was submitted on March 31, 2014, which laid out a timeline: EPA would propose standards in June 2014, EPA would finalize the standards in June 2015,[67] and states would submit SIPs to EPA in June 2016.[68]

On June 2, 2014, the EPA proposed the *Clean Power Plan* (CPP) to cut carbon emissions from existing power plants. The plan proposed to begin meaningful reductions in 2020, and to cut carbon emission from the power sector by 30 percent nationwide below 2005 levels by 2030, as well as cut particle pollution, nitrogen oxides, and sulfur dioxide by more than 25 percent as a co-benefit.[69] Under the plan,

[65] *See* U.S. Environmental Protection Agency website. Accessed January 27, 2015. Available at: http://www2.epa.gov/carbon-pollution-standards/fact-sheet-clean-power-plan-carbon-pollution-standards-key-dates

[66] "Legal Challenges to Obama Administration's Clean Power Plan," Michael B. Gerrard, New York Law Journal, September 11, 2014. Available at: http://www.arnoldporter.com/resources/documents/NYLJ_Legal Challenges to Obama Administration's Clean Power Plan_09112014.pdf

[67] John Podesta, former White House Chief of Staff, is said to believe that a final rule won't be issued until late summer 2015.

[68] *See* U.S. Environmental Protection Agency website. Accessed December 2, 2014. Available at: http://www2.epa.gov/carbon-pollution-standards/clean-power-plan-proposed-rule

[69] President Obama and Chinese President Xi Jinping announced in November 2014 that the United States intends to set an economy-wide target of reducing CO_2 emissions by 26-28 percent below 2005 levels by 2025. This is roughly consistent with the 30% reduction from 2005 levels by 2030 proposed in the CPP.

each state has the flexibility to choose how to meet the goal using a combination of measures that reflect its particular circumstances and policy objectives. The basic formula for the state goal is a rate: CO_2 emissions from fossil fuel-fired power plants in pounds divided by state electricity generation from fossil-fuel fired power plants and certain low- or zero-emitting power sources in megawatt hours (MWh). EPA is proposing a two-part goal structure: an "interim goal" that a state must meet on average over the ten-year period from 2020-2029 and a "final goal" that a state must meet at the end of that period in 2030 and thereafter. As described above, the EPA also proposed alternative "Option 2" goals, which reflect emissions reductions that are less stringent but must be met earlier, with an interim goal set for 2020–2024 and a final goal for 2025.

Under CAA section 111(d), state plans must establish standards of performance that reflect the degree of emission limitation achievable through the application of the "best system of emission reduction" (BSER). The BSER proposed in the rule is based on a range of measures that fall into four main categories, or "building blocks," which comprise (1) improved generator operations, (2) dispatching lower-emitting generators and (3) zero-emitting energy sources and end-use energy efficiency. Only Building Block 1 is required; the others are optional. The proposed state-level goals reflect the level of reductions in CO^2 emissions and emission rates and the extent of the application of the building blocks that would be presumptively approvable in a state plan during the ramp-up to achieving the final goal.

EPA is also proposing to give states the option to convert the rate-based goal to a mass-based goal if they choose to in their state plans—something the RGGI states have heartily endorsed—and has published proposed conversion factors and methodology.[70] Adopting a mass-based goal would better allow a state or group of states to cap their CO_2 emissions and set up a trading program if they choose that option to meet the goals outlined in the proposal, and would make it easier to avoid double counting contributions of energy efficiency and renewable energy produced in one state and counted in another. EPA is only proposing goals for states with fossil fuel-fired power plants; Vermont and Washington, DC are excluded for that reason.

On October 28, 2014, EPA issued a supplemental proposal, which sets area-specific goals for Indian country and territories and provides options for meeting those goals in a flexible manner. Under a modified timeline announced in late 2014, EPA in summer 2015 would issue final rules on CPP and propose a federal plan for meeting CPP goals for public review and comment. By summer 2016, EPA will be in a position to issue a final federal plan for meeting Clean Power Plan goals in areas that do not submit plans.[71]

It is expected that the EPA is likely to do away with or waive the interim goals, not because of legal challenges, but because of significant push-back from the states. It is also possible that there will be

[70] *See* U.S. Environmental Protection Agency website. Accessed December 2, 2014. Available at: http://www2.epa.gov/carbon-pollution-standards/clean-power-plan-proposed-rule-technical-documents-rate-to-mass

[71] *See* U.S. Environmental Protection Agency website. Accessed January 27, 2015. Available at: http://www2.epa.gov/carbon-pollution-standards/fact-sheet-clean-power-plan-carbon-pollution-standards-key-dates

some adjustment to the stringency of the prescribed state-specific emissions rates. One possibility is that the final overall rate will be the same as that in the proposed rule, but the individual rates will differ from those proposed. The latter is likely because of possible changes in the way Building Block 3 (renewable energy) amounts are calculated.

Although there are current legal challenges to the proposed rule, those are unlikely to succeed because the rulemaking is still in progress, and so are not likely to delay implementation of the rule. Although future lawsuits on the final rule may ultimately be successful, they are unlikely to cause delays in implementation, which would happen only in the rare event that a court issues a stay (as happened with CSAPR). A Supreme Court case on any of the challenges would likely be decided sometime between the spring 2017 and December 2019.

Carbon Pollution Standards for Modified and Reconstructed Power Plants

On June 2, 2014, EPA proposed standards to address carbon dioxide emissions from modified and reconstructed power plants. Like the proposed Carbon Pollution Standards for newly constructed power plants, the proposed Carbon Pollution Standards for modified and reconstructed power plants are also set under the authority of Clean Air Act Section 111(b). A modification, according to the rule, is "any physical or operational change to an existing source that increases the source's maximum achievable hourly rate of air pollutant emissions." A reconstructed source is "a unit that replaces components to such an extent that the capital cost of the new components exceeds 50 percent of the capital cost of an entirely new comparable facility."[72]

The fact that these provisions of Section 111(b) do not rely on new technology may be what ultimately enables the final rule to survive challenges aimed the new source provisions' reliance on CCS.

EPA Regulations—Other Emissions

National Ambient Air Quality Standards

National Ambient Air Quality Standards (NAAQS) set maximum air quality limitations that must be met at all locations across the nation. Compliance with the NAAQS can be determined through air quality monitoring stations, which are stationed in various cities throughout the United States, or through air quality dispersion modeling. States with areas found to be in "nonattainment" of a particular NAAQS are required to set enforceable requirements to reduce emissions from sources contributing to nonattainment such that the NAAQS are achieved and maintained. The U.S. Environmental Protection Agency (EPA) has established NAAQS for six pollutants: sulfur dioxide (SO_2), nitrogen dioxides (NO_2), carbon monoxide (CO), ozone, particulate matter—measured as particulate matter less than or equal to 10 micrometers in diameter (PM10) and particulate matter less than or equal to 2.5 micrometers in diameter (PM2.5)—and lead.

[72] *See* U.S. Environmental Protection Agency website. Accessed December 2, 2014. Available at: http://www2.epa.gov/carbon-pollution-standards/proposed-carbon-pollution-standards-modified-and-reconstructed-power

In nonattainment areas, pollutant sources must comply with emission reduction requirements known as "Reasonably Available Control Technology" (RACT) to bring the areas into attainment of the NAAQS. New major sources, including major modifications at existing sources, must comply with very strict emissions reductions consistent with "lowest achievable emissions reductions" (LAER) and obtain emission offsets.

EPA is currently in the process of drafting new, more stringent NAAQS for SO_2, PM2.5, and ozone.

- On June 22, 2010, EPA revised[73] the standard for SO_2 by establishing a new 1-hour standard at a level of 75 parts per billion (ppb) in place of the existing annual and 24-hour standards for SO_2. EPA on July 25, 2013 designated parts of 16 states as nonattainment for the 2010 SO_2 standard, and the designations were finalized in August 2013. For New England, parts of three counties in central New Hampshire were designated, and New Hampshire revised its state implementation plan (SIP) accordingly.[74] States have until October 2018 to attain the NAAQS.[75] On April 17, 2014, EPA issued a proposed rule that would allow state and local air agencies to use air quality monitoring or modeling to determine whether areas meet the 2010 air quality standards.[76]
- On December 14, 2012, EPA strengthened the annual PM2.5 standard from 15 µg/m3 to 12 µg/m3, and retained the current 24-hour standard at 35 µg/m3. On April 25, 2014, in response to a decision of the D.C. Circuit Court regarding implementation of the PM2.5 standard, EPA classified as "moderate" nonattainment areas for the 1997 and 2006 fine particle pollution standards and set December 31, 2014 as the deadline for states to submit remaining implementation plan requirements, outlining how they will reduce pollution to meet the standard by 2020.[77]
- In March 2008, EPA strengthened the 8-hour ozone standard from 84 ppb to 75 ppb. On September 16, 2009, EPA announced that because the 2008 standard was not as protective as recommended by EPA's panel of science advisors, it would reconsider the 75 ppb standard. In 2010, EPA proposed lowering the 8-hour ozone standard from 75 ppb to between 60 and 70 ppb, and on September

2, 2011, the Administration announced that EPA would not finalize its proposed reconsideration of the 75 ppb standard ahead of the regular 5-year NAAQS review cycle. On November 25, 2014, the EPA proposed lowering the standard to within a range of 65 to 70 ppb. EPA projections show the vast majority of U.S. counties would meet the proposed standards by 2025 just with the rules and programs now in place or under way. States with nonattainment areas would have until 2020 to late 2037 to meet the proposed health standard. The agency will issue a final decision by Oct. 1, 2015.[78]

Cross State Air Pollution Rule

The Cross State Air Pollution Rule (CSAPR), which replaces the 2005 Clean Air Interstate Rule (CAIR), was finalized in 2011, establishing the obligations of each affected state to reduce emissions of NO_x and SO_2 that significantly contribute to another state's PM2.5 and ozone non-attainment problems. CSAPR requires a total of 28 states to reduce annual SO_2 emissions, annual NO_X emissions and/or ozone season NO_X emissions to assist in attaining the 1997 ozone and fine particle and 2006 fine particle NAAQS. The rule targets electric generating units, and uses a cap and-trade approach to limit each state to emissions below a level that significantly contributes to non-attainment in downwind states.

On August 21, 2012, the U.S. Court of Appeals for the District of Columbia vacated CSAPR by leaving the CAIR requirements in place. The EPA and various environmental groups petitioned the Supreme Court of the United States to review the D.C. Circuit Court's decision on CSAPR. On April 29, 2014, the U.S. Supreme Court issued an opinion reversing the D.C. Circuit decision. Following the remand of the case to the D.C. Circuit, EPA requested that the court lift the CSAPR stay and toll the CSAPR compliance deadlines by three years. On October 23, 2014, the D.C. Circuit granted EPA's request. Accordingly, CSAPR Phase 1 implementation is now scheduled for 2015, with Phase 2 beginning in 2017.[79] While CSAPR-related litigation remains pending, none is considered a threat to the rule.

None of the New England states have obligations under CSAPR, although a replacement or follow-up rule, expected to be developed during 2016-2017 for implementation in 2018-2019, could affect sources in Connecticut or Massachusetts.

Regional Haze Rules

One of the national goals set out in the Clean Air Act is reducing existing visibility impairment from human-made air pollution in all "Class I" areas (e.g., most national parks and wilderness areas).[80] EPA's

[78] *See* U.S. Environmental Protection Agency website. Accessed December 2, 2014. Available at: http://www.epa.gov/groundlevelozone/actions.html

[79] *See* U.S. Environmental Protection Agency website. Accessed December 2, 2014. Available at: http://www.epa.gov/airtransport/CSAPR/

[80] 42 U.S.C. § 7491(a)(1)

Regional Haze Rule—issued in 1999, and revised in 2005—requires states to create plans to significantly improve visibility conditions in Class I areas with the goal of achieving natural background visibility conditions by 2064. These requirements are implemented through state plans with enforceable reductions in haze-causing pollution from individual sources and with other measures to meet "reasonable further progress" milestones.[81] The first progress milestone is 2018.

A key component of this program is the imposition of air pollution controls on existing facilities that impact visibility in Class I areas. Specifically, the rules require installation of "best available retrofit technology" (BART) that is developed for such facilities on a case-by-case basis. In addition, EPA's BART determinations specify particular emission limits for each BART-eligible facility. EPA evaluates BART for the air pollutants that impact visibility in our national parks and wilderness areas—namely SO_2, PM, and NO_x. Under the Clean Air Act, states develop Regional Haze requirements, but EPA approves state plans for compliance. If EPA finds the plans are not consistent with the Clean Air Act, it adopts a federal plan with BART and reasonable progress requirements. Affected facilities must comply with the BART determinations as expeditiously as practicable but no later than five years from the date EPA approves the state plan or adopts a federal plan.[82]

Mercury and Air Toxics Standards (MATS)

In 2000, EPA determined it was appropriate and necessary to regulate toxic air emissions (or hazardous air pollutants) from steam electric generating units. As a result, EPA adopted strict emission limitations for hazardous air pollutants that are based on the emissions of the cleanest existing sources.[83] These emission limitations are known as Maximum Achievable Control Technology (MACT). The final MATS rule, approved in December 2011, sets strict stack emissions limits for mercury, other metal toxins, other organic and inorganic hazardous air pollutants, as well as acid gasses. Compliance with MATS is required by 2015, with a potential extension to 2016.

On March 28, 2013, the EPA finalized updates to certain emission limits for new power plants under MATS. This includes emission limits for mercury, PM, SO_2, acid gases and certain individual metals. On

[81] 40 C.F.R. §51.308-309

[82] EPA's regulations allow certain states in the "Grand Canyon Visibility Transport Region" to participate in an SO_2 trading program in lieu of adopting source-specific SO_2 BART requirements, if the trading program will result in greater reasonable progress toward attaining the national visibility goal than source-specific BART. Although nine states were originally eligible to participate, today only three states are opting to participate in this program – New Mexico, Utah, and Wyoming. These states agreed to a gradually declining cap on SO_2 emissions from all emission sources. If the declining caps are exceeded in any year, then even greater SO_2 emission reductions have to be achieved—although the reductions can be met through emissions trading, rather than imposition of specific emission limitations on any one facility. This program is called the Backstop Trading Program.

[83] Clean Air Act §112(d)

November 7, 2014, EPA finalized an action reconsidering the provisions applicable during periods of startup and shutdown under MATS and Utility New Source Performance Standards (Utility NSPS).[84]

According to ISO New England, approximately 7.9 GW of existing coal- and oil-fired capacity in the region are subject to MATS.[85] The ISO considers less than 1 GW of affected fossil capacity in New England to be at risk for retirement because of an inability to comply with MATS, because most remaining coal-fired generators already are retrofitted with needed controls to comply with state air toxics regulations, and most remaining larger oil-fired generators in New England are only subject to *de Minimis* work practice standards under MATS and not required to add any emission control devices.

MATS continues to face litigation, notably before the U.S. Supreme Court. The Court, on November 25, 2014, accepted three petitions, consolidated them and granted review: *Michigan v. EPA*, *Utility Air Regulatory Group v. EPA*, and *National Mining Association v. EPA*. The Court will consider "Whether the Environmental Protection Agency unreasonably refused to consider costs in determining whether it is appropriate to regulate hazardous air pollutants emitted by electric utilities." The implications of the case reach potentially beyond MATS.[86]

Coal Combustion Residuals Disposal Rule

Coal-fired power plants generate a tremendous amount of ash and other residual wastes, which are commonly placed in dry landfills or slurry impoundments. The risk associated with wet storage of coal combustion residuals (CCR) was dramatically revealed in the catastrophic failure of the ash slurry containment at the Kingston coal plant in Roane County, Tennessee in December 2008, releasing over a billion gallons of slurry and sending toxic sludge into tributaries of the Tennessee River.

On June 21, 2010, EPA proposed to regulate CCR for the first time either as a Subtitle C hazardous waste or Subtitle D solid waste under the Resource Conservation and Recovery Act. The current rulemaking is 30 years overdue. If the EPA classifies CCR as hazardous waste, a cradle-to-grave regulatory system would apply to CCR, requiring regulation of the entities that create, transport, and dispose of the waste. Under a Subtitle C designation, the EPA would regulate siting, liners, run-on and run-off controls, groundwater monitoring, fugitive dust controls, and any corrective actions required; in addition, the EPA would implement minimum requirements for dam safety at impoundments. For Subtitle C, requirements will go into effect in authorized states when the state adopts the rule. Timing will vary from state to state. Under a solid waste Subtitle D designation, the EPA would require minimum siting and construction standards for new coal ash ponds, compel existing unlined impoundments to install

[86] Lyle Denniston, *Court to rule on disability rights, mercury pollution*, SCOTUSblog (Nov. 25, 2014, 1:39 PM), http://www.scotusblog.com/2014/11/court-to-rule-on-disabiity-rights-mercury-pollution/

liners, and require standards for long-term stability and closure care. For Subtitle D, the rule would be effective six months after promulgation.

The EPA is currently evaluating which regulatory pathway will be most effective in protecting human health and the environment. In 1999, EPA released a series of technical papers to Congress documenting cases in which damages are known to have occurred from leakages and spills from coal ash impoundments.[87] In the current proposed rule, the EPA recognizes a substantial increase in the types and quantities of potentially toxic CCR caused by air pollution control equipment.

Use of more advanced air pollution control technology reduces air emissions of metals and other pollutants in the flue gas of a coal-fired power plant by capturing and transferring the pollutants to the fly ash and other air pollution control residues. The impact of changes in air pollution control on the characteristics of CCRs and the leaching potential of metals is the focus of ongoing research by EPA's Office of Research and Development.[88] EPA has not yet set a date for issuance of a final rule.

Steam Electric Effluent Limitation Guidelines

Following a multi-year study of steam-generating units across the country, EPA found that coal-fired power plants are currently discharging a higher-than-expected level of toxic-weighted pollutants into waterways. Current effluent regulations were last updated in 1982 and do not reflect the changes that have occurred in the electric power industry over the last thirty years, and do not adequately manage the pollutants being discharged from coal-fired generating units. Coal ash ponds and flue gas desulfurization systems used by such power plants are the source of a large portion of these pollutants, and are likely to result in an increase in toxic effluents in the future as environmental regulations are promulgated and pollution controls are installed. On April 19, 2013, EPA signed a notice of proposed rulemaking that would strengthen existing controls on discharges, and a proposed rule was published on June 7, 2013. The public comment period closed on September 20, 2013. EPA is under a court order to issue a final action no later than September 30, 2015. New requirements will be phased in over 2017 to 2022.[89]

The proposal sets the first federal limits on the levels of toxic metals in wastewater that can be discharged from power plants. Under the most stringent preferred regulatory option, EPA's projects no plants will close and at most a few units will retire. Under the most stringent preferred regulatory

[88] 75 Fed. Reg. 35139 (June 21, 2010).

[89] *See* U.S. Environmental Protection Agency website. Accessed December 2, 2014. Available at: http://water.epa.gov/scitech/wastetech/guide/steam-electric/proposed.cfm

option, EPA projects national average prices to increase minimally by only 0.025 cents/KW-hr, or 0.27 percent.[90]

Clean Water Act Cooling Water Intake Structure Rule

On March 28, 2011, the EPA proposed a long-expected rule implementing the requirements of Section 316(b) of the Clean Water Act at existing power plants.[91] Section 316(b) requires "that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact." Under this new rule, EPA set new standards reducing the impingement and entrainment of aquatic organisms from cooling water intake structures at new and existing electric generating facilities.

The rule provides that:

- Existing facilities that withdraw more than two million gallons per day are subject to an upper limit on fish mortality from impingement, and must implement technology to either reduce impingement or slow water intake velocities.
- Existing facilities that withdraw at least 125 million gallons per day are required to conduct an entrainment characterization study to establish a "best technology available" for the specific site.

EPA released a final rule for implementation of Section 316(b) of the Clean Water Act on May 19, 2014. The final rule became effective October 14, 2014, and requirements will be implemented in NPDES permits as they are renewed. The rule, including design enhancements and operational requirements to reduce impingement mortality and new requirements to protect threatened and endangered species and critical habitats federally listed and designated under the *US Endangered Species Act*, will be implemented by delegated states in New England, and EPA anticipates most retrofits occurring between 2018 and 2022.[92] According to ISO New England, as much as 12.1 GW of existing fossil fuel and nuclear capacity in New England may need cooling water intake structure modification, and 5.6 GW of facilities with larger water withdrawals of once-through cooling systems will need to prepare and submit entrainment characterization reports by 2018.[93]

As of October 2014, the rule is being litigated in the 4th Circuit Court of Appeals (consolidating six petitions from other circuits). Environmental advocates challenged provisions for control technology flexibility and discretion, while industry narrowly challenged the new unit criteria as contradictory.[94]

4.2.3 Impact of Energy Efficiency Programs on CO_2 Emissions under a Cap and Trade Regulatory Framework

With CO_2 emissions regulated under a cap and trade system, as assumed in this market price analysis, it is conceivable that a load reduction from an energy efficiency program will not lead to a reduction in the amount of total system CO_2 emissions. The annual total system emissions for the affected facilities in the relevant region are, after all, capped. In the analysis documented in this report, the relevant cap and trade regulation is the RGGI for the period 2015 to 2020, and thereafter an assumed continuation of that regional cap and trade system (perhaps with other states joining), modified as needed to bring about CPP compliance in the member states. There are, however, a number of reasons why an energy efficiency program could nonetheless result in CO_2 emission reductions. Specifically:

- A reduction in load that reduces the cost (marginal or total cost) of achieving an emissions cap can result in a decision to tighten the cap. This is a complex interaction between the energy system and political and economic systems, and is difficult or impossible to model, but it's reasonable to assume the dynamic exists.
- Specific provisions in RGGI provide for a tightening or loosening of the cap (via adjustments to the reserve provisions that are triggered at different price levels). It is plausible that those provisions can be modified as needed to ensure compliance with the CPP as proposed.
- It is also possible that energy efficiency efforts will be accompanied by specific retirements or allocations of allowances that would cause them to have an impact on the overall system level of emissions (effectively tightening the cap).
- To the extent that the cap and trade system "leaks" outside of its geographic boundaries, one would expect the benefits of a carbon emissions reduction resulting from an energy efficiency program to similarly "leak." That is, a load reduction in New York could cause reductions in generation (and emissions) at power plants in New York, Pennsylvania, and elsewhere. Because New York is in the RGGI cap and trade system, the emissions reductions realized at New York generating units may accrue as a result of increased sales of allowances from New York to other RGGI states. Since Pennsylvania is not in the RGGI system, however, the emissions reductions at Pennsylvania generating units would be true reductions attributable to the energy efficiency program.

The first three of these points, above, would also apply to a future CO_2 cap and trade program which expands the RGGI footprint and is designed to comply with the CPP. The fourth point, regarding leakage and boundaries, would apply as well in an expanded cap and trade footprint, but to a lesser extent the larger the footprint is.

4.3 Non-Embedded Environmental Costs

Non-embedded costs are impacts from the production of a good or service that are not reflected in price of that good or service, and are not considered in the decision to provide that good or service.[95] Air pollution generated in the production of electricity is a classic example of a non-embedded cost: pollutants released from a power plant impose health impacts on a population, cause damage to the environment, or both. In this example, health impacts and ecosystem damages not reflected in the price of electricity and not considered in the power plant owner's decision of how much electricity to provide are "non-embedded," whereas adverse impacts that are reflected in the market price of electricity (e.g., through regulation) and are considered in decisions regarding production are "embedded."

For AESC 2015, the non-embedded carbon cost continues to be the dominant non-embedded environmental cost associated with marginal electricity generation in New England. This is the case for two main reasons. First, regulations to address the greenhouse gas emissions responsible for global climate change have yet to be implemented with sufficient stringency to reduce carbon emissions, particularly in the United States.[96] The damages from the EPA's criteria air pollutants are relatively bounded, and to a great extent embedded, as a result of existing regulations. In contrast, global climate change is a problem on an unprecedented scale with far-reaching and potentially catastrophic implications.

Second, New England avoided electric energy costs over the study period are dominated by natural gas-fired generation, which has minimal SO_2, mercury, and particulate emissions, as well as relatively low NO_x emissions.

4.3.1 History of Non-Embedded Environmental Cost Policies in New England

In the 1980s and 1990s, several New England states had proceedings dealing with non-embedded costs that influence current utility planning and decision-making.[97] In Massachusetts, dockets DPU 89-239 and 91-131 served as models for other states. Docket DPU 89-239 was opened to develop "Rules to Implement Integrated Resource Planning" and included the determination and application of non-embedded environmental cost values. This docket adopted a set of dollar values for air emissions, including a CO_2 value of $38 per ton of CO_2 (in 2015 dollars).[98] Docket DPU 91-131 examined

[95] In economics, a non-embedded impact can be positive (a non-embedded benefit) or negative (a non-embedded cost); in this discussion we are focusing on negative impacts (non-embedded costs).

[96] On April 17, 2009; EPA issued a proposed finding that concluded that greenhouse gases posed an endangerment to public health and welfare under the Clean Air Act ("Proposed Endangerment and Cause or Contribute Findings for Greenhouse Gases Under Section 202(a) of the Clean Air Act" 74 Fed. Register 78: 18886–18910). This proposed finding initiates the process of potentially regulating greenhouse gases as an air pollutant. http://epa.gov/climatechange/endangerment.html

[97] A more detailed description of the history of electricity generation environmental externalities and policies in New England may be found in AESC 2007 (p. 7-6–7-8).

[98] Exhibit DOER-3, Exhibit. BB-2, p. 26. $22 in 1989 dollars.

environmental costs to develop recommendations of various approaches for quantifying the non-embedded CO_2 value. The Department of Public Utilities' (DPU) Order in Docket DPU 91-131 was noteworthy for its foresight regarding climate change, albeit optimistic about the timing of the adoption of climate change regulations in the U.S.[99] Based on information in the record, the Department reaffirmed the CO_2 value it had adopted in the previous case, $38 per ton (in 2015 dollars).

In May 2014, the Department of Environmental Protection (DEP) and the Department of Energy Resources (DOER) filed a joint petition with the Massachusetts DPU requesting the DPU to commence a proceeding to determine whether the existing method of calculating the costs (associated with GHG emissions) to comply with the Global Warming Solutions Act (GWSA), should be replaced by the marginal abatement cost curve method.[100] The matter, discussed further below in Section 4.6, is still pending before the DPU.

4.3.2 Estimating Non-Embedded CO_2 Costs

Setting a Threshold for Global CO_2 Emissions

The level of global CO_2 emissions thought to be consistent with avoiding the most serious forms of climate damage is essentially unchanged since AESC 2011.[101] Sustainability targets for CO_2 equivalent concentrations in the atmosphere are roughly 350 to 450 ppm,[102] consistent with an approximately 50 percent chance of limiting the change in the average global temperature to 2°C above pre-industrial levels.[103] The Copenhagen Agreement, drafted at the 15th session of the Conference of the Parties to the United Nations Framework Convention on Climate Change in 2009, recognizes the scientific view that in order to prevent the more drastic effects of climate change, the increase in global temperature should be limited to no more than 2°C.[104]

The Intergovernmental Panel on Climate Change (IPCC 2014, Table SPM.1) indicates that reaching concentrations of 430 to 480 ppm CO_2 equivalent, in order to limit temperature change to between 1.5 °C to 1.7 °C above pre-industrial levels by the end of the century will require a reduction in 2050 global

[99] AESC 2009 provides more detail about the Massachusetts DPU Order in Docket DPU 91-131.

[100] Massachusetts Department of Public Utilities, Docket No. 14-86, May 16, 2014.

[101] AESC 2011 Section 6.6.4.1 page 6-97.

[102] According to IPCC, "Only a limited number of individual model studies have explored levels below 430 ppm CO_2eq… Assessing this goal is currently difficult because no multi-model studies have explored these scenarios." *See* IPCC, 2014: Summary for Policymakers, In: Climate Change 2014, Mitigation of Climate Change. Contribution of Working Group III to the Fifth Assessment Report of the Intergovernmental Panel on Climate Change. Cambridge University Press. (Hereinafter, "IPCC 2014"). The information and analysis presented here therefore focuses on the 450 ppm target.

[104] IPCC, 2007: Summary for Policymakers. In: *Climate Change 2007: Mitigation. Contribution of Working Group III to the Fourth Assessment Report of the Intergovernmental Panel on Climate Change* [B. Metz, O.R. Davidson, P.R. Bosch, R. Dave, L.A. Meyer (eds)], Cambridge University Press, Cambridge, United Kingdom and New York, NY, USA.

CO_2 emissions of 41 to 72 percent below 2010 emissions levels. To accomplish such stabilization, the U.S. and other industrialized countries would have to reduce greenhouse gas emissions on the order of 80 to 90 percent below 1990 levels, and developing countries would have to achieve reductions from the baseline increase in emissions caused by improvements in the standard of living as soon as possible (den Elzen and Meinshausen, 2006).

In the U.S., several states have adopted state greenhouse gas abatement targets of 50 percent or more reduction from a baseline of 1990 levels or then-current levels by 2050 (Arizona, California, Connecticut, Florida, Illinois, Maine, Massachusetts, Minnesota, New Hampshire, New Jersey, New Mexico, Oregon, Vermont, and Washington).[105] In Massachusetts, the GWSA, signed into law by Governor Patrick in August 2008, calls for initial reductions in greenhouse gas emissions of between 10 percent and 25 percent below 1990 levels by 2020.[106] The *Massachusetts Clean Energy and Climate Plan for 2020* (CECP), released on December 29, 2010 by the Massachusetts Executive Office of Energy and Environmental Affairs, sets out policies, with associated emissions reductions, necessary to meet the 2020 target of 25 percent below 1990 levels.[107] In early January 2015, the Massachusetts Department of Environmental Protection ("Mass DEP") published a proposed "Clean Energy Standard" (CES) regulation for public comment. A Massachusetts CES would implement one of the strategies in the CECP, and providing a long-term incentive to ensure ongoing progress toward reducing greenhouse gas emissions by 80 percent by 2050.[108]

Methods to Monetize Non-Embedded CO_2

Several different methods are available to monetize environmental costs. These include "damage cost" approaches that seek to assign a value to damages associated with a particular pollutant, and "control cost" approaches that seek to quantify the marginal cost of controlling a particular pollutant. For the same reasons outlined in AESC 2013, AESC 2015 recommends using the control cost approach to estimate non-embedded CO_2 costs for the study period.

Damage Cost Approach: The Social Cost of Carbon

Damage cost methods generally rely on travel costs, hedonic pricing, or contingent valuation to assign values in the absence—by definition—of market prices for non-embedded impacts. These are forms of "implied valuation," asking complex and hypothetical survey questions, or extrapolating from observed behavior, to impute a price to something that is never bought or sold in a market. For example, data on how much people will spend on travel, subsistence, and equipment on fishing can be used to measure

the value of those fish, and the value of *not* killing fish with waterborne pollution. Even human lives sometimes have been valued based on wage differentials for jobs that expose workers to different risks of mortality. Comparing the difference in wages between two jobs—one with higher hourly pay rate and higher risk than the other—can serve as a measure of the compensation that someone is "willing to accept" in order to be exposed to a life-threatening risk and, by analogy, as a controversial estimate of the value of life itself.

Valuation of the societal damages caused by the emission of an additional ton of CO_2—a measure often called the "social cost of carbon"—typically combines cost estimates, using a variety of implied valuation techniques, for numerous damages from climate change that are expected around the world. In 2010, the U.S. government began to include a social cost of carbon in the valuation of federal rulemakings with the goal of accounting for the damages resulting from climate change, defined as "an estimate of the monetized damages associated with an incremental increase in carbon emissions in a given year."[109] A range of four social cost of carbon values was initially calculated by the Interagency Working Group on the Social Cost of Carbon (the "Working Group"), a group composed of members of the Department of Agriculture, Department of Commerce, Department of Energy, Environmental Protection Agency, and Department of Transportation, among others.

The Working Group's estimates, presented in Exhibit 4-4, seek to represent the range of social cost of carbon values for three discount rates as well as the high-cost tail-end of the uncertain distribution of impacts in 2015 dollars per short ton CO_2.[110] It is important to note that social cost of carbon values represent the damages associated with an incremental increase in CO_2 emissions *in a given year*; for this reason, they are time-dependent and are expected to increase in future years as atmospheric concentrations of CO_2 increase. As of May 2012, these estimates had been used in more than 20 federal government rulemakings, for policies including fuel economy standards, industrial equipment efficiency, lighting standards, and air quality rules.[111] In May 2013 and again in November 2013, the Working Group released technical updates that revised its estimate of the Social Cost of Carbon.[112]

2050	$27	$73	$100	$227

Source: US EPA, Technical Support Document: Technical Update of the Social Cost of Carbon for Regulatory Impact Analysis - Under Executive Order 12866 - Interagency Working Group on the Social Cost of Carbon, United States Government, November 2013 (original values in 2007$ per metric ton). http://www.whitehouse.gov/sites/default/files/omb/assets/inforeg/technical-update-social-cost-of-carbon-for-regulator-impact-analysis.pdf

These social cost of carbon values are the result of the Working Group's reanalysis using the DICE, PAGE, and FUND integrated assessment models, which simplify the relationships among complex climate and economic systems with the goal of providing information useful in making climate policy decisions.[113] The social cost of carbon values are calculated as the net present value of the discounted path of hundreds of years of future damages computed by each of the three models resulting from the addition of a ton of CO_2 emissions in a given year.

The Working Group based its common sets of assumptions regarding emissions, population, and gross domestic product (GDP), used for all three models, on four business-as-usual scenarios from an Energy Modeling Forum (EMF) model comparison exercise and an average of 550 ppm CO_2e scenarios from the same four EMF models.[114] The process-based integrated assessment models used in the EMF survey contain substantially more detailed representations of the climate and energy systems than the DICE, PAGE, and FUND models, but only provide results out to 2100. The Working Group analysis extrapolates these trends out to 2300 based upon assumptions regarding changes in fertility rates, GDP per capita, and carbon intensities.

DICE, PAGE, and FUND all employ simplified climate modules to convert emissions into atmospheric concentrations, and then use a climate sensitivity parameter to convert concentrations into temperature increases. To address the substantial uncertainty in this climate sensitivity parameter, the Working Group conducted a Monte Carlo analysis that averages results from a distribution of likely

[113] The DICE model was further simplified by the Working Group for use in its analysis, see Interagency Working Group 2010.

[114] Clarke, L. (2009). Overview of EMF 22 international scenarios. Available at: https://emf.stanford.edu/projects/emf-22-climate-change-control-scenarios

sensitivities. Three of the four social cost of carbon values are based on the average of this distribution, with the fourth based on the high-cost tail-end 95th percentile.

The DICE, PAGE, and FUND integrated assessment models rely on implied valuations of future climate damages to calibrate their "damage functions," which translate temperature changes into changes in GDP. Climate damage valuation is hampered by significant uncertainty in the climate system itself, long time intervals separating cause and effect, and practical difficulties in assigning monetary values to projected damages that fall outside of the range of past experience. A common practice used in these and other climate-economics models is to set a point estimate for the expected cost of near-term, low-level climate damages and then to extrapolate the costs as rising with the square of temperature change.[115] The climate damage values used in the Working Group analysis represent the most likely level of damage given these estimation techniques, ignoring any uncertainty in the range of damages expected to occur from a given rise in temperature. The EPA notes,

> However, given current modeling and data limitations, [Social Cost of Carbon] does not include all important damages. As noted by the IPCC Fourth Assessment Report, it is "very likely that [SCC] underestimates" the damages. The models used to develop SCC estimates, known as integrated assessment models, do not currently include all of the important physical, ecological, and economic impacts of climate change recognized in the climate change literature because of a lack of precise information on the nature of damages and because the science incorporated into these models naturally lags behind the most recent research.

AESC 2013 discussed various flaws of the overall methodology and application of the Working Group's Social Cost of Carbon estimates, and presented alternate estimates of the Working Group's Social Cost of Carbon estimates by various researchers, produced by varying several of the analyses' assumptions. The alternate estimates were up to more than an order of magnitude larger than the Working Group's. While beyond the scope of AESC 2015, it is worth mentioning that ongoing research and analysis continues to quantify the degree to which the Working Group's estimates are significantly too low because they fail to account for what are potentially first order effects, effects supported by mounting empirical evidence.[116]

As noted previously, in May and then again in November 2013, the Working Group released a technical update to its Social Cost of Carbon that used the same methodology as 2010, but used updated versions of the DICE, FUND, and PAGE models. The revised modeling exercise resulted in change in the working Group's average, 3-percent-discount-rate social cost of carbon—for 2015, $25 to $38 per short ton in 2015 dollars.

[115] Stanton, Ackerman and Kartha (2009) "Inside the Integrated Assessment Models: Four Issues in Climate Economics." Climate and Development 1:2(166-184). DOI 10.3763/cdev.2009.0015

[116] For example, see Moore, F. and Diaz, D., "Temperature impacts on economic growth warrant stringent mitigation policy," *Nature Climate Change* 5, 127–131 (2015). The analysis addresses the impact of climate change on GDP growth, which the Working Group's models consider to be exogenous.

For the purposes of AESC 2015, the Working Group's revised $38/t may be viewed as an extreme lower bound to possible non-embedded CO_2 values in 2015.

Control Cost Approach

The Marginal Cost of Stabilizing CO_2 Emissions

Control cost methods generally look at the marginal cost of abating CO_2 emissions—that is, the last (or most expensive) unit of emissions reduction required to comply with regulations. The cost of control approach is often based on regulators' revealed preferences. For example, if air quality regulators require a particular technology that costs $X for each ton of emissions that it achieves, then this can be taken as an indication that regulators value emission reductions at or above $X/t. For CO_2 emissions, however, regulators' preferences are not as yet fully revealed.

A marginal cost of abatement can also be based on a sustainability target of staying at or below the highest level of damage or risk that is considered to be acceptable. In this case, the marginal cost of abatement is the cost per ton of the most expensive technology needed to achieve the sustainability target. A sustainability target for CO_2 emissions relies on the assumption—well established in documents related to international climate policy negotiations—that there is a threshold beyond which the nations of the world deem climatic changes and their associated damages to be unacceptable.

A wealth of well documented, compelling research exists both on setting an acceptable threshold for CO_2 emissions and on current and projected costs of CO_2 emissions abatement technologies. Here, we review several recent analyses of strategies and technologies that would contribute to emission reductions consistent with an increase in average temperature of no more than 2°C above preindustrial levels or atmospheric concentrations no greater than 450 ppm CO_2 equivalent.

The 350 ppm target has been identified and is viewed as a more current target to maintain the global temperature increase above pre-industrial levels at no more than 2°C. According to one source, "The measured energy imbalance [of +0.5 W/m^2] indicates that an initial CO_2 target '<350 ppm' would be appropriate, if the aim is to stabilize climate without further global warming."[117] While there is a lack of abatement cost estimates associated with a 350 ppm target, given the factors described in the following text it is reasonable to conclude that such an abatement cost would be equal or more than the abatement cost associated with a 450 ppm target, and could potentially be considerably higher.[118] The information and analysis presented here focuses on the 450 ppm target, entirely because the available

[117] Hansen J, et al. (2013) "Assessing 'Dangerous Climate Change': Required Reduction of Carbon Emissions to Protect Young People, Future Generations and Nature. *See also* Hansen J, et al. (2008) "Target Atmospheric CO2: Where Should Humanity Aim?" The Open Atmospheric Science Journal, 2: 217-231.

[118] If the more ambitious target could be achieved using more of the same abatement resource, the marginal cost would be the same. If a different (and therefore more expensive) resource were needed to achieve the target, the cost would be higher.

studies used the 450 ppm level in their analyses. The associated cost estimate can therefore be considered to be a conservative choice.

McKinsey & Company examined abatement technologies in a 2010 report entitled *Impact of the Financial Crisis on Carbon Economics: Version 2.1 of the Global Greenhouse Gas Abatement Cost Curve*. The CO_2 mitigation options identified by McKinsey and the costs of those options are reproduced in Exhibit 4-3. The figure represents a marginal abatement cost curve, where the per-ton cost of abatement is shown on the vertical axis and cumulative metric tons of CO_2 equivalent reductions are shown on the horizontal axis. Global CO_2 mitigation technologies are ordered from least to most expensive with the width of each bar representing each technology's expected total emission reduction. If technologies are assumed to be implemented in order of their costs, beginning with the cheapest abatement options, the marginal cost of maintaining the sustainability threshold is the cost per ton of the most expensive technology needed to provide the appropriate reduction (here, 38 metric gigatons CO_2 equivalent in 2030).

As shown in Exhibit 4-3, the marginal technology for the year 2030 is a gas plant carbon capture and storage (CCS) retrofit costing $120 per short ton in 2015 dollars.[119] This figure also shows a variety of technologies for carbon mitigation that are available to the electric sector, including those related to energy efficiency, nuclear power, renewable energy, and CCS for fossil-fired generating resources.

In *Energy Technology Perspectives 2014* (ETP 2014), the IEA has modeled the implications of several emissions scenarios, and presents marginal CO_2 abatement costs for each. Its 2DS Scenario, an emissions trajectory with at least a 50% chance of limiting average global temperature increase to 2°C, is broadly consistent with IEA's World Energy Outlook (WEO) 450 Scenario, which stabilizes CO_2 levels at 450 ppm.[120] IEA projects global marginal cost of abatements under this and other scenarios for 2020, 2030, 2040, and 2050, with the cost for each year generally spanning a $20 range. The averages of the cost ranges for the 2DS Scenario increase over time from $42 to $163 in 2015 dollars.

[119] 2005 Euro to Dollar conversion factor, 1.25, http://www.oanda.com/convert/fxhistory accessed 4/28/09

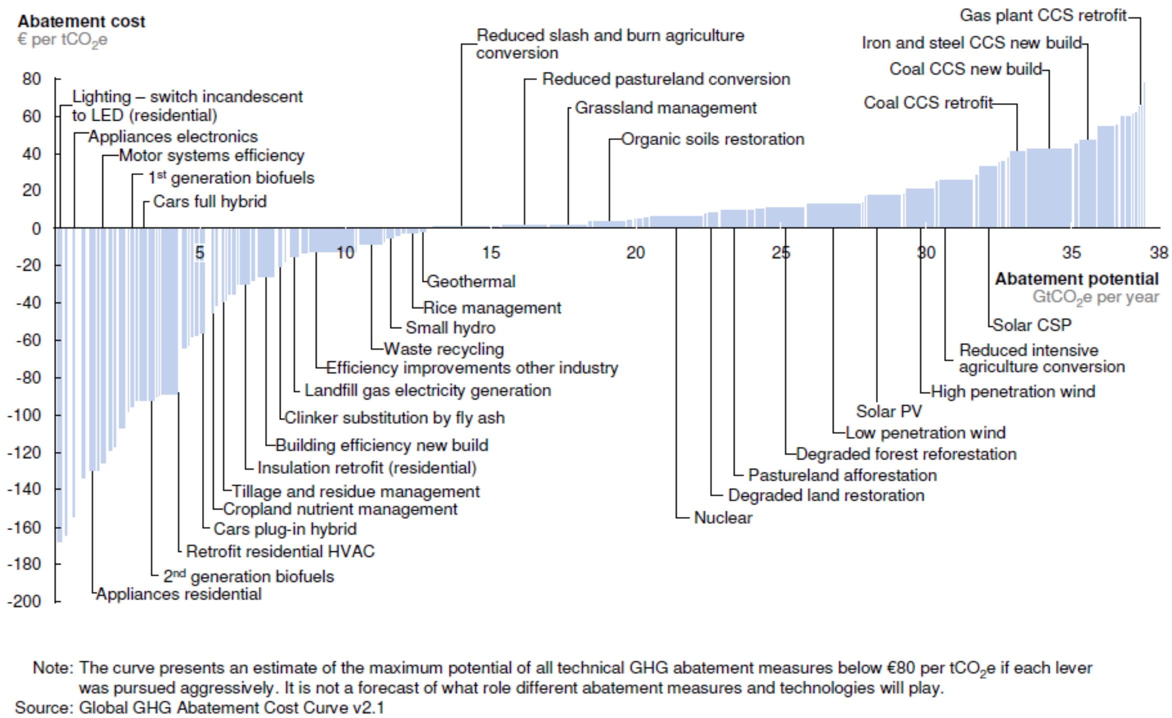
Exhibit 4-5. Marginal Abatement Technologies and Associated Costs for the Year 2030



Source: McKinsey & Company. Impact of the Financial Crisis on Carbon Economics: Version 2.1 of the Global Greenhouse Gas Abatement Cost Curve. 2010. Page 8.

In *ETP 2014*, the IEA examines two additional scenarios. Its 4DS scenario, broadly consistent with the WEO New Policies Scenario, projects a long-term temperature rise of 4°C. The WEO New Policies Scenario stabilizes CO_2 levels at 660 ppm.[121] The 6DS scenario, which projects a long-term temperature rise of 6°C, is largely an extension of current trends, and is broadly consistent with the WEO Current Policy Scenario, which stabilizes CO_2 levels at 950 ppm.[122] The 2050 costs for the 4DS and 6DS Scenarios are $53/t and $63/t respectively, in 2015 dollars per short ton.

The global marginal costs of abatement for all of these scenarios are roughly the same as those presented for equivalent scenarios in *WEO 2012* and *ETP 2012*, cited in AESC 2013, whereas those costs represented a decrease on the order of $20/t from the earlier *Energy Technology Perspectives 2010*, primarily as a result of higher projected prices for fossil fuels and more optimistic forecasts for low-carbon technologies.

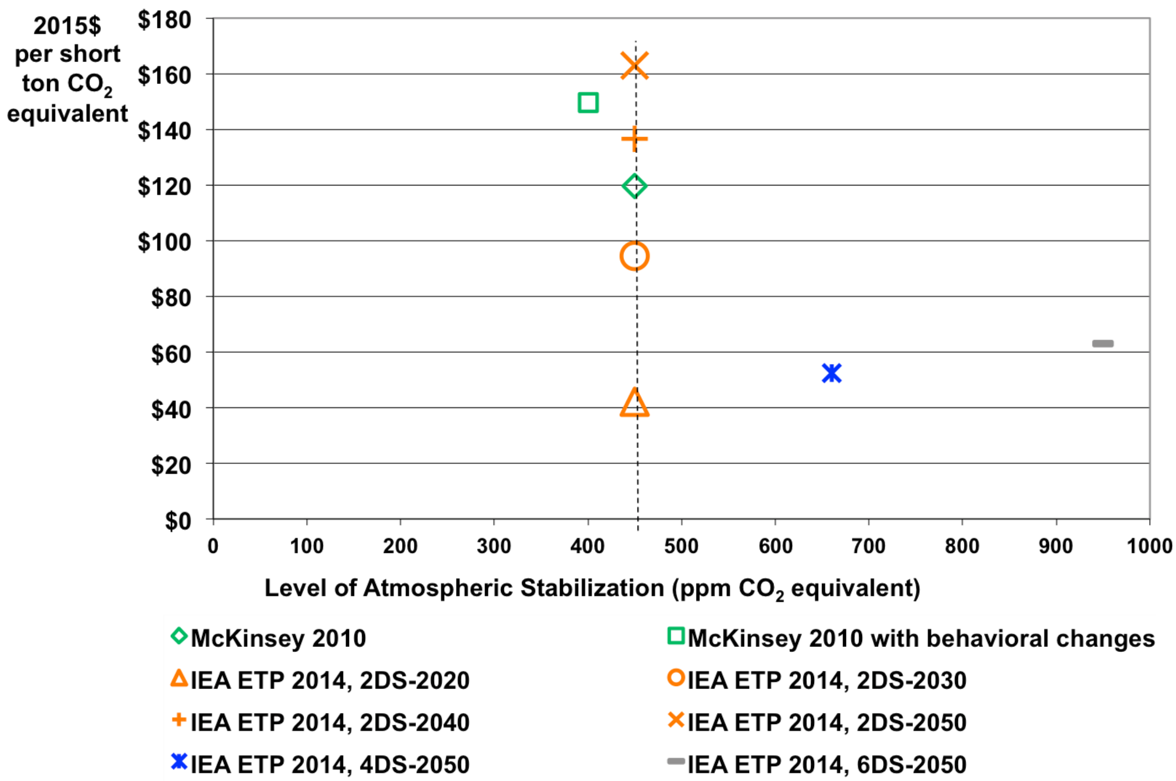
The results of these studies are summarized in Exhibit 4-4. The dotted line is drawn at the value of atmospheric stabilization of 450 ppm CO_2 equivalent, which corresponds to a good chance of limiting

[121] IEA (2012). *World Energy Outlook 2012*. Available at: http://www.worldenergyoutlook.org/publications/weo-2012/

[122] *Ibid.*

global temperature increase to 2°C above pre-industrial levels. Based on this analysis—as well as the CCS costs presented in the section below, and our own judgment and experience—we recommend an AESC 2015 abatement cost of $100 per short ton (in 2015 dollars). This value is unchanged in nominal terms from that of AESC 2013.

Exhibit 4-6. Summary Chart of Marginal Abatement Cost Studies



Source: See text.

CCS Technology Costs

CCS for electricity generation is often at or near the margin for targets of limiting temperature rise to 2°C above pre-industrial levels. For this reason, we expect that CCS costs may be viewed as providing an alternate, first-order approximation of the marginal cost of abating CO_2 emissions. Due to the relatively nascent state of the technology and few projects that are either operating or at advanced stages of development,[123] projected technology costs vary widely, with gas CCS typically more expensive than

[123] As of November 2014, only two of the 40 large-scale CCS projects in the "operate," "execute" or "define" stages as defined by the Global CCS Institute (GCCSI) were on gas-fired generation: the Peterhead CCS Project in Scotland (340 MW, 1 $MtCO_2$ per year integrated CCS), and Sargas Texas Point Comfort Project (250 MW, 0.8 MtCO2 /year), both in the "define" stage. *See* GCCSI (2014), Status of CCS Project Database. Available at: http://www.globalccsinstitute.com/content/ccs-around-world

coal on a per ton of avoided emissions basis. As presented in AESC 2013, mature CCS deployment estimates are commonly in the range of $60 to $100 per short ton of CO_2 avoided. According to IEA, carbon prices need to approach $84 per short ton (2015 dollars) to drive adoption of CCS—prices above which a CCGT with CCS will have a lower LCOE than either a CCGT or supercritical pulverized coal plant.[124]

Substantial uncertainty still exists in the long-term costs of CCS deployment. CCS costs can provide an important cross-check of long-term forecasts of mitigation costs, but should be coupled with other metrics such as complete marginal cost of abatement curves constructed from energy system modeling results.

CO_2 Abatement Cost in AESC 2015

Based on our review of the most current research on marginal abatement and CCS costs, and our experience and judgment on the topic, we believe that it is reasonable to use a CO_2 marginal abatement cost of $100 per short ton in 2015 dollars. This value is the same in nominal terms as the AESC 2013 value. Because the AESC 2015 embedded CO_2 cost is lower than that of AESC 2013, the non-embedded component is correspondingly higher.

A value of $100/short ton is a practical and reasonable measure of the total societal cost of carbon dioxide emissions. This CO_2 marginal abatement cost can be applied to the emissions reductions that result from lower electricity generation as a result of energy efficiency, in order to quantify these reductions' full value to society. A portion of this CO_2 marginal abatement cost will be reflected in the allowance price for emissions, and thus embedded in the avoided costs; the balance may be referred to as a non-embedded cost.

States that have established targets for climate mitigation comparable to the targets discussed in section 4.3.1, or that are contemplating such action, could view the $100/t CO_2 marginal abatement cost as a reasonable estimate of the societal cost of carbon emissions, and hence as the long-term value of the cost of reductions in carbon emissions required to achieve those targets.

Like any long-run projections, this estimate of the marginal abatement cost includes important uncertainties in underlying assumptions regarding the extent of technological innovation, the selected emission reduction targets, the technical potential of key technologies, and the evolution of international and national policy initiatives, along with a variety of other influencing factors. It will be necessary to review available information and reassess what value is reasonable given the best state of knowledge at the time of future reviews.

[124] ETP 2014, converted from $80/metric ton in 2012 dollars. This calculation assumes gas prices of $4/MMBtu.

Estimating Non-Embedded CO_2 Costs for New England

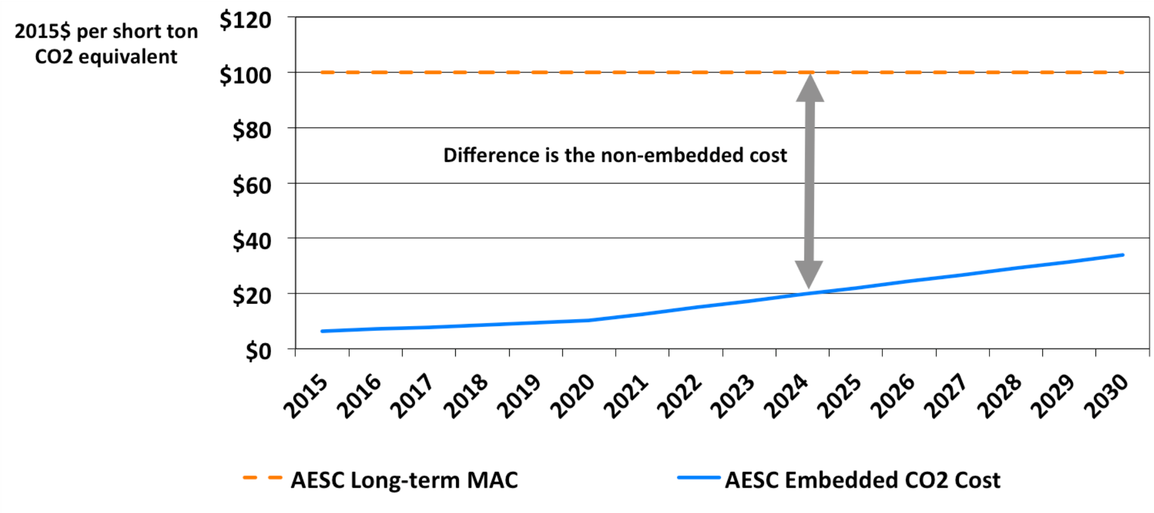
The non-embedded value for New England's CO_2 emissions in each year was calculated as the estimated marginal abatement cost of $100 per short ton in 2015 dollars less the annual allowance values embedded in the projected electric energy market prices. These values are summarized in Exhibit 4-5.

Exhibit 4-7. AESC 2015 Non-Embedded CO_2 Costs (2015 dollars per short ton CO_2)

	Marginal Abatement Cost	Allowance Price	Externality
	a	b	c = a - b
2015	$100	$6.28	$93.72
2016	$100	$7.26	$92.74
2017	$100	$7.87	$92.13
2018	$100	$8.47	$91.53
2019	$100	$9.32	$90.68
2020	$100	$10.16	$89.84
2021	$100	$12.54	$87.46
2022	$100	$14.92	$85.08
2023	$100	$17.30	$82.70
2024	$100	$19.67	$80.33
2025	$100	$22.05	$77.95
2026	$100	$24.43	$75.57
2027	$100	$26.80	$73.20
2028	$100	$29.18	$70.82
2029	$100	$31.56	$68.44
2030	$100	$33.94	$66.06

The annual allowance values embedded in the projected electric energy market prices are shown in column b. These carbon prices were included in the generators' bids in the dispatch model runs and therefore are embedded in the AESC 2015 avoided electricity costs. The non-embedded value in each year is the difference between the marginal abatement cost ($100/t) and the value of the embedded carbon price shown in column c. Exhibit 4-6 illustrates the relationship between the embedded and non-embedded CO_2 cost.

Exhibit 4-8. Non-Embedded Cost of CO_2 Emissions (2015$/short ton of CO_2 equivalent)



Comparison to AESC 2013

The AESC 2015 value for the CO_2 marginal abatement cost of $100/ton is the same in nominal terms as the AESC 2013 value. Because the AESC 2015 embedded CO_2 cost is lower than that of AESC 2013, the non-embedded cost is correspondingly higher.

Applying Non-Embedded CO_2 Costs in Evaluating Energy Efficiency Programs

The non-embedded values from Exhibit 4-5 are incorporated as a separate value in the avoided electricity cost workbooks and expressed as dollars per kWh based upon our analysis of the CO_2 emissions of the marginal generating units summarized below. We recommend that program administrators include these values in their analyses of energy efficiency programs unless specifically prohibited from doing so by state or local regulations. At a minimum, program administrators should calculate the costs and benefits of energy efficiency programs with and without these values in order to assess their incremental impact on the cost-effectiveness of programs.

4.4 Value of Mitigating Significant Pollutants

4.4.1 Electricity Generation

Pollutants and Their Significance

Impacts associated with electricity production and uses include a wide variety of air pollutants, water pollutants, and land use impacts. These include the following:

- Air emissions (including SO_2, NO_x and ozone, particulates, mercury, lead, other toxins, and greenhouse gases) and the associated health and ecological damages

- Fuel cycle impacts associated with "front end" activities such as mining and transportation, and waste disposal
- Water use and pollution
- Land use
- Aesthetic impacts of power plants and related facilities
- Radiological exposures related to nuclear power plant fuel supply and operation (routine and accident scenarios)
- Other non-embedded impacts, such as economic impacts (generally focused on employment), energy security, and others

Over time, regulations limiting emission levels have forced suppliers and buyers to consider at least a portion of these costs in their production and use decisions, thereby embedding a portion of these costs in electricity prices. We anticipate that the non-embedded carbon cost will continue to be the dominant non-embedded environmental cost associated with marginal electricity generation in New England.

For AESC 2015, our approach to quantifying the reduction in physical emissions due to energy efficiency is as follows:

- Identify the marginal unit in each hour in each transmission area from our energy model;
- Draw the heat rates, fuel sources, and emission rates for NO_x and CO_2, of those marginal units from the database of input assumptions used in our pCA simulation; and
- Calculate the physical environmental benefits from energy efficiency and demand reductions by calculating the emissions of each of those marginal units in terms of lbs/MWh. We do this by multiplying the quantity of fuel burned by each marginal unit by the corresponding emission rate for each pollutant for that type of unit and fuel.

The calculations for each pollutant in each hour are as follows:

$$\text{Marginal Emissions} = [\text{Fuel Burned}_{MU}\ (\text{MMBtu}) \times \text{Emission Rate}_{MU}\ (\text{lbs/MMBtu}) \times 1\ \text{ton}/2000\ \text{lbs}]/\text{Generation}_{MU}\ (\text{MWh})$$

Where:

Fuel Burned$_{MU}$	=	the fuel burned by the marginal unit in the hour in which that unit is on the margin,
Emission Rate$_{MU}$	=	the emission rate for the marginal unit, and
Generation$_{MU}$	=	generation by the marginal unit in the hour in which that unit is on the margin.

Value of Mitigating Significant Pollutants

The scope of work for AESC 2015 asks for the heat rates, fuel sources, and emissions of NO_x, and CO_2 of the marginal units during each of the energy and capacity costing periods in the 2015 base year. It also asks for the quantity of environmental benefits that would correspond to energy efficiency and demand reductions, in pounds per MWh, respectively, during each costing period.

Exhibit 4-9 summarizes the marginal heat rate and marginal fuel characteristics from the model results. The results are based on the marginal unit in each hour in each transmission area, as reported by the model. Once the marginal units are identified, we extracted the heat rates, fuel sources, and emission rates for the key pollutants from the database of input assumptions used in our pCA simulation of the New England wholesale electricity market.

Exhibit 4-9. 2015 New England Marginal Heat Rate by Pricing Period

	Summer		Winter		Grand Total
	Off Peak	On Peak	Off Peak	On Peak	
Marginal Heat Rate (BTU/kWh)	8,261	9,551	8,236	8,866	8,495

Exhibit 4-10. 2015 New England Marginal Fuel by Percentage

Marginal Fuel Type	Summer		Winter		Grand Total
	Off Peak	On Peak	Off Peak	On Peak	
Natural gas	85%	85%	85%	83%	85%
Oil	1%	3%	11%	16%	9%
Coal	9%	12%	4%	1%	5%
Nuclear	0%	0%	0%	0%	0%
Other	4%	0%	1%	0%	1%
Renewable	0%	0%	0%	0%	0%
Grand Total	100%	100%	100%	100%	100%

The avoided emissions values shown in the exhibits below represent the averages for each pollutant over each costing period for all of New England in pounds per MWh. The emission rates are presented by modeling zone; however, differences between zones tend to be relatively minor.

Exhibit 4-11. 2015 New England Avoided CO_2 and NO_x Emissions by Pricing Period

Marginal Emission Type	Summer		Winter		Grand Total
	Off Peak	On Peak	Off Peak	On Peak	
CO_2 Rate (lbs/MWh)	1,040	1,086	1,007	1,019	1,029
NO_x Rate (lbs/MWh)	0.446	0.412	0.405	0.480	0.437

Our recommended dollar values to use for relevant "embedded" avoided pollutant emissions are summarized in Exhibit 4-1. Our recommended dollar value to use for non-embedded carbon costs is provided in Exhibit 4-7.

4.4.2 End-Use Natural Gas

We estimate the environmental benefit from reduced combustion of end-use natural gas due to energy efficiency programs with the following analyses:

- Identifying the various pollutants created by the combustion, and assessing which of them are significant and how, if at all, the impact of those pollutants is currently embedded in the cost of natural gas.
- Finding the value associated with mitigation of each significant pollutant and the portion that should be treated as a non-embedded cost.

Natural gas consists of methane (generally above 85 percent) and varying amounts of ethane, propane, butane, and inert gases (typically nitrogen, carbon dioxide, and helium) (EPA 1999).

In general, the combustion in boilers and furnaces generate the following pollutants (EPA 1999, 1.4-2–5):

- Oxides of nitrogen (NO_x)
- Sulfur oxides (SO_x) (trace levels),[125]
- CO_2 and other greenhouse gases
- Particulates (trace levels)
- Volatile organic compounds
- Carbon monoxide

Pollutants and their Significance

To estimate the absolute quantities of each pollutant from the combustion of natural gas relative to the absolute quantity of each from all sources, we began by estimating the quantity of each that is emitted per MMBtu of fuel consumed. Exhibit 4-12 provides emissions factors for NO_x and CO_2 for three generalized boiler type categories.

[125] Sulfur is generally added as an odorant to natural gas, which generates trace quantities of sulfur oxides when combusted.

Exhibit 4-12. Emission Rates of Significant Pollutants

Boiler Type	NO_x (lbs/MMBtu)	CO_2 (lbs/MMBtu)
Residential boiler	0.092	118
Commercial boiler	0.098	118
Industrial boilers	0.137	118

Notes:

NO_x emissions from industrial boilers without low NO_x burners would be 0.274 lb/MMBtu. We assumed these boilers were controlled in order to be conservative.

NO_x and CO_2 emissions factors for all boilers utilized conversion rate of 1,020 Btu/scf.

Source:

Environmental Protection Agency, AP-42, Volume I, Fifth Edition, January 1995, Chapter 1, External Combustion Sources. http://www.epa.gov/ttnchie1/ap42/

We apply the pollutant emission rates for these sectors to the quantity of natural gas consumed by each in New England in 2013. The resulting estimated annual quantities of NO_x and CO_2, along with those for electric generation, are presented in Exhibit 4-13.

Exhibit 4-13. 2013 Pollutant Emissions in New England from Natural Gas

Sector	NO_x (tons)	CO_2 (tons)
Residential	9,766	12,466,973
Commercial	8,150	9,780,545
Industrial	8,675	7,435,983
R, C & I Total [a]	**26,592**	**29,683,501**
Electric Generation [b]	3,582	22,521,319

Sources:

[a] Based on gas volumes from Energy Information Administration, http://tonto.eia.doe.gov/dnav/ng/ng_cons_sum_a_EPG0_vrs_mmcf_a.htm

[b] Electric generation emissions from Environmental Protection Agency AMPD Database, http://ampd.epa.gov/ampd/?bookmark=5342

Exhibit 4-13 illustrates that combustion of natural gas is a source of both NO_x and CO_2 emissions. Moreover, these emissions are not currently subject to regulation, as explained below.

- **CO_2:** RGGI applies to electric generating units larger than 25 MW. New England CO_2 emissions for 2013 were 22.5 million tons. The total CO_2 emissions from the end-use sectors above would represent about 57 percent of the total CO_2 emissions, if such emissions were included.
- **NO_x:** The Clean Air Interstate Rule applied only to Massachusetts and Connecticut during the ozone season, as its successor is likely to. New England NO_x emissions for 2013 were

approximately 3,600 tons for just the electric generating sector.[126] The total NO_x emissions from the end-use sectors above would represent about 88 percent of the total NO_x budget if such emissions were included.

Value of Mitigating Significant Pollutants

We estimate the value associated with mitigation of NO_x and CO_2 as the product of the emissions allowance prices presented in Exhibit 4-1 and emission rates in Exhibit 4-12.[127] In addition, for states with aggressive carbon mitigation targets, we provide a value of reducing CO_2 based upon the $100/ton long-term marginal abatement cost of carbon dioxide reduction. The values by end-use sector are summarized below in Exhibit 4-14.

As noted previously, natural-gas combustion is not a significant source of SO_2 emissions. Consequently, we have not included an emission value for SO_2.

[126] A few large sources in the industrial sector are included in CAIR. These include municipal waste combustors, steel and cement plants, and large industrial boilers (such as those located at Pfizer in New London, CT and General Electric in Lynn, MA). However, the number of NO_x allowances used, sold, and traded for the industrial sector is very small. A few allowances in each state are allocated to non-electric generating units compared to thousands of allowances used, sold and traded for electric generating units.

[127] The full non-embedded value associated with NO_x emissions is probably not captured in the allowance price from electricity generation; however, determining that non-embedded value is beyond the scope of this project.

Exhibit 4-14. Annual Pollutant Emission Values by Sector (2015$/MMBtu)

	Residential			Commercial			Industrial		
	NO_x	CO_2	CO_2 at $100/ton	NO_x	CO_2	CO_2 at $100/ton	NO_x	CO_2	CO_2 at $100/ton
2015	$0.000	$0.37	$5.88	$0.000	$0.37	$5.88	$0.001	$0.37	$5.88

2028	$0.001	$2.20	$5.88	$0.001	$2.20	$5.88	$0.001	$2.20	$5.88
2029	$0.001	$2.43	$5.88	$0.001	$2.43	$5.88	$0.001	$2.43	$5.88
2030	$0.001	$2.66	$5.88	$0.001	$2.66	$5.88	$0.001	$2.66	$5.88
Levelized (2015$/MMBtu)									
5 year (2016-20)	$0.000	$0.54	$5.88	$0.001	$0.54	$5.88	$0.001	$0.54	$5.88
10 year (2016-25)	$0.001	$0.84	$5.88	$0.001	$084	$5.88	$0.001	$084	$5.88
15 year (2016-30)	$0.001	$1.24	$5.88	$0.001	$1.24	$5.88	$0.001	$1.24	$5.88

Notes:
Based on Emission Rates of Significant Pollutants for Natural Gas in Exhibit 4-12.
Pollutant values based on emission allowance prices detailed in Exhibit 4-1 and $100/short ton long-term marginal abatement cost for CO_2.

The entire amount of each value is a non-embedded cost. With the exception of those industrial sources subject to the EPA NO_x budget programs, which represent a small fraction of the total emissions, none of these emissions are currently subject to environmental requirements. Therefore, none of these values are embedded in their market prices.

4.4.3 End-Use Fuel Oil and Other Fuels

We estimate the environmental benefit from reduced combustion of fuel oil and other fuels due to energy efficiency programs with the following analyses:

- Identifying the various pollutants created by the combustion, and assessing which of them are significant and how, if at all, the impact of those pollutants is currently embedded in the cost of the studied fuels.
- Finding the value associated with mitigation of each significant pollutant and the portion that should be treated as a non-embedded cost.

The pollutant emissions associated with the combustion of fuel oil are dependent on the fuel grade and composition, boiler characteristics and size, combustion process and sequence, and equipment maintenance (EPA 1999 1.3-2). [128]

In general, the combustion in boilers and furnaces generate the following pollutants (EPA 1999, 1.4-2–5):

- Oxides of nitrogen (NO_x)
- Sulfur oxides (SO_x)
- CO_2 and other greenhouse gases
- Particulates
- Volatile organic compounds
- Carbon monoxide
- Trace elements
- Organic compounds

Pollutants and Their Significance

Like the combustion of natural gas, NO_x, SO_x, and CO_2 are potentially the most significant pollutants.[129] NO_x is a precursor to the unhealthy concentrations of ozone that areas in New England continue to experience. The region is also required to reduce NO_x and SO_x emissions by EPA programs, implement state low sulfur fuel requirements, and participate in the RGGI program to reduce CO_2 from the power sector, as described in Section 4.2.2.

For the electric generation sector, the forecast of emissions allowance prices value of mitigating emissions of from the combustion of NO_x, SO_x, and CO_2 is shown in Exhibit 4-1.

In order to estimate the absolute quantities of each pollutant from the combustion of fuels by sector, we began by estimating the quantity of each pollutant that is emitted per MMBtu of fuel consumed.[130] The pollutant emissions associated with the combustion of wood are dependent on the species of wood, moisture content, appliance used for its combustion, combustion process, and sequence and equipment

[128] EPA, 1999. "Stationary Point and Area Sources" v. 1 of Compilation of Air Pollutant Emission Factors 5th Ed. AP-42. Triangle Park, N.C.: U.S. Environmental Protection Agency. (Section 1.3-2)

[129] Wood combustion may contribute to an accumulation of unhealthy concentrations of fine particulate matter ($PM_{2.5}$). This is especially true in many valleys, where pollutants accumulate during stagnant meteorological conditions. The regulation of $PM_{2.5}$ from wood combustion is a state by state process. No comparable regionally consistent or market-based program of allowances have been established for $PM_{2.5}$, like those described above for SO_x, NO_x, and CO_2.

[130] Number-6 fuel oil has about the same rate of SO_2 emissions as distillate, about twice the rate of NO_x emissions and about seven percent higher rate of CO_2 emissions.

maintenance. The pollutant emissions associated with the combustion of kerosene are similar to those associated with the combustion of distillate oil, and depend upon boiler characteristics and size, combustion process and sequence, and equipment maintenance (EPA 1999, 1.3-2).

Exhibit 4-15 provides emissions factors for each fuel based on predominant sector-specific characteristics.

Exhibit 4-15. Emission Rates of Significant Pollutants from Fuel Oil

Sector and Fuel	SO_2 (lbs/MMBtu)	NO_x (lbs/MMBtu)	CO_2 (lbs/MMBtu)
#2 Fuel Oil [a,b]			
Residential, #2 oil	0.002	0.129	163
Commercial, #2 oil	0.002	0.171	163
Industrial, #2 oil	0.002	0.171	163
Kerosene—Residential heating [c]	0.152	0.129	173
Wood—Residential heating [d]	0.020	0.341	N/A

Notes:
For fuel oil, assumed sulfur content of 15 ppm.

Next, we applied those pollutant emission rates to the quantity of each fuel consumed by sector in New England in 2012 (Exhibit 4-16), with one exception: EIA supply data for 2012 indicated a supply mix of approximately 20% low sulfur distillate and 80% ULSD. For this reason, we assumed a weighted average sulfur content of 112 ppm rather than 15 ppm. The results are shown in Exhibit 4-17.

SO_2 emissions for #2 fuel oil based on weighted average fuel sulfur content of 112 ppm for low sulfur heating oil.
Includes entire state of Maine, not just portion within ISO-NE.

Value of Mitigating Significant Pollutants

Emissions of NO_x, SO_x, and CO_2 from the combustion of these fuels are not currently subject to regulation, as explained below.

All of these values are non-embedded values.

- SO_2 and CO_2: The acid rain program and RGGI apply to electric generating units larger than 25 MW. New England SO_x emissions from electric generating units for 2012 were approximately 35,800 tons. The total SO_x emissions from the end-use sectors above would represent approximately 5 percent of the total SO_x emissions, if such emissions were included.[131] New England electric generation CO_2 emissions for 2012 were approximately 38.2 million tons. The calculated CO_2 emissions from the non-electric end-use sectors above would represent approximately 55 percent of the total CO_2

[131] Northeastern states began in 2012 to phase in requirements for ultra-low sulfur distillate (ULSD, 15 ppm sulfur). With the exception of New Hampshire, the transition to new requirements will be complete by mid-2018. In conjunction with this transition, the Northeast Home Heating Oil Reserve converted to ULSD in 2011, and in 2013, NYMEX switched its specification for the heating oil futures contract to the ULSD specification. As a result, approximately 80% of the supply (as indicated by 2012 EIA data) had shifted to the new specification by 2012. Taking the lower sulfur content into account in our analysis of 2012 resulted in a significant decrease in the estimate for fuel oil SO_2 emissions, relative to the AESC 2013 estimate for 2011.

emissions shown here, with natural gas accounting for 30 percent and other fuels accounting for 24 percent.

- NO_x: The Ozone Transport Commission–EPA NO_x budget program applies to electric generating units larger than 15 MW and to industrial boilers with a heat input larger than 100 MMBtu per hour. New England NO_x emissions for 2012 were approximately 43,000 tons for just the electric generating sector.[132] The calculated NO_x emissions from the non-electric end-use sectors above would represent approximately 52 percent of the total NO_x emissions shown here, split evenly between natural gas and other fuels.

The allowance prices associated with electricity generation for NO_x and SO_x represent the value associated with mitigating these emissions on the 2015 NO_x and SO_2 emissions allowance prices per short ton in Exhibit 4-1, the value AESC 2015 has internalized in its forecast consistently across fuels as noted elsewhere in this chapter.[133] Those values, per MMBtu of fuel, are presented in Exhibit 4-18.

Because we have estimated the full cost of CO_2 mitigation, and because none of that cost is embedded in the prices of non-electricity fuel use, the value of CO_2 shown in Exhibit 4-18 is the long-term marginal abatement cost of $100/ton, presented here per MMBtu of fuel.

Exhibit 4-18. Value of Pollutant Emissions from Fuel Oil in 2015 (2015$/MMBtu)

Sector	SO_2	NO_x	CO_2
Residential	$0.0000	$0.0001	$8.16
Commercial	$0.0000	$0.0001	$8.15
Industrial	$0.0000	$0.0001	$8.15

With the exception of those industrial sources subject to the EPA NO_x budget program, which represent a small fraction of the total emissions, none of the non-electric emissions shown in Exhibit 4-17 are currently subject to environmental requirements.[134] None of the values shown in Exhibit 4-18, therefore, are internalized in the relevant fuels' market prices.

The values by year for fuel oil over the study period are presented in Appendix E.

[132] A few large sources in the industrial sector are included in the NO_x budget program. These include municipal waste combustors, steel and cement plants and large industrial boilers (such as those located at Pfizer in New London, Connecticut, and General Electric in Lynn, Massachusetts). However, the number of NO_x allowances used, sold and traded for the industrial sector is very small. A few allowances in each state are allocated to non-electric generating units compared to thousands of allowances used, sold, and traded for electric generating units.

[133] The full externality value associated with SO_x and NO_x emissions is probably not captured in the allowance price from electricity generation associated with these two pollutants; however, determining that externality value is beyond the scope of this project.

[134] EPA. Factsheet: EPA's Final Air Toxics Standard Major and Area Source Boilers and Certain Incinerators Overview of Rules and Impacts. Available at http://www.epa.gov/airquality/combustion/docs/overviewfsfinal.pdf. Accessed January 30, 2015.

4.5 Discussion of Non-Embedded NO_x Costs

This section addresses the request in the AESC 2015 scope of work to provide a discussion of non-embedded NO_x costs. We are not recommending an additional non-embedded NO_x value additive to the embedded allowance prices based on the analysis discussed in this section; rather, we recommend an approach consistent with AESC 2013, and detailed below.

4.5.1 Health Impacts and Damages

NO_x emitted from the combustion of coal and natural gas reacts with compounds in the air ("precursors") to produce ozone, particulate matter ("PM2.5"), and acid rain. Both PM2.5 and ozone are EPA criteria pollutants that have been shown to have harmful effects on human health, and are regulated under the Clean Air Act. Quantifying the value associated with damages from NO_x emissions is a particularly complicated process. Most studies look at incidence rates of premature death and chronic respiratory diseases such as bronchitis, emphysema, and asthma in order to evaluate health impacts. The reaction of NO_x with precursors to form PM2.5 and ozone is highly dependent on atmospheric conditions and local emissions of other precursors. Fowlie and Muller use a stochastic model to estimate damages and quantify health impacts for 565 coal plants, with average impacts on human health to be valued at $1,795/ton NOx. The intra-source variation in damage estimates they found was considerable; their damage estimate for a representative source in Ohio was $1,549/ton NO_x, with a standard deviation of $1,859/ton (2015 dollars).[135] Mauzerall et al. found a similar level of uncertainty in an earlier study, citing one location where the health impact of emissions nearly doubled within a short span of time as the temperature changed. [136] EPA has used the BenMAP tool to calculate benefits of NO_x reduction based on reduced mortality from particulate matter, and calculates 2015 national benefits of approximately $20,000/ton for electricity generation and $13,000/ton for non-electricity sources (2015 dollars), with considerable variation in benefit levels among the nine metropolitan areas examined.[137]

The analyses above do not include valuation of the impacts of environmental effects resulting from nitrogen deposition, or visibility impairment from increased haze.

[135] Fowlie, M. N. Muller (2013) "Market-Based Emissions Regulation When Damages Vary Across Sources: What Are the Gains from Differentiation?" (With appendices). National Bureau of Economic Research. NBER Working Paper No. 18801. $1,734, $1,496, and $1,976 in 2013 dollars, respectively. http://nature.berkeley.edu/~fowlie/papers.html

[136] Mauzerall, D.L., B. Sultan, N. Kim, and D.F. Bradford. 2005. "NO_x emissions from large point sources: Variability in ozone production, resulting health damages and economic costs." Atmos. Environ. 39(16):2851-2866

[137] EPA (2015). "RSM-based Benefit per Ton Estimates." Values in 2006$: $17,000 and $11,000. Accessed January 30, 2015. Available at: http://www.epa.gov/oaqps001/benmap/bpt.html

4.5.2 Abatement Costs

In New England, significant progress on NO_x abatement has already been made, marked by rapid reductions over the past decade (see Exhibit 4-19).

Market prices for NO_x emissions fall far below the estimated costs of health impacts. AESC 2013 embedded NO_x prices were approximately $28 per ton; by the end of 2014, values for costs of NO_x mitigation under CAIR had fallen substantially from those cited in AESC 2013 to levels in the $10/ton range. With the replacement of CAIR by CSAPR, NO_x mitigation costs in New England are currently uncertain.[138]

Connecticut and Massachusetts had been included in the ozone-season CAIR program, but not in CSAPR because air quality modeling shows they no longer contribute significantly to nonattainment of the 1997 ozone or 1997 and 2006 PM NAAQS in other states.[139] Nevertheless, the two states had relied on CAIR reductions to comply with air quality obligations under Regional Haze and ozone NAAQS. Options to maintain the reductions include intrastate NO_x trading programs, and enforceable ozone season emission limits on CAIR units; a number of SIPs in the two states will likely need amending in order to meet remaining obligations. Once more information is available about a potential Federal CAIR replacement for New England, and amended SIPs are in place, the impact on future compliance costs should become more apparent.

[138] With the restarting of CSAPR in January 2015, CSAPR NO_x allowance prices traded in the $250/ton range, although those prices are irrelevant to generators in the New England states, which are not subject to the rule.

4.6 Compliance with State-Specific Climate Plans

The AESC 2015 scope of work required the project team to determine if there was some component of compliance with state-specific regulations or climate plans that would directly impact generators and that the project team could quantify and credibly support. The scope of work further required the project team, if it made such a determination, to include their estimate of that compliance cost in one of the three categories of costs related to emissions control reflected in the AESC 2015 avoided energy cost forecast. (Those three categories of emissions control costs are "currently enforced," "enacted, but not yet in effect," and "reasonably expected to be enacted.") This is because, due to the nature of the regional market, the costs of complying with one state's law may also affect avoided costs in other states in the New England market. The scope notes that AESC 2015 was not to determine the value of full compliance with these plans, laws, or regulations or the impact of energy efficiency on other sectors that may also be covered by them, such as transportation or industry, in achieving the overall objectives of the plan, law or regulation.

The project team is not aware of any instances of state-specific climate plans that will *directly* affect generators, other than those already discussed and accounted for in the analysis of embedded environmental costs associated with state compliance with regional or Federal standards and costs associated with renewable portfolio standards.

As described above, there is one proceeding that could impact the estimate of non-embedded costs in Massachusetts, i.e., DPU Docket No. 14-86. In that proceeding the Massachusetts DEP and DOER filed a joint petition requesting the DPU to determine whether the existing method of calculating the costs of reducing GHG emissions to comply with the Global Warming Solutions Act (GWSA) should be replaced by a marginal abatement cost curve approach, and that Program Administrators incorporate estimates of avoided GWSA compliance costs in energy efficiency cost-effectiveness analyses. The petitioners have filed estimates of GWSA compliance costs and have asked the DPU to order that these values be used.[140] The proceeding is still underway as of this writing, and the DPU has not yet made a determination. It should be noted that the marginal abatement cost for Massachusetts to achieve compliance with the GWSA are not comparable with the global marginal abatement costs to achieve specific atmospheric CO_2 concentrations, discussed above.

Additionally as described above, Mass DEP in early January 2015, published a proposed "Clean Energy Standard" regulation for public comment. A Massachusetts CES would implement one of the strategies in the CECP, and providing a long-term incentive to ensure ongoing progress toward reducing greenhouse gas emissions by 80 percent by 2050. The proposed regulation would qualify clean energy generators based on a generic 50 percent-below-natural-gas threshold, and would count RPS compliance toward CES compliance, with CES targets exceeding RPS targets. Resources outside ISO-NE such as Canadian hydro would be required to use transmission that commenced operation after 2010.[141] Public comment on the proposed regulations is being accepted through April 27, 2015.

[140] For the proposed values and a description of the proposed approach, see "Amended Direct Testimony of Elizabeth A. Stanton On Behalf of the Department of Energy Resources and the Department of Environmental Protection Regarding the Cost of Compliance with the Global Warming Solutions Act," September 16, 2014, filed in MA D.P.U. No. 14-86.

[141] "Summary of Proposed MassDEP Regulation: Clean Energy Standard (310 CMR 7.75)," Available at: http://www.mass.gov/eea/docs/dep/air/climate/ces-fs.pdf. Additional information available at http://www.mass.gov/eea/agencies/massdep/climate-energy/climate/ghg/ces.html.

Chapter 5: Avoided Electric Energy and Capacity Costs

This chapter provides projections of avoided electric energy and capacity market prices, as well as Renewable Portfolio Standard (RPS) compliance costs that are not embedded in those market prices. We present the projections of electric energy and capacity market prices in the same chapter because these projections are directly interrelated, capacity prices in the long-term affect energy prices in the long-term and vice versa.

The chapter presents projections of avoided electric energy and capacity market prices for two cases, a Base Case and a BAU Case. The Base Case assumes no reductions from new ratepayer funded energy efficiency programs approved from January 2015 onward except for the reductions which have been bid into the Forward Capacity Auctions for power years through May 2018. The BAU Case assumes a continuation of reductions from ratepayer funded energy efficiency at the levels reflected in ISO-NE forecasts.

This chapter is organized as follows:

- Section 5.1S provides an overview of wholesale energy and capacity markets in New England.
- Section 5.2 describes the model AESC 2015 used to simulate the operation of those two markets.
- Section 5.3 describes the common assumptions AESC 2015 used to simulate the operation of those two markets.
- Section 5.4 describes the assumptions AESC 2015 used solely to simulate the operation of the capacity market;
- Section 5.5 presents the Base Case projections and compares those results to AESC 2013. Appendix B provides detailed results for each year of the study period, by zone by season, by period (i.e. on-peak, off-peak);
- Section 5.6 presents the projections of RPS compliance costs. Appendix F provides detailed renewable energy certificate (REC) price forecasts and avoided RPS costs by state for each year of the study period; and
- Section 5.7 presents an assessment of alternative electric energy costing periods.

5.1 New England Wholesale Energy and Capacity Markets

5.1.1 Wholesale Energy Markets

ISO New England (ISO-NE) manages two primary wholesale energy markets, Day-Ahead and Real-Time, with the objective of:

> The primary objective of the electricity markets operated by ISO New England is to ensure a reliable and economic supply of electricity to the high-voltage power grid. The markets include a Day-Ahead Energy Market and a Real-Time Energy Market. In what is termed a multi-settlement system, each of these markets produces a separate but related financial settlement.142

Most transactions are scheduled in the Day-Ahead Market, with transactions in the Real-Time Market limited to balancing actual supplies with actual demands in real time. On average energy prices in the markets are very close, although real-time market prices exhibit greater volatility.

The Day-Ahead Energy Market produces financially binding schedules for the sale and purchase of electricity one day before the operating day. However, supply or demand for the operating day can change for a variety of reasons, including forecast error for load and for variable resources such as wind and solar, generator reoffers of their supply into the market, real-time hourly self-schedules (i.e., generators choosing to be on line and operating at a fixed level of output regardless of the price of electric energy), self-curtailments, transmission or generation outages, and unexpected real-time system conditions.

Physically, real-time operations balance instantaneous changes in supply and demand and ensure that adequate reserves are available to operate the transmission system within its limits. Financially, the Real-Time Energy Market settles the differences between the day-ahead scheduled amounts of load and generation and the actual real-time load and generation. Participants in this market either pay, or are paid, the real-time locational marginal price (LMP) (see below) for the amount of load or generation in megawatt-hours (MWh) that deviates from their day-ahead schedule.

Unit Commitment

In a power system the supply curve in a given hour is defined by the set of generating units committed to run in that hour. The process through which the system operator, in New England it is ISO NE, schedules individual generating units to be run in a given hour of a given day, or not run in that hour of that day, is referred to as "unit commitment". [143]

[142] ISO-New England 2010 Annual Market Report (2011, 29–30)

[143] Lelic, Lzudin. Unit Commitment & Dispatch, Introduction to Wholesale Electricity Markets (WEM 101), ISO NE, September 15-19, 2014

Unit commitment is related to, but different from, economic dispatch. The goal of the unit commitment decision is find the least-cost mix of units to supply energy for the 24 hours period for which the decision is being made, plus at least another 24 hours of the look-ahead time to correctly assess the future implications of decisions made for the first 24 hours. Thus, ISO NE is making unit commitment decisions for a 24 hour period, not a 1 hour period. ISO NE makes unit commitment decisions for each unit based on the unit's operational constraints in addition to the load to be served and the economics of the unit. The operational constraints include minimum up- and down-times, minimum operating limits, and start-up costs

ISO New England makes its initial unit commitment decision prior to the power day, and then makes additional decisions during the day. For a given day, ISO New England makes its first (and financially binding) unit commitment decision by 13:30 on a preceding day – Day-ahead market clearing and formation of day-ahead LMPs. After that ISO-NE immediately opens re-offer period and by 17:00 of the preceding day produces an update to the unit commitment decision through the process known as Resource Adequacy Assessment (RAA)/security constrained reliability assessment (SCRA). During the operating day, ISO NE continues to perform SCRA for that day. At each unit commitment decision ISO NE effectively modifies the set of committed generating resources influencing price formation. One of the most critical inputs into the unit commitment process is the level of demand anticipated to be served during the entire optimization horizon of the unit commitment process. In the day ahead market, the demand is determined through demand bids, decrement bids and export external transactions. In the RAA/SCRA, ISO New England augments bid information with current demand forecasts.

ISO NE produces unit commitment decisions by solving advanced algorithms of the mixed integer linear programming problem. In formulating and solving this problem, ISO NE considers not only fuel and variable O&M costs submitted by generation owners though supply offers, but also start-up costs and opportunity costs associated with running energy limited resources such as hydro and pumped storage resources. This problem is essentially a dynamic optimization problem with economic and operational considerations spanning over 24 hours of the day for which the problem is being solved plus at least another 24 hours of the look-ahead time to correctly assess the future implications of decisions made for the first 24 hours. The solution to this problem is sensitive to the level of load that the power system is projected to serve.

Locational Marginal Prices

Wholesale electric energy prices are set at various pricing points or "nodes" throughout New England referred to as "pnodes". These prices, referred to as "locational marginal prices" (LMP), reflect the value of electric energy at those specific locations by accounting for the patterns of load, generation, and the physical limits of the transmission system at those locations. New England wholesale electricity prices are identified at 900 pnodes on the bulk power grid. If the system were entirely unconstrained and had no losses, all LMPs would be the same, reflecting only the cost of serving the next increment of load. This incremental megawatt of load would be served by the generator with the lowest-cost energy offer available to serve that load, and electric energy from that generator would be able to flow to any node on the transmission system. LMPs differ among locations during time periods when transmission and reserve constraints prevent the next-cheapest megawatt (MW) of electric energy from reaching all locations of the grid. In addition, even during periods when the cheapest megawatt can reach all locations, the marginal cost of physical losses will result in different LMPs across the system.

New England has five types of pnodes, with "hub" nodes representing load-weighted prices for uncongested areas, or load zones. New England currently has eight load zones: Maine (ME), New Hampshire (NH), Vermont (VT), Rhode Island (RI), Connecticut (CT), Western/Central Massachusetts (WCMA), Northeast Massachusetts and Boston (NEMA), and Southeast Massachusetts (SEMA). Generators are paid the day-ahead and real-time LMP for electric energy at their respective nodes, and participants serving demand pay the price at their respective load zones.

Import-constrained load zones are areas within New England that must use more expensive generators than the rest of the system because local, inexpensive generation or transmission-import capability is insufficient to meet both local demand and reserve requirements. Export-constrained load zones are areas within New England where the available resources, after serving local load, exceed the areas' transmission capability to export excess electric energy.

5.1.2 Wholesale Capacity Markets

ISO New England describes this market as follows:

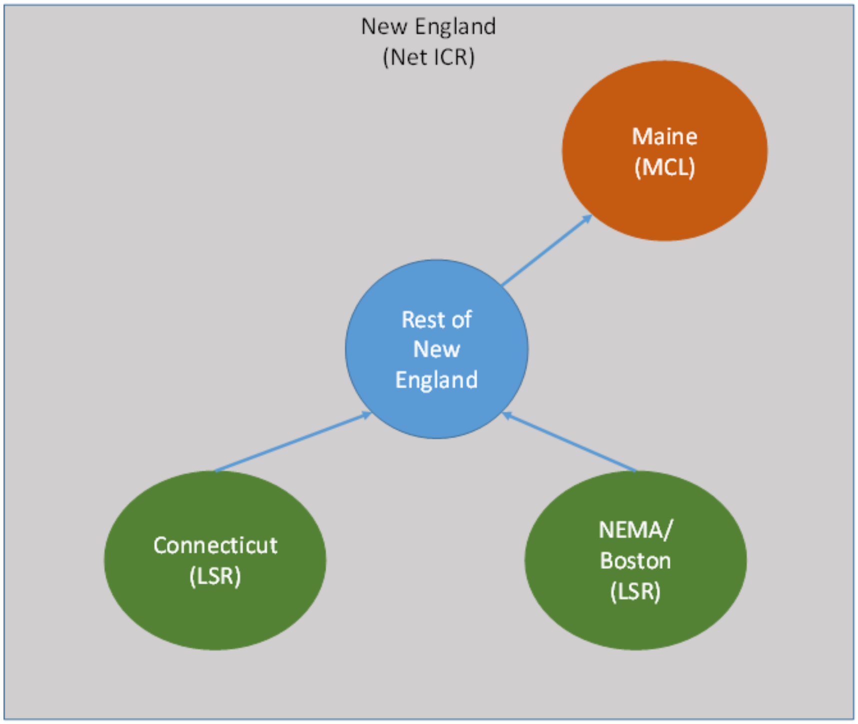
> [t]he Forward Capacity Market is a long-term wholesale market that assures resource adequacy, locally and system wide. The market is designed to promote economic investment in supply and demand resources where they are needed most. Capacity resources may be new or existing resources and include supply from power plants, import capacity, or the decreased use of electricity through demand resources. To purchase enough qualified resources to satisfy the region's future needs and allow enough time to construct new capacity resources, Forward Capacity Auctions (FCAs) are held each year approximately three years in advance of when the capacity resources must provide service. Capacity resources compete in the annual FCA to obtain a commitment to supply capacity in exchange for a market-priced capacity payment.[144]

ISO NE uses FCAs to ensure a sufficient quantity of capacity is available to serve the region in each power year, i.e., June 1 to May 31. This quantity, the "installed capacity requirement' or ICR, is equal to the projected peak for the year plus a reserve margin. The ICR defined for the entire system does not reflect locational capacity requirements due to transmission constraints preventing ISO NE from using every MW of installed capacity to meet demand at any location on the system. Unlike energy market, in which transmission constraints are represented explicitly, in the FCA design transmission limitations are implicit in the determination of locational requirements for installed capacity. To determine these locational requirements, ISO New England uses a sophisticated probabilistic modeling of the electrical

[144] "Introduction to New England's Forward Capacity Market. ISO 101," ISO New England.

grid. This modeling is conducted annually and employs General Electric Multi Area Reliability Simulator (GE MARS). The most recent study published by ISO New England is for the 2017-2018 commitment period.[145] Exhibit 5-1 depicts the schematics of locational installed capacity requirements in New England.

Exhibit 5-1. Schematics of FCA Capacity Requirements[146]



As shown in this figure, installed capacity requirements in New England are set as follows:

- System-wide Installed Capacity Requirement (ICR). For the purpose of the study, AESC 2015 used ICRs that are net of capacity supply provided by imports from Hydro Quebec across HVDC interties (Net ICR represented by the gray rectangle).
- Local Sourcing Requirements (LSRs) for import constraint zones – Connecticut and NEMA/Boston represented by green ovals. Local sourcing requirements specify the minimum level of capacity that must be procured from resources electrically located in import-constrained zones.

[145] ISO New England Installed Capacity Requirement, Local Sourcing Requirements, and Maximum Capacity Limit for the 2017/18 Capacity Commitment Period.

[146] This schematics does not show SEMA as another import constrained zone. At the time when TCR was preparing this analyses, it had no sufficient information to explicitly model SEMA as a capacity zone.

- Maximum Capacity Limit (MCL) for export constrained zone – Maine represented by the orange oval. MCL is the maximum capacity that can be procured in the export constrained zone.
- The diagram in Exhibit 5-1 also depicts a notional Rest of New England Zone (blue circle) for which no requirements are specified. The arrows between constrained zones and the Rest of New England simply reflect the directions in which excess capacity can be sold. Thus, capacity in an excess constrained zones that is in the excess of LSR in that zone can be sold to meet system-wide ICR. However, as the direction of the arrow indicates, the reverse is not true, capacity not located in the import-constrained zone cannot be sold to meet LSR in that zone. In contrast, for the export constrained zone, capacity located elsewhere can be used to meet MCL in that zone. However, no capacity in Maine in excess of MCL can be sold to meet system-wide requirements.

During the auction, suppliers submit offers to meet installed capacity requirements: MW quantities of generation and/or demand resources and offered prices. In addition, suppliers may submit delist bids indicating that certain capacity will not be available to meet the demand. The auctioneer ultimately selects a set of offers which are sufficient to meet capacity requirements while minimizing the total costs (as offered) of meeting those requirements. The outcome of the auction is the set of resources selected to meet ICAP requirement and capacity prices. Each FCA is held to acquire capacity commitments for that power year.

5.2 Market Simulation using *pCloudAnalytics* (*pCA*)

AESC 2015 developed projections of electric energy and electric capacity prices by simulating the operation of the ISO New England markets for energy and ancillary services (E&AS) and for capacity, i.e., the Forward Capacity Market (FCM) interactively using pCloudAnalytics (pCA).

pCA utilizes the Power System Optimizer Model ("PSO") developed by Polaris Systems Optimizations, Inc. ("Polaris")[147] to perform the production cost modeling of the ISO New England power system. PSO is a detailed, MIP based, unit commitment and economic dispatch model that simulates the operation of the electric power system. PSO determines the security-constrained commitment and dispatch of each modeled generating unit, the loading of each element of the transmission system, and the locational marginal price (LMP) for each generator and load area. PSO support both hourly and sub hourly timescales. The analytical structure of PSO is graphically presented in Exhibit 5-2 which distinguishes four important components of PSO: Inputs, Models, Algorithms and Outputs. This document primarily focuses on data sources and analytical steps used by NEG to develop Inputs to the PSO. Where relevant,

[147] http://www.psopt.com

this assumptions document describes how PSO Models are configured to provide adequate representation of the ISOE New England's energy market.

pCA is a cloud based power market simulation environment implemented on Amazon EC2 commercial cloud and organized as Software as a Service (SaaS). TCR licenses this service from Newton Energy Group, pCA developer and vendor. Exhibit 5-3 provides a graphical representation of *pCA* architecture. *pCA* manages formation of data inputs for PSO organized into distinct simulation scenarios, partitions each scenario into concurrently simulated segments, provides virtual machines on the cloud to process segments through PSO, collects and reassembles simulations results into scenario specific outputs and loads them into the Power Explorer (pEx), multi-dimensional data structure accessible through Microsoft Excel via pivot tables. The user prepares input data and accesses modeling results in MS Excel. The user communicates with cloud resources through pLINC, a special software tool linking user's local environment with the cloud environment in Amazon EC2.

Exhibit 5-2. Analytical Structure of PSO

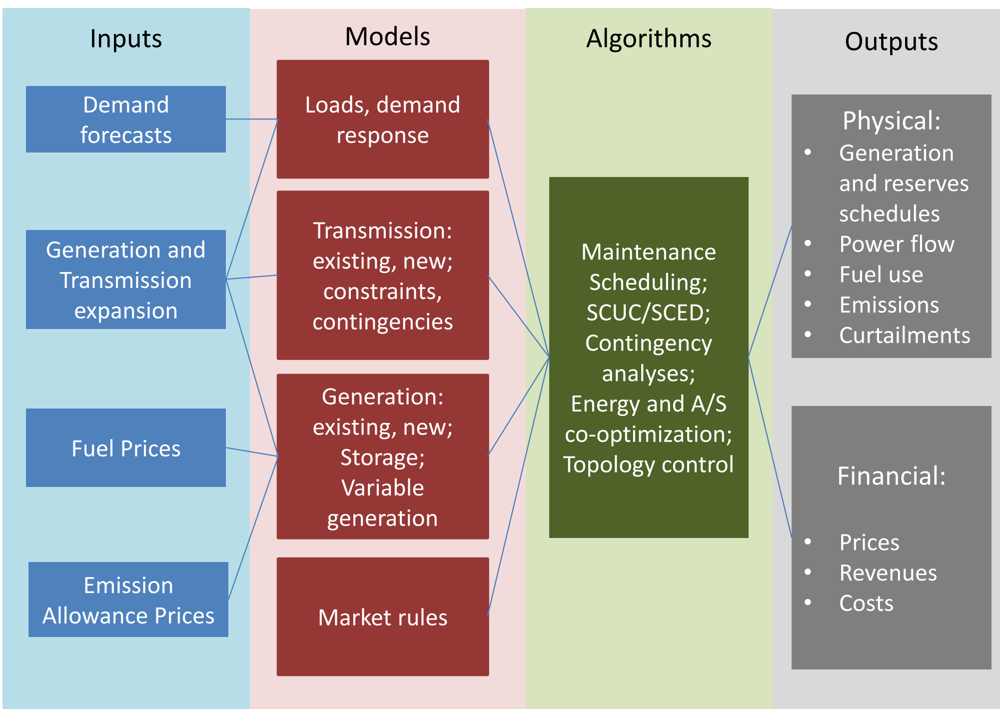


Exhibit 5-3. Architecture of *pCloudAnalytics*

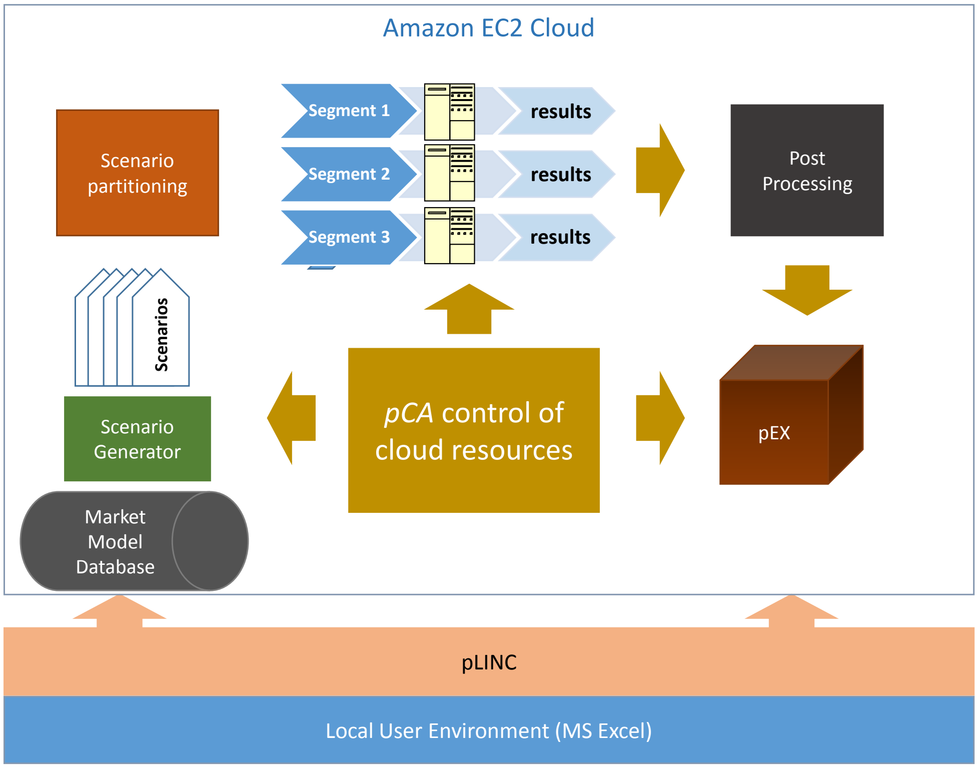


In the PSO modeling used for this project, there is a commitment (next-day) step and a dispatch (real-time) step. In the commitment process, generating units in a region are turned on or kept on in order for the system to have enough generating capacity available to meet the expected peak load and required operating reserves in the region for the next day. PSO then uses the set of committed units to dispatch the system on an hourly real-time basis, whereby committed units throughout the modeled footprint are operated between their minimum and maximum operating points to minimize total production costs. The unit commitment in PSO is formulated as a mixed integer linear programming optimization problem which is solved to the true optima using the commercial Gurobi solver.

5.2.1 Configuration of pCloudAnalytics for AESC 2015

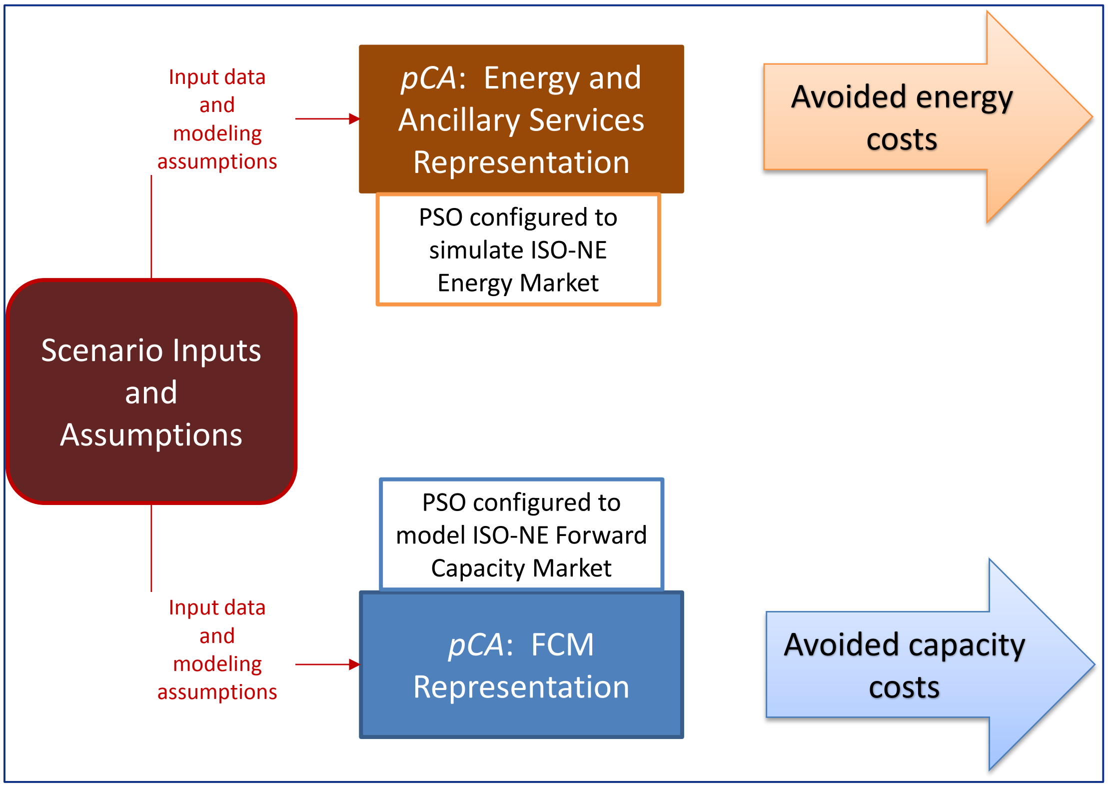
TCR configured *pCloudAnalytics* (pCA) to iteratively model two distinct ISO New England markets: market for energy and ancillary services (E&AS) and the Forward Capacity Market (FCM). As shown in Exhibit 5-4, the E&AS configuration of pCA produces the projection of energy prices while the FCM configuration produces the projection of capacity prices.

The critical element of this analysis is development of input assumptions which are consistent between the two market configurations. To achieve this consistency, two conditions must hold:

- The set of generating units included in the E&AS model should be sufficient to meet system-wide and local resource adequacy requirements. Otherwise, E&AS simulation will yield avoided energy costs that are too high.

- On the other hand, the generating resources modeled in the E&AS configuration should include only those resources that clear in the market in the FCM configuration. Otherwise, E&AS simulations will yield energy costs that are too low.

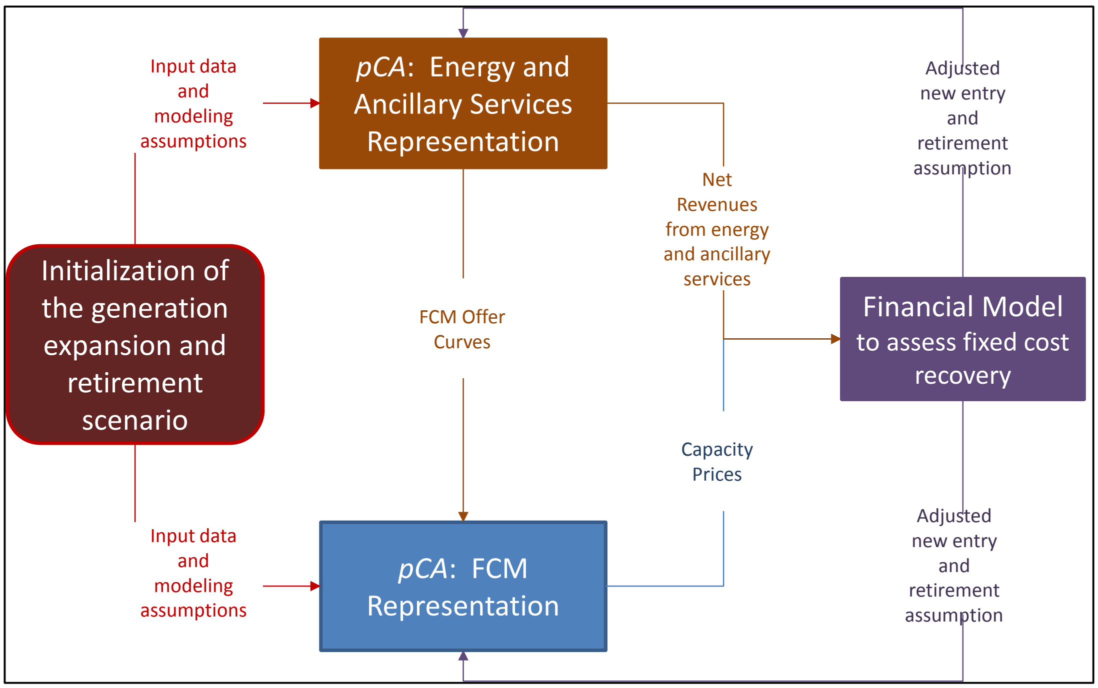
Exhibit 5-4. Use of pCloudAnalytics in AESC 2015



5.2.2 Iterative Use of pCA to develop a Consistent Set of Generating Resources

To develop a consistent set of resources across two markets, TCR ran E&AS and FCM iteratively as shown in Exhibit 5-5.

Exhibit 5-5. Iterative Use of pCA



In the initial iteration, TCR developed a forward-looking capacity balance to make sure that system wide and local resource adequacy requirements are met.

Next, TCR ran its E&AS simulations. TCR used the results of these simulations to project the energy market revenues capacity resources would receive each year. Based on those projected energy revenues, and our projection of the total cost a generating unit would need to recover each year to earn its threshold level of earnings, TCR projected the bids that new units would submit in the FCAs. TCR represents these projected bids as "offer curves" in the FCM model to simulate the outcome of the FCAs. (TCR made this interactive analysis using the results of the E&AS and FCM simulations as inputs to a financial model which it ran for each potential capacity resource addition. The financial model computed the net cash flow of each resource over the modeling horizon.)

- For existing resources the key question is whether the resource can consistently recover its fixed O&M costs given E&AS and FCM revenues. AESC 2015 assumes that if a resource cannot recover its fixed O&M costs for 2-3 subsequent years, it will be removed from the dataset as if retired while a generic new resource will be added to the dataset to maintain capacity balance.

- For potential new resources the key question is whether the resource recovers its fixed O&M and capital cost given E&AS and FCM revenues during the commitment period when the resource first enters the market. If the resource does not recover these costs for a given assumed generating technology and/or load zone, TCR would consider whether the new resource should be placed in a different location or should be of different technology.

After reviewing these changes to the assumed generation mix, TCR did another run of the E&AS model and the FCM model. TCR continued this iterative process until the results met the two consistency conditions described above.

5.3 Input Assumptions Common to E&AS and FCM Modes

This section describes assumptions that are used to simulate the operation of the E&AS market and the Forward Capacity Market (FCM).

5.3.1 Load Forecasts

AESC 2015 ran market simulations for two different load forecasts, a Base Case and a BAU Case. It developed the load forecasts for both Cases through 2023 from ISO New England (ISO NE) forecasts presented in the 2014 Regional System Plan (2014 RSP). The forecasts for 2024 through 2030 are extrapolations using the Compound Aggregation Growth Rates (CAGRs) for 2018 through 2023.

ISO NE presents several load-related forecasts in its 2014 RSP. First, ISO-NE provides an econometric forecast through 2023 of the hypothetical level of electricity consumption that would occur had no energy efficiency measures been installed in the past and if no new energy efficiency measures are installed in the future. energy and peak load by area.

Exhibit 5-6 and Exhibit 5-7 summarize this high or "gross" forecast of annual energy and peak load by area.

Exhibit 5-6: Gross Annual Energy Forecast summary by ISO-NE area

Second, ISO-NE provides a forecast of passive demand resources (PDR) that have cleared in FCAs for power years through May 2018. PDR reduces the level of electric energy consumption that would otherwise have to be supplied from generation resources. PDR includes such resources as energy efficiency and “behind-the meter” distributed generation (DG) used on site at locations that have net metering, which allows power customers who generate their own electricity to feed their excess back into the grid. PDR resources participate in the energy market under normal conditions, and should therefore be accounted for in modeling energy and capacity markets.

Exhibit 5-8. ISO NE Projected Peak Reduction Due to PDR

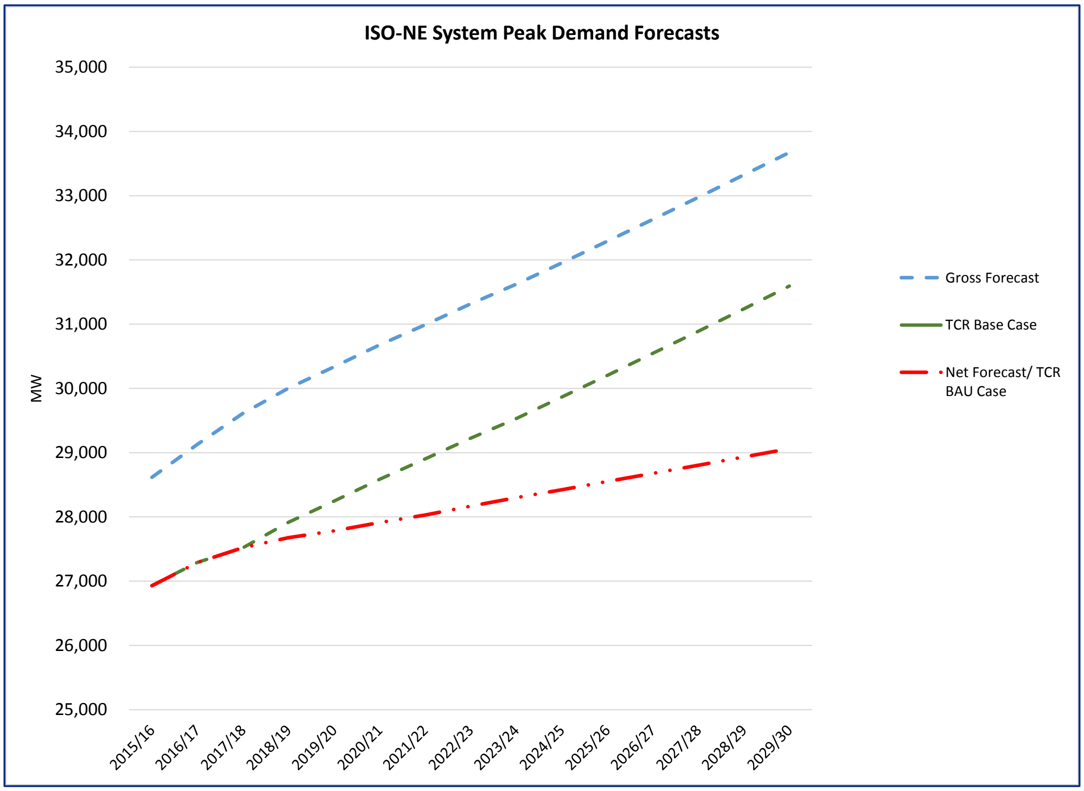
Third, ISO-NE provides a forecast of the level of electricity consumption that it expects to occur through 2023. This lower, or "net", forecast is equal to the gross load forecast minus the PDR through May 2018 and its projection of additional reductions from new ratepayer funded energy efficiency measures implemented from 2018 through 2023. (ISO NE develops its energy-efficiency forecast based on data that each state provides on actual funding and actual reductions.[148] (ISO-NE does not adjust the data it receives from each state. As a result the ISO NE projected reductions for state "A" are consistent with the energy efficiency accounting and cost recovery policies of state A. However, the composition of the projected reductions for state A may differ from those projected for state B due to differences in energy efficiency policies between state A and state B.)

5.3.2 Development of AESC 2015 Load Forecasts

Exhibit 5-10 presents the ISO NE gross forecast of system peak demand, the AESC 2015 Base Case forecast and the ASEC 29015 BAU Case forecast.

[148] ____, ISO New England Energy Efficiency Forecast Report for 2018 to 2023. June 3, 2014.

Exhibit 5-10 ISO New England System Peak Forecasts



The AESC 2015 Base Case forecast through May 2018 is equal to the ISO-NE gross load forecast minus the PDR that have cleared in the FCA through that period. From June 2018 through December 2023 the Base Case forecast is equal to the ISO-NE gross load forecast minus the PDR that cleared in the FCA for 2017/2018. This adjustment is consistent with an assumption of no new EE or DR from 2015 onward. The forecast through this period is consistent with an assumption of no new ratepayer funded EE or DR from 2015 onward, except PDR for which program administrators are financially committed, and with the fact that the measures causing the 2017/18 PDR reductions will continue to have an impact for several more years. From 2024 to 2030 the Base Case load is an extrapolation based on the 2018-2023 CAGR of that forecast. The resulting energy and peak projections are presented in Exhibit 5-11 and Exhibit 5-12.

5.3.3 Development of Hourly Load Shapes for AESC 2015 Load Forecasts

RSP 2014 provides projections of summer and winter peak, and annual energy, by load zone. However, to simulate the ISO New England market on an hourly basis, PSO requires an hourly load shape for each simulated time frame and area modeled. AESC 2015 constructed load shapes for each area from the following data:

- Template hourly load profiles
- Annual energy and summer/winter peak forecasts for the study period

AESC 2015 uses 2006 historical load shapes by zone as a template for load profiles. AESC 2015 selected 2006 to ensure the load profiles were synchronized with the most recent modeling of wind generation patterns in New England available from the National Renewable Energy Laboratory (NREL), which is 2006. To develop hourly load forecast for future years, pCA load algorithms first calendar shifts the template load profile to align days of the week and NERC holidays between 2006 and the forecast year. pCA algorithms then modify calendar shifted template profiles in such a manner that the resulting load shape exhibits the hourly pattern close to that of the template profile while the total energy for the year match the energy forecast and summer and winter peaks match the summer and winter peak forecast.

5.3.4 Interchange Data

pCA models New England interchanges with neighboring regions, i.e., the Canadian provinces of New Brunswick and Quebec and the New York ISO, using ISO-NE reported historical hourly interchange schedules for calendar year 2006. Similarly to load profiles, interchange flow data are calendar shifted for each forecast year and therefore remain synchronized with load pattern in ISO New England. Explicitly distinguished interchange schedules include:

- New Brunswick Interface at Keswig external node

- Phases I and II Interface with Hydro Quebec via HVDC
- Highgate interface with Hydro Quebec via HVDC
- Cross Sound Cable HVDC interconnection with NYSIO
- Roseton AC interface with NYSIO

These interfaces are mapped to electrical points of interconnection with the ISO New England in the power flow model used for pCA simulations.

5.3.5 Transmission

The geographic footprint PSO modeled encompasses the six New England states: Maine, Massachusetts, New Hampshire, Vermont, Rhode Island, and Connecticut, whose electricity movement and wholesale markets are coordinated by ISO-NE.

The physical location of all network resources is organized using substation and node mapping. The transmission topology is modeled based on the 2011 FERC 715 power flow fillings for summer peak 2016. NEG verified the power flow model against the ISO-NE queue to make sure that essential transmission projects are represented in the power flow case. Generators are mapped to bus bars/electrical nodes (eNodes). Bus bars are mapped to substations and substations are in turn mapped to ISO New England SMD Zones. The mapping of bus bars to zones allows PSO to allocate hourly area load forecasts to load busses in proportion to the initial state from the power flow.

In determining a representative list of transmission constraints to monitor, NEG includes all major ISO-NE interfaces and frequently binding constraints, as reported by ISO-NE. Key interface limits are specified in Exhibit 5-15. For certain interfaces, limits obtained from the ISO New England's FERC Form 715 filing represent Critical Energy Infrastructure Information (CEII) and are not shown in that table. All single line normal and emergency ratings are taken directly from the power flow.

Exhibit 5-15: Interface Limits

Interface	Max MW	Min MW

Sources:
*ISO New England, Transmission Interface Transfer Capabilities: 2014 Regional System Plan Assumptions, Part 3, March 17, 2014. Available online at http://www.iso-ne.com/committees/comm_wkgrps/prtcpnts_comm/pac/mtrls/2014/mar172014/a8_rsp14_transmission_interface_transfer_capabilities.pdf

The 2014 RSP describes a considerable number of "Elective Transmission Upgrades" that are currently under review by ISO New England. These include a number of major proposed AC and HVDC projects to increase transfer capabilities between New England and the Canadian provinces of Quebec and New Brunswick, as well as between the Maine Zone and major load centers in New England. One of the Elective Transmission Upgrades is Northern Pass Transmission (NPT), which received Proposed Plan Application approval from ISO New England on December 31, 2013.

Based upon its review, AESC 2015 did not assume any of these proposed projects in its Base or BAU Cases because of the high degree of uncertainty regarding the key assumptions require to model any of them. Those key assumptions include whether the project will receive approval at the Federal and state levels, when it might come into service, the location of its ultimate interconnection points within New England and the technical and economic characteristics of the electric energy the project would deliver into the New England market.

5.3.6 Generating Unit Retirements and Additions

Exhibit 5-16 summarizes the generation retirements approved by ISO-NE and assumed in our simulations.

Exhibit 5-16: Approved retirements in ISO-NE

Full Name	Retire Date	Area	Capacity (MW)
Mt. Tom	6/2/2014	WCMA	145
Salem Harbor 3	6/1/2014	NEMA	150
Salem Harbor 4	6/1/2014	NEMA	437
VT Yankee Nuclear	12/31/2014	VT	620
Brayton Point 1-4	6/1/2017	SEMA	1,534
Total			**2,886**

Over the AESC 2015 time horizon, new generation resources will be needed to satisfy renewable portfolio standards and resource adequacy requirements. Since pCA is not a capacity expansion model, these additions are exogenous. Section 5.6 provides the AESC 2015 assumptions for renewable resource additions to comply Renewable Portfolio Standard (RPS) requirements. Exhibit 5-17 summarizes known near-term new generation additions included in the pCA database. These are projects listed in ISO-NE's interconnection queue which are either under construction or which have major interconnection studies completed.

5.3.7 Generating Unit Operational Characteristics

Thermal Units

Thermal generation characteristics are generally determined by unit type. These include: heat rate curve shape, non-fuel operation and maintenance costs, startup costs, forced and planned outage rates, minimum up and down times, and quick start, regulation and spinning reserve capabilities.

Capacity ratings were obtained from SNL Financial. Fully Loaded Heat Rates (FLHRs), forced outage rates and planned outage rates were not available from ISO-NE. Instead, NEG used information by similar unit type as obtained from both the North American Electric Reliability Corporation (NERC) Generating Availability Report and power industry data provided by SNL Financial. Similarly, given the lack of information from ISO-NE on Variable O&M costs, NEG used its assumptions by unit type for existing and planned units that are consistent with modeling these units in other markets.

Due to the large number of small generating units, NEG aggregates all units below 20 MWs by type and size into a smaller set of units. Full load heat rates for the aggregates are calculated as the average of the individual units and all other parameters are inherited from the unit type.

Heat rate curves are modeled as a function of full load heat rate ("FLHR") by unit type:

- CT: Single block at 100% capacity at 100% of FLHR.
- CC: 4 blocks: 50% capacity at 113% of FLHR, 67% capacity at 75% of FLHR, 83% capacity at 86% of FLHR, and 100% capacity at 100% of FLHR. As an example, for a 500 MW CC with a 7000 Btu/KWh FLHR, the minimum load block would be 250 MW at a heat rate of 7910, the 2nd step would be 85 MW at a heat rate of 5250, the 3rd step would be 80 MW at a heat rate of 6020, and the 4th step would be 85 MW at a heat rate of 7000.
- Steam Coal for all MW: 4 blocks: 50% capacity at 106% of FLHR, 65% capacity at 90%, 95% capacity at 95% FLHR, and 100% capacity at 100% FLHR.
- Steam Gas for all MW: 4 blocks: 25% capacity at 118% of FLHR, 50% capacity at 90%, 80% capacity at 95% FLHR, and 100% capacity at 100% FLHR.

Exhibit 5-18 below shows other assumptions by type for thermal plants. The abbreviations in the Unit Type column are structured as follows: First 2-3 characters identify the technology type, the next 1-2 characters identify the fuel used (**g**as, **o**il, **c**oal, **r**efuse) and the numbers identify the size of generating units mapped to that type.

Exhibit 5-18. Thermal Unit Assumptions by Type and Size

Unit Type	Min Up Time (h)	Min Down Time (h)	EFORd	VOM ($/MWh)	Startup Cost ($/MW-start)	Startup Failure Rate

Source: NEG Analysis

Nuclear Units

Nuclear plants are assumed to run when available, and have minimum up and down times of approximately one week (164 hours). Capacity ratings, planned outage rates and forced outage rates are the same as those obtained from the NERC Generating Availability Report. The values represent a normalized annual rate that does not directly capture the timing of refueling outages. In general, nuclear facilities are treated as must run units. Production costs were modeled using NEG input assumptions for fuel and variable O&M.

Hydro and Pumped Storage

Hydro units are specified as a daily pattern of water flow, i.e. the minimum and maximum generating capability and the total energy for each plant. Of those, NEG assumed that hydro plants use 40% of the daily energy at the same level in each hour of the day. The remaining 60% of the daily energy is optimally scheduled by PSO to minimize system-wide production costs. Daily energy was estimated using plant specific capacity factors under the assumption that hydro conditions do not vary significantly across seasons.

PSO fully optimizes pumped storage operation schedules.

Renewable Energy Resources

We model wind, solar, and biomass generating capacity.[149] Technology-specific assumptions for each are described below.

Wind

Onshore and offshore wind generation is represented in the model using hourly generation profiles developed using the 10-minute wind power output profiles, averaged hourly, which are obtained from the National Renewable Energy Laboratory (NREL).[150] The pCA database stores wind generation profiles provided by NREL based on 2006 weather data, so as to be consistent with the 2006 load profiles used in the analysis. Each wind site in ISO-NE is mapped to the nearest NREL wind site to obtain the appropriate hourly schedule. The resulting schedule is scaled to the installed capacity of the corresponding wind site and then calendar-shifted for each forecast year making it synchronized with load profiles and interchange schedules.

Solar Photovoltaics

PV generation is represented in the model using hourly generation profiles for three system sizes in each of the six states (for a total of 18 profiles). The profiles were developed using the NREL SAM PV Watts

[149] The modeling of hydro resources is discussed in the previous section.

[150] National Renewable Energy Laboratory (US), "Wind Systems Integration - Eastern Wind Integration and Transmission Study," nrel.gov, 2010. [Online]. Available at: http://www.nrel.gov/electricity/transmission/eastern_wind_methodology.html

module, with 2006 weather data files obtained from NREL. The array types (fixed open rack or roof mount) and tilt were selected based on the system size and location to conform to typical practice in New England. The hourly profiles were adjusted so that the capacity factors matched those used by ISO New England in its PV forecast,[151] listed below in Exhibit 5-19.

Exhibit 5-19. PV Capacity Factor Assumptions

	CT	MA	ME	NH	RI	VT
Capacity Factor (AC)	16.0%	15.4%	15.4%	15.1%	15.5%	14.0%

Biomass is modeled as dispatchable generation subject to generation technology parameters and fuel prices.

5.3.8 Operating Reserves

AESC 2015 modelled four types of Ancillary Services: Regulation, Ten-Minute Spinning Reserve, Ten-Minute Non-Spinning Reserve and Thirty-Minute Operating Reserve. Reserves are cascading – excess regulation counts toward spinning reserves. Excess spinning reserves counts toward Non-spinning. Spinning reserve requirements are considered bi-directional. Non-Spinning reserves can be provided by offline peaking capacity and can handle upward ramping only.

- Regulation must be provided by online resources at the level of ramp rate (in MW/min) limited by a 5 minute activation time.
- Ten-Minute Spinning Reserve (TMSR) must be provided by online resources at the level of ramp rate (MW/min) limited by a 10 minute activation time. Hydro can provide Synchronized reserve up to 50% of its dispatch range.
- Ten-Minute Non-Spinning Reserve (TMSNR) is provided by offline resources capable of supplying energy within 10 minutes of notices. TMSNR can only be provided by quick start capable CTs and Internal Combustion (IC) units.
- Thirty-Minute Operating Reserve (TMOR) can be provided by either on-line or off-line resources with less than 30 minutes activation time.

Hydro generators are assumed to provide regulation and reserves for up to 50% of available dispatch range. Nuclear and wind provide no ancillary services.

[151] ISO New England PV Energy Forecast Update, available at: http://www.iso-ne.com/static-assets/documents/2014/09/pv_energy_frcst_update_09152014.pdf.

Exhibit 5-200 below summarizes reserve requirements in ISO-NE.

Exhibit 5-20 ISO-NE Regulation and Reserve Requirements

Reserve Type	Requirement (MW)
Regulation	Hourly schedule per ISO-NE requirements
Ten min spinning reserves	820
Ten min non-spinning reserves	820
Thirty min operating reserves	750

5.3.9 Emission Rates and Allowances

Emission rates for most plants were obtained from historical SNL emission rate data. For plants for which there were no emission rates (i.e., those under construction) generic EIA emission data were used.

Emission allowance price assumptions are presented in Chapter 4.

5.4 Capacity Market-Specific Modeling Assumptions

5.4.1 Projection of System-Wide Installed Capacity Requirements

Exhibit 5-21 below summarizes actual ICR through 2017/18 (FCA 8) and the AESC 2015 projections.

Exhibit 5-21. Base Case Projection of System-Wide ICRs

	ISO New England Data[152]				Projection					
Period	2014/15	2015/16	2016/17	2017/18	2018/19	2019/20	2020/21	2021/22	2022/23	2023/24
FCA	5	6	7	8	9	10	11	12	13	14
Gross 50/50 Peak (MW)	29,025	29,380	29,400	29,790	30,005	30,335	30,675	30,990	31,315	31,620
ICR (MW)	34,154	34,498	34,023	34,922	35,109	35,495	35,893	36,262	36,642	36,999
Margin	17.67%	17.42%	15.72%	17.23%	17.01%	17.01%	17.01%	17.01%	17.01%	17.01%
HQ ICC (MW)	954	1,042	1,055	1,068	1,068	1,068	1,068	1,068	1,068	1,068
Net ICR (MW)	33,200	33,456	32,968	33,854	34,041	34,427	34,825	35,194	35,574	35,931

152 ISO New England Installed Capacity Requirement, Local Sourcing Requirements, and Maximum Capacity Limit studies for 2014/15, 2015/16, 2016/17 and 2017/18 capability periods

Starting with the data provided in the four most recent ICR studies, we estimated implied reserve margin requirements – a difference between ICR and projected summer peak demand divided by the peak demand. A simple average of these margins is 17.01%. AESC 2015 assumed ISO NE would continue to require this level of reserve margin. AESC 2015 also assumes import capacity from Hydro Quebec will remain at the level of 1068 MW and computed the resulting net ICRs.

5.4.2 Projection of Local Sourcing Requirements (LSRs) for NEMA /Boston and Connecticut Import Constrained Zones

Local Sourcing Requirements are minimum levels of installed capacity that must be procured within an import-constrained zone. There are two currently recognized import-constrained zones in New England – NEMA/Boston and Connecticut. Exhibit 5-22 summarizes the AESC 2015 projection of Local Sourcing Requirements for import-constrained zones.

Exhibit 5-22 Projection of LSRs for Import Constrained Zones

	ISO NE Data			Projection					
Period	**2015/16**	**2016/17**	**2017/18**	**2018/19**	**2019/20**	**2020/21**	**2021/22**	**2022/23**	**2023/24**
NEMA/Boston									
90/10 Peak	6,530	6,520	6,745	6,615	6,700	6,785	6,865	6,950	7,025
N-1 Import Limit	4,850	4,850	4,850	4,850	4,850	4,850	4,850	4,850	4,850
LSR	3,288	3,209	3,427	3,329	3,434	3,540	3,638	3,744	3,836
Margin	24.6%	23.6%	22.7%	23.6%	23.6%	23.6%	23.6%	23.6%	23.6%
Connecticut									
90/10 Peak	8,250	8,201	8,330	8,530	8,605	8,680	8,750	8,825	8,890
N-1 Import Limit	2,600	2,600	2,800	2,950	2,950	2,950	2,950	2,950	2,950
LSR	7,542	7,603	7,319	7,537	7,629	7,721	7,807	7,900	7,979
Margin	22.9%	24.4%	21.5%	22.9%	22.9%	22.9%	22.9%	22.9%	22.9%

Starting with the data provided in the three most recent ICR studies[153], we estimated implied reserve margin requirements for import-constrained zones. For each zone, the implied reserve margin was computed as a difference between the sum of LSR and N-1 contingency import limit into the zone and the 90/10 peak demand in that zone divided by the 90/10 peak demand. 90/10 peak demand is the ISO New England estimated summer peak which is likely to occur under the 1 in 10 years most critical weather conditions. For each zone, AESC 2015 computed a simple average of that zone's margin (23.6%

[153] ICR study for 2014/15 did not contain sufficient details for this analysis and was not used.

for NEMA Boston and 22.9% for Connecticut) and assumed that this margin will persist in the future. Using this assumption, AESC 2015 projected future LSR values for import constraint zones.

5.4.3 Projection of Maximum Capacity Limit (MCL) for Maine

A Maximum Capacity Limit is the maximum level of installed capacity that can be procured within the export constrained zone. Main is the only export constrained zone in New England. Exhibit 5-233 below summarizes the AESC 2015 projection of the Maximum Capacity Limit for the Maine export constrained zone. Starting with the data provided in the four most recent ICR studies, we estimated ratio of the MCL determined by ISO New England in that period over the sum of the peak demand in Maine and Maine export Limit. AESC 2015 computed the average ratio for this four-year period, 94.4% and assumed that that ratio would persist in the future. Based on that assumption and using ISO New England's forecast of summer peak demand for the Maine zone, AESC 2015 developed projections for the MCL value.

Exhibit 5-23. Projection of MCL for the Maine Zone

	ISO NE Data				**Projection**					
Period	**2014/15**	**2015/16**	**2016/17**	**2017/18**	**2018/19**	**2019/20**	**2020/21**	**2021/22**	**2022/23**	**2023/24**
Peak	2,050	2,150	2,160	2,200	2,220	2,240	2,255	2,275	2,295	2,315
Export Limit	1,900	1,900	1,900	1,900	1,900	1,900	1,900	1,900	1,900	1,900
MCL	3,702	3,888	3,709	3,960	3,890	3,909	3,923	3,942	3,961	3,980
Ratio	93.7%	96.0%	91.4%	96.6%	94.4%	94.4%	94.4%	94.4%	94.4%	94.4%

5.4.4 PDR Levels

PDR levels used in the Base Case and BAU Cases are summarized in Exhibit 5-24 below.

Exhibit 5-24. PDR levels used in modeling FCA

BAU	2018/19	2019/20	2020/21	2021/22	2022/23	2023/24

ME	184	184	184	184	184	184

Demand Curve Assumptions

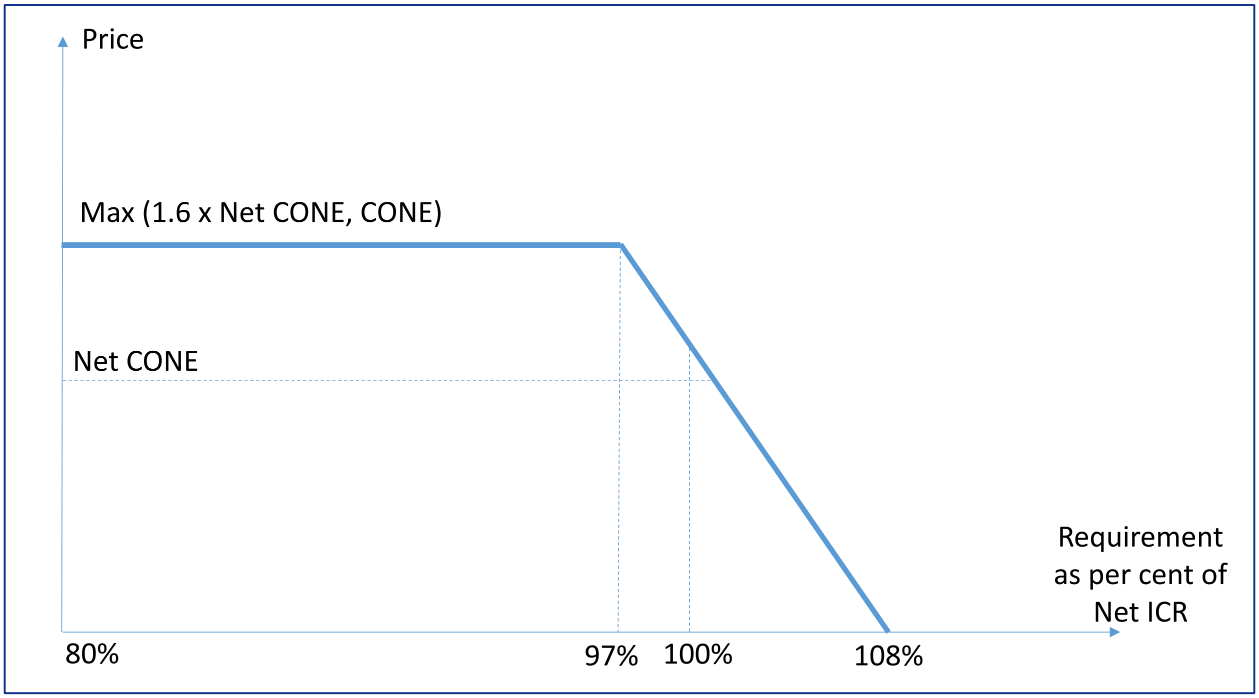
Starting with FCA9 (2018/19 Commitment Period) ISO New England plans to incorporate sloped demand curves into the FCM market design. Introduction of sloped demand curves will significantly impact the capacity price formation mechanism by making capacity prices less volatile in response to changes in reserve margins.

The introduction of demand curves will be implemented in two phases. First, starting with FCA9 (2018/19 commitment period auctioned in 2015) ISO New England will implement only a system-wide demand curve. Second, starting with FCA10, sloped demand curves will be introduced for constrained capacity zones. The system-side demand curve has already been approved by FERC. The design of demand curves for constrained capacity zones is still ongoing. However, the consensus appears to be emerging with ISO New England presenting a revised design in which it agrees with the proposal developed by the New England State Committee on Electricity (NESCOE)[154]. AESC 2015 modeled the FCM market using the system-wide and zone-specific demand curves described below.

Exhibit 5-25 depicts the system-wide sloped demand curve. The curve expresses the system-wide capacity price as a function of the relative level of supply expressed as a percent of Net ICR. The price floor is zero and the price cap is the maximum between 1.6 times of Net CONE and CONE (CONE stands for the Cost of New Entry).

[154] Presentation of Matt Brewster of ISO New England to the NEPOOL Markets Committee, December 9-10, 2014. Available online at http://www.iso-ne.com/static-assets/documents/2014/12/a10a_iso_presentation_12_10_14.pptx

Exhibit 5-25. System-Wide Sloped Demand Curve



Along the demand curve, the price reaches the cap when the supply falls below 97% of Net ICR and falls to zero when supply exceeds 108% of Net ICR. AESC 2015 assumes the net ICR values for each commitment period will be those specified in Exhibit 5-21.

The proposed CONE and Net CONE values, shown in Exhibit 5-26 are[155]

Exhibit 5-26. CONE and Net CONE Assumptions

Parameter	Value in real 2018 $/kW-month	Value (in real 2015 $/kW-year)
CONE	14.04	159.32
Net CONE	11.08	132.96
1.6 x Net CONE	16.672	212.74

Demand curves for import and export constrained zones are shown in Exhibit 5-27 and Exhibit 5-28, respectively. Structurally these curves are similar to the system-wide curve using the same 97% and 108% parameters. For import-constrained zone, the relationship between the price and quantity also factors in the Total Transfer Capability (import limit) into the zone. For the Maine export constrained zone, the curve is defined in terms of MCL as opposed to the Net ICR used in the definition of the system-wide curve but uses the same coefficients of 97% and 108%.

Exhibit 5-27. Demand Curve for Import Constrained Zone

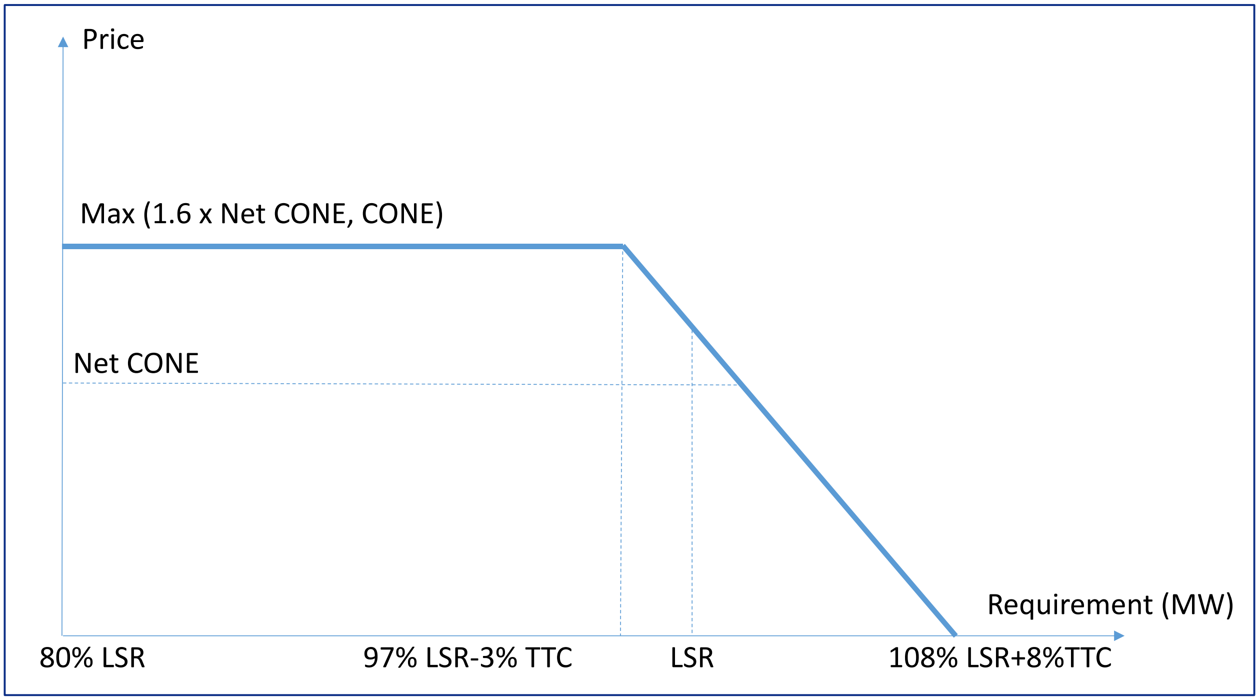

Exhibit 5-28. Demand Curve for Export Constrained Zone

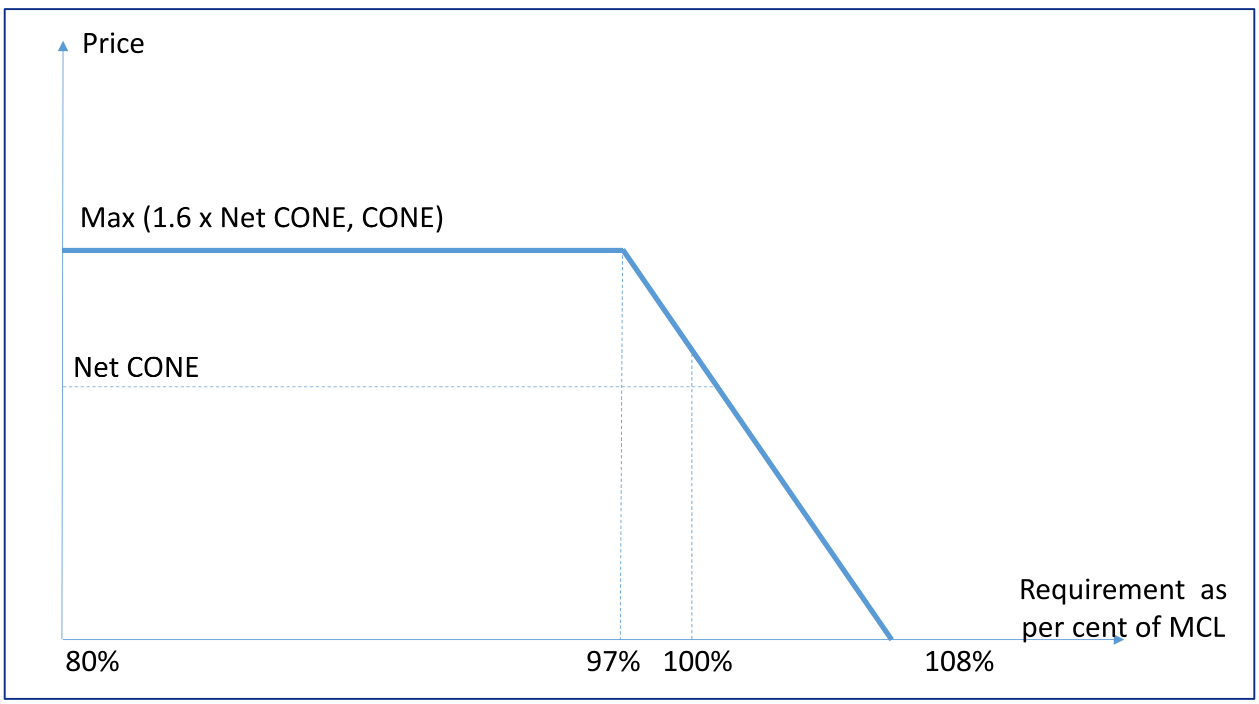

Supply Offers to the FCM

AESC 2015 assumes that generators will set their offers to the FCM at a level which would recover their estimate of the revenue shortfall between the total revenues they require and the net E&AS revenues they expect to receive (i.e., gross E&AS revenues minus their variable operating costs)). The total revenues they require is based on their capital and total operating costs. The net revenues they expect from the energy market is their estimated operating margin from selling energy and ancillary services.

- TCR estimated the offers of existing generators as the difference between estimates of their fixed O&M costs and their net margins per kW of installed capacity per our modeling of the energy market. (We excluded their capital costs since those are "sunk" costs)
- TCR estimated offers from new generators, those to come online during the commitment period, as the difference between the sum of the annualized capital cost and fixed O&M costs and net margins per kW of installed capacity.

The AESC 2015 assumptions for fixed O&M costs of existing generating units are generic by unit type as shown in Exhibit 5-29. These assumptions were reviewed and approved by the stakeholders of the Eastern Interconnection Planning Collaborative **(**EIPC) Phase I study.

Source:
EIPC Online, http://www.eipconline.com/uploads/MRN-NEEM_Modeling_Assumptions_Draft_Jan_25_2011_Input_Tables_Exhibits.xls

AESC 2015 assumptions with respect to capital costs of new generating units are summarized in Exhibit 5-30 below. For gas fired generating technology AESC 2015 used cost assumptions that are consistent with parameters used to develop CONE estimates and provided in the Brattle Group and Sargent & Lundy study. For other technologies capital cost assumptions are per 2013 EIA Capital Cost Estimates. The EIA study provides only overnight capital costs. To convert overnight costs to annualized capital costs AESC 2015 used Fixed Charge Rates applied in the EIPC study.

Contribution of Variable Resources toward ICAP Requirements

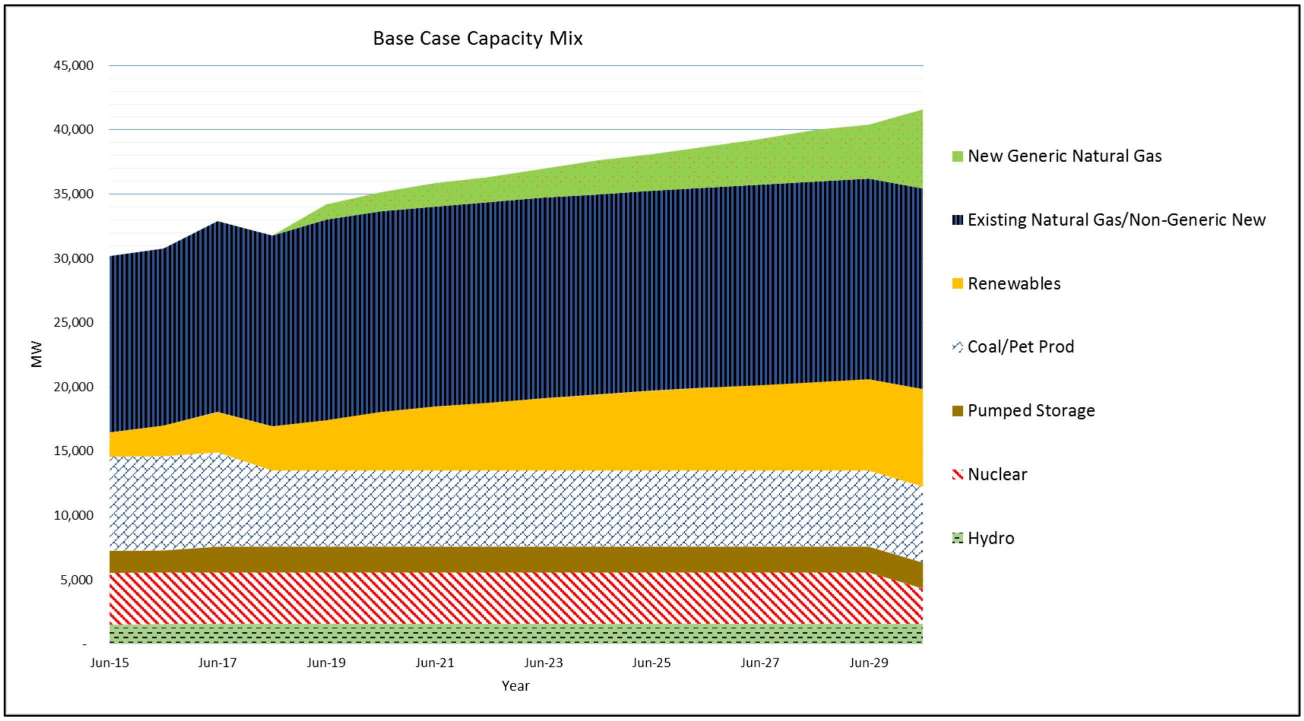
To model the contribution of variable resources such as wind and solar toward ICAP requirements, AESC 2015 followed ISO-NE Market Rule III.13.1.2.2.2.2. According to this rule, Summer Qualified Capacity (contribution to ICAP) should be set as the median of the intermittent source's net output during summer reliability hours (14:00 – 18:00). For each variable resource modeled AESC 2015 used the assumed resource hourly profile to compute the specified median output.

5.5 BASE CASE Projections

5.5.1 Forecast of Capacity and Capacity Prices

The projected level and mix of capacity in the Base Case is presented in Exhibit 5-31. New capacity additions include renewable resources to comply with RPS requirements, as well as new natural gas generators added to meet energy and reserve margin requirements. A substantial portion of the existing oil (Pet Prod) and coal capacity is forecast to retire by 2025. Because of the relatively high price of oil compared to other fuels, these generating plants are rarely dispatched.

Exhibit 5-31. Base Case Capacity by Technology (MW)



Results and Comparison to AESC 2013 Base Case Forecast

The capacity market model explicitly incorporated constraints and demand curves for NEMA-Boston, Connecticut and Maine zones. The modeling results did not show any capacity prices differences between those zones and Rest of Pool.

Exhibit 5-32 compares the AESC 2015 Base Case forecast of capacity prices to the AESC 2013 forecast. The Exhibit presents forecasts of prices by power year (June through May), and by calendar year. On a 15 year levelized basis, the AESC 2015 Base Case forecast by calendar year is approximately 60 percent higher than AESC 2013.

Exhibit 5-32. Capacity Costs – AESC 2015 Base Case and AESC 2013

Power Year (June - May)	AESC 2013	AESC 2015 Base Case	Calendar Year	AESC 2013	AESC 2015 Base Case
	2015$/kW-month	2015$/kW-month		2015$/kW-year	2015$/kW-year
2015/16	$ 3.42	$ 3.38	2015	$40.99	$39.67

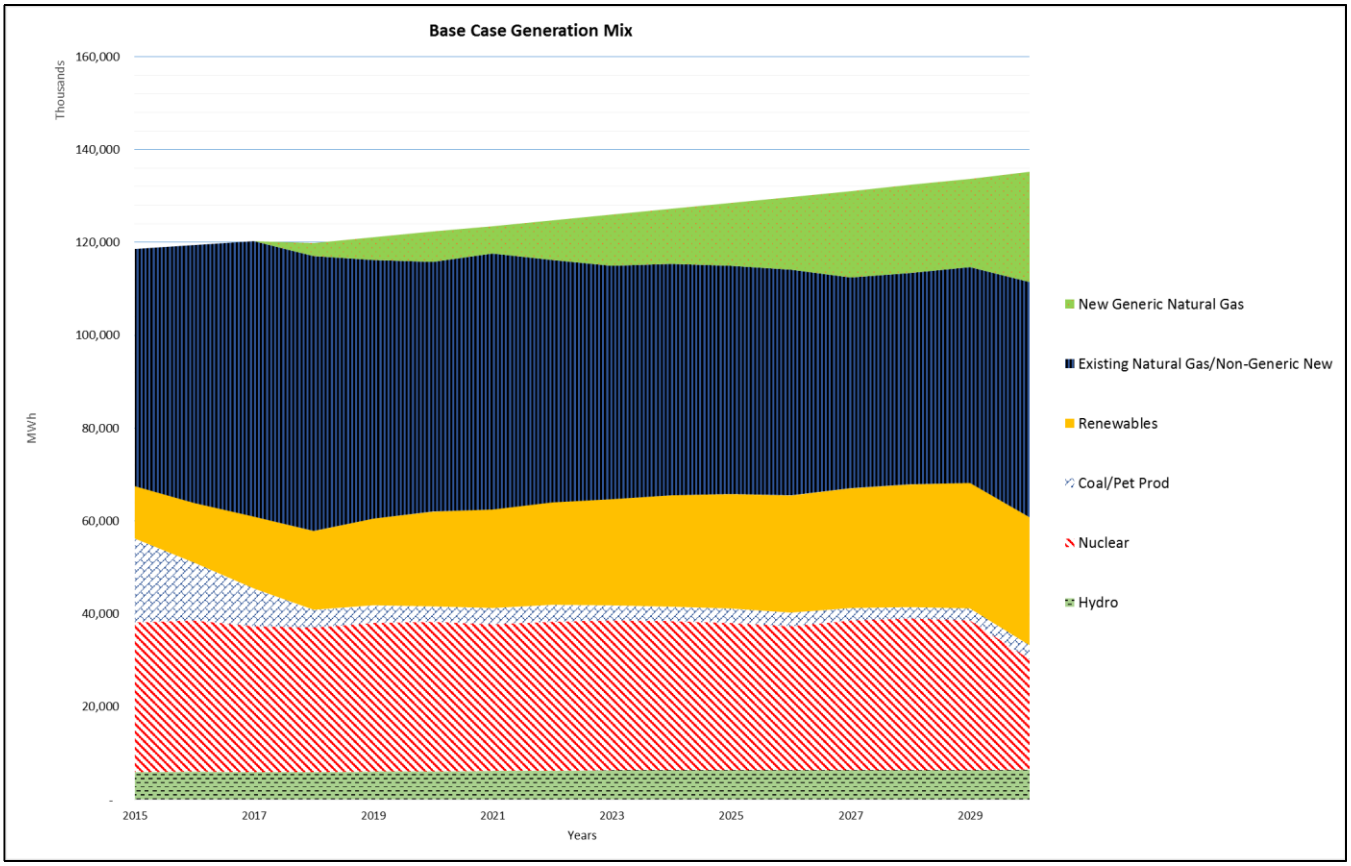
2018/19	$ 3.85	$ 12.96	2018	$46.20	$132.93
2019/20	$ 4.25	$ 11.29	2019	$51.05	$123.29
2020/21	$ 7.86	$ 11.33	2020	$94.27	$135.75
2021/22	$ 9.56	$ 11.71	2021	$114.76	$138.60
2022/23	$ 9.56	$ 11.62	2022	$114.76	$139.90
2023/24	$ 9.56	$ 11.37	2023	$114.76	$137.73
2024/25	$ 9.56	$ 11.96	2024	$114.76	$140.57
2025/26	$ 9.56	$ 11.96	2025	$114.76	$143.50
2026/27	$ 9.56	$ 12.04	2026	$114.76	$144.08
2027/28	$ 9.56	$ 11.79	2027	$114.76	$142.75
2028/29	$ 9.56	$ 12.46	2028	$114.76	$146.18
2029/30	$ 9.56	$ 12.79	2029	$114.76	$151.86
			2030	$114.76	$153.53
15 yr Levelized					
15/ 16 to 29/30	$7.95	$11.74	**2016 -2030**	$100.74	$142.08
AESC 2015 vs AESC 2013		48%			41%

The AESC 2015 capacity prices are actuals for the Rest of Pool (ROP) for power years 2015/16 through 2017/18 and are projections for 2018/19 through 2029/30. Note that in 2016/17capacity prices in the NEMA-Boston zone were different from the Rest of Pool. In addition, these projections do not reflect the FCA 9 results for 2018/19, which were not available at the time the AESC 2015 projections were made. However, the avoided electricity costs by zone provided in Appendix B reflect the actual results by zone for FCA 8 and FCA 9.

5.5.2 Forecast of Energy and Energy Prices

The projected level and mix of generation in the Base Case is presented in Exhibit 5-33. Generation from nuclear remains flat until year 2029 and declines in 2030 assuming retirement of Seabrook in March of that year, and coal generation declines substantially as most units are retired. Generation from natural gas is the dominant resource, and renewable generation increases over time in compliance with RPS requirements. Generation mix shown does not add up to the total energy demand because it does not account for the interchange with neighboring systems and for net pumping of energy by pumped storage generators.

Exhibit 5-33. Base Case Generation Mix



Forecast of Wholesale Electric Energy Prices

For AESC 2015, we present streams of energy values for all of New England in the form of the hub price. This is separately presented for four periods—summer on-peak, summer off-peak, winter on-peak, winter off-peak.[156]

The hub price representing the ISO-NE Control Area is located in central Massachusetts, and the WCMA zone in the pCA model is used as the proxy for that location. Exhibit 5-34 presents monthly, on-peak and off-peak energy prices as produced by the model through 2030 for Central Massachusetts. The higher

[156] Summer is defined as the four months June through September, with winter the other eight months, as done in AESC 2013. By combining the true winter season within spring and fall, the effects of high prices during the coldest months are moderated. AESC 2013 defined "on-peak" hours as 7 am – 11 pm.

winter on-peak price in the initial years represents the current high winter natural gas basis prices, which moderate as more pipeline capacity is added.

Exhibit 5-34. AESC 2015 Base Case Wholesale Energy Price Forecast for Central Massachusetts

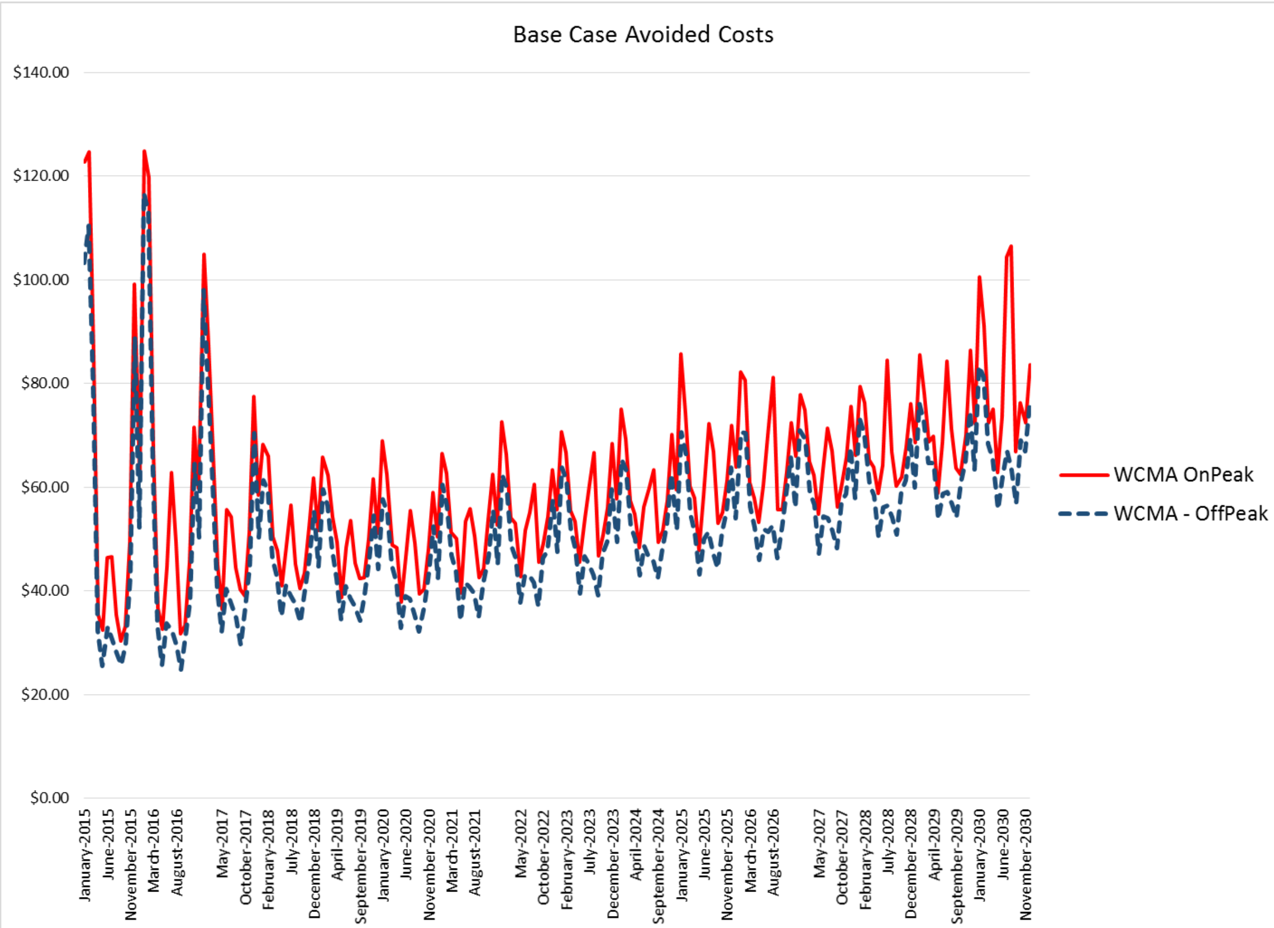


Exhibit 5-35 provides annual summaries by year, season and Peak vs. Off-Peak time periods.

Exhibit 5-35. AESC 2015 Base Case Wholesale Energy Price Forecast for Central Massachusetts (2015$/MWh)

	Summer			Winter		
Year	Off-Peak	OnPeak	AllHours	Off-Peak	OnPeak	AllHours
2015	$30.43	$39.83	$34.99	$64.89	$73.33	$68.90
2016	$30.79	$47.42	$38.67	$61.76	$66.69	$64.10
2017	$36.46	$48.93	$42.36	$59.05	$63.80	$61.30
2018	$39.30	$47.88	$43.34	$49.33	$54.02	$51.58
2019	$38.86	$47.60	$43.01	$48.61	$53.30	$50.86
2020	$37.33	$47.86	$42.38	$46.87	$51.95	$49.31
2021	$40.25	$50.69	$45.26	$49.19	$54.04	$51.50
2022	$42.36	$53.34	$47.65	$51.95	$57.22	$54.43
2023	$44.90	$57.13	$50.74	$53.67	$58.56	$55.98
2024	$47.14	$57.28	$51.95	$55.85	$60.69	$58.19
2025	$49.23	$62.74	$55.65	$57.79	$64.58	$61.07
2026	$51.50	$66.79	$58.74	$60.06	$66.02	$62.89
2027	$53.22	$64.54	$58.63	$61.89	$67.28	$64.46
2028	$55.81	$69.01	$61.99	$64.06	$68.86	$66.32
2029	$58.48	$72.05	$64.90	$68.02	$72.70	$70.24
2030	$63.40	$87.96	$75.13	$71.22	$79.63	$75.30

In sum, these benchmarking results demonstrate that the pCA modeling environment and supporting datasets provide a reliable tool for developing electric energy price projections.

5.5.3 Comparison to AESC 2013 Base Case

The following section summarizes differences between the AESC 2015 Base case and the AESC 2013 Base Case. Exhibit 5-36 compares the two AESC forecasts on a levelized basis. On a levelized annual basis, the AESC 2013 Base Case wholesale energy prices for WCMA are 7%below those of AESC 2013.[157]

The AESC 2015 Base Case levelized values are lower than the AESC 2013 Base Case in winter and summer periods, ranging from 3.3% to 15.6%. The lower summer prices reflect overall lower natural gas prices. The difference in winter prices is relatively small.

[157] Levelized values have been calculated for AESC 2015 using a discount rate of 2.43 percent, and for AESC 2013 using a discount rate of 1.36 percent.

Exhibit 5-36. 15-Year Base Case Levelized Cost Comparison for Central Massachusetts (2015$/MWh)

	Winter Peak Energy	Winter Off-Peak Energy	Summer Peak Energy	Summer Off-Peak Energy	Annual All-Hours Energy
AESC 2015 (2016-2030)	$62.10	$56.82	$57.68	$45.04	$56.58
AESC 2013 (2014 - 2028)	$66.64	$58.78	$66.03	$53.33	$61.95
% Difference	-6.8%	-3.3%	-12.6%	-15.6%	-8.7%

Notes:
All prices expressed in 2015$ per MWh.
Discount Rate 1.36% for AESC 2013, 2.43% for AESC 2015

5.5.4 Forecast of Electric Energy Prices by State

TCR developed monthly on-peak, off-peak and all-hours prices for eight SMD zones, five zones represent individual states and Massachusetts is represented by three zones – NEMA-Boston, SEMA and WCMA. On average, our results show very little price separation between these zones and very little transmission congestion in the future.

5.6 Avoided Cost of Compliance with RPS

The Base Case electric energy and capacity market prices presented in Section 5.5 reflect the projected impact of energy and capacity from renewable resources developed to comply with RPS requirements. This Section describes those resource additions and provides our projection of renewable energy certificates (REC) prices.

5.6.1 Resource Additions to Meet Renewable Portfolio Standards

AESC 2015 assumes load-serving entities (LSEs) will comply fully with RPS requirements, either through acquisition of GIS Certificates/RECs or through making Alternative Compliance Payments (ACP). The rate at which the ACP is set—which varies across the New England states and RPS subcategories[158]—will, however, influence the manner in which compliance is achieved. All else equal (e.g., in the absence of bilateral contracts or asset ownership that would dictate otherwise), states with lower ACPs (Connecticut and New Hampshire) will tend to see a shift from REC to ACP compliance during periods of shortage, while RECs flow to markets where the ACP and REC prices are higher.

The gross requirements for each RPS class were derived by multiplying the load of obligated entities (those retail LSEs subject to RPS requirements, often with exemptions for public power) by the applicable annual class-specific RPS percentage target. The exemptions, which differ somewhat from

[158] State RPS requirements are differentiated by resource type, size/application, or age, resulting in multiple subcategories—also referred to as tiers or classes—within each state's RPS.

those used in AESC 2013, are presented in Exhibit 5-37, along with notes on their derivation. Projected voluntary demand for new resources is added to Class 1 requirements.

Exhibit 5-37. Exemptions from RPS Obligations

State	Percentage of Load Exempt from RPS Requirements	Methodology
CT	6.9%	Determined by comparing 2011 compliance data to ISO-NE real-time load data
MA	17.3%	Mass. DOER forecasts RPS obligated load for 2014 and beyond as 2013 obligated load escalated by ISO-NE CELT MA growth rate.
ME	2.2%	For portion of ME in ISO-NE only. Comparison of 2012 compliance data with ISO-NE real-time load data, using 2010 MPUC load data to determine exempt company load; added exemption for Pine Tree Development Zone.
NH	1.7%	Ratio of EIA municipal load from 2010 EIA-861 to total of that load plus RPS-obligated load from compliance report.
RI	1.2%	Determined by comparing 2012 compliance data to ISO-NE real-time load data

Analysis based on data from the following sources:

NH: "2011 Renewable Energy Portfolio Standard Review," Report of the New Hampshire Public Utilities Commission To the New Hampshire General Court, November 1, 2011; US EIA (2010), Form EIA-861, available at http://www.eia.gov/electricity/data/eia861/index.html.

RI: "Rhode Island Renewable Energy Standard (RES), Annual RES Compliance Report For Compliance Year 2012," Revised 3/25/14, Rhode Island Public Utilities Commission; ISO-NE real time load data for 2012 available at http://www.iso-ne.com/isoexpress/web/reports/pricing/-/tree/zone-info.

The RPS percentage requirements by class and year are listed in Appendix F. The load by state is the AESC 2015 Base Case load forecast (i.e., the gross load forecast assuming no new energy efficiency), as detailed in section 5.3.

The net demand for incremental renewable generation within New England is derived by subtracting from the gross demand:

a) Existing eligible generation already operating

b) Known near-term renewable additions

c) ISO New England's most recent long-term forecast of photovoltaic installations (largely distributed generation), which we extended from 2023 to 2030

d) RPS imports

An estimate of RPS-eligible imports over existing tie lines beyond current certified levels is phased in toward a maximum import, consistent with tie line capacity, competing uses of the lines and appropriate capacity factors of imported resources, the historical trend in RPS-eligible imports, and uncertainties in those factors.

Projected PV generation, based on ISO New England's PV forecast, is netted from demand because PV development is largely driven by policies other than the Class 1 RPS requirements.[159] The majority of PV development is projected to occur in Massachusetts. In AESC 2013, it was assumed that Governor Patrick's April 2013 announcement targeting 1,600 MWdc of solar installed by 2020 increased the MA Solar Carve Out by an incremental 800 MW, for a total Solar Carve-Out obligation of 1,200 MW by 2020. In April 2014, DOER launched the SREC-II program to continue the growth of solar market to meet Governor's 1,600 MWdc by 2020, and has continued to evolve its various incentives to encourage solar development. As of the end of 2014, there were approximately 700 MWdc installed in the state, approximately 280 MW of which was installed in 2014.[160]

In the near term (from 2015 to 2019), we assume that the aggregate net demand for new RPS supply will be met by a mix of renewable resources consistent with: (1) RPS-eligible resources in the New

[159] "2014 Interim Forecast of Solar Photovoltaic (PV) Resources," May 1, 2014, and "PV Energy Forecast Update," September 15, 2014. Presentations to the ISO-NE Distributed Generation Forecast Working Group. The PV forecast includes detailed estimates of installations in each state, developed in conjunction with those states. The projected new entry is primarily policy-forced, but includes a post-policy component; both components embody explicit realization rates that vary over the period.

[160] Analysis based on data from the following sources: MA DOER, "RPS Solar Carve-Out II Qualified Renewable Generation Units," updated February 15, 2015; MA Office of Energy and Environmental Affairs (MA EEA), "Current Status of the Solar Carve-Out II Program," accessed February 22, 2015, available at http://www.mass.gov/eea/energy-utilities-clean-tech/renewable-energy/solar/rps-solar-carve-out-2/current-statis-solar-carve-out-ii.html; MA EEA, "Current Status of the Solar Carve-Out Program," accessed February 22, 2015, available at http://www.mass.gov/eea/energy-utilities-clean-tech/renewable-energy/solar/rps-solar-carve-out/current-status-of-the-rps-solar-carve-out-program.html; Massachusetts 225 CMR 14.00: RENEWABLE ENERGY PORTFOLIO STANDARD - CLASS I.

England administered systems, plus (2) other expected RPS-eligible generation in the development pipeline, which has not entered the queue. This includes both large projects that have not yet filed for interconnection studies, and distributed wind, solar, biomass, small hydro and tidal, and CHP projects, which—due to their size—are not required to go through the large generator interconnection process. Due to the increasing expense of entering and maintaining a position in the interconnection queue, some proposed projects must delay this stage of the process until early site evaluation and permitting progress has been sufficient to attract substantial development capital.

Renewable generation in the ISO interconnection queue that is under construction is listed in Section 5.3.6. Additional proposed generation for which information has entered the public domain, as well as generic renewable supply of various types are added as a result of policies and incentives. This information is grouped by load area as an input to the pCA model.

For the longer term (generally after 2019), we estimate the quantity and types of renewables that will be developed using a supply-curve approach based on resource potential studies. In this approach, discussed further below, resource build decisions are simulated by selecting from a supply curve of potentially available resources based on the resources' REC premium required to attract financing, subject to their ability to qualify under each state's main tier eligibility criteria, given their characteristics. This approach identifies the incremental resources required to meet net incremental Class 1 demand in each year through 2030. The one exception to this approach is solar PV, which as noted above is based on ISO New England's PV forecast.

5.6.2 Impact of Policy Uncertainty on RPS Supply

In some cases, the development and interconnection processes are also delayed by regulatory uncertainty. Examples of such uncertainty are available in each state in today's market—making the regional RPS marketplace increasingly complex and challenging for developers and investors.

A significant example of uncertainty around RPS requirements has to do with resource development in Vermont, the one state in New England without an RPS substantiated by REC retirement. In 2014, Vermont enacted legislation that significantly increased the amount of resources eligible for the state's net-metering program.[161] Formerly capped at 4% of a distribution utilities' load, the quantity of renewable resources eligible for net metering increased to 15%. The legislature has in the past defeated RPS bills and continued to support the resale of RECs associated with SPEED program resources into other New England RPS markets, although that appears to be changing, in part due to developments in other states. The Connecticut PURA was to rule in November 2014 in Docket No. 14-05-36, on whether and to what extent RECs associated with Vermont SPEED resources can be counted for compliance in

[161] State of Vermont, *An Act Relating to Self-Generation and Net Metering*, H.702 (April 2, 2014), http://www.leg.state.vt.us/docs/2014/bills/Passed/H-702.pdf

Connecticut's RPS (or whether that would constitute impermissible double-counting). Other states, notably Massachusetts, are watching the outcome of the proceeding.

The Vermont legislature is currently considering a bill (H.40) to replace the SPEED program with a program called the Renewable Energy Standard and Energy Transformation Program (RESET).[162] As of this writing, the bill is making its way through committee. For the purposes of AESC 2015, we assume no RPS demand for Vermont and that only RECs associated with existing Vermont renewable resources (but not new ones) will be allowed to be counted against RPS obligations in other states, and only through 2016.

5.6.3 REC Prices and Avoided Cost of RPS Compliance

REC prices are, simplistically speaking, effectively the premiums by which the cost of renewable energy exceeds the revenues available to renewable resources through the energy and capacity markets, with the marginal premium setting the market REC price.

RPS targets for Connecticut, Maine, Massachusetts, New Hampshire, and Rhode Island are a percentage of retail load as defined by state-specific legislation and regulation, estimated for AESC 2015 using the provisions in effect as of December 2015. Energy-efficiency programs reduce the cost of compliance because RPS requirements are generally volumetric, in proportion to the total load (in MWh) that must be supplied.[163] Reduction in load due to DSM will reduce the RPS requirements of LSEs and therefore reduce the costs they seek to recover associated with complying with these requirements. The RPS compliance costs that retail customers avoid through reductions in energy usage are equal to the product of REC prices multiplied by the percentage of retail load that a supplier must meet using renewable energy under the RPS regulations.

The following exhibit summarizes the change in Avoided RPS costs between AESC 2013 and AESC 2015. As detailed below, these avoided RPS costs represent a significant increase over the corresponding values in AESC 2013, due primarily to two factors. First, because AESC 2015 Base Case electric energy prices (and generator revenues) are considerably lower than those of AESC 2013, the REC premium for a given resource must be correspondingly higher to make up the shortfall below its levelized cost. The second factor is methodology. AESC 2013 used all-hours average prices to estimate renewable resources' revenues, which would tend to overestimate revenues—and therefore underestimate REC premium—for onshore wind resources, whose output is more heavily weighted toward off-peak / lower-

[162] "New renewable standard would revolutionize energy use in Vermont," J. Herrick, vermontbiz.org, accessed February 28, 2015. Available at: http://www.vermontbiz.com/news/february/new-renewable-standard-would-revolutionize-energy-use-vermont. A draft of the bill can be found at http://legislature.vermont.gov/assets/Documents/2016/WorkGroups/House Natural Resources/Bills/H.40/Draft, Summaries and Amendments/H.40~Aaron Adler~Draft No. 3.1 %282-50pm%29, 2-13-2015~2-17-2015.pdf

[163] Exceptions in New England include solar carve-outs, for which compliance targets are fixed MW quantities.

cost hours. By contrast, AESC 2015 used hourly prices and hourly production for each of the resources in the supply curve.

Exhibit 5-38. Comparison of Avoided RPS Costs

Comparison of Avoided RPS Costs
$/MWh of Load
Levelized Price Impact 2016 - 2030

	CT	ME	MA	NH	RI	VT

Notes
Conversion from 2013$ to 2015$: 1.035
AESC 2013 levelization period (2014-2028) using a 1.36 percent discount rate.

Methodology

The method generally used in AESC 2015 to forecast REC prices, similar to that used in AESC 2013, varies by time period, as follows:

- **2015-2016**: Forecast REC prices are based on historical average broker quotations or bid-ask spreads for short-term forward transactions as of February 2015.
- **2017-2019:** Prices are interpolated by scrutinizing the expected balance between RPS-eligible supply and RPS demand.
- **2020 onward**: REC prices reflect the forecasted cost of new entry, modeled as described herein.

Estimating New or Incremental Renewable Additions and the Cost of New Entry

As with AESC 2013, the AESC 2015 analysis assumes that in the long run, the price of renewable energy certificates (and therefore the unit cost of RPS compliance) will be determined by the cost of new entry of the marginal renewable energy unit, relative to energy and capacity market revenues.

To estimate the REC premium, we forecast REC prices for each RPS subcategory, by state and by year, using a renewable resource expansion model that builds the least-cost set of resources needed to satisfy the RPS requirements net of existing resources. The “cost” of each renewable resource in this sense is the premium it needs above the energy and capacity market revenues it would receive, expressed as revenues per unit of energy generated, to equal its levelized cost of energy.

The model captures the various subcategory-specific nuances of the RPS requirements, including the degree to which rules limit resource eligibility based on characteristics and location, limitations on banking and borrowing, and ACPs that change over time.[164] The model also constrains the amount of a given resource that can be built in a given year in a given location to an estimate of technical potential. This is a different approach than AESC 2013, which calculated the market revenues of a renewable resource based on the all-hours average forecast LMP, the resource's capacity factor and forecast capacity prices. AESC 2015 calculates the annual market revenues of a renewable resource for each year based on the location of the resource, the forecast output of the resource in each hour, the AESC forecast of hourly energy prices for that location in that year and the AESC forecast of capacity prices for that location in that year. Revenues past 2030 for post-2020 installations are assumed to stay at the level of 2030 revenues in real terms.

AESC 2015 obtained or derived levelized costs and technical potential data for each resource type from various publicly available resource potential studies and economic analysis.[165] The estimated levelized costs are based on several key assumptions, including projections of capital costs, capital structure, debt terms, required minimum equity returns, and depreciation. Those assumptions are specific to the resource type and size and in some cases cover a range to account for a diversity of arrangements. The assumptions also include fixed and variable operations and maintenance costs, transmission and interconnection costs (as a function of voltage and distance from transmission), and wind integration costs.

As in AESC 2013, our analysis assumes there will be adequate transmission to accommodate the additional generation from these new renewable resources, and that the costs of any needed transmission upgrades will be socialized. Estimating the extent to which existing transmission facilities would require major upgrades (to integrate renewables or for any other reason) was beyond the scope

[164] In the event that an LSE purchases RECs in excess of its current year RPS obligation, states generally allow LSEs to save and count that quantity of compliance against either of the following two compliance years, subject to limitations. This compliance flexibility mechanism is referred to as banking. LSEs are also allowed to meet prior-year deficiencies with current year RECs (again, subject to limitations)—a provision sometimes called "borrowing." LSEs may only bank compliance within a single state, and may not transfer banked compliance credit to other entities.

[165] These assumptions are based on technology data compiled by Longwood Energy Group from a range of publicly available studies and interviews with industry participants. Public studies include: *Renewable Resource Supply Curve Report*, NESCOE, January 2012, *New England Wind Supply Curve*, Sustainable Energy Advantage, November 2011, *Lazard's Levelized Cost of Energy Analysis*—Version 8.0, Lazard, September 2014, *Recent Developments in the Levelized Cost of Energy from U.S. Wind Power Projects*, R. Wiser et al., NREL and LBNL, February 2012, *Levelized Cost and Levelized Avoided Cost of New Generation Resources in the Annual Energy Outlook 2014*, EIA, April 2014, *Levelized Costs of Electricity from CHP and PV*, Program Record 14003, T. Nguyen et al., US DOE, March 2014, and *Energy Efficiency and Renewable Energy Potential Study of New York State*, Final Report, Report Number 14-19, NYSERDA, April 2014. Data from these and other sources served as inputs to our own analysis to adjust and control for various parameters including vintage, cost trends, inflation, financing, penetration, geographic location, plant size and capacity factor.

of work for AESC 2015. Hence we do not provide the costs of any such upgrades or include them in our estimates of avoided costs.

AESC 2015 differentiates the levelized costs of resources by type, project size, and geographic location. Each of the resource blocks making up the potential supply curve are characterized by total nameplate capacity, hourly production profile, levelized cost, and operation applicable to projects coming online in each year. The potential supply curve consists of land-based wind, biomass, hydro, landfill gas, and offshore wind.

The Federal Production Tax Credit (PTC), renewed in December 2014, is assumed not to be extended again, such that only resources beginning construction before the end of 2014 are eligible. The Investment Tax Credit (ITC) is assumed to expire after 2016.

Unless the revenue from REC prices can make up the required REC premium, a project is unlikely to be developed, and in our simulation it will not be built. The highest REC premium of any resource built in a given subcategory, i.e., the marginal price, will set the REC price. Our projections assume that Class 1 REC prices for new renewables will not fall below $2/MWh—the estimated transaction cost associated with selling renewable resources into the wholesale energy market—except in the presence of an administratively set floor price. This estimate is consistent with effective market floor prices observed in various markets for renewable resources.

To project Maine Class 1 REC prices, we used an approach different from that of the other states, because Maine has put in place eligibility criteria that depart considerably from regional Class 1 norms, resulting in idiosyncratic market behavior. Under the Maine rules, compliance can be achieved largely with refurbished biomass generation that is ineligible in other states. The potential supply of eligible refurbished biomass resources in and outside Maine is not likely to be constrained in the time horizon of this analysis, given the modest increase in the Base Case Maine RPS obligation over the period. Beyond 2016, we estimated Maine Class 1 REC prices as the greater of (1) the difference between (a) an imputed levelized cost of energy based on 2015 REC prices and simulated biomass revenues and (b) simulated revenues going forward, and (2) the $2/MWh assumed floor described above.

Existing solar facilities across New England are eligible for NH Class II. As such, this market is expected to remain in balance and settle marginally above the MA Class I REC price for the remainder of the study period. As in AESC 2013, New Hampshire Class II REC prices are estimated at the lesser of (1) 90% of the ACP rate and (2) 105% of the Massachusetts/Maine/Rhode Island Class 1 ACP.

For RPS tiers for which we are not projecting prices using simulation, and for which no liquid forward market exists, we assume prices to stay, in real terms, at the level of broker-derived prices across the time horizon. The exception to this approach is for RPS classes focused on existing supply but for which such existing supply has not been certified by the applicable RPS authority in a quantity sufficient to meet demand. Near-term REC prices for such classes are estimated based on current broker quotes and the applicable ACP. REC prices are assumed to trend toward values which reflect a market in equilibrium or modest surplus over time, as existing generators become certified and participate in the program.

Exhibit 5-39 lists near-term REC market prices.

Exhibit 5-39. REC and APS Prices for 2015 and 2016 compliance years

		2014 REC Prices Q3&Q4 2014 Average (2015$/MWh)	2015 REC Prices Feb 2015 (2015$/MWh)	2016 REC Prices Feb 2015 (2015$/MWh)

We use the terms "Class 1" or "main tier" generally to refer to new or incremental renewable resources that qualify as Class I in Connecticut, Massachusetts, New Hampshire, Maine, and as "New" in Rhode Island. Class 1 REC prices will be driven both by the costs of renewable resources eligible in each state and by the quantity of state-specific supply compared to state-specific demand. Because RPS eligibility criteria differ by state, REC prices are differentiated by state and reflect state-specific expectations with respect to generator certification.

Massachusetts is unique in its treatment of the solar carve-out portion of its Class 1 obligation. While the carve-out itself is not unique, Massachusetts establishes an annual MWh obligation, which is then allocated among the obligated LSEs. In aggregate, this solar target is converted into a percentage of state load and is removed from the Class 1 percentage target for that year—thereby reducing the Class 1 RPS compliance obligation avoidable through energy efficiency activities. Because the solar carve-out represents an LSE obligation to procure a fixed quantity (MWh) of Solar RECs (SRECs) each year, we therefore treat it as not avoidable through energy efficiency measures that reduce all other RPS obligations.

Connecticut's current eligibility definitions also allow for certain biomass supply to be uniquely eligible in Connecticut, but its RPS targets have increased at a pace such that this supply is now sub-marginal.

Secondary tiers

While Class I RPS requirements generally spur the development of new renewable resources, Class II, III, and IV requirements are generally designed as "maintenance tiers," with the exception of special categories for new thermal and CHP resources. The maintenance tier programs are intended to provide just enough financial incentive to keep the existing fleet of renewable resources in reliable operation. Due to their maintenance orientation, Class II, III and IV percentage targets are generally held constant, with annual obligations varying only based on changes in the demand forecast.

CT Class II, MA Class II-WTE (waste to energy), ME Class II, and RI "Existing" REC markets have been in surplus. Therefore, REC prices in these markets are expected to remain relatively constant at levels just above the transaction cost. The MA Class II-RE (non-waste) market (which has overlapping eligibility with CT Class I), has an obligation that rises annually until 2016, whereas the Class II-WTE obligation remains fixed.

While there is theoretically ample supply to meet MA Class II and New Hampshire Class III, fewer generators than expected have undertaken the steps necessary to comply with the eligibility criteria and become certified. As a result, those two markets have been in shortage. As a result, steps have been taken in both markets to address the imbalance. Retroactive regulatory revisions to MA Class II were announced in February 2014 and completed in June in part to bring the market into a balance more consistent with a policy targeting existing resources, with less reliance on the ACP mechanism. The changes have left the market much less short of demand in 2013 than it was in 2012.[166] The market is still short, however, with obligated entities paying ACPs to cover the shortfall, albeit few of them; the current REC price is essentially unchanged from the then-current price in AESC 2013. For these reasons we continue the assumption that long-run MA Class II REC prices to be the lesser of CT Class I REC prices and 50 percent of the MA Class II ACP rate.

The NH Class III (existing biomass/methane) and NH Class IV (existing small hydro) markets[167] have overlapping eligibility with the higher-priced CT Class I, and have historically competed with that program for resources, resulting in compliance that has relied heavily on ACP payments. The New Hampshire PUC in 2014 solicited comments regarding adjusting RPS requirements for 2013-2015, in particular for Class III.[168] The order reduced only the Class III requirement for 2013 (to 0.5 percent), it is

[166] Massachusetts RPS & APS Annual Compliance Report for 2013, MA DOER, December 17, 2014.

[167] Several Class III biomass and Class IV hydroelectric facilities have been certified in both NH III or IV, respectively, and CT Class I.

[168] Order Reducing Class III Requirements for 2013 to 0.5% of Retail Sales. Order No. 25,674 in Docket No. DE 14-104, ELECTRIC RENEWABLE PORTFOLIO STANDARD, Adjustments to Renewable Portfolio Class Requirements, June 3, 2014.

slated to rise to 8% in 2015, and the PUC may make further changes after continuing to monitor the markets.

Responding to a recommendation by the Connecticut Department Of Energy and Environmental Protection (DEEP) to reduce reliance on out of state biomass and landfill gas to meet Connecticut's Class 1 targets, the legislature in 2013 passed a law requiring the Commissioner of Environmental Protection to "…establish a schedule to commence on January 1, 2015, for assigning a gradually reduced renewable energy credit value to all biomass or landfill methane gas facilities that qualify as a Class I renewable energy source…"[169] Such a change could enhance New Hampshire's ability to meet its Class III targets, although the law is rather vague and it's unclear what shape the changes will take.[170] DEEP is now recommending delaying a reduction in biomass REC values until 2018.[171]

In the long-run, NH-III and NH-IV REC prices are assumed to be the lesser of CT Class I and 90 percent of their respective ACP rates.

The MA Alternative Energy Portfolio Standard (APS), which provides incentives for investments in efficient thermal or storage resources such as CHP (including natural gas fuel cells), flywheel storage, geothermal heat pumps, and waste heat recovery, is in significant shortage. Both the APS and the similar CT Class III are less fungible than other REC markets because of the need to use any thermal energy produced in-state. The CT Class III market, like the APS, has had difficulty meeting its goals, given insufficient CHP development.[172] The CT Class III goal remains fixed at 4 percent, and Connecticut ACPs are fixed in nominal terms, which mean they decline in real terms rather than rise with inflation as those of most other states. By contrast, the APS goal continues to increase, and its ACP is indexed for inflation. REC prices for MA APS are forecasted at 90 percent of the ACP rate; CT Class III prices are expected to remain at about 86 percent of ACP (therefore declining in real terms) over the period.

Existing solar facilities across New England are eligible for NH Class II. As such, this market is expected to remain in balance at about 90 to 95 percent of ACP, as solar resources age out of solar carve outs and competing Class 1 prices drop.

Class I requirements will outpace the other classes on a GWh basis over time. This phenomenon is shown in Exhibit 5-40, which summarizes New England's total renewable energy requirements by year,

[169] Subsection (h) to Connecticut General Statue section 16-245a, effective June 5, 2013.

[170] "The Gradually Reduced Credit for Biomass Energy in Connecticut: A Vague But Still Constitutional Standard," Brian M. Gibbons, Connecticut Law Review, V.47, December 2014.

[171] 2014 Integrated Resource Plan For Connecticut, Draft For Public Comment, Prepared by The Connecticut Department Of Energy and Environmental Protection, December 11, 2014. "The Department proposes to monitor RPS compliance and the capacity market and, in the next IRP, consider establishing a schedule for reduced REC value beginning in 2018 subject to the comments and feedback from stakeholders."

[172] Beginning in 2014, ratepayer-funded energy efficiency resources were no longer eligible in Connecticut Class III formerly included energy conservation and load management. Prior to that time, prices remained near the $10 administratively set floor. Since the phase-out of energy efficiency resources, prices have been more reflective of the gap between demand and supply.

based on the RPS percentage targets by state and the AESC 2015 Base Case / gross load forecast, as discussed in Chapter 5. Exhibit 5-41 distinguishes between the quantities of Class I renewables that are required and the *aggregate* quantity of all other classes of renewables combined.

Exhibit 5-40. Summary of New England RPS Demand

New England Annual RPS Demand (GWh)			
Year	**Class 1**	**Other Classes**	**Total**
2015	10,931	11,387	22,318
2016	12,325	11,872	24,197
2017	13,718	12,051	25,769
2018	14,882	12,145	27,027
2019	16,542	12,378	28,920
2020	17,474	12,613	30,088
2021	18,265	12,853	31,118
2022	19,069	13,097	32,166
2023	19,887	13,343	33,230
2024	20,721	13,594	34,315
2025	21,570	13,848	35,418
2026	22,315	14,106	36,421
2027	23,072	14,368	37,440
2028	23,842	14,634	38,476
2029	24,626	14,903	39,529
2030	25,422	15,177	40,599

Notes:

Based on Base Case load forecast and RPS targets as of 12/31/2014, with exemptions for non-obligated entities, and Maine NMISA demand excluded. Class I includes Solar Carve Outs. Does not include voluntary demand.

The major sources of the renewable supply forecast used to meet the RPS requirements by year are shown in Exhibit 5-41. These sources include wind (onshore and offshore), biomass, and hydro.

2028	9,705	4,569	2,906	1,053	1,694	3,111	**23,038**
2029	10,499	4,598	2,971	1,054	1,694	3,248	**24,064**
2030	11,322	4,627	3,037	1,055	1,694	3,386	**25,122**

Includes existing and projected energy production by Class 1 renewables and CHP. Hydro includes tidal. CHP includes natural gas fuel cells. CHP listed in terms of GWhe, except for MA CHP, listed in terms of AEC GWh.

The expected distribution of Class 1 RPS supplies between ISO-NE and adjacent control areas is summarized in Exhibit 5-42. Supply is categorized as follows:

- Existing eligible generation already operating
- Known additions not yet operating
- Projected incremental renewable resources by fuel type
- Energy / RECs currently imported from RPS-eligible facilities located outside of ISO-NE
- Assumed incremental energy / RECs imported from outside of ISO-NE

Exhibit 5-42. Expected Distribution of New Renewable Energy between ISO-NE and Adjacent Control Areas

	Class 1 RPS Supply (GWh)					New Renewable Requirement (GWh)	New Renewable Energy Surplus (Shortage)
	ISO-NE Supply		Imported Supply				
Year	Operating	Incremental	Current	Expected	Total Supply

2030	7,181	14,578	1,662	2,938	26,359	26,358	0

Notes:

RPS requirement is scaled to Base Case load. Requirement and supply quantities here reflect those of main tiers for new renewables, including solar carve-outs, plus voluntary demand. The Massachusetts APS and similar programs are not included here. Vermont supply is included only through 2016, resulting in a decrease in column (a) quantity thereafter. Much of the column (g) shortages shown for 2019-2020 could be offset by banked surpluses from 2014 (not shown) through 2016, parlayed forward by banking in each intervening year.

Exhibit 5-42 also compares total Class 1 RPS supply to total Class 1 RPS demand. The combination of operating supply, projects currently under development, imported supply and resource potential from the renewable energy supply curve analysis are expected to keep supply and demand in balance through 2030.

The eligibility details and target percentages for main tier and secondary tier resources are summarized in Appendix F.

5.6.4 Estimated Cost of Entry for New or Incremental Renewable Energy

Our general approach to estimating the cost of entry for new or incremental renewable supply is described above.

Beginning in 2020, regional REC prices are expected to converge as all states rely on new or incremental renewable resources to meet their RPS demands—with only modest price differentials between states based on eligibility, bank balances and utility-specific decisions to retire the RECs from long-term contracts in satisfaction of RPS obligations. Our projection of the cost of new entry for each state is summarized in Exhibit 5-43.

Exhibit 5-43. REC Premium for Market Entry

AESC 2015 Class 1 REC Premium (2015$/MWh)						
	CT	**ME**	**MA**	**NH**	**RI**	**VT**
2015	$53.10	$4.38	$57.56	$54.97	$53.50	$0.00
2016	$49.96	$5.41	$56.34	$52.50	$49.16	$0.00
2017	$47.62	$4.27	$52.40	$49.52	$47.02	$0.00
2018	$45.27	$5.99	$48.46	$46.54	$44.87	$0.00
2019	$42.92	$7.39	$44.52	$43.56	$42.72	$0.00
2020	$40.57	$8.04	$40.57	$40.57	$40.57	$0.00
2021	$36.75	$5.60	$50.50	$49.61	$48.78	$0.00
2022	$46.63	$2.39	$46.69	$46.69	$46.69	$0.00
2023	$43.94	$2.00	$43.62	$43.94	$43.39	$0.00
2024	$42.00	$2.00	$41.38	$41.38	$41.38	$0.00
2025	$38.74	$2.00	$38.74	$38.74	$38.74	$0.00
2026	$35.79	$2.00	$35.72	$35.72	$35.72	$0.00
2027	$32.86	$2.00	$32.86	$32.86	$32.86	$0.00
2028	$30.13	$2.00	$35.28	$30.13	$30.13	$0.00
2029	$32.66	$2.00	$32.66	$32.66	$32.66	$0.00
2030	$30.46	$2.00	$30.46	$30.46	$30.46	$0.00
2016-2030 levelized	**$40.32**	**$3.84**	**$42.74**	**$41.66**	**$40.93**	**$0.00**

These REC premium results reflect the RPS demands of the post-2018 Base Case load forecast. (The load in the BAU Case is lower and would have a commensurately lower RPS requirement). The REC premiums are highly dependent upon the forecast of wholesale electric energy market prices, including the underlying forecasts of natural gas and carbon allowance prices. A lower forecast of market energy prices would yield higher REC prices than shown, particularly in the long term. In most cases, project developers will need to be able to secure long-term contracts (or financial equivalents, such as synthetic PPAs), and attract financing based on the aforementioned natural gas, carbon, and resulting electricity price forecasts. This presents an important caveat to the projected REC prices, because such long-term electricity price forecasts (particularly to the extent that they are influenced by expected carbon regulation) are not easily taken to the bank.

In contrast to the long-term REC cost of entry, spot prices in the near term will be driven by supply and demand, but are also influenced by REC market dynamics and to a lesser extent to the expected cost of entry (through banking), as follows:

- Market shortage: Prices approach the cap or Alternative Compliance Payment
- Substantial market surplus, or even modest market surplus without banking: Prices crash to approximately $0.50 to $2/MWh, reflecting transaction and risk management costs
- Market surplus with banking: Prices tend towards the cost of entry, discounted by factors including the time-value of money, the amount of banking that has taken place, expectations of when the market will return to equilibrium, and other risk management factors

These Class 1 REC prices, with the exception of Maine, represent a significant increase over the corresponding values in AESC 2013. The increase is due primarily to two factors. First, because AESC 2015 Base Case electric energy prices (and generator revenues) are considerably lower than those of AESC 2013, the REC premium for a given resource must be correspondingly higher to make up the shortfall below its LCOE. Although capacity revenues are higher in AESC 2015 than in 2013, capacity payments don't comprise a large share of market revenues wind resources whose REC premiums set the clearing price for much of the period. Part of the increase is likely attributable to methodology. AESC 2013 used all-hours average LMPs to estimate renewable resources' revenues. By contrast, AESC 2015 used hourly LMPs and hourly production for each of the resources in the supply curve. Onshore wind resources tend to produce more during off-peak periods when prices are lower, so an all-hours average energy price may overestimate energy revenue, leading to an underestimate of the required REC premium. Finally, Class 1 RPS requirements, which on average increase over time, are in many cases higher for the 2015-2030 period than for the 2013-2028 period analyzed in AESC 2013.

In the AESC 2015 analysis, REC prices decline over the period—although not uniformly—as revenues increase and technology learning curves reduce LCOEs—countering the effect of moving further up the supply curve as less expensive resources are exhausted.

REC premiums hit the caps set in the model in only one instance—in Connecticut (2022).[173] This year corresponds to the tightest period of supply relative to net demand, and it is possible that more significant banking might have alleviated the shortfall. Unlike in all other states where ACPs are indexed to inflation (CPI) , Class 1 ACPs in Connecticut and New Hampshire decline in real terms over time, while demand increases.[174] As a result, during times when REC premiums are high, supply naturally flows to other states.

[173] The caps were set at 90% of ACP in all states but Connecticut and New Hampshire, set at 97% of ACP.

[174] ACPs in Connecticut are fixed in nominal terms; Class I and II ACPs in New Hampshire escalate at only half of CPI, and thus also decrease in real terms.

As described above, Maine is an outlier with regard to Class 1 market prices, owing to its eligibility criteria significantly less constraining than those of other states. Compliance with Maine's Class 1 requirement is predominantly achieved using new or refurbished biomass resources that are ineligible in other states. As a result, the market there is somewhat oversupplied, with prices currently in the range of $5 per MWh. Prices rise somewhat before falling to the assumed floor in 2023.[175]

Detailed projections of REC prices by state for Class I renewables are presented in Appendix F.

5.6.5 Calculating Avoided RPS Compliance Cost per MWh Reduction

The RPS compliance costs that retail customers avoid through reductions in their energy usage is equal to the price of renewable energy in excess of market prices (e.g., the REC price) multiplied by the portion of retail load that a supplier must meet from renewable energy under the RPS. In other words,

Avoided RPS cost = REC price × RPS requirement as a percentage of load

We calculate the RPS compliance costs that retail customers in each state avoid through reductions in their energy usage in each year for each major applicable RPS tier as follows:

$$\frac{\sum_n P_n \times R_n}{1 - L}$$

Where:

n = the RPS class

P_n = projected price of RECs for RPS class n

R_n = RPS requirement, expressed as a percentage of energy load, for RPS class n, from Appendix F

L = the load-weighted average loss rate from ISO wholesale load accounts to retail meters

For example, in a year in which REC prices are $30/MWh and the RPS percentage target is 10 percent, the avoided RPS cost to a retail customer would be $30 × 10% = $3/MWh. Detailed results from Appendix C are incorporated into the Appendix B Avoided Cost Worksheets by costing period.

For the purposes of calculating the avoided RPS cost associated with the MA Class 1 requirement, of which the MA Solar Carve-Out is a subset, we project the incremental capacity of SCO resources installed in each year and the energy generated during the first ten years after installation, and divide

[175] A scenario in which Maine Class 1 prices fall even sooner is possible should Governor Paul LePage's proposal to lift the 100 MW cap on hydro resources be adopted. The Governor has pushed for this policy change four years in a row, but it has failed amid bipartisan opposition.

the cumulative energy generated by the RPS-eligible load to yield a load percentage for each year that is subtracted from the MA Class 1 requirement. The carve-out percentage increases to a maximum of 3.6% in 2020, and decreases to 0.1% by 2030.

The year-by-year RPS percentages for each RPS class are shown in Appendix F. The levelized RPS price impact for the 2016 to 2030 period, in 2015$ per MWh of load, is shown below.

Exhibit 5-44. Avoided RPS Cost by Class, Levelized Price Impact 2016 - 2030

	CT	ME	MA	NH	RI	VT
Class 1	$7.13	$0.41	$6.72	$4.90	$5.17	$0.00
All Other Classes	$1.08	$0.10	$2.09	$3.77	$0.02	$0.00
Total	$8.22	$0.51	$8.81	$8.67	$5.18	$0.00

The exhibit shows (with the exception of Maine) levelized avoided costs of 1.4 - 1.9 times those of AESC 2013, with the increase attributable primarily to higher REC premiums, and to a lesser extent, RPS requirements that increase with time.[176]

5.7 Assessment of Alternative Electric Energy Costing Periods

The Study Group asked the AESC 2015 project team to recommend alternative costing periods if an analysis of avoided cost results indicates that the alternative costing periods may more accurately and reasonably reflect seasonal and hourly variation of marginal energy costs than the existing on-peak and off-peak costing periods. In essence the goal is to determine whether more granular costing periods, referred to as "super on-peak" periods, may provide a more accurate value of reductions which occur primarily during that time period. This section describes our analyses and recommendations regarding super on-peak periods.

5.7.1 Analysis of alternative costing periods

AESC 2015 analyzed electric energy prices by hour in summer on-peak periods and in winter on-peak periods in four steps.

First it identified the months within each season during which on-peak period energy prices by hour were consistently the highest. That analysis indicated that on-peak period energy prices by hour in June,

[176] AESC 2013 calculated 15-year levelized costs for 2014-2028, while the period 2016-2030 is used here. This has the effect of dropping the two years with the lowest RPS requirements (2014-2015) while adding two years with the highest (2028-2030).

July and August were consistently higher than September. Using a similar approach we identified three winter months for further assessment - December, January and February.

Second, it analyzed five data sets of hourly prices for the WCMA zone for each of those months, three sets of historical energy prices and two sets of projected energy prices. The historical data sets are from 2012, 2013 and 2014, the projected prices are from the Base Case for June 2019 through May 2020 and for June 2025 to May 2026. For each dataset we computed average prices for each on-peak hour in each of the three summer months and each of the three winter months. For example, for June 2012 we computed average hourly prices for each of the 16 on-peak hours, i.e. hours beginning at 07:00 and ending at 23:00.

Third, it analyzed energy prices by hour in blocks of four consecutive hours for several different possible blocks in order to identify candidate super on-peak periods by season. For winter months we analyzed the following 4 hour blocks: between hours beginning at 14:00 and ending at 18:00, 15:00 -19:00, 16:00 -20:00 and 17:00 -21:00. For summer months we analyzed the following 4 hour blocks: between hours beginning at 11:00 and ending at 15:00, 12:00 -16:0, 13:00 -17:00 and 14:00 -18:00.

Fourth, it ranked each different 4 hour block within each season according to the block's average price of energy by hour during each season. The block with the highest average price was ranked 1 and the block with the lowest average price was ranked 4. Exhibit 5-45 presents the ranking results.

Exhibit 5-45. Ranking of candidate super on-peak Periods for avoided energy costs

Winter Blocks	**2012**	**2013**	**2014**	**2019/20**	**2025/26**	**Total of Ranks**
14:00-18:00	4	3	4	4	3	18
15:00-19:00	3	2	3	3	2	13
16:00-20:00	**1**	**1**	**2**	**2**	**1**	**7**
17:00-21:00	2	4	1	1	4	12
Summer Blocks	**2012**	**2013**	**2014**	**2019/20**	**2025/26**	**Total of Ranks**
11:00-15:00	4	3	4	4	4	19
12:00-16:00	3	1	3	2	1	10
13:00-17:00	**1**	**2**	**1**	**1**	**2**	**7**
14:00-18:00	2	4	2	3	3	14

The summer block with the highest ranking begins at hour 13:00 and ends at 17:00. This block coincides with the summer Demand Resource Forecast Peak Hours defined by ISO-NE.[177] The winter block with the highest ranking begins at 16:00 and ends at 20:00 in the winter. This block encompasses the winter Demand Resource Forecast Peak Hours defined by ISO-NE as the two-hour block beginning at 17:00 and ending at 19:00 on non-holiday weekdays during the months of December and January.

[177] ISO-NE Tariff, Section I – General Terms and Conditions, Definition of Demand Resource Forecast Peak Hours.

Exhibit 5-46 presents the key statistics on the duration and prices during super-peak hours relative to the average on-peak period price for that season for each of the five datasets.

Exhibit 5-46. Ratio of average price in top ranked candidate super-peak to average price for season on-peak

	2012	2013	2014	2019/20	2025/26	Average
Winter						
HOURS						
Peak (Oct – May, 1)	2800	2800	2784	2784	2768	2787

Notes

1. Peak period is weekday hours, 7 am to 11 pm.

Based on the results of this analysis, AESC 2015 recommends the following super on-peak periods for avoided electric energy costs. For summer months of June through August, weekdays only (excluding holidays defined by ISO-NE), four hour interval from hour beginning at 13:00 to hour ending at 17:00, EDT. For winter months of January, February and December, weekdays only (excluding holidays defined by ISO-NE), four hour interval from hour beginning at 16:00 to hour ending at 20:00, EST.

Chapter 6: Sensitivity Cases

AESC 2015 prepared two sensitivity analyses, a lower load case and a higher gas price case, to provide information on how major changes to key assumptions used in the Base Case may affect electric avoided costs. The two sensitivity cases are a BAU Case, which is the lower load case, and a High Gas Price Case.

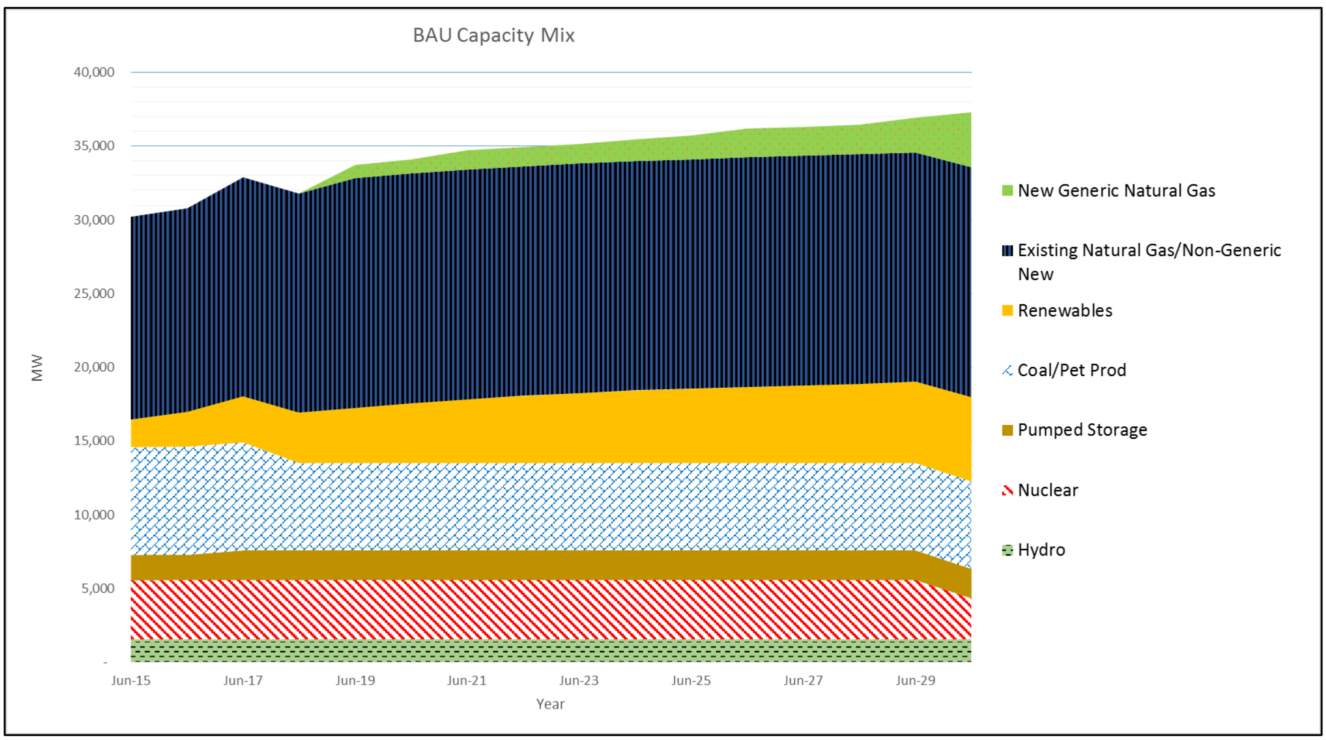
6.1 BAU Case

The BAU Case, also referred to as the market price sensitivity Case, represents a future under which ratepayer energy efficiency continues to be approved at the levels projected by ISO NE. The projected prices are a forecast of market prices under this future.

6.1.1 Forecast of Capacity and Capacity Prices

The projected level and mix of capacity in the BAU Case is presented in Exhibit 6-1. New capacity additions include renewable resources to comply with RPS requirements, as well as new natural gas generators added to meet energy and reserve margin requirements. A substantial portion of the existing oil (Pet Prod) and coal capacity is forecast to retire by 2025. Because of the relatively high price of oil compared to other fuels, these generating plants are rarely dispatched.

Exhibit 6-1. BAU Case Capacity by Technology vs. Peak Demand (MW)



6.1.2 Forecast of Energy and Energy Prices

Exhibit 6-2 illustrates the projected level and mix of generation in the BAU Case.

Generation from nuclear remains flat until year 2029 and declines in 2030 assuming retirement of Seabrook in March of that year, and coal generation declines substantially as most units are retired. Generation from natural gas is the dominant resource, and renewable generation increases over time in compliance with RPS requirements. However, given the absence of the load growth during the planning horizon under the BAU/ Case the projected growth of renewable generation is relatively mild. Generation mix shown does not add up to the total energy demand because it does not account for the interchange with neighboring systems and for net pumping of energy by pumped storage generators.

Exhibit 6-2. BAU Case Generation by Fuel (MWh)

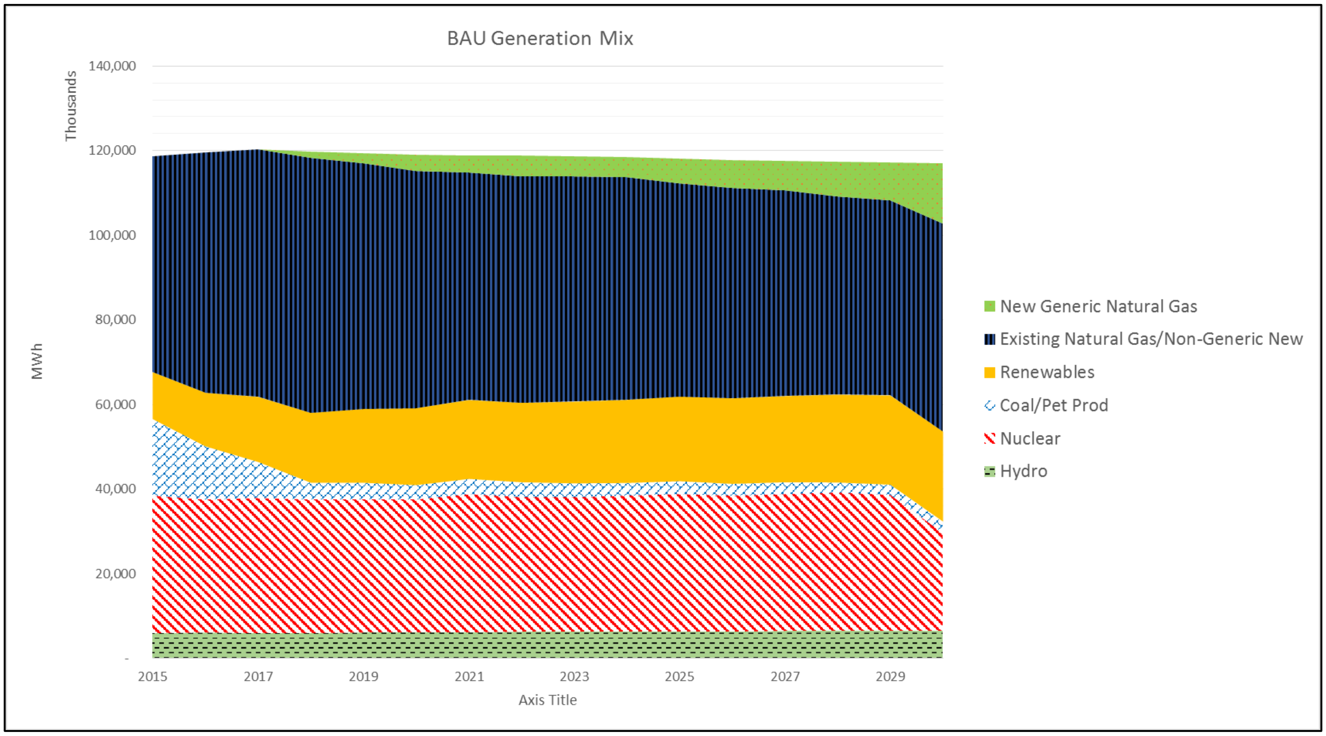


Exhibit 6-3 provides annual summaries by year, season and Peak vs. Off-Peak time periods.

Exhibit 6-3. Wholesale Energy Price Forecast for Central Massachusetts (2015$/MWh)

	Summer			Winter		
Year	Off-Peak	OnPeak	AllHours	Off-Peak	OnPeak	AllHours
2015	$30.50	$39.46	$34.84	$64.88	$73.24	$68.85
2016	$30.93	$47.01	$38.54	$61.75	$66.61	$64.05
2017	$36.63	$48.58	$42.29	$59.06	$63.74	$61.28
2018	$39.86	$48.03	$44.19	$49.04	$53.70	$51.35
2019	$38.85	$50.00	$44.16	$48.74	$53.29	$51.26
2020	$36.96	$46.27	$41.43	$47.72	$53.13	$50.29
2021	$40.25	$48.69	$44.29	$50.22	$54.13	$52.06
2022	$43.00	$58.05	$50.21	$52.15	$57.21	$54.54
2023	$45.13	$56.94	$50.76	$53.77	$58.72	$56.11
2024	$47.22	$58.45	$52.54	$56.02	$61.89	$58.85
2025	$49.27	$63.20	$55.86	$59.09	$65.95	$62.39
2026	$51.14	$63.23	$56.93	$60.30	$67.21	$63.58
2027	$53.54	$69.23	$61.02	$62.78	$68.17	$65.35
2028	$55.81	$68.11	$61.69	$64.48	$69.87	$67.04
2029	$58.36	$71.54	$64.61	$67.50	$74.82	$71.01
2030	$61.77	$82.38	$71.66	$70.22	$77.51	$73.73

6.1.3 Benchmarking of Energy Model

The scope of work requested the following analyses of the AESC 2015 wholesale electric energy price forecast:

- Comparisons with other trends and forecasts, including comparisons to a trend of actual monthly prices from ISO-NE and a forecast as represented by the NYMEX futures market and the most recent relevant EIA forecast;
- A high-level discussion of reasons for differences identified in the comparisons; and
- Explanation of any apparent price spikes and key variables that affect the outcome, as well as identification of potential cases worthy of investigation.

6.1.4 ISO NE 2013 Actuals

TCR benchmarked the ability of its model to simulate the actual operation of the energy market by doing a “back cast” simulation of the ISO New England system for 2013. In that simulation, TCR used pCa to project hourly energy prices in 2013 using as inputs actual hourly loads by zone, actual interchange schedules between ISO-NE and neighboring systems, actual daily natural gas prices and estimated daily distillate and residual fuel oil prices derived from actual daily crude oil prices and TCR regression models. TCR compared its simulated prices to actual 2013 Day-ahead LMPs. The comparison of simulated prices by SMD Zone is presented in Exhibit 6-4. The solid bars in that Exhibit represent actual prices and the patterned bars represent simulated prices. As shown in that Exhibit, pCA model accurately captures the magnitudes and the locations spread of LMPs in New England over that historical time period.

Exhibit 6-4. Comparison of Actual and Simulated Locational Marginal Prices in ISO New England by SMD Zone (2015$/MWh)

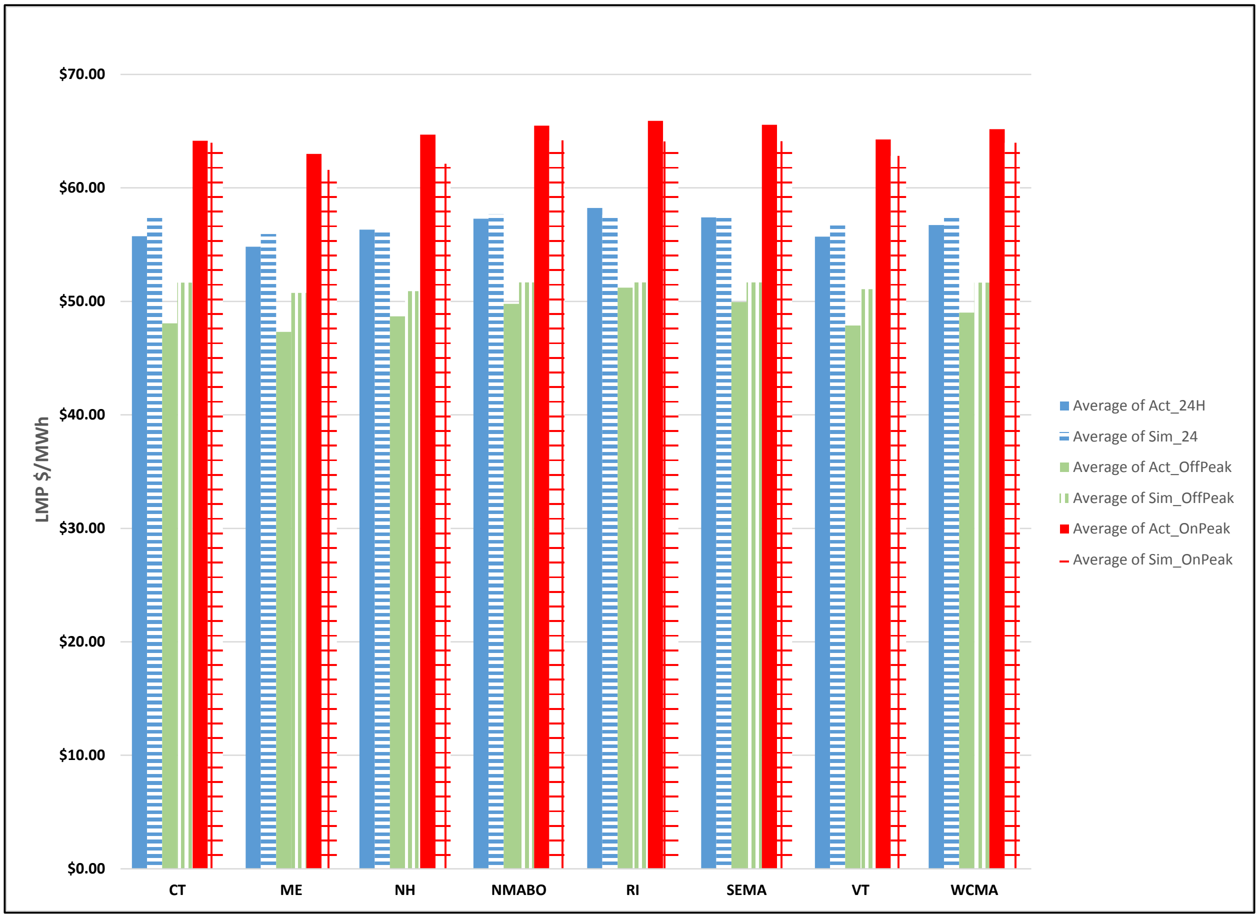

Exhibit 6-5 compares simulated and actual monthly prices for the WCMA Zone.

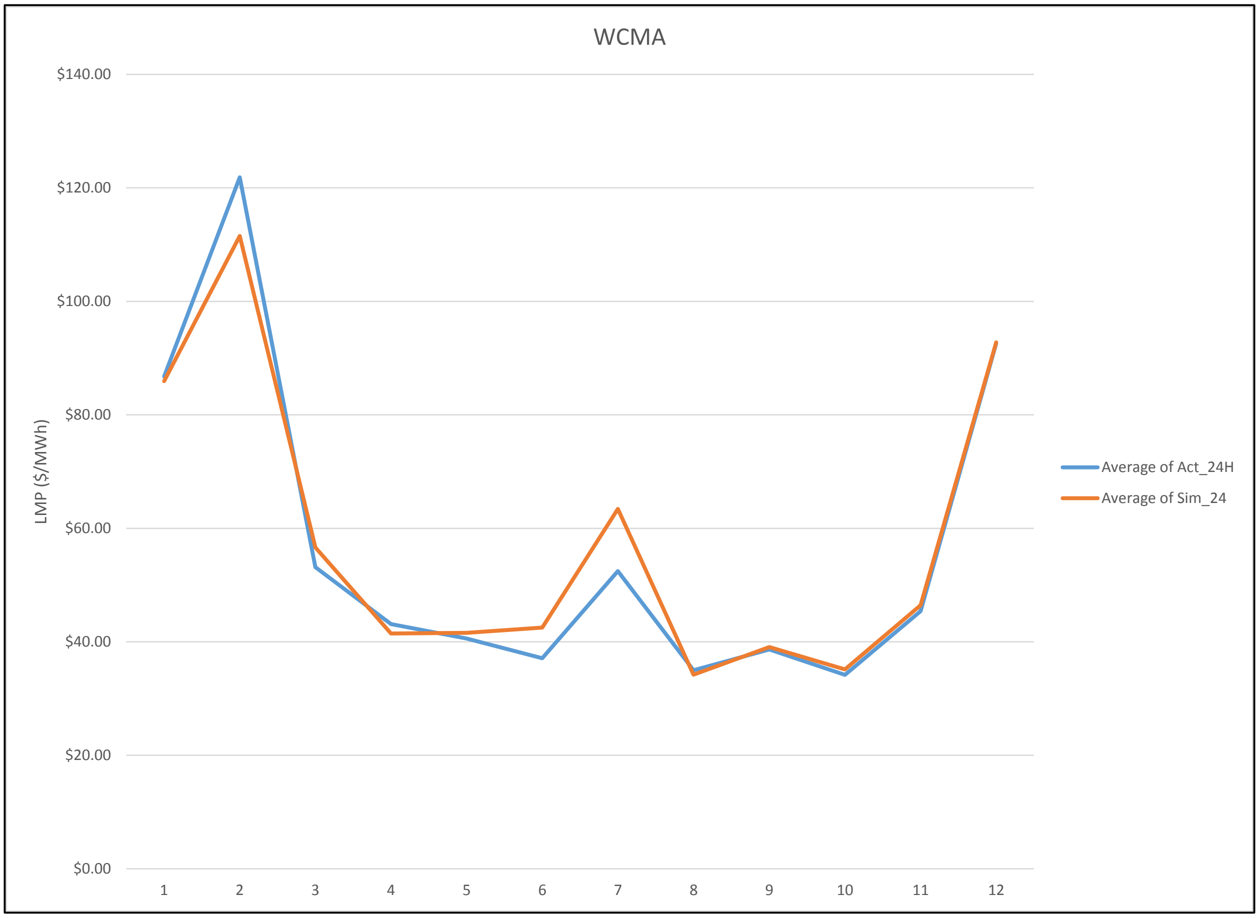
Exhibit 6-5. Comparison of Actual and Simulated Locational Marginal Prices in ISO New England, Monthly for WCMA Zone, 2015$/MWh



As shown in this Exhibit, the pCA simulation replicated actual price patterns in 9 out of 12 months. This benchmarking validates the pCA commitment and dispatch algorithms and the quality of the heat rate data provided by pCA vendor – Newton Energy Group. The simulations results somewhat under-estimated actual prices in February and over-estimated actual prices in June and July. This could be related to the difference between assumed and actual generator and transmission forced outages and maintenance schedules and well as other factors, such as operator discretion, which are difficult to fully represent in the model.

New England Hub Futures

TCR also benchmarked BAU/ simulation results for years 2015-2017 against futures prices for the New England Internal Hub as cleared on NYMEX on December 18, 2014. This clearing date coincides with the clearing date for natural gas and oil prices used in the development of fuel price inputs. The comparison of futures and projected On-Peak and Off-Peak prices is presented graphically in

Exhibit 6-6 and Exhibit 6-7 respectively. As these exhibits indicate, pCA projections well correspond to NYMEX futures both for on-peak and off-peak products.

Exhibit 6-6. On-Peak LMPs: Projection vs. Futures, 2015$/MWh

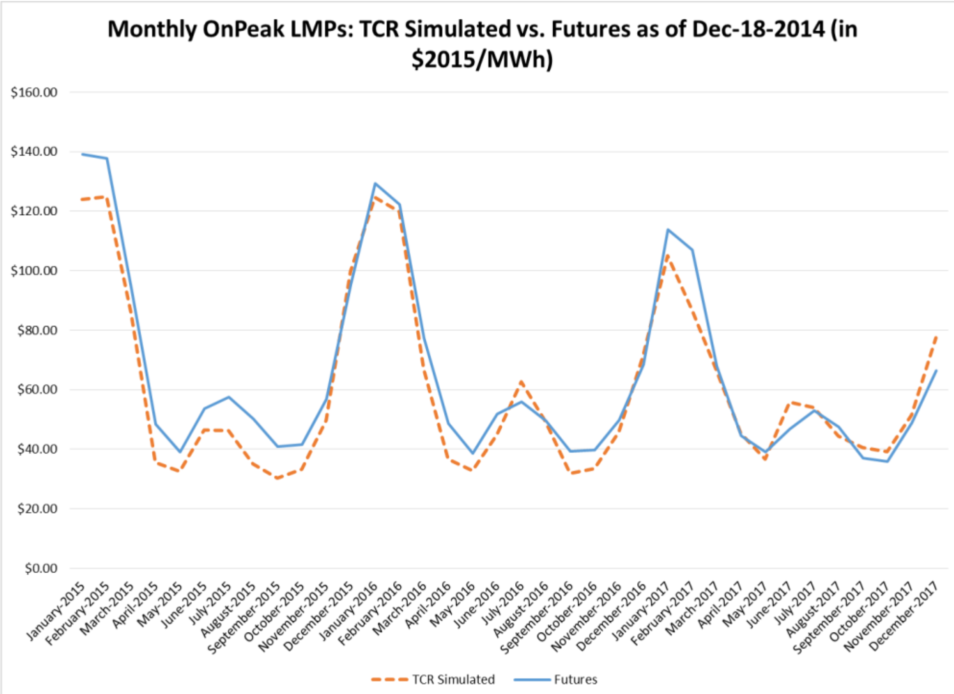


Exhibit 6-7. Off-Peak LMPs, Projections vs. Futures, 2015$/MWh

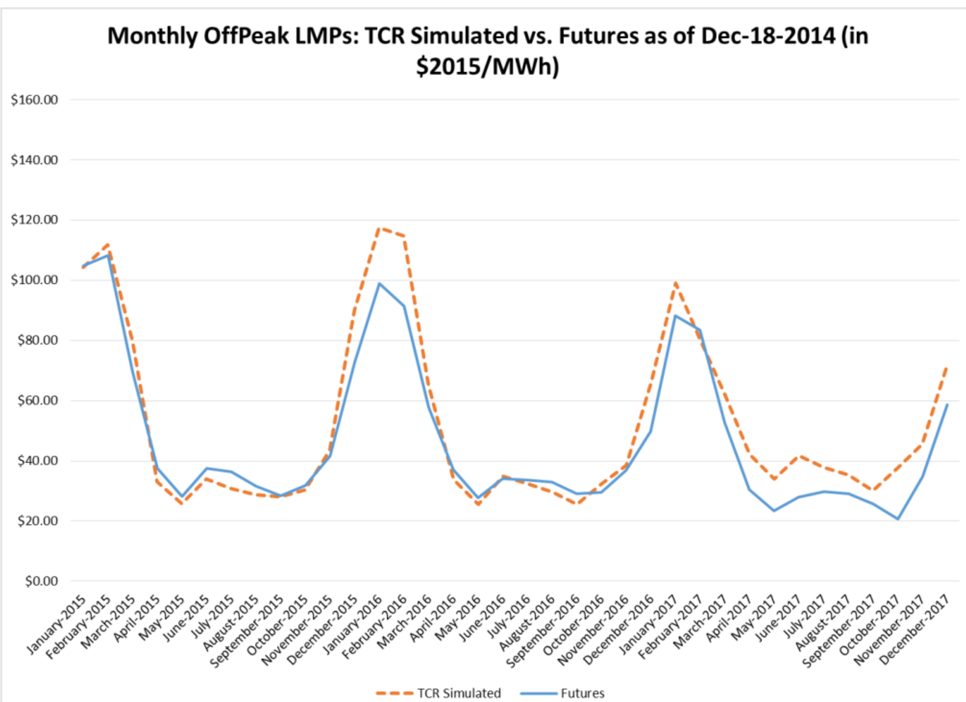

In sum, these benchmarking results demonstrate that the pCA modeling environment and supporting datasets provide a reliable tool for developing electric energy price projections.

Comparison to the Base Case

On a 15 year levelized basis, the Base Case avoided costs for Central Massachusetts are within 1 % of the BAU avoided costs, as shown in Exhibit 6-20. The levelized Base Case avoided costs are slightly lower than BAU avoided costs. The differences vary by seasons and time periods, ranging between 0.17% (summer off-peak) and negative 0.8% (winter peak).

Exhibit 6-8. 15-Year Levelized Cost Comparison for Central Massachusetts, Base Case v. BAU Case (2015$/MWh)

	Winter Peak Energy	Winter Off-Peak Energy	Summer Peak Energy	Summer Off-Peak Energy	Annual All-Hours Energy
BAU Case	$62.59	$57.06	$57.89	$44.96	$56.87
Base Case	$62.10	$56.82	$57.68	$45.04	$56.58
% Difference	-0.8%	-0.4%	-0.4%	0.17%	-0.5%

A year-to year comparison of Base Case and BAU avoided costs for the summer and winter season is presented in Exhibit 6-9 and Exhibit 6-10, respectively. Avoided costs are identical in the first three years (2015-2017) since the load forecasts are identical during that period. Beyond 2017 the differences between the Base Case and BAU Case do not exhibit a consistent trend. As this comparison shows, the year-to-year deviations are small, especially during off-peak hours. Summer off-peak deviations are between -2% and +2%, winter – between -2% and +2%. On-peak fluctuations are bigger in magnitude, ranging between -9% and +7% in summer and between -3% and +3% in winter.

Exhibit 6-9. Base Case as a Percent Difference from the BAU Case, Summer Season Comparison

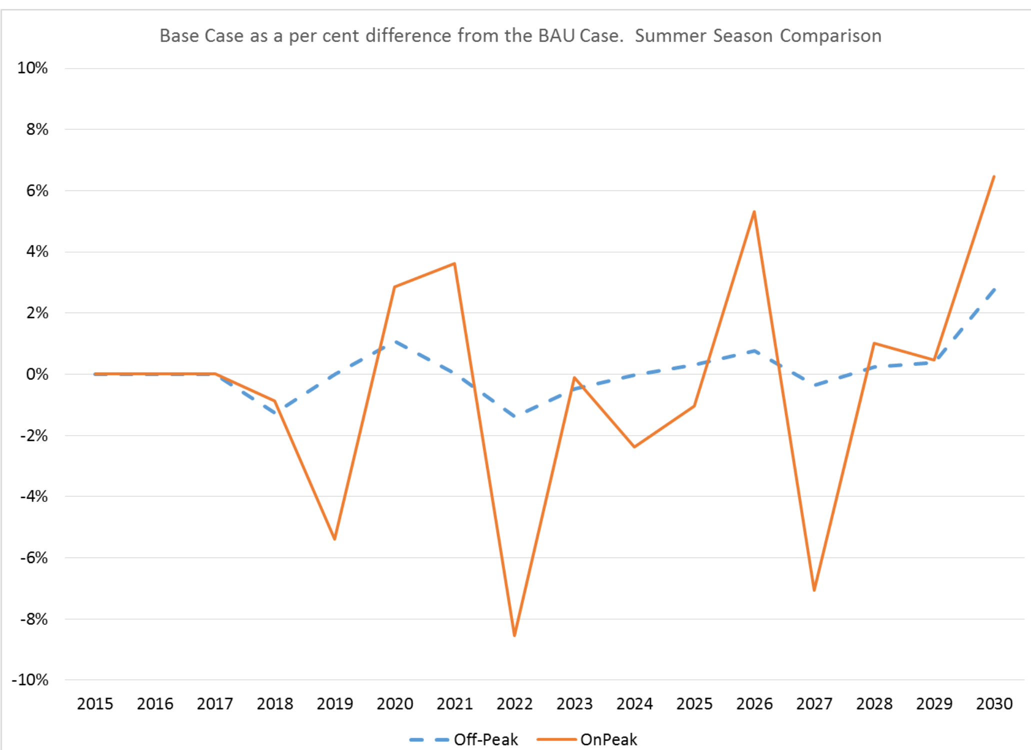

Exhibit 6-10. Base Case as a Percent Difference from the BAU Case, Winter Season Comparison

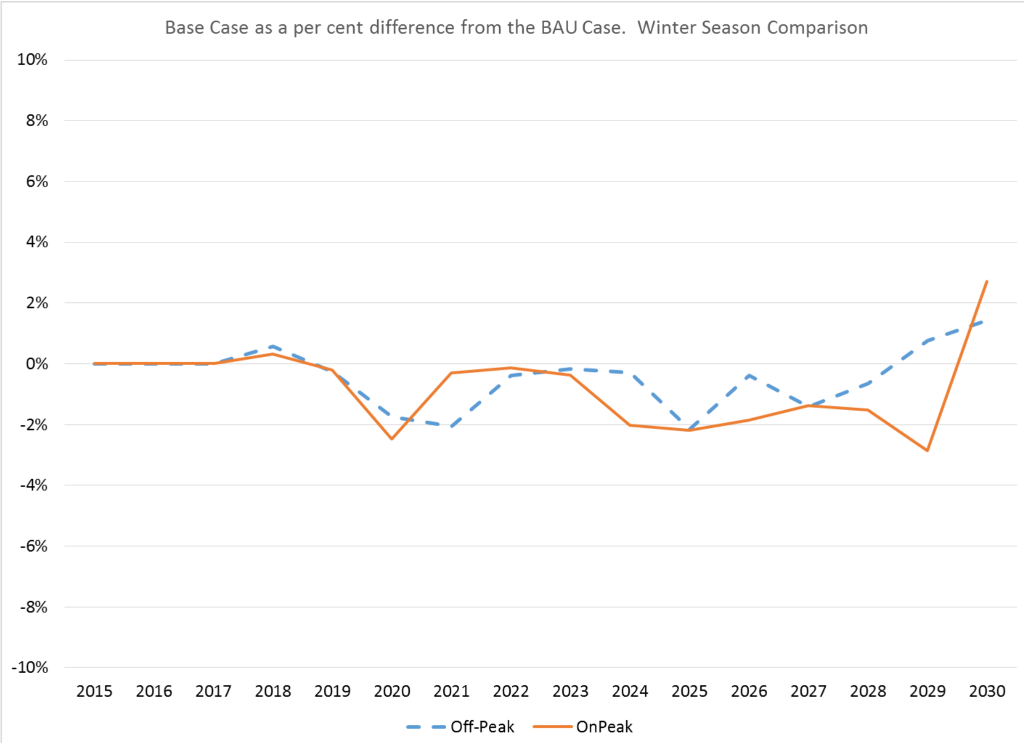


6.2 Explanation of BAU Case Results Relative to Base Case

In the long-term, from 2015 through 2029, AESC 2015 has not identified any material, statistically significant, difference in energy or capacity prices between the Base Case and the BAU case. We conclude that there is no long-term price suppression or DRIPE impact under the current outlook for the power system in New England.

The results of our two sets of simulations, and our conclusion, is explained by the following three major factors which are driving the DRIPE effect in the New England electric market over the study period:

- Close coordination between investments in energy efficiency and investments in capacity additions,
- Marginal sources of capacity with very similar cost characteristics, and
- A market which is in equilibrium.

The magnitude of the DRIPE effect of energy efficiency investments in a particular electric market over a given study period is dependent on three major conditions or factors in that particular market. The three factors are coordination between investments in energy efficiency and investments in capacity additions, cost characteristics of capacity additions, and whether the market is in surplus or in equilibrium.

Coordination of Energy Efficiency and Capacity Investments

In New England, investments in energy efficiency are well-coordinated with investments in new capacity additions and with decisions to retire existing capacity. The forward capacity auction (FCA) enables decisions to retire existing generating capacity and to add new generating capacity to be well coordinated with investments in energy efficiency. The FCA simultaneously clears energy efficiency investments, in the form of Passive Demand Resources (PDR) and investments in new generation capacity. As a result, investments in energy efficiency can have a virtually instantaneous impact on investments in new capacity additions.

Cost Characteristics of Capacity Additions

In New England, the marginal sources of new capacity are gas-fired combined cycle (CC) units and gas-fired combustion turbine (CT) units. All new gas CCs have very similar cost characteristics and all new gas CTs have very similar cost characteristics.

Market in Surplus or Equilibrium

Prior to 2013, the New England market was generally forecast to be in surplus; now it is forecast to be in equilibrium. DRIPE effects fall along a continuum: DRIPE is most likely to be material in an electric market in surplus and least likely to be material in an electric market in equilibrium.

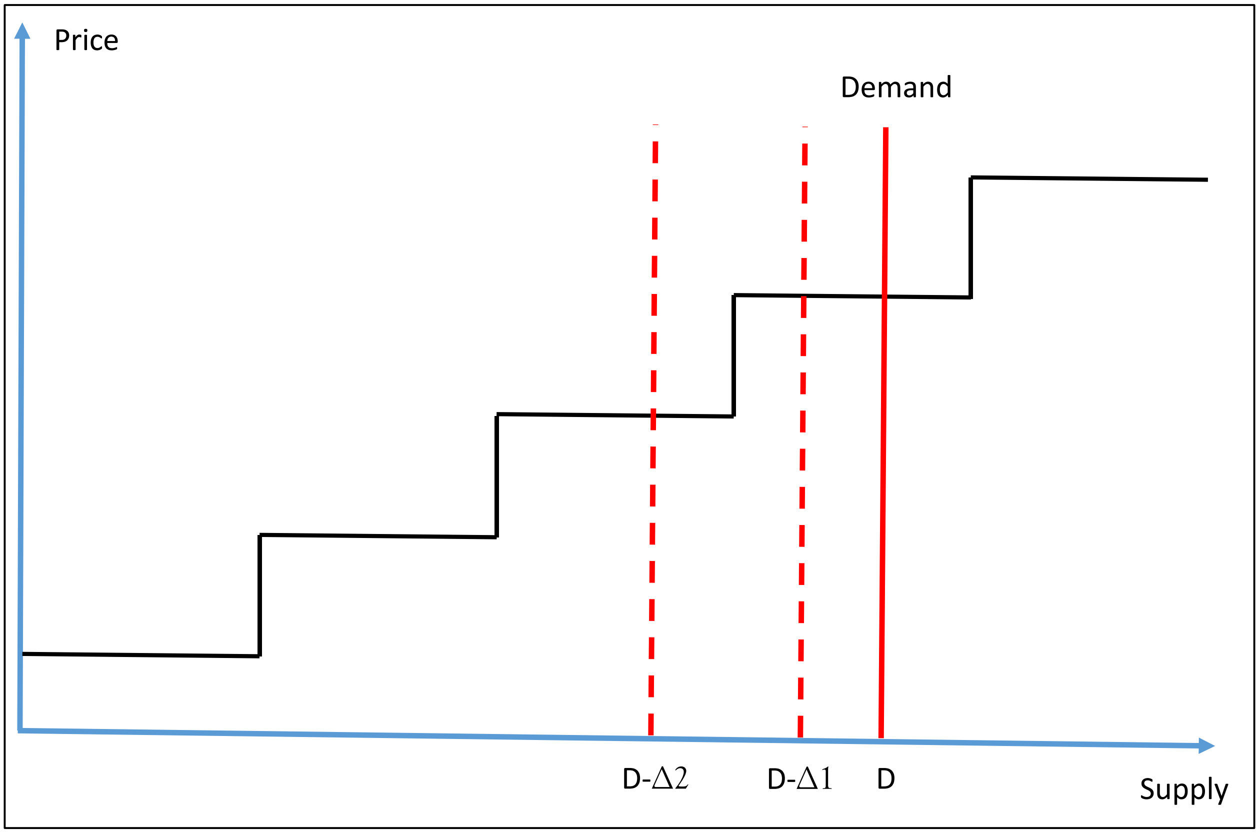
- In a power system which is in surplus, i.e., its existing generating capacity exceeds reserve requirements, investments in energy efficiency increase the level of surplus and delay the timing of new generating capacity additions. These incremental investments in energy efficiency tend to affect both capacity and energy markets. Energy efficiency reduces capacity prices through the delay of new additions; it reduces energy prices by reducing the need to use more expensive generation resources, which will be dispatched less frequently when demand is reduced

- In a power system which is in equilibrium, i.e., in which just enough new capacity is being added to meet reserve requirements, incremental investments in energy efficiency reduce the quantity of new capacity additions through FCA, and similarly reductions in energy efficiency investments increase the quantity of capacity additions through the FCA. As a result, increments or decrements in energy efficiency investments are unlikely to materially reduce prices in either the capacity or energy markets under equilibrium conditions. Capacity prices are not affected because capacity prices are set by new capacity additions, all of which have similar cost characteristics. Energy prices are not affected because the supply curve remains virtually the same relative to load—when demand increases (decreases), the supply curve expands (shrinks). The shape of the supply curve, however, remains virtually the same—which results in almost no impact on the marginal costs of serving the load.

6.2.1 Magnitude and Shape of Demand Reduction

As Exhibit 6-11 illustrates, very small levels of load reduction may not impact electricity prices. Their impact depends on the shape of the supply curve in the vicinity of the change in demand. As the exhibit shows, supply curves in the electric system are typically shaped as step functions with significant blocks of capacity offered to the market at the same price. As a result, a small reduction in electricity demand (Δ1 in the exhibit) causes no reduction in the price of electricity. To create a discernible price impact, the demand reduction must be sufficiently large (Δ2 in the exhibit). Furthermore, because supply curves are essentially non-linear, demand reductions of different magnitudes will result in different magnitudes of price reduction not only in absolute but also in relative terms. The relative price impact per MW of demand reduction associated with a 100 MW reduction will be different from the relative per MW price suppression associated with a 500 MW reduction.

Exhibit 6-11. DRIPE is Function of the Size and Shape of Load Reduction



The magnitude of the price impact of a load reduction during a specific time period also depends on the shape of that load reduction. The shape of the load reduction not only affects the price resulting from a shift along the supply curve, it can also affect the shape of the supply curve itself due to the unit commitment process, discussed in Section 5. 1. Because of the unit commitment process the supply, demand, price relationship in the New England energy market is much more complex than shown in Exhibit 6-11. A given day with a high load may have a supply curve that is different from the supply curve that would be used if the load on that day was much lower.

BAU Case vs Base Case

Exhibit 6-12 reports the difference in system-wide peak demand between the Base Case and the BAU Case. That difference ranges from 239 MW in 2018/19 to 2,531 MW in 2029/30.

Exhibit 6-12. Difference in System Peak Demand between Base Case and BAU Case

Period	Difference
2018/19	239
2019/20	464
2020/21	675
2021/22	873
2022/23	1,059
2023/24	1,233
2024/25	1,441
2025/26	1,653
2026/27	1,867
2027/28	2,085
2028/29	2,306
2029/30	2,531

Despite this large difference in projected demand, the projections of energy prices and capacity prices in the BAU Case are very close to those in the Base Case. On a 15-year levelized basis energy prices under the Base Case are 0.7% **lower** than under the BAU Case. Capacity prices under the Base Case are 0.09% lower than under the BAU Case. Thus there is virtually no direct relationship between the assumed reductions from new energy efficiency and prices.

Analysis of Energy Prices – BAU Case versus BASE Case

The lack of a material difference in prices under the two Cases can be attributed to the following factors:

- Absence of significant transmission congestion effectively combining all generating resources into a single supply stack serving the entire market
- Significant reliance of the New England on combined cycle gas fired generation technology driving prices in the majority of hours
- A market in equilibrium in which long-term increases (decreases) in demand are matched with corresponding increases (decreases) in capacity additions

Absence of significant transmission congestion creates a competitive electricity market in which geographically dispersed generating resources could compete for serving electricity demand in all states and zones almost all the time. As a result, the supply stack in New England is effectively market wide and not fractured into smaller sub-zones.

Exhibit 6-13 presents the supply stack and load duration curve for the New England system as modeled for the month of July of 2025 under the BAU Case. This exhibit shows supply (a blue curve) and demand (a red curve) measured in MW along the horizontal axis. Two vertical axes in this exhibit show short-run production costs (left axis) for the supply curve and hours (right axis). The supply curve here is a “real” supply stack already accounting for generator outages and for average availability for hydro and renewable resources. The first flat zero cost portion of the supply stack represents hydro, wind and solar generation. The second flat segment primarily corresponds to nuclear capacity, the third and the largest flat portion of the supply stack corresponds to the combined cycle technology.

A vertical line connecting the load curve with the supply curve identifies the “marginal cost” of serving that level of supply. Letters A through E positioned along the demand curve identify different segments of that curve with different generating technologies on the margin. Thus, for segment A – B, marginal technology will be hydro and nuclear, for B – C – biomass, cogeneration, refuse and other technologies that have lower costs than CCs. For C – D the marginal technology is CC and for D – E – gas –fired and oil-fired peakers. The bars along the y (hours) axis indicate number of hours the technology is considered marginal. Peakers appear marginal for approximately 70 hours out of 744 (9% of the time); CCTGs appear marginal for approximately 510 hours (69% of the time). The remaining 22% of low load hours are typically hours when baseload generators are dispatched at minimum operating conditions with some of baseload technologies being on the margin.

Exhibit 6-13. Generation Supply Stack. BAU Case, July 2025

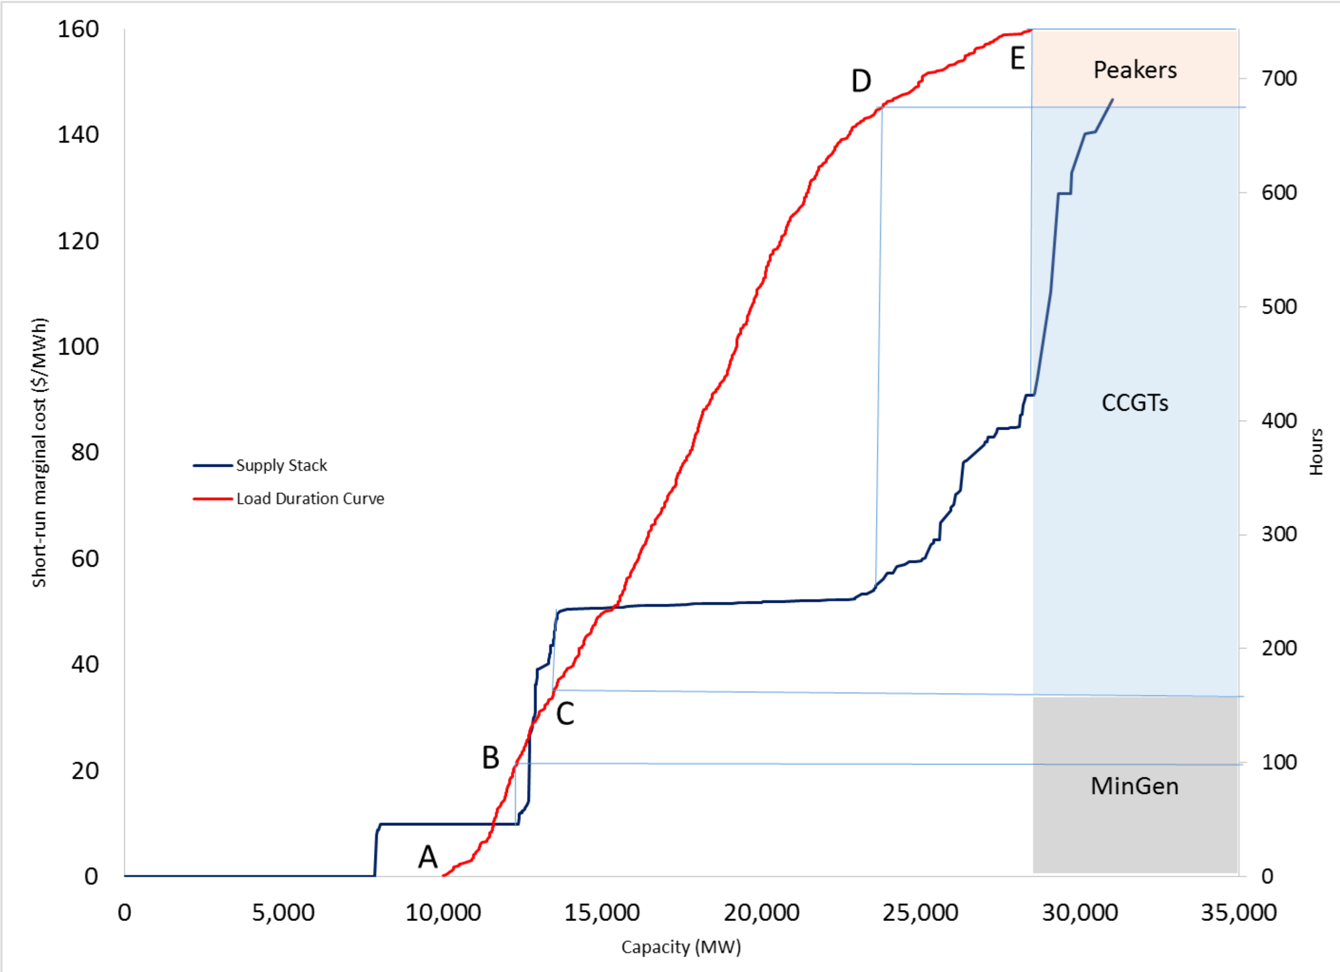


Exhibit 6-14 compares supply stacks and load duration curves under the BAU and Base Cases. Base Case characteristics are represented by dashed lines. As shown in this exhibit, the Base case supply stack is similar to the BAU Case but in a very special way. The parts of the stack that are left of the combined cycle segment are almost identical.

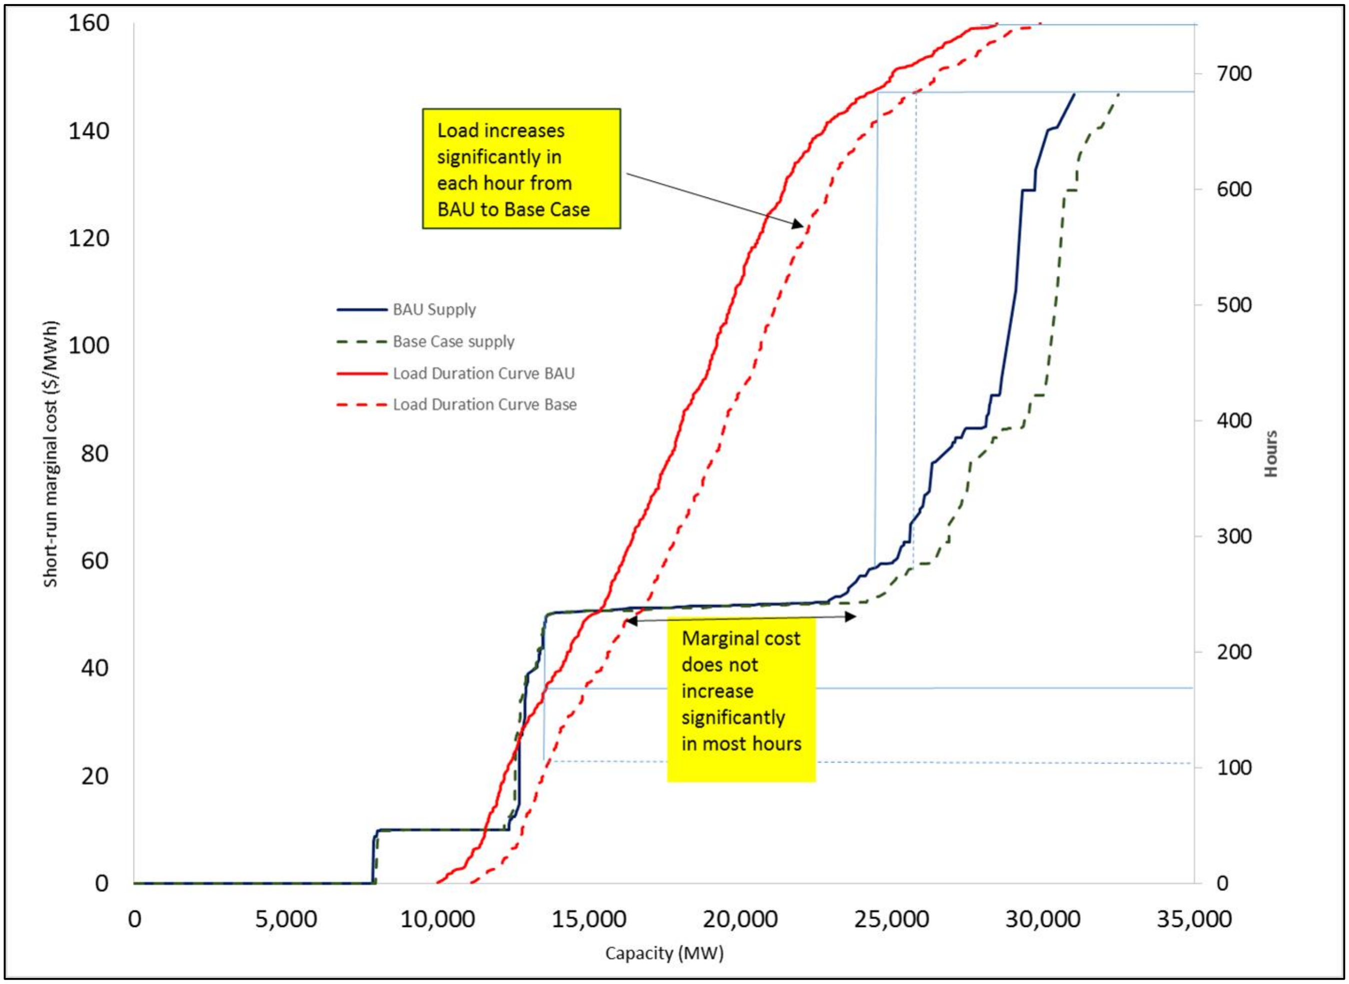
Under the Base Case demand curve shifts to the right, but so does the portion of the supply curve – combined cycle segment gets extended and portion to the right of the combined cycle segment shifts to the right. What is important here is that under both cases the number of hours when peaking units, typically CTs, are on the margin (segments D-E and D’-E’) is approximately the same. Under the Base Case, the number of hours when CCs are theoretically on the margin (segment C’ – D’) is bigger than under the BAU scenario. However, some of these hours are low load hours. In other words, Exhibit 1-5 demonstrates that although Base Case load exceeds the BAU load by over 1400 MW, the short-run marginal costs of serving the load in the Base Case and BAU case are essentially the same.

Exhibit 6-14. Supply Stacks BAU and Base Cases, July 2025

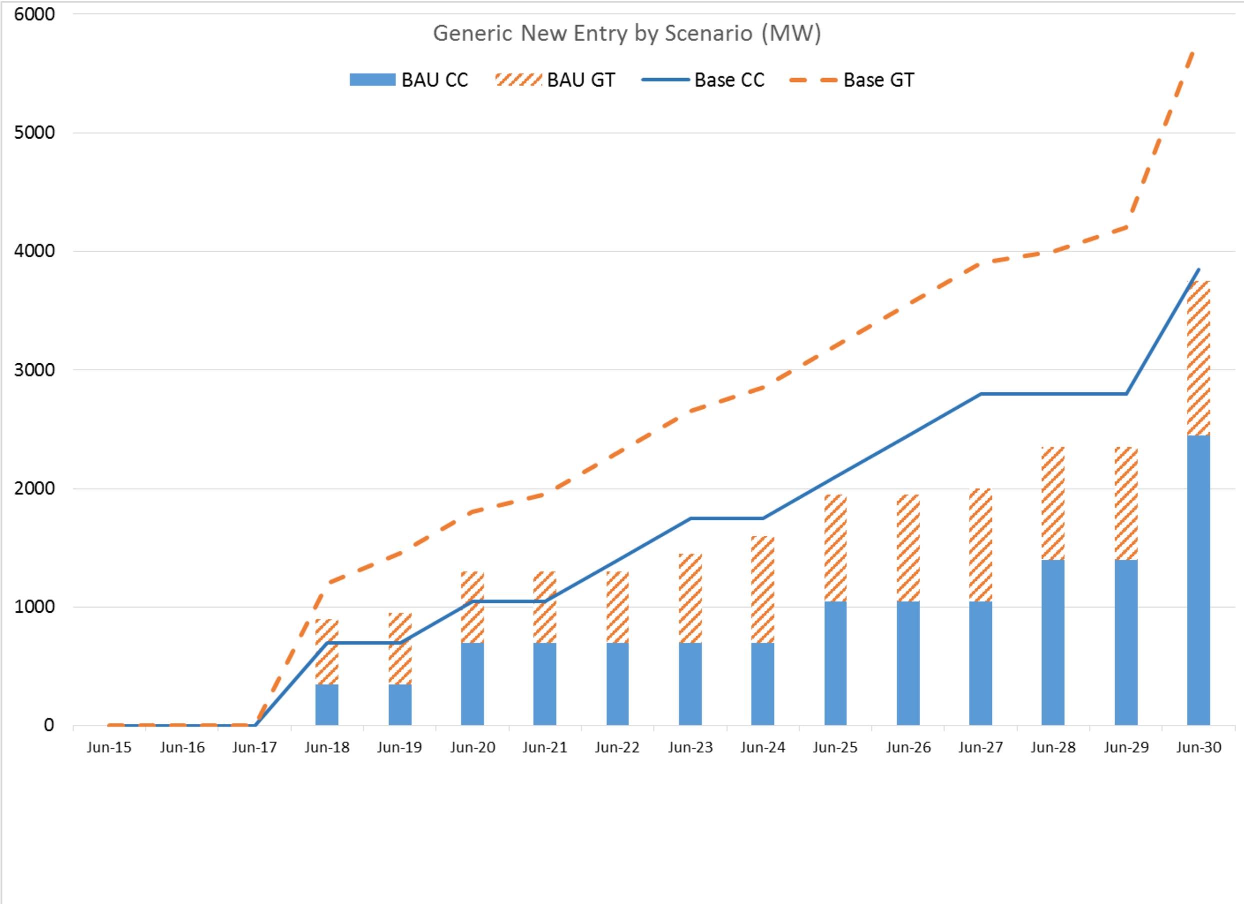


Analysis of Capacity Prices – BAU Case versus BASE Case

Starting with FCA #9 (2018/19) capacity prices in New England are driven by the cost of new entry reflecting the system need for new capacity[178]. To meet system-wide and locational installed capacity requirements, AESC 2015 added new capacity in the form of combined cycle or (CC) and simple cycle (CT) gas-fired generating units. The dynamics of generic capacity additions under both scenarios is shown in Exhibit 6-15.

[178] When TCR prepared its capacity price projections, the FCA 9 results for 2018/19 were not known. However, the avoided electricity costs in Appendix B are based on FCA9 results for 2018/19.)

Exhibit 6-15. Additions of Generic New Capacity under Base and BAU Cases



Simulated capacity prices begin with FCA#9 (2018/19). The differences between capacity prices over the 2018/19 to 2029/30 period is within a plus/minus 6% range each year. However, on average over 15 years levelized capacity prices are within 0.09%.

Exhibit 6-16. Capacity Prices – BAU Case vs. BASE Case

	ASEC 2015 BAU	AESC 2015 Base	Base Case vs BAU Case
	2015$/kW-month	2015$/kW-month	% difference
2015/16	3.38	3.38	0.00%
2016/17	3.15	3.15	0.00%
2017/18	14.19	14.19	0.00%
2018/19	13.13	12.96	-1.27%
2019/20	11.54	11.29	-2.17%
2020/21	11.45	11.33	-1.08%
2021/22	11.21	11.71	4.48%
2022/23	11.87	11.62	-2.11%
2023/24	11.87	11.37	-4.23%
2024/25	12.04	11.96	-0.69%
2025/26	11.29	11.96	5.93%
2026/27	12.04	12.04	0.00%
2027/28	12.54	11.79	-6.00%
2028/29	11.79	12.46	5.67%
2029/30	12.54	12.79	2.00%
15 yr Levelized	10.76	10.75	-0.09%

Market Equilibrium

AESC 2015 considers the New England capacity market to be in equilibrium through the operation of the Forward Capacity Auctions (FCAs). The FCAs are designed to acquire just enough new capacity for a given power year to meet the reserve requirements for that year. Those auctions give supply-side resources and demand-side resources the opportunity to bid to provide that additional capacity. As a result, in any given FCA, the greater the reduction from investments in energy efficiency that is bid in, i.e. "passive demand resources (PDR), the lower the quantity of supply side resources will be selected. Similarly, the lower the level of PDRs that is bid in, the greater the quantity of supply side resources will be selected. Under these market conditions increments or decrements in energy efficiency investments are unlikely to materially reduce prices in either the capacity or energy markets under. Capacity prices are not affected because capacity prices are set by new capacity additions, all of which have similar cost characteristics. Energy prices are not affected because the supply curve remains virtually the same relative to load. Under a Case in which demand increases, the supply curve expands correspondingly. Under a Case when the demand does not increase, the supply curve does not increase. However, the shape of the supply curve remains virtually the same under each Case. As a result, the marginal costs of serving the load is essentially the same under each Case.

It is possible that the New England capacity market might not be in equilibrium in a given year but we do not believe that circumstance would result in DRIPE values materially higher than our estimates for several reasons.

First, for the market to be in a material surplus year after year, PAs would have to not be bidding a material percent of their efficiency reductions into the FCAs causing actual demand to be materially less than ISO NE forecast year after year, such that ISO NE would continue to acquire more new capacity in each FCA than was ultimately required to be brought on year after year. It is not reasonable to assume ISO NE would fail to notice these material discrepancies. On the contrary, ISO NE is clearly aware of this possibility, as indicated by the following text from Energy Efficiency Forecast 2018 to 2023 (footnotes excluded):

Given the significant changes that have occurred in the New England EE programs over the past 10 years, some New England states believed that significant EE resources that had been developed as a result of state-sponsored EE programs did not participate in the FCM and were therefore unaccounted for by the ISO. To address this issue, in 2011, the ISO conducted a detailed survey of the region's EE program administrators concerning their participation in the FCM. The results of this analysis showed that essentially all the EE capacity the PAs developed was indeed participating in the FCM. While stakeholders indicted that other non-regulated entities may be engaged in deploying EE through performance contracts, these projects were small relative to the state-funded programs. Consequently, the projections of EE in the ISO's planning process only focus on state-sponsored EE programs.

> 2.3 Development of the Energy-Efficiency Forecast
>
> In addition to the one-to-four-year planning timeframe of the FCM, the ISO routinely plans and forecasts energy and demand looking 10 years into the future, but grid planners had assumed constant levels of EE in the long-term planning, four to 10 years out. This resulted in the planning assumption that there would be no additional growth in EE beyond the FCM. Concerned that the presumption of constant levels of future EE, beyond the FCM horizon, would not capture the anticipated growth in EE resources from year to year, stakeholders and the ISO investigated possible methods to forecast future savings in the annual and peak use of electric energy from EE programs.
>
> Beginning in 2009, the ISO and the region's energy-efficiency stakeholders conducted an intensive, multiyear research, data-collection, and analysis process resulting in a comprehensive assessment of historical spending on EE programs by PAs. The study analyzed EE programs and studied how to model incremental, future long-term EE savings for four to 10 years into the future. This deliberate and analytic effort advanced the anecdotal understanding of EE to empirical knowledge about production costs, spend rates, realization rates, and performance at the program level. The result of this effort was a fully vetted approach to accounting for future EE investment and savings and the nation's first regional (multistate) long-term forecast of energy efficiency. The current EE forecast now equips system planners and stakeholders with reliable information about the long-term impacts of state-sponsored EE programs.

Second, if actual demand in a given year was less than the forecast for that year would have little or no effect on capacity prices in that year or subsequent years. First, capacity prices are set through FCAs that are run 3 years in advance of the power year. Second, the categories of new capacity being added have the same cost and operating characteristics.

6.3 High Gas Price Case

The High Gas Price case assumes a higher Henry Hub price forecast than the AESC 2015 Base Case and less new pipeline capacity additions to serve New England over the study period than the Base Case.

- Those two assumptions result in higher avoided wholesale gas supply costs in New England than under the Base Case. For example, the 15 year levelized wholesale city-gate cost of gas under the high gas price Case is $ 7.03/MMBtu (2015$), 18% higher than under the Base Case.
- Those higher avoided wholesale gas supply costs also result in correspondingly higher avoided wholesale electric energy costs. For example the 15 year levelized avoided wholesale electric energy cost in central Massachusetts under the high gas price Case is $65.09/MWh (2015$), 17% higher than under the Base Case.
- The avoided electric capacity costs under the High Gas Price case are essentially the same as under the AESC 2015 Base Case.

The AESC 2015 high gas price Case reflects two major differences in assumptions from the Base Case, as summarized in Exhibit 6-17.

Exhibit 6-17. Major assumptions in AESC 2015 Base Case and High Gas Price Case

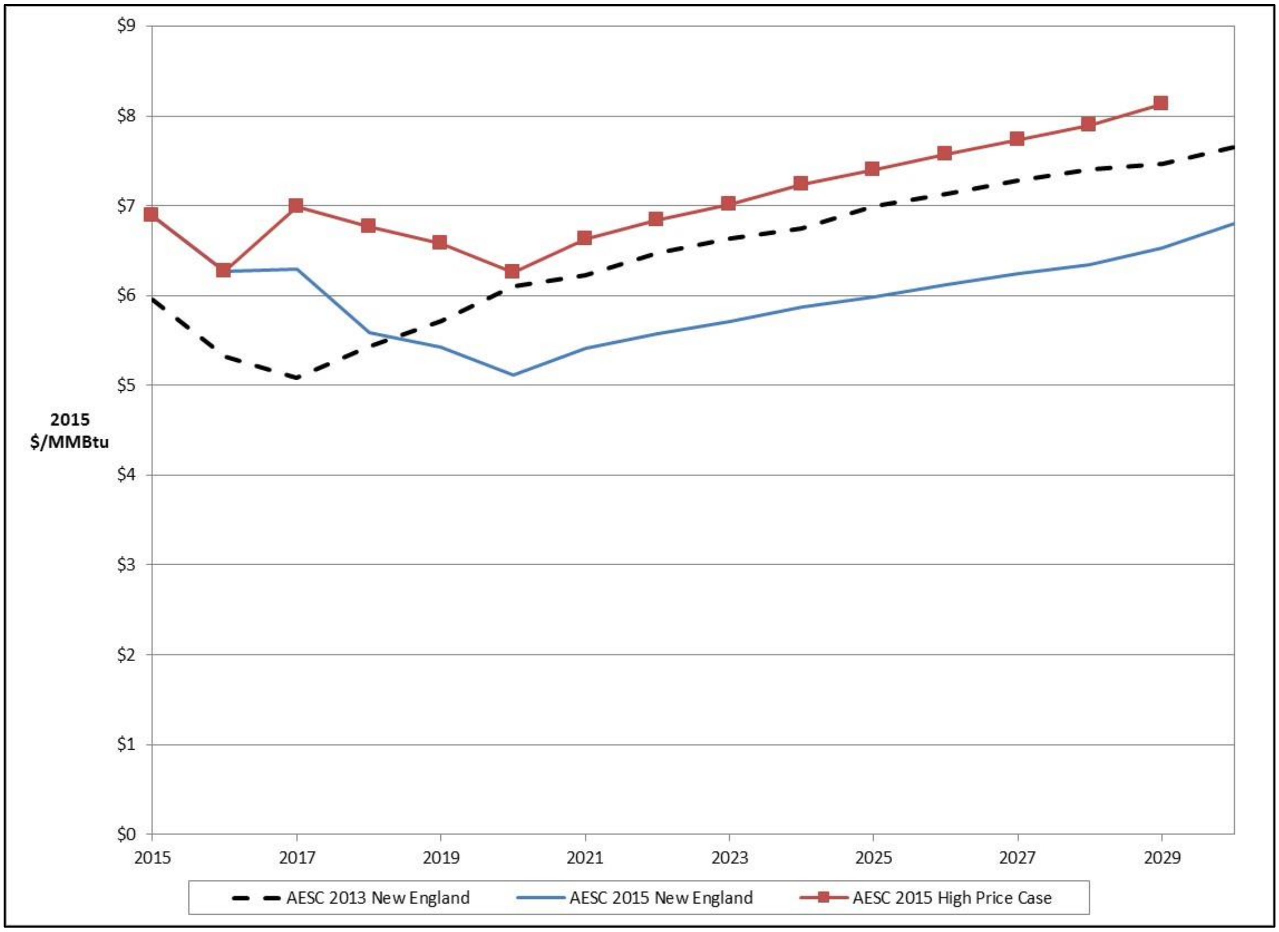
Assumption	Base Case	High Price Case
Henry Hub Prices	NYMEX Futures through 2016, AEO 2014 Reference Case from 2017 onward	NYMEX Futures through 2016, AEO 2014 Reference Case plus 15% from 2017 onward.
New pipeline capacity able to deliver gas to New England from producing areas west of New England	AIM &Tennessee CT expansions enter service 11/2017 (0.4 Bcf/day); Kinder Morgan capacity expansion enters service 11/2018 11/2018 (0.6 Bcf/day)	AIM &Tennessee Connecticut pipeline expansions enter service in 11/2017 (0.4 Bcf/day).

The High Gas Price Case reflects less aggressive shale gas development than under the Base Case and less gas pipeline capacity expansion. It assumes LDC load in New England will grow supplied by the new pipeline capacity that is added and additional supplies of LNG. Internationally, LNG prices ease as non-U.S. supplies increase and demand falls as Asia Pacific countries complete nuclear plants non-Mediterranean Europe replaces high-cost gas supplies with coal and, eventually, nuclear power and renewables.

This Case contrasts with the AESC 2015 Base Case, in which a broad array of U.S. dry gas-prone shale regions continue to develop, and Marcellus/Utica gas production rises to approx. 25 Bcf/day by 2020. All currently subscribed pipeline capacity proceeds to construction and enters service before 2020, as described in the Task 3A report. LNG market prices fall only slightly, remaining costly, thus LDC growth is limited to levels enabled by expanded gas pipeline capacity.

Exhibit 6-18 presents a year-by-year comparison of the avoided wholesale city-gate cost of gas under the High Gas Price Case and the Base Case respectively. The major difference in avoided costs between the two Cases begins in 2017 for two reasons. First, Henry Hub prices under both Cases are based on NYMEX futures through 2016. Second, pipeline capacity into New England under both cases is the same through November 2018.

Exhibit 6-18. Annual Wholesale City-Gate Cost of Gas in New England High Price Case vs. Base Case ($/MMBtu) (2015$)



6.3.1 Electric Energy Prices under the High Gas Price Case

On a 15 year levelized basis, the High Gas Case avoided electric energy costs for Central Massachusetts are 18% higher than the Base Case avoided costs, as shown in Exhibit 6-20. The magnitude of High Gas Case avoided cost increases above the Base Case varies by pricing zone, season and time period, ranging between 8.8% (summer peak) and 21% (winter off-peak).

Exhibit 6-20. New England wholesale gas costs and Electric Energy Prices, High Gas Case vs Base Case

Year	Annual Wholesale Gas Price, AGT hub (2015$/MMBtu)				Annual Energy Price, WCMA (2015$/MWh)			
	CASES		High Gas Case - Base Case		CASES		High Gas Case - Base Case

2017	$ 6.33	$ 7.02	$0.69	11%	$54.99	$57.46	$2.48	5%
2018	$ 5.59	$ 6.78	$1.19	21%	$48.83	$60.04	$11.21	23%
2019	$ 5.43	$ 6.59	$1.16	21%	$48.24	$59.37	$11.13	23%
2020	$ 5.13	$ 6.27	$1.15	22%	$47.00	$57.68	$10.68	23%
2021	$ 5.42	$ 6.64	$1.22	22%	$49.42	$61.03	$11.61	23%
2022	$ 5.58	$ 6.85	$1.27	23%	$52.17	$63.88	$11.71	22%
2023	$ 5.72	$ 7.04	$1.32	23%	$54.23	$65.93	$11.70	22%
2024	$ 5.88	$ 7.25	$1.37	23%	$56.11	$68.07	$11.96	21%
2025	$ 5.99	$ 7.41	$1.42	24%	$59.26	$71.81	$12.55	21%
2026	$ 6.12	$ 7.59	$1.47	24%	$61.51	$74.15	$12.64	21%
2027	$ 6.25	$ 7.76	$1.51	24%	$62.52	$75.02	$12.51	20%
2028	$ 6.35	$ 7.91	$1.56	24%	$64.88	$77.63	$12.75	20%
2029	$ 6.54	$ 8.15	$1.61	25%	$68.46	$80.88	$12.42	18%
2030	$ 6.81	$ 8.48	$1.68	25%	$75.24	$87.93	$12.68	17%
15 yrs Levelized (2016-2030)								
	$5.94	$7.14	$1.21	20%	$56.58	$66.83	$10.25	18%

Exhibit 6-20 and **Exhibit 6-21** present year-by-year comparisons of avoided energy costs under the High Gas Price Case and the Base Case respectively. The major difference in avoided energy costs between the two Cases begins in 2017 because city-gas gas prices are basically the same under both Cases through 2016 for the reasons discussed above. After 2016 the summer differences between the High Gas Price Case and Base Case fluctuate between 7% and 12 % during On-peak hours and between 10% and 13% in off-peak hours. In winter, under the High Gas Price case, avoided costs are 6%-8% above the Base Case in 2017 and 20% - 30% above Base Case in 2018 and beyond.

It is also worth noting that in relative terms, higher gas prices have a greater impact on electric avoided costs during off-peak hours than during on-peak hours. In absolute terms, over the long-term in a given season the changes in on-peak and off-peak prices are of similar magnitude, as shown in Exhibit 6-20.

Exhibit 6-20. High Gas Case as a Percent Difference from the Base Case, Summer Season Comparison

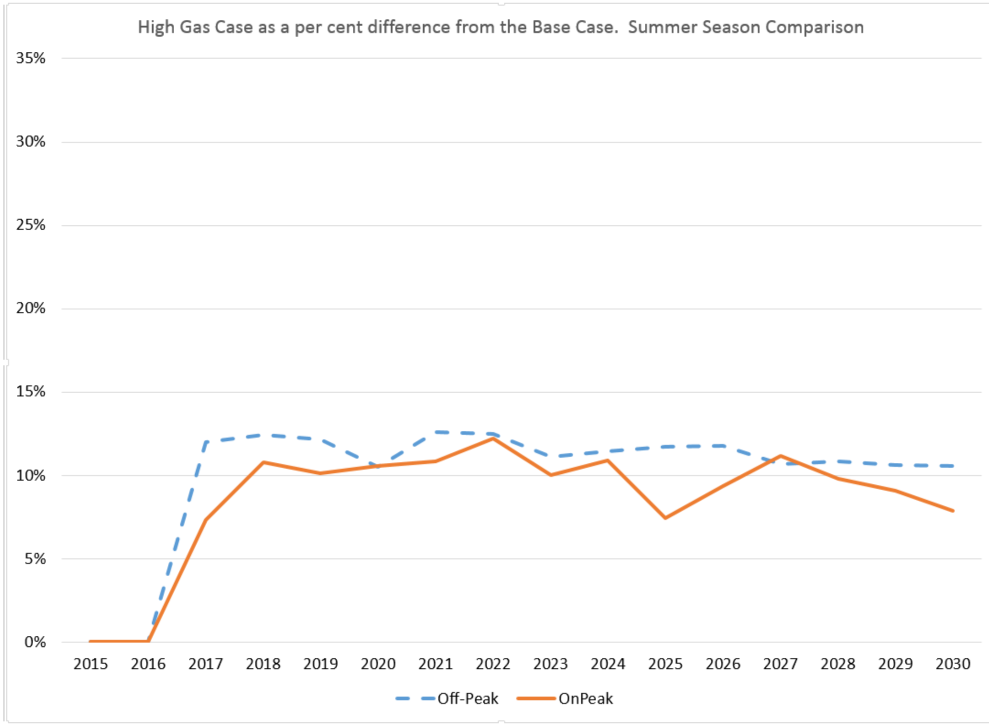

Exhibit 6-21. High Gas Case as a Percent Difference from the Base Case, Winter Season Comparison

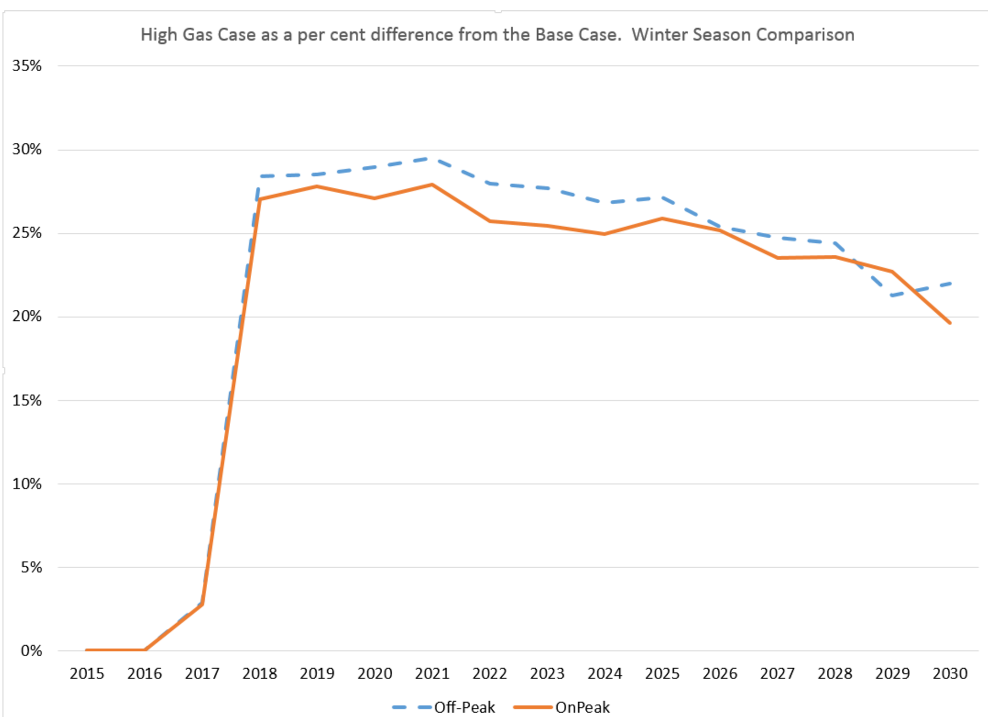

6.3.2 Electric Capacity Prices under High Gas Price Case

The projected level and mix of capacity in the High Gas Price Case is identical to that of the Base Case. As a result, as shown in Exhibit 6-22, the avoided capacity costs under the High Gas Price Case are very close to those under the Base Case. Capacity prices are set by marginal capacity units – newly constructed CT generators which earn little net revenues in the energy market. Since both Cases have the same generation mix and identical patterns of new entry, the revenue requirements that new capacity bid into the capacity market are very similar under both the Base Case and the High Gas Price Case.

Exhibit 6-22. Capacity Prices under High Gas Price Case and Base Case

	ASEC 2015 High Gas	AESC 2015 Base	Base Case vs BAU Case

Chapter 7: Demand Reduction Induced Price Effect

7.1 Introduction

DRIPE refers to the reduction in wholesale market prices for energy and/or capacity expected from reductions in the quantities of energy and/or capacity required from those markets during a given period due to the impact of efficiency and/or demand response programs. Thus, DRIPE is a measure of the value of efficiency received by all retail customers during a given period in the form of expected reductions in wholesale prices.

DRIPE effects are typically very small when expressed in terms of their impact on wholesale market prices, i.e., reductions of a fraction of a percent. However, DRIPE effects may be material when expressed in absolute dollar terms, e.g., a small reduction in wholesale electric energy price multiplied by the quantity of electric energy purchased for all consumers at that wholesale market price, or at prices / rates tied to that wholesale price.

- The avoided cost value of DRIPE during a given time period is equal to the projected impact on the wholesale market price during that period, expressed as a $ per unit of energy, multiplied by the quantity of energy purchased at rates or prices tied directly to that given market price. As illustrated in

Exhibit 7-1, this chapter calculates the avoided cost value of three broad categories of DRIPE:

- **Electric efficiency direct DRIPE:** The value of reductions in retail electricity use resulting from reductions in wholesale electric energy and capacity prices from the operation of those wholesale markets.
- **Natural gas efficiency direct and cross-fuel DRIPE:** The value of reductions in retail gas use from reductions in wholesale gas supply prices and reductions in basis to New England. Gas efficiency cross-fuel DRIPE is the value of the reductions in those prices in terms of reducing the fuel cost of gas-fired electric generating units, and through them wholesale electric energy prices.
- **Electric efficiency fuel-related and cross-fuel DRIPE:** The value of reductions in retail electricity use from reductions in wholesale gas supply prices and reductions in basis to New England. The reductions in those prices reduces the fuel cost of gas-fired electric generating units, and through them wholesale electric energy prices. Electric efficiency cross-fuel DRIPE is the value of the reductions in the wholesale gas supply price to retail gas users.

Exhibit 7-1. Overview of Impacts of wholesale DRIPE

Reduction in Retail Load	Cost Component Affected	DRIPE Category	Exhibit Reporting Results
Electricity	Electric Energy Prices	Own-price (energy DRIPE)	
Natural Gas	Gas Production Cost	Own-price (gas Supply DRIPE)	
	Gas Production Cost	Cross-fuel (gas to electric)	
	Basis to New England	Cross-fuel (gas to electric)	
Electricity	Gas Production Cost	Own-price (gas Supply DRIPE)	
	Basis to New England	Own- price (basis DRIPE)	
	Gas Production Cost	Cross - fuel (electric to gas)	

The AESC 2015 DRIPE results are lower than the corresponding AESC 2013 DRIPE results. The electric efficiency direct DRIPE results are lower primarily because the New England market is not projected to have surplus capacity during the study period and because AESC 2015 has reflected this change in market condition on a forward looking basis using a differential approach based on a direct simulation of these projected market conditions. The natural gas efficiency direct and cross-fuel DRIPE results and the electric efficiency fuel-related and cross-fuel DRIPE results are lower primarily because of the lower AESC 2015 estimate of basis.

This chapter describes the methods and assumptions AESC 2015 used to calculate electric and gas DRIPE effects, and the results of those calculations. This chapter is organized as follows:

- Section 7.2 describes the methods, assumptions and calculation of wholesale electric DRIPE.
- Section 7.2.4 describes the methods, assumptions and calculation of wholesale gas DRIPE.
- Section 7.4 describes the methods, assumptions and calculation of direct DRIPE effects from electric efficiency on retail customers.
- Section 7.5 describes the methods, assumptions and calculation of gas supply and gas basis DRIPE effects of gas efficiency and of electric efficiency.
- Section 7.6 describes the calculation of own-price and cross-fuel DRIPE effects from gas efficiency.
- Section 7.7 describes the calculation of own-fuel and cross-fuel fuel DRIPE effects from electric efficiency.

7.2 Wholesale Electric DRIPE

This section describes the AESC 2015 projections of the size of the capacity and energy price effects, provides empirical evidence which confirms these projections are reasonable, and explains why the projections are smaller than those in AESC 2013. As explained below, Section 6-10 provides an explanation of why our projections of electricity DRIPE duration is shorter than the AESC 2013 projection.

7.2.1 Overview

The value of DRIPE is a function of the projected impact of a given load reduction on wholesale capacity and/or energy market prices, and the projected duration of those price effects. Analysts cannot directly measure either the size of the price effect, or its duration. Instead analysts must estimate both of those two driving actors using some form of "counterfactual". For example, looking back in time we know the actual energy prices in 2013 but we do not know the counterfactual, i.e., what energy prices would have been in 2013 had load been higher due to less reduction from efficiency measures. Looking forward, we do not know future prices. However, we can project market prices under a Case that assumes some level of reductions from continued ratepayer funding of efficiency and also project market prices under a "counterfactual" Case without those assume reductions. We can then estimate the size of the DRIPE effect on prices, and the duration of that DRIPE effect, by comparing the projections of market prices under the two Cases.

The analytical approach most commonly used to estimate DRIPE, or price suppression, is a "differential approach" based on market simulations. A list of studies which have estimate DRIPE and price suppression is provided in in Tables 1 and 2 of Appendix A. The other, less common, approach is regression analysis. Under that approach the analyst determine the relationship between electric prices and load during a past period and then use that relationship to forecast DRIPE based on an assumption that the historical relationship will apply in the future.

AESC 2015 estimated electricity DRIPE in New England, both capacity and energy, by projecting market prices under several different cases. AESC 2015 used the BAU Case, described in Chapter 6, as the reference point against which it measured the size and duration of DRIPE effects under each of the other Cases. The other cases are the BAU Case, described in Chapter 5, and state-specific DRIPE Cases for each New England state, which we will describe in this section. AESC developed the projections of market prices for each Case directly by simulating the operation of the market for the load forecasts used in that Case. The projected electric DRIPE effects from this approach are smaller than those projected in AESC 2013 because the projected price effects are smaller in size and shorter in duration.

AESC 2015 is projecting the price effects to be shorter in duration for the reasons presented earlier in the comparison between the Base Case and the BAU Case in Section 6.10. In summary, the projected shorter duration is attributable to differences between the two studies in terms of projected market conditions and differences in analytical approach. AESC 2015 projects that ISO-NE will begin adding gas-fired capacity in all zones starting in the 2018/19 power year under both the Base Case and the BAU

Case, approximately 3 years earlier than ASESC 2013. Also, AESC 2015 developed its projections of capacity and energy DRIPE from 2018 onward directly using simulation modelling of the energy market. The AESC 2013 projections of energy DRIPE duration are based on qualitative estimates of price effect duration.

Size of Electricity DRIPE effects

AESC 2015 is projecting a capacity price DRIPE effect of zero. In the short term ISO-NE has already set capacity prices through the 2018 power year. In the long term, as discussed in Section 6.10, ISO-NE has designed its auctions to avoid acquiring surplus capacity and because the cost characteristics of the new gas CT and CC units that will be setting the capacity market price are essentially the same. Note, however, that AESC 2013 is projecting much higher capacity prices than AESC 2013.

AESC 2015 is projecting energy DRIPE effects from January 2015 through May 2018. During that period all Cases rely on the same installed capacity, i.e., there is no difference in new generation additions or retirements. As a result, the difference in demand between the Cases is the primary driver of energy prices.

Exhibit 7-2. Incements in state DRIPE cases, 2017 provides an illustration of the levels of increments used in each state specific DRIPE Case, from 2017. These levels are small relative to total ISO-NE load. They vary in size and shape by state.

Exhibit 7-2. Incements in state DRIPE cases, 2017

Summer		CT	MA	ME	NH	RI	VT	ISO-NE Total

The negative results for a few seasonal periods in a few zones are consistent with actual experience, as indicated by a third of the days experiencing higher prices despite lower loads. Those results are explained by the impact of various factors in addition to unit commitment, including zone-specific transmission constraints on certain days and differences in PDR size and shape.

7.2.2 Impact of Supply Curve and Unit Commitment on Size of Energy DRIPE

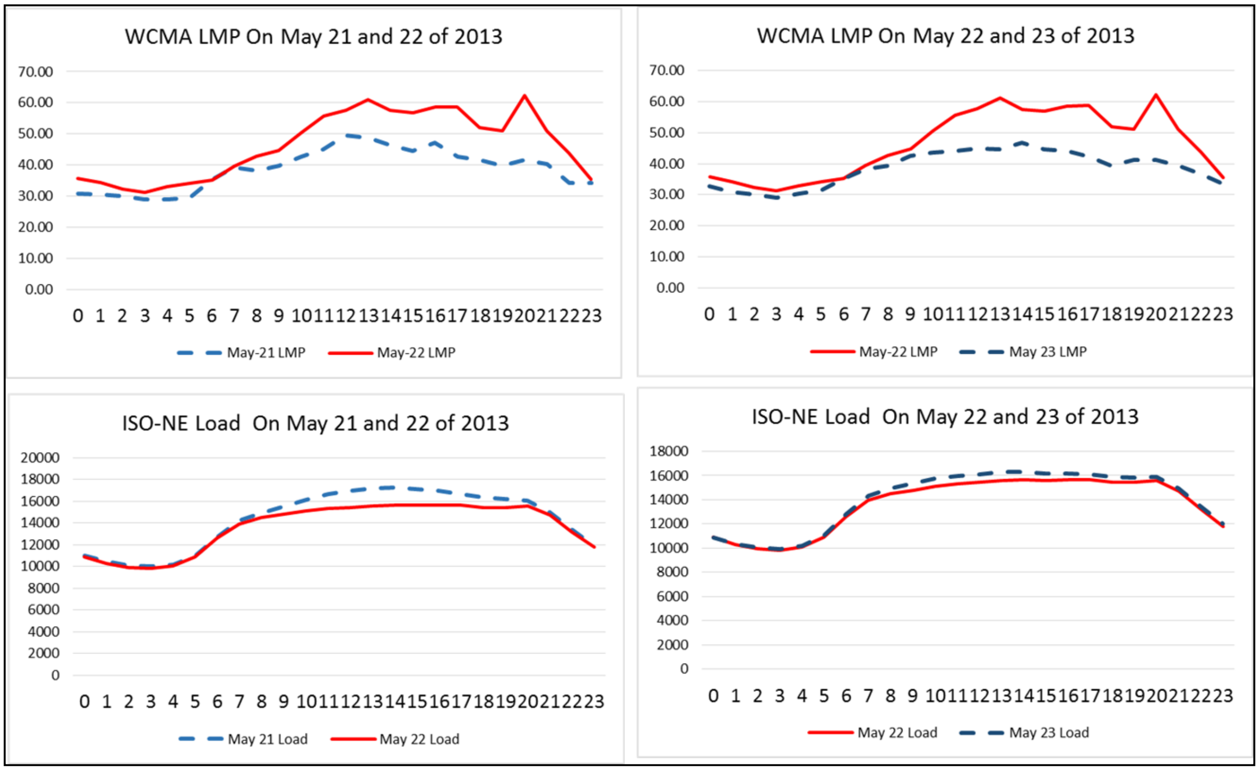
AESC 2015 projects the energy market prices under the BAU case and each state specific DRIPE case by simulating the formation of energy prices based on the energy supply curve and the ISO-NE unit commitment process. The formation of energy prices under those cases is largely driven by two main factors, the supply curve and unit commitment. As a result, the size of the energy DRIPE AESC 2015 is projecting is also largely driven by those two factors, both of which tend to dampen the size of energy DRIPE.

The supply curve dampens the energy DRIPE because the section which sets energy prices on most days is essentially flat, as described in Section 6.10. The unit commitment process dampens the energy DRIPE because ISO NE makes its decisions regarding which units to commit to serving load based on its projection of load for 24 hours, not for just 1 hour, as described in Chapter 5. Because of those two factors, there is not a simple linear relationship between the energy load in a given hour and the load in that hour. Instead, the relationship between energy prices and loads is affected by load on a given day, fuel prices on that day and unit availability on that day.

There will be days on which actual conditions will differ from the ISO NE forecast conditions due to market conditions that ISO-NE did not expect, e.g., an unexpected outage, oversupply or unexpectedly high or low demand. However, it is not clear that energy DRIPE effects would occur under those types of unexpected market conditions, i.e. when the market did not operate exactly as planned, i.e. “perfectly” or according to perfect foresight. We are not aware of specific examples of energy DRIPE impacts during days or hours when the energy market did not work “perfectly”. On the contrary, many factors can cause unexpected market conditions, and one would have to identify and analyze those factors in order to determine if lower load due to reductions from energy efficiency would have had any effect on prices under those conditions. In other words, to estimate the energy DRIPE effect of efficiency reductions on a day when actual conditions are materially different from forecast conditions, one must know the specific cause of the difference in prices between actual and forecast market conditions. It is also important to note that reduction in load from efficiency is a long-term, passive demand resource. As such, it is very different from a reduction in load from Active Demand Resources, which provide reductions only at the time of and only in response to unexpected market conditions.

To demonstrate the impact of unit commitment on energy prices we have assembled empirical evidence from 2013. To start, consider the following example based on actual New England loads and LMPs for three consecutive days: May 21, 22 and 23 of 2013 as shown in **Exhibit 7-4**.

Exhibit 7-4. Loads and LMPs for May 21, 22, 23 of 2013

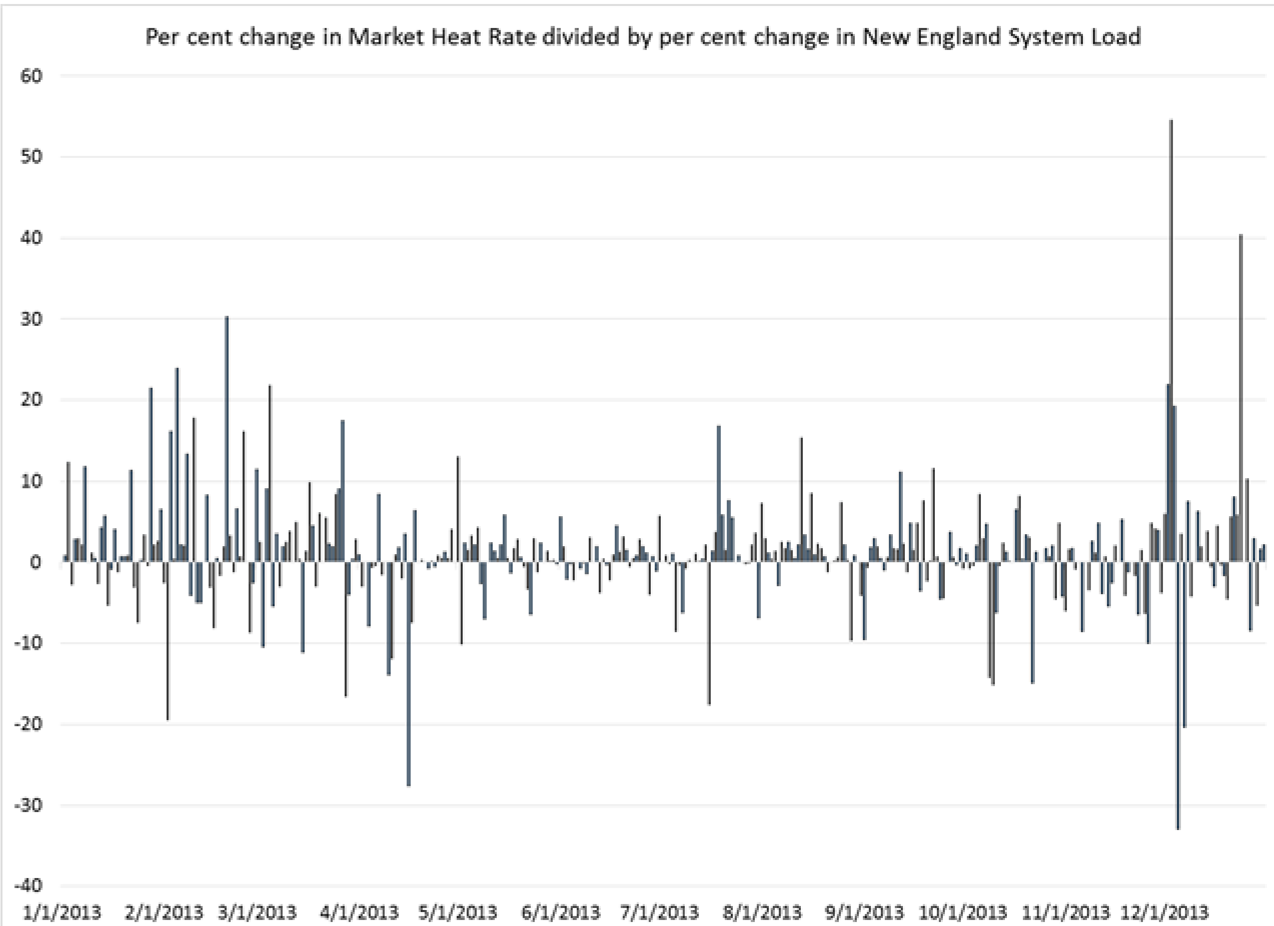


On all three days natural gas prices were close: $4.47, $4.64, and $4.63 per MMBtu on May 21, 22 and 23, respectively. As one can see, load on May 22 was lower than on May 21 in every hour of the day. In fact, at 14:00 on May 22 load was 1,625 MW less than at 14:00 on May 21. In contrast, LMPs on May 22 were higher than on May 21. For example, at 20:00 on May 22 the price was $20/MWh higher than at 20:00 on May 21 Similarly, load on May 23 increased from May 22 levels by as much as 682 MW (hours 12:00 and 13:00) but LMPs declined by as much as $21/MWh at 20:00. The hourly energy prices corresponding to the hourly loads on these three days is not consistent with, and cannot be explained by, a single high-level supply curve.

That Exhibit provides a clear illustration of why a market simulation approach, one that reflects the unit commitment process and other market factors that drive the formation of energy prices each day, is required to develop an accurate estimate of energy DRIPE. The difference in load between May 21 and May 22 could be interpreted as a demand reduction on May 21 to the May 22 level. However, on that day, demand reduction would result in price increase. Similarly, demand reduction on May 23 to the May 22 level would again result in price increase.

Second, to estimate the frequency of these price effects we analyzed changes in average daily LMPs during 2013 relative to changes in daily loads. The goal of this analysis was to assess how often an increase in demand from one day to another would result in a decrease in the average daily LMPs, and vice versa. In other words, the frequency of changes in price moving in the opposite direction to changes in demand. Recognizing that load on a given day is not the only determinant of average prices for that day we controlled for differences in gas prices from day to day. We did this by computing the average market heat rate for each day, which is the ratio of the average LMP each day to the average spot price of gas on that day. Then we computed the ratio of the change in market heat rates from day to day to the change in daily load from day to day. (We removed outliers where small changes in load resulted in very large ratios). The results are plotted in Exhibit 7-5. Again, these actual results are not consistent with, and cannot be explained by, a single high-level supply curve.

Exhibit 7-5. Change in Average daily Market Heat Rate versus Change in average daily System Load



Finally, Exhibit 7-6 and Exhibit 7-7 further illustrate that many days in 2013 had the same or similar loads but a range of energy prices. These two figures plot daily on-peak period market heat rates versus daily on-peak loads from 2013 for the summer and winter seasons respectively. This actual data demonstrate that energy prices are not solely driven by load, they are affected by the unit commitment process, fuel prices and outages.

7.2.3 Comparison with regression analysis of 2013 data

TCR prepared two different regression analyses of 2013 hourly prices and loads and compared them to the coefficients from its simulation modeling to compare against the AESC 2015 modeled DRIPE methodology. Exhibit 7-8 provides these comparisons for annual on-peak periods.

Row 1 of the Exhibit reports the projected energy DRIPE coefficients for 2015 to 2017 from the state-specific DRIPE Case. The coefficients represent the % change in average daily price in the state for the relevant period divided by the change in average daily load in the state as a % of ISO NE system wide load. (The coefficients are computed monthly and averaged across all months between January 2015 and May 2018). These coefficients measure change in price versus load in the period by day rather than by hour because the model simulates the operation of the market by ISO NE, which sets the prices each day through its unit commitment process. The on-peak energy DRIPE coefficients range from 0.33 to 1.4, The range in coefficients is attributable to the fact that the decrement in each state specific DRIPE Case occurs in a different state (i.e. location) and is of a different size and load shape. On a state load weighted basis, the resulting coefficient for New England is 0.7 which rounds to 1.

Row 2 of the Exhibit reports energy DRIPE coefficients in 2013 Cases from a TCR multi-regression analyses of 2013 actual average period prices by day versus actual period system-wide loads by day and fuel prices by day. (TCR did the regression for load and fuel price to control for variation in fuel prices from day to day.)   The on-peak result is an energy DRIPE coefficient of 1.1, which also rounds to 1. These result are the same order of magnitude as the coefficients from the state-specific DRIPE Cases. (The regression has an R^2 of 0.83, which is not an explanatory variable, instead it is a measure of how well the regression model / formula explains variances in the dependent variable)

Row 3 of the Exhibit reports energy DRIPE coefficients in 2013 Cases from a TCR multi-regression analyses of 2013 actual hourly on-peak prices versus actual hourly on-peak system-wide loads and daily fuel prices. TCR did this regression for hourly prices and loads to demonstrate that the energy DRIPE coefficient will be less accurate, in this case, 1.3 instead of 1.1, because it does not reflect the impact of the unit commitment process on the formation of energy prices each day. (The AESC 2013 energy DRIPE coefficients, which are higher, are based upon a regression of hourly prices by period versus hourly loads by period from 2009 to 2012).

The results from the regression analysis of 2013 hourly prices and loads, presented in row 3 of Table 1, are less accurate than the regression analysis of 2013 hourly prices by day and loads by day, presented in row 2 of Table 1, because the row 3 regression does not reflect the impact of the daily unit commitment process.

The results from the regression analysis of 2013 hourly prices by day and loads by day, presented in row 2 of Table 1, to be less accurate than the coefficients from the simulation model because the simulation model reflects differences in impacts by state due to differences in size and shape of PDR.

Exhibit 7-8. Electric Energy DRIPE coefficients, peak periods, AESC 2015 simulation versus regression analyses of 2013 data

Electric energy DRIPE. % change in energy price for a % change in load relative to ISO NE load

Table 1. Annual On-Peak Period

Source	Data source / Time Period	Dependent Variable	Independent Variables	CT	MA	ME	NH	RI	VT	ISO NE (1)
state-specific DRIPE Cases	2015 - 2018	peak period energy prices by day in state	peak period load and fuel price by day in state	0.33	0.89	0.27	1.13	1.4	0.19	0.72
TCR regression analysis daily prices	2013	peak period energy prices by day at WCMA	peak period load and fuel price by day							1.10
TCR regression analysis hourly prices	2013	peak period energy prices by hour at WCMA	peak period load by hour and fuel price by day							1.30

Note 1: ISO NE result is a state load weighted average per 2015 annual loads

7.2.4 Comparison with AESC 2013 estimated size of energy DRIPE effect

The AESC 2015 projections of energy DRIPE price effects are smaller than the AESC 2013 projections for peak periods, which ranged from 1.9 to 2.2[179]. The differences between the energy DRIPE estimates from the two studies is primarily attributable to a difference in analytical approach. AESC 2015 projections are developed directly by simulating the operation of the energy market under the BAU Case and under each of the state-specific Cases (i.e., CT, ME, MA, NH, RI, VT). The AESC 2015 simulation modelling reflects the impact of the ISO-NE daily unit commitment process as well as differences in impacts by state due to differences in size and shape of PDRs. The AESC 2013 regression analysis of hourly prices and loads from 2009 to 2012 provides a less accurate projection because it does not reflect that detailed level of market operation.

7.3 Wholesale Gas DRIPE

Reducing natural gas demand for electricity generation in a market area such as New England is, all else being equal, expected to reduce the quantity of gas supplied to that location. Classical economic theory suggests, in turn, that we may expect the price of natural gas at that location to fall in response to the reduction in gas requirements. The AESC 2015 RFP refers to this response as a gas demand reduction-induced price effect (herein, gas DRIPE).

This section presents the basic assumptions and methodology that underpin the AESC 2015 analysis of gas DRIPE, which consists of two components, production area price DRIPE and New England basis DRIPE.

Based upon our review of gas supply price elasticity (also referred to as the price elasticity of gas supply), we are assuming a production area supply price elasticity of 1.52 which indicates a percentage change of 1.52% in quantity for a 1% change in price. This implies an inverse price elasticity of 0.6579 (1/ 1.52) under which, for example, a 10% change in gas demand in the relevant production area would produce a 6.58% change in the price of gas production. The inverse supply price elasticity is used for the gas DRIPE analysis, i.e., the greater the supply elasticity, the less the DRIPE effect. The AESC 2015 estimate of production area gas DRIPE is approximately 23% less than the AESC 2013 estimate (i.e., $0.49/MMbtu for a 1 quad decrease in demand versus $0.632/MMBtu).

The AESC 2015 estimate of New England basis DRIPE in the three peak winter months is less than the AESC 2013 estimates, ranging from 50% less in the winter of 2014 to 80% less in the winter of 2019.

[179] AESC 2013, page 7-8.

7.3.1 Supply Price Elasticity Methodology

Our gas DRIPE analysis is based on the identification and assessment of estimates of the price elasticity of gas supply acquired at two different locations, gas production areas and the New England market area. As such, it is worthwhile to begin by referring to a standard economics textbook definition of supply price elasticity. In her widely used energy economics textbook,[180] Carol Dahl defines supply elasticity this way: "The responsiveness of quantity supplied to a variable is called the elasticity of supply with respect to that variable." (Dahl, 2004). Dahl then simplifies: "[Supply elasticity] is the percentage change in quantity divided by the percentage change in the variable. We can write the elasticity of supply [*Q*] with respect to price P as:

$$\varepsilon_s = \frac{\%\text{ change } Q_s}{\%\text{ change P}} = \frac{\frac{\Delta Q_s}{Q_s}}{\frac{\Delta P}{P}}.$$

Where delta represents a discrete change in the variable." (Dahl 2004, p. 32)

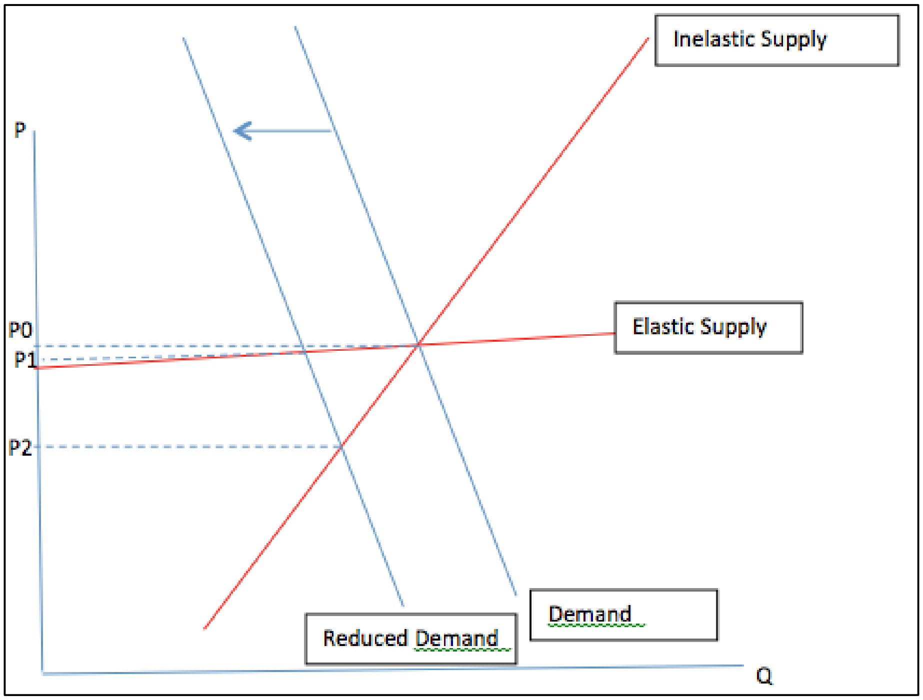
In the foregoing definition, the quantity (Q) and price (P) refer to the same commodity, in other words, "own price elasticity," as opposed to a cross-elasticity. In effect, price elasticity of supply (herein, supply elasticity) is the % change in quantity supplied divided by the % change in supply price. This is distinct from the price elasticity of demand (demand elasticity), which characterizes quantity demanded at a price.

We take the elasticity of gas supply (in shorthand: gas supply elasticity), then, to be related to the slope of the price-quantity (P-Q) supply curve for gas at the relevant location. This kind of curve is illustrated in the diagram in Exhibit 7-9.

As in AESC 2013, we also assume the cause-effect relationship works both ways i.e., symmetrically. Thus, for example, if the P-Q supply curve is steep (the line labeled "Inelastic Supply" in Exhibit 7-9, supply elasticity is relatively low, so a given change in gas demand would produce a relatively large change in price i.e., a large gas DRIPE effect as P0 falls to P2. Conversely, if the P-Q supply curve is flat (the line labeled "Elastic Supply" in Exhibit 7-9), then supply elasticity is high, so a given change in gas demand would produce a relatively small change in price (i.e., P0 to P1, a small gas DRIPE effect). In the latter case, Elastic Supply, the gas DRIPE effect would be low because even a large decrease in demand would induce only a small price reduction.

180 Carol A. Dahl, Professor Emeritus, Mineral and Energy Economics Program, Division of Economics and Business, Colorado School of Mines, "International Energy Markets: Understanding Pricing, Policies & Profits," Pennwell Press, April 2004. Note this definition remains in Dahl's revised edition, forthcoming in 2015.

Exhibit 7-9: Illustrative Supply Price-Quantity Curves



Thus, the analysis of gas DRIPE is actually a study of gas supply elasticity. Studying gas supply elasticity requires statistical analysis of a large number of relevant quantity and price data points in order to establish a P-Q supply curve. The data making up the P-Q gas supply curve must be accurate or the curve, and its elasticity at the point where the demand reduction takes place, will not be useful. In addition, the data must be able to "explain" the majority of a change in quantity as a function of change in price, or vice versa, otherwise the curves will not provide a reasonable estimate. For example, R2 is a generally accepted statistical test of the correlation of one set of data with another, i.e., to explain changes in the dependent variable as a function of changes in the independent variable. For example, sets of data with an R2 over 0.8 are considered to correlate well, while sets of data with an R2 of less than 0.4 are not considered to correlate. Thus, in the latter case of a 40% R2 correlation, variations in one data set cannot be used to explain variations in the other.

7.3.2 Production Area Price Gas DRIPE: Assumptions and Methodology

The 2013 AESC report considered a number of data sources, but ultimately developed production area price gas DRIPE based on a summary-level analysis involving comparisons of gas production quantities and Henry Hub prices from a number of AEO 2012 cases. The AESC 2015 team has also reviewed numerous estimates of production area gas supply elasticities. In light of the rapid changes taking place in the Northeast U.S. gas industry as a result of burgeoning Marcellus/Utica and other shale gas production, however, we have attempted to confine our focus on relatively recent estimates of supply curves and elasticities that hopefully reflect these dramatic changes.

Before reviewing this literature, it can be seen in plain terms that supply elasticity in rapidly growing shale fields like the Marcellus/Utica formation is obviously quite high, even to the point of being almost flat in the short-term time frame. In other words, the P-Q supply curve for the Marcellus/Utica shale basin is much like the flat curve marked “Elastic Supply” in Exhibit 7-9, so that even a large decrease in gas demand is unlikely to induce a downward price effect because local supplies already outstrip demand. In a business in which further drilling awaits further demand, and in which drilling productivity is rising dramatically in response to very low prices, there can be almost no gas DRIPE effect in the short term. Longer-term gas DRIPE is possible, of course, in the expectation that some kind of movement may take place toward the kind of supply-demand balance that would enable gas DRIPE to take place – i.e., gas DRIPE would be enabled because it would be set in a context of otherwise rising gas demand and, ultimately, gas production cost increases consistent with the beginnings of local resource depletion.

The frustrations of trying to develop supply elasticity in the unique economic environment we find ourselves in with respect to gas development for New England are only beginning to surface in the literature. A recent report by Resources for the Future (Mason et al 2014)[181] cites findings by Arora and others (Arora 2014)[182] that the supply based on shale production is more elastic than conventional sources. In looking at 2008-2012 data, Arora notes his data suggest, “…supply based on shale production is more elastic than conventional sources.” (Arora 2014). Rice University professor Kenneth B. Medlock has been far more pointed: “The domestic supply curve is much more elastic as a result of shale gas developments. Domestic long run elasticity with shale = 1.52; without = 0.29.”[183] Medlock, whose work relies on experientially derived field-by-field gas supply curves, is indicating findings that suggest earlier estimates of gas supply elasticity may be off by a factor of as much as five.

The difficulty in estimating supply elasticity with precision in a changing world (and with varying data sets) is illustrated in Exhibit 7-10, taken from Stanford University’s Energy Modeling Forum (EMF) recent comparison of energy models.[184] The EMF results, and its past studies, show that different models are likely to produce a very wide range of estimates of supply elasticity, even if provided with similar macroeconomic, resource base, and other common assumptions.

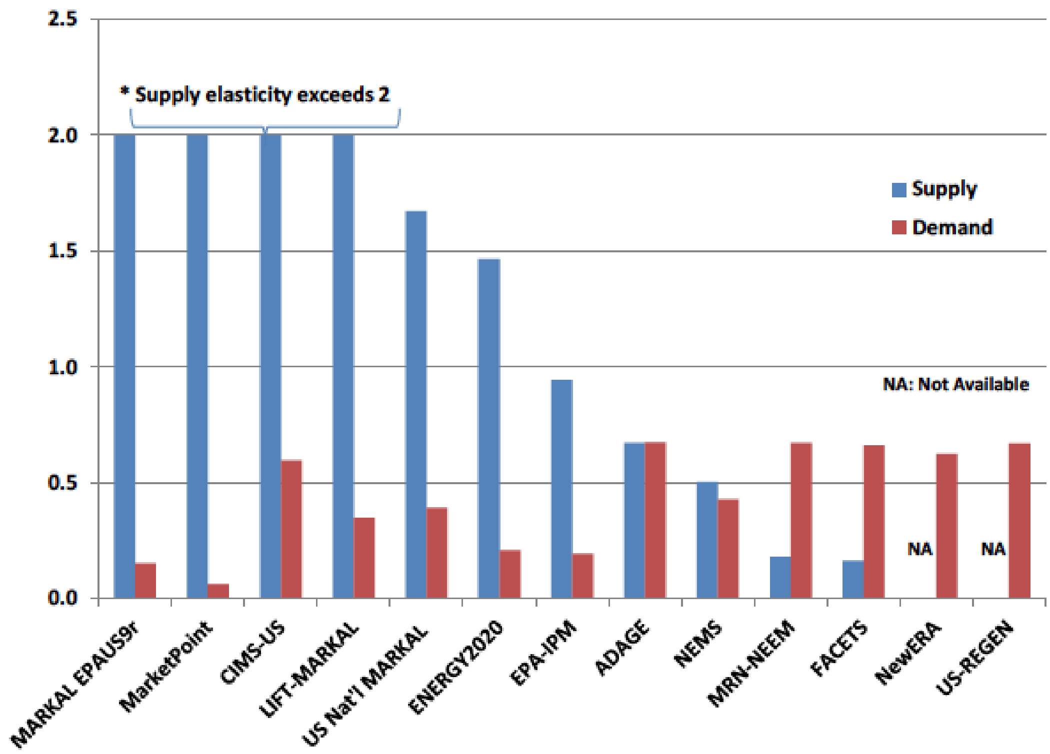
Exhibit 7-10: Inferred Price Elasticities for 2035 in 13 Forecasting Models



As a surrogate for precise field elasticities that are unavailable, therefore, we consider three separate approaches to estimate gas production area price DRIPE:

- Extracting gas supply elasticities implicit in a number of recent studies of the impacts of changes in gas demand caused by LNG exports.
- Following the methodology that underpinned calculations of gas production area price DRIPE in AESC 2013, i.e., inferring elasticities inherent in the NEMS model, as developed through analysis of different AEO 2014 cases.[185]
- Relying on the Rice/Baker modeling results.

Recent Assessments of the Impact of LNG Exports on Gas Prices

A number of analysis reports have been produced in the past several years describing the potential extent of US LNG exports and their domestic economic impact. AESC 2013 contained a useful review of

[185] It should be noted that AESC 2013 rejected a number of outdated elasticity estimates but, even so, events have moved quickly beyond the elasticity estimates it finally relied on.

the reports that were available at that time. We summarize below these and another, more recent EIA report, with respect to their implied gas supply elasticities:

***EIA, 2014*[186]**

In its update of earlier studies, the EIA states it reached these conclusions regarding domestic natural gas prices:

> Starting from the AEO2014 Reference case baseline, projected average natural gas prices in the Lower 48 states received by producers in the export scenarios are 4% (12-Bcf/d scenario) to 11% (20-Bcf/d scenario) more than their base projection over the 2015-40 period. Percentage changes in delivered natural gas prices, which include charges for gas transportation and distribution, are lower than percentage changes in producer prices, particularly for residential and commercial customers. Starting from the AEO2014 Reference case baseline, projected average Lower 48 states residential natural gas prices in the export scenarios are 2% (12-Bcf/d scenario) to 5% (20-Bcf/d scenario) above their base projection over the 2015-40 period. (EIA 2014)

The lower end of the range studied by EIA, 12 Bcf/day, represents about 16.25% of projected U.S. gas demand in the AEO 2014 Reference Case. Dividing the 16.25% increase in demand by the 4% increase in production area price (apart from costs of transportation and distribution) yields an estimated elasticity of 4.06, which implies that a 10% change in overall U.S. gas quantity would produce a 2.46% change in price.

***NERA, 2012*[187,188]**

The DOE-sanctioned study of U.S. domestic economic effects of LNG exports examined two scenarios in terms of export volumes – 6 Bcf/day and 12 Bcf/day (NERA 2012). Under sponsorship from Cheniere Energy, Inc., not the government, NERA prepared a follow-up of its report for the DOE (Baron et al 2014) that examined a large number of additional LNG export scenarios, ranging from 1 Bcf/day up to 19.5 Bcf/day. In each case, NERA based its forecasts in part on Annual Energy Outlook scenarios that were available at the time it prepared the studies, AEO 2012 in the case of NERA 2012 and AEO 2013 in the case of its follow-up report (Baron, et al 2014).

186 EIA, Effect of Increased Levels of Liquefied Natural Gas Exports on U.S. Energy Markets, October 2014, http://www.eia.gov/analysis/requests/fe/

187 National Economic Research Associates (NERA), Macroeconomic Impacts of LNG Exports from the United States, December 2012, http://energy.gov/sites/prod/files/2013/04/f0/nera_lng_report.pdf.

188 Robert Baron, Dr. Paul Bernstein, Dr. W. David Montgomery, and Dr. Sugandha D. Tuladhar, Updated Macroeconomic Impacts of LNG Exports from the United States," NERA, February 2014. http://www.nera.com/publications/archive/2014/updated-macroeconomic-impacts-of-lng-exports-from-the-united-sta.html.

NERA's more recent report assumes the natural gas resource supply elasticity varies with the U.S. natural gas supply scenario. In the study's reference scenario, the elasticity of supply for North American natural gas begins at 0.3 in 2018 and increases to 0.68 by 2038." (Baron, 2014, p. 159). We note these estimates were grounded in EIA/NEMS model runs that have since been updated. In other words, since AEO 2014 has long since replaced AEO 2013, and EIA's efforts toward AEO 2015 are well underway, the reasonable course here would be to examine updated AEO cases for this purpose, see the following subsection.

Deloitte MarketPoint, 2012[189]

Deloitte's analytic group issued two successive analysis reports, in November 2011 and November 2012. Both projecting the effects of exporting 6 Bcf/d of LNG, mainly from the US Gulf Coast. Deloitte's MarketPoint group licenses and includes authors of the most widely regarded natural gas analysis methodology, the World Gas Trade Model (WGTM), which was developed out of the North American Regional Gas Model (NARG). In the November 2012 study, Deloitte projected LNG exportation of 6 Bcf/day would cause a producer price increase of about $0.22/MMBtu, on average, in 2020-2030. This estimate represents an average 3.86% change in price from 2020 to 2030[190] and the 6 Bcf/day assumed by Deloitte represents an 8.13% change in quantity, as above. Hence, Deloitte's result implies a supply elasticity of 2.11, i.e., a 10% change in quantity would produce a 4.74% change in price.

Other LNG Export Impact Studies

Results of the foregoing studies are corroborated by a number of other reports, including those issued by:

- Brookings Institution – a compendium and critique of all US LNG export studies issued up to its publication in May 2012, entitled "Liquid Markets: Assessing the Case for U.S. Exports of Liquefied Natural Gas." The Brookings report, which was assembled by a panel consisting of the authors of each major study and other gas industry experts, is a useful review of the issues that each study is attempting to address, and a summary of their collective results from a policy perspective. This report concludes that macroeconomic effects of LNG exports would greatly outweigh effects on domestic gas consumers.

[189] Deloitte Center for Energy Solutions and Deloitte MarketPoint LLC, Exporting the American Renaissance Global impacts of LNG exports from the United States, November 2012, https://www2.deloitte.com/content/dam/Deloitte/global/Documents/dttl-er-exportingamericanrenaissance-08072013.pdf.

[190] Deloitte's gas price projection is shown in Exhibit 1-8.

- Rice/Baker – an analysis using the same generalized equilibrium model discussed above (and below) of the likely global effects of US LNG exportation, and likely volumes.[191] Rice/Baker's World Gas Model (WGM) employs essentially the same methodology as the Deloitte WGTM, with some differences in data and assumptions. In particular, Deloitte's version of the same basic model incorporates a large number of foreign contractual realities (as constraints); the Rice/Baker model generally does not embody such constraints and provides, therefore, an assessment of purely economic effects.[192] Rice/Baker's analysis concludes that US gas consumers will experience virtually no increase in retail gas prices due to LNG exports and that only minor volumes (about 2 Bcf/d) of US LNG will be exported because other world gas suppliers will out-compete the US.
- Council on Foreign Relations – a special report that critiques existing studies. This influential report provides a review of more in-depth studies it considers to be the best information available, and concludes that LNG exports are in the nation's economic and strategic interest.

In summary, the crop of LNG export impact studies conducted in the past several years provides an important, although mixed, source of information about gas supply elasticity for the gas production area price DRIPE study.

AEO 2014 Low Economic Growth Case versus AEO Reference Case

Following along lines of the methodology employed to calculate gas DRIPE in the AESC 2013 report, we estimated gas supply elasticities implicit in the NEMS model, as gleaned from a comparison of AEO 2014 cases.[193] AESC 2013 compared a large number of AEO 2012 cases to assess elasticities, and based its conclusions on that part of its review. Instead, AESC 2015 makes only a single comparison, namely, that most directly related to a gas demand reduction in isolation of other factors. In effect, this method tries to identify gas supply elasticities inherent in the NEMS model – not really different from the methodology in the AESC 2013 report, but simpler, again, with the realization that the pace of ongoing change has been so great in the Marcellus/Utica shale fields, that use of AEO's models represents a

[191] Reported in Kenneth B. Medlock III, "U.S. LNG Exports: Truth or Consequence," Rice/Baker, August 10, 2012.

[192] Unlike in the U.S., long-term take-or-pay gas sales and purchase contracts (SPAs) dominate commerce in most other gas industries, including pipeline gas and LNG markets. In the U.S., Canada and the UK, however, gas is traded fluidly in short term or spot arrangements; even where long-term SPAs exist, they take pricing signals from spot gas indices. Consequently, differences between the Deloitte and Baker/Rice models with respect to treatment of SPAs are confined to gas markets outside the U.S., as these kinds of constraints would not be relevant in the U.S, including in the Marcellus/Utica region.

[193] Note, this step is problematic because the NEMS model specifically eschews the use of price-quantity supply curves (thus supply elasticities) in its methodology and, instead, bases its analysis on the extant mix of drilling opportunities known at the time. In other words, EIA recognizes that the real world of gas well drilling actually does not follow a smooth, least-cost-first sequence of activities, thus efforts to impute elasticities inherent in NEMS are somewhat artificial.

snapshot for comparison purposes, and cannot be held out as comprehensive. In addition, we do so despite the caution in the preceding footnote.

In Exhibit 7-11, we find the foregoing discussion demonstrated vividly. Implied short-term elasticity is 10.42), mainly because demand evolves only gradually in the low economic growth case. In contrast, long-term elasticity changes drastically to 1.05 as the impact of reductions in demand are reflected in lower Henry Hub prices.

Exhibit 7-11: Gas Production Area Price Elasticities Implied in AEO 2014 Reference and Low Economic Growth Cases

	AEO 2014 Reference Case	AEO 2014 Low Economic Growth Case	Diff - Change in Sensitivity Case	Implied Elasticity
2015-2020				
Total Consumption/year	26.389	26.012	1.427%	
Average Lower 48 Price	4.354	4.348	0.137%	10.42
2020-2030				
Total Consumption/year	28.452	26.946	5.295%	
Average Lower 48 Price	5.305	5.037	5.061%	1.05

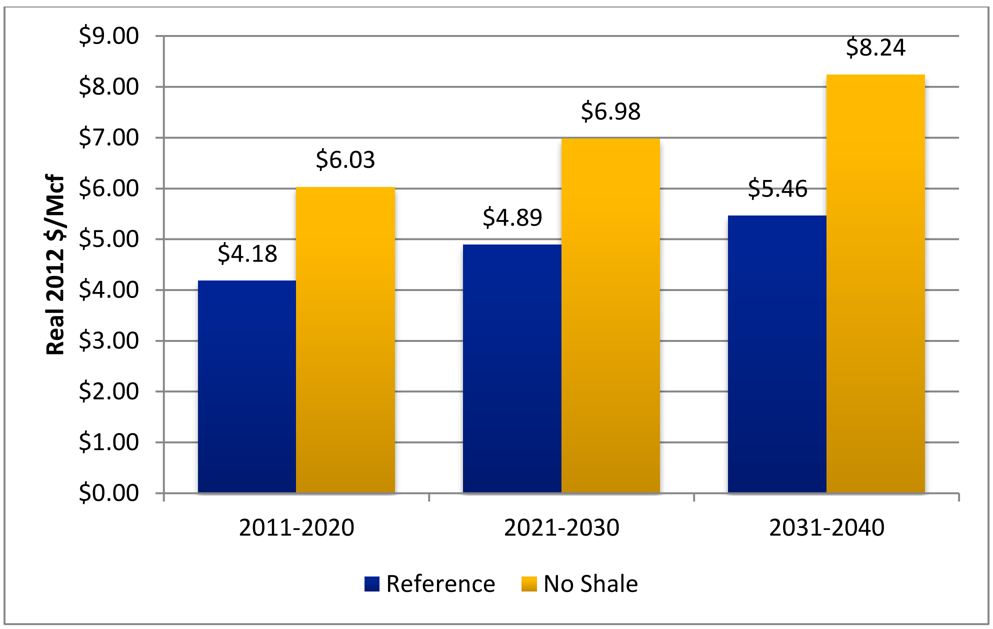
The foregoing analysis continues to have the difficulty plaguing other studies described above, namely, that the NEMS model was only gradually assimilating shale field realities and growth during mid-2013, when EIA was preparing AEO 2014. This concern may explain the rather low 2020-2030 estimate of elasticity we glean from this comparison.

Rice/Baker Studies

As discussed above, focusing specifically on the impact of shale gas, the Rice/Baker team makes use of its World Gas Trade Model, which is essentially the same model methodology employed by the Deloitte MarketPoint team. The Rice/Baker estimates of far greater gas supply price elasticity with shale versus without shale gas, i.e., 1.52 with shale nationally, versus 0.29 without shale – are derived from detailed assessment of field-level economics and emerging rig productivity (Medlock, 2013). EIA's process for reporting drilling productivity grew in part out of this pioneering work. Gas supply price-quantity curves (and, therefore, elasticities) form an inherent component of the Rice/Baker model. Such curves are derived by gleaning information from experienced geologists, field operators, and available local area data. Consequently, the Rice/Baker model comprehends a large number of disaggregated gas supply curves, some field by field. This fine-grained approach facilitates a shale-versus-no-shale analysis by adjusting supply curves for some regions to eliminate the influence of shale gas resources, or removing shale-only curves from the model altogether, depending on the locale. As an illustration, the gas supply curve for Pennsylvania would either include recoverable shale resources of, say, 400 Tcf or it would not, thus leaving only, say, 20 Tcf of recoverable resources. These and other (although not as pronounced) differences in gas supply curves for other locations were developed and incorporated into the Rice/Baker model. Building up regions to the nation as a whole, the Rice/Baker model was used to develop overall elasticities for with-versus-without shale gas scenarios, for the nation as a while. Along with aggregated elasticity measurements, the model results include Henry Hub and regional gas prices at more than 200 locations (hubs, pricing points, and the like), pipeline flows over time, sector-by-sector gas consumption in each of more than a dozen gas demand regions, pipeline gas and LNG imports and exports, and other information consistent with the scenario being examined.

The implications of the Rice/Baker analysis of the impact of shale gas production on Henry Hub prices are shown in Exhibit 7-12. These results illustrate the cost savings to U.S consumers inherent in the shale gas revolution, provided they have access to sufficient pipeline capacity.

Exhibit 7-12: Rice/Baker Estimate of Shale Gas Impact on Projected Henry Hub Prices



AESC 2015 Production Area Gas DRIPE - Conclusions

Based upon our review of the foregoing estimates and our own experience, the TCR team is proposing a production area supply price elasticity of 1.52, drawn from the Rice/Baker studies. That elasticity reflects the impact of Marcellus/Utica shale production, which has a relatively high production area price elasticity that is reasonably expected to last throughout most of the planning horizon. A production area supply price elasticity of 1.52 implies an inverse elasticity of 0.6579 (1/ 1.52) under which a 10% change in gas demand would produce a 6.58% change in the price of gas production. We note that Deloitte MarketPoint and a number of other model-based comprehensive studies (see Exhibit 7-10) produce higher estimates of elasticity than the one used by AESC 2015, thus we deem the 1.52 elasticity as a conservative estimate.

The following example places this elasticity in a New England perspective. If gas fired power plants throughout New England were to reduce gas demand by 100,000 MMBtu/day evenly during the study period (i.e. 0.1 Bcf/day) and if Marcellus/Utica gas production were to remain at 18.4 Bcf/day, the demand reduction would be 0.1 / 18.4 = 0.005435, or about 0.54%.[194] Applying the production area elasticity of 1.52 to that reduction in demand implies that Henry Hub gas prices would decline by 0.54% / 1.52 or about 0.3576%. Applying that decline to the AESC 2015 15 year levelized Henry Hub price of $4.99 per MMBtu (2015$) produces a production area price gas DRIPE effect of $0.0178 per MMBtu ($4.99 * 0.3576%).

The AESC 2015 production area price gas DRIPE is calculated and expressed in a different manner than the AESC 2013 estimate. The AESC 2013 estimate was a "$0.632/MMBtu decrease in Henry Hub gas price for every quad (quadrillion Btu or 10^9 MMBtu) decrease in annual gas consumption."[195] A one quad per year decrease in annual gas consumption is 27.4 times greater than the 100,000 MMBtu/day gas demand reduction example discussed above. Hence, to provide a production area gas DRIPE comparable to a 1 quad decrease in gas demand we multiply the AESC 2015 production area price gas DRIPE estimate of $0.0178 per MMBtu by 27.4 to get an impact of = $0.49/MMBtu for a 1 quad decrease in gas demand. Thus, the AESC 2015 estimate of production area gas DRIPE is approximately 23% less than the AESC 2013 estimate (i.e., 0.49/MMbtu versus 0.63/MMBtu).

7.3.3 New England Basis Gas DRIPE: Assumptions and Methodology

The second component of gas DRIPE is New England basis DRIPE. Much like natural gas, crude oil or agricultural products, some basis differentials are, themselves, commodities that may be traded fluidly in spot and commodity futures markets. Algonquin Citygate basis qualifies in that respect, i.e., Algonquin Citygate basis futures are actively traded on both the New York Mercantile Exchange (NYMEX) and the Inter-Continental Exchange (ICE), the latter with substantial front-month liquidity. As described earlier (see Chapter 2), Algonquin Citygate basis market on ICE (referred to as "ALQ") is a commodity that represents the difference between the wholesale Algonquin Citygate spot gas price and the corresponding price of gas at Henry Hub.

AESC 2013 estimated New England basis using the results of a correlation of daily pipeline nomination quantities and daily basis between Algonquin city-gates and TETCO M-3[196]. The correlation has an R^2 of

[194] Relatively close pricing and correlations among pricing points that lie purely within the supply region per se – Dominion Appalachia and Transco Leidy – suggests that natural gas moves about within the supply region from lower priced points to higher priced points, thus we cannot limit the supply field (the denominator) to volumes on one or another pipeline or within a particular sub-region, especially in a 15-year planning horizon.

[195] _____, AESC 2013, page 7-21.

[196] Ibid. Exhibit 7-21.

0.3525, which indicates that changes in daily nomination quantities do not correlate with changes in daily basis in the manner the regression model implies.

We considered estimating New England basis gas DRIPE from data on Algonquin Citygate basis, in a manner similar to AESC 2013. However, we determined that approach would not provide a reasonable estimate of New England basis gas DRIPE for two main reasons.

First, the attribution of gas basis DRIPE to gas efficiency measures assumes that LDCs will respond to reductions in retail gas use by existing retail customers by releasing temporarily spare pipeline capacity to allow deliveries of gas to gas-fired electric generators. The ASESC 2015 team do not consider this a reasonable assumption other than in the very short term. It is much more likely that LDCs in New England will want to use any pipeline capacity not required to supply existing customers to serve prospective new customers who wish to convert to gas from their existing fuel.

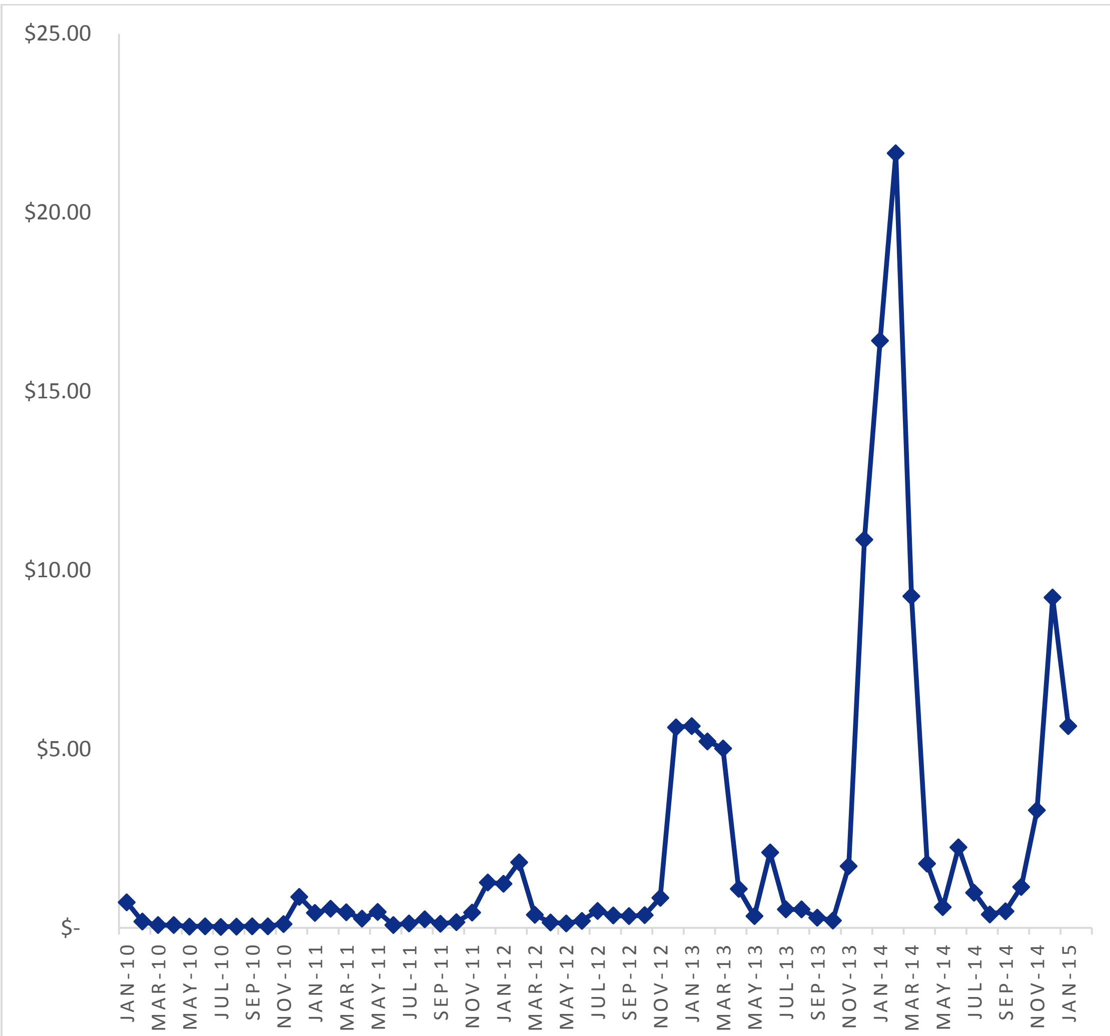
Second, numerous factors drive New England basis, whether referenced to Henry Hub or a Marcellus/Utica gas price index, making it extremely complicated to estimate. Basis on a given day is equal to the value of the marginal source of gas on that day minus the price of gas in the relevant supply region, which is the Henry Hub in this part of our analysis. During winter months the value of the marginal source of gas on a given day will be influenced by:

- The maximum price that marginal generating units are willing to pay for fuel that day. That value will in turn be driven by the market price of electricity expected for the day, the heat rates of their units, their ability to burn a fuel, low sulfur diesel, other than natural gas and the penalty, if any, they face for not generating.
- The price of low sulfur diesel
- The price of the marginal source of gas, which on peak days may be from LNG. (LNG is priced in global gas market competition, its price does not relate to New England so much as to other bidders that may be entirely reliant on its supply, e.g., Japan, South Korea, Taiwan and Spain are largely reliant on global LNG markets, and <u>their</u> alternate fuel is often gas priced to an index of costly liquid fuels.)
- The quantity of gas available from ALG & TGP
- The quantity of gas available from M&NP

Hence, efforts to correlate basis with one pipeline's nominations are problematic. Basis on any day is being driven by numerous factors in addition to pipeline nomination quantities. A correlation of basis with pipeline nomination quantities during winter months especially does not accurately reflect the impacts of these additional factors.

In addition, New England winter gas market conditions have changed dramatically beginning with the winter of 2012/2013, even before the "polar vortex." Falling gas prices in the Marcellus/Utica region coupled with declines in deliveries on M&NP, and costly LNG imports, have all led to dramatic increases in basis in the peak months of December, January and February. For example, Exhibit 7-13 shows how radically winter New England basis has changed since the AESC 2013 and a somewhat earlier study by Concentric[197] (Concentric 2012) were prepared. Not only were the correlations between Algonquin Basis and pipeline nominations presented in those reports clouded by the additional factors discussed above, particularly LNG, but they were prepared before there was a general recognition of the dramatic changes underway in New England winter gas markets. Neither study, however diligent they were, may be used as a foundation to estimate elasticities in the pipeline capacity-starved New England basis markets as we know them now.

Exhibit 7-13: Monthly Index Basis Differential between Algonquin Citygates and Tetco M-3, $/MMBtu



[197] Concentric Energy Advisors, "New England Cost Savings Associated with New Natural Gas Supply and Infrastructure," May 2012.

Consequently, we are proposing a relatively high-level generalized estimate New England basis DRIPE. Using a broad brush, we apply the same basic math described above in order to estimate production area gas DRIPE. Here, instead of referencing supply elasticities with respect to the Marcellus/Utica region's production of 18.4 Bcf/day, we consider the pipeline capacity available to deliver gas into the region from producing areas west of New England, particularly the Marcellus/Utica fields. As developed in Exhibit 4-5 of AESC 2015 Task 3A report, that existing Delivery Capacity equals 2.6 Bcf/day. Using our earlier example: a gas demand reduction of 100,000 MMcf/day (0.1 Bcf/day) amounts to a change of 0.10/2.6= 3.8%. We further assuming basis is highly inelastic in the winter months due to the limited quantity of capacity to deliver gas from the west, for a winter basis elasticity of 1:1, and highly elastic in the summer for a zero impact. The 0.1 Bcf/day reduction in demand in winter would produce a 3.8% reduction in winter month basis. AESC 2015 New England basis DRIPE is less than the 2013 estimates, as shown below.

Exhibit 7-14. Estimate of New England basis DRIPE

Estimate of New England basis DRIPE

Month	Pipeline Capacity able to deliver Marcellus gas into western New England	Reduction in wholesale gas Use	% change	Basis Elasticity	New England basis to HH	Change in New England basis		Three Peak winter Months (D, J, F)			AESC 2013	Aesc 2015 vs AESC 2013

7.4 Direct DRIPE Effects from Electric Efficiency

Section 7.2 provides estimates of the effect of reductions in electric energy use from energy efficiency programs on wholesale market prices for energy through May 2018. This section calculates the impact of those DRIPE effects on the retail rates of electric customers by year.

Electric energy DRIPE affects wholesale energy market prices immediately. Prior AESC studies have assumed that those wholesale energy price effects do not flow through to all retail electric customers immediately because most energy purchased for retail load is bought at prices set several months in advance of delivery. While that assumption is correct, it is reasonable to assume that the prices that are set several months in advance are based upon and /or tied to a projection of market prices for the period during which the electricity would be used. Moreover, the exact details of those contract quantities and prices are confidential. For those reasons, and because AESC 2015 is calculating energy DRIPE effects relative to a BAU Case, which is a realistic projection of market prices, we do not reduce the forecast load subject to wholesale energy market prices in each year by assumed levels of hedging.

Exhibit 7-15 presents the energy DRIPE effects by year by state.

Exhibit 7-15. Energy own-price DRIPE effects by year by state

7.5 Gas DRIPE and Electric Fuel-Related DRIPE Assumptions and Methodology

This section describes the major assumptions and methods AESC 2015 used to calculate natural gas efficiency direct and cross-fuel DRIPE as well as electric efficiency fuel-related and cross-fuel DRIPE.

Exhibit 7-16 provides an overview of our calculations of these three categories of DRIPE.

Exhibit 7-16. Summary of Gas-Related DRIPE Effects

Efficiency Programs	Value of Usage Reduction	Wholesale Gas Cost Component	Avoided Cost Calculation
Gas	Avoided Cost to retail gas consumers	Supply	Supply price DRIPE * retail gas use subject to wholesale gas supply price
		Pipeline transportation and Storage services	No impact
	Cross-fuel : Avoided Cost to retail electric consumers via reduction in fuel cost to gas-fired electric generation	Supply	Price DRIPE * retail electric use subject to wholesale electric energy market price
		Basis	Price DRIPE * retail electric use subject to wholesale electric energy market price
Electricity	Avoided Cost to retail electric consumers via reduction in fuel cost to gas-fired electric generation	Supply	Price DRIPE * retail electric use subject to wholesale electric energy market price
		Basis	Price DRIPE * retail electric use subject to wholesale electric energy market price
	Cross-fuel : Avoided Cost to retail gas consumers via reduction in gas supply cost	Supply	Supply price DRIPE * retail gas use subject to supply price
		Pipeline transportation and Storage services	No impact

7.5.1 DRIPE Value of Reduction in Retail Gas Use – Assumptions and Method

The gas supply DRIPE effect of reductions in retail gas use is:

- the quantity of retail gas saved (MMBtu), multiplied by
- the gas supply DRIPE from Chapter 6 of $0.49 × 10^{-9}/MMBtu per MMBTU saved, multiplied by
- the quantity of retail gas use (MMBtu) paying a price tied to the wholesale supply price. (AESC 2015 assumes this to be 100 per cent since the details of gas utility hedging arrangements, to the extent they exist, are confidential).

As in AESC we do not calculate a basis DRIPE because only a very small portion of gas delivered to retail gas users in New England is subject to market basis the reduction in retail gas use.

Cross-Fuel

The avoided cost to retail electric consumers from reductions in retail gas use results from the impact of savings from gas efficiency on the fuel cost of gas-fired electric generation. The reductions in retail gas use result in both gas supply DRIPE, ($0.49 × 10^{-9}/MMBtu per MMBTU saved) and gas basis DRIPE. Those two sources of DRIPE result in a lower price for wholesale gas in New England, i.e. the fuel cost of gas-fired electric generating units. Those lower wholesale gas prices will, in turn, tend to reduce wholesale electric energy prices by reducing the production costs of gas-fired units. While generators are free to set their bid prices, the optimal bidding strategy for a gas fired generator that may set the market price is to bid an electric energy price close to its fuel price multiplied by its heat rate.

The cross-fuel gas supply DRIPE effect of reductions in retail gas use is:

- the quantity of retail gas saved (MMBtu), multiplied by
- the gas supply DRIPE from Chapter 6 of $\$0.49 \times 10^{-9}$/MMBtu per MMBTU saved, multiplied by
- the MMBtu required to produce a MWh of electricity. This is 7.2 MMBtu/MWh based on gas units setting the marginal energy price (directly or indirectly) in 85 percent of hours at an annual average heat rate of 8,500 Btu/kWh (i.e. 7.2 MMBTU/MWh = 8.5 MMBtu/MWh $\times$ 0.85), multiplied by
- the quantity of retail electric use (MWh) subject to wholesale energy prices.

Steps two and three reduce to $\$3.54 \times 10^{-9}$/MWh per MMBTU saved, which is the gas supply DRIPE of \$0.49 × 10 9/MMBtu per MMBTU multiplied by the quantity of MMBtu required to produce a MWh of electricity of 7.2 MMBtu/MWh.

The cross-fuel basis DRIPE effect of reductions in retail gas use each year is:

- the quantity of retail gas saved (MMBtu), multiplied by
- the basis DRIPE (\$/MMBtu per Mcf/day saved) from Chapter 6 each year multiplied by
- the MMBtu required to produce a MWh of electricity, i.e., 7.2 MMBtu/MWh, multiplied by
- the quantity of retail electric use (MWh) subject to wholesale energy prices.

7.5.2 Fuel and Cross-Fuel DRIPE Value of Reduction in Retail Electric Use – Assumptions and Method

The gas supply DRIPE effect on energy market prices of reductions in retail electric use is:

- the reduction in electric energy (MWh), multiplied by
- $\$3.54 \times 10^{-9}$/MMBtu per MWh saved, multiplied by
- the MMBtu required to produce a MWh of electricity, 7.2 MMBtu, multiplied by
- the quantity of retail electric use (MWh) subject to wholesale energy prices.

Steps two and three reduce to $\$2.55 \times 10^{-8}$/MWh per MMBTU saved. This is \$3.54 × 10 9/MMBtu per MMBTU multiplied by the quantity of MMBtu required to produce a MWh of electricity of 7.2 MMBtu/MWh.

The basis DRIPE effect of reductions in retail electric use each year is:

- the reduction in electric energy (MWh), multiplied by.
- the basis DRIPE from Chapter 6 each year , expressed as $/TWh per quad saved, multiplied by
- the quantity of MMBtu required to produce a MWh of electricity, i.e., 7.2 MMBtu/MWh, multiplied by
- the quantity of retail electric use (MWh) subject to wholesale energy prices.

Cross-Fuel

The cross-fuel gas supply DRIPE effect of reductions in retail electric use is:

- the reduction in electric energy (MWh), multiplied by
- $2.55 × 10^{-8}/MMBtu per MWh saved, multiplied by
- the quantity of retail gas use (MMBtu) paying a price tied to the wholesale supply price.

7.6 DRIPE Effects from Gas Efficiency on Retail Customers

7.6.1 Gas Efficiency Direct DRIPE

The gas supply DRIPE for each New England state, and the total benefit for all New England gas end-use consumers, is shown in Exhibit 7-17.

Exhibit 7-17. Supply DRIPE Benefit in Annual MMBtu Load Reduction, by State

	CT	MA	ME	NH	RI	VT	New England
Annual Use in 2013 (quads)	0.1232	0.2800	0.0423	0.0243	0.0380	0.0095	0.5172
Gas efficiency supply price DRIPE effect ($ x 10^{-9}/MMBTU per MMBtu saved)	$0.060	$0.137	$0.021	$0.012	$0.019	$0.005	$0.253

The speed at which that supply DRIPE is reflected in retail rates depends upon the extent to which utilities, marketers, and self-supplying customers are hedging their purchases. Since we do not know the extent to which the gas utilities, marketers, and self-supplying customers in each state hedge their purchases, and since the specific details of those hedging arrangements are confidential, AESC 2015 assumes no hedging. Thus 100 per cent of retail gas use is assumed to benefit from gas supply price DRIPE.

AESC 2015 assumes gas supply DRIPE benefits would continue as long as the efficiency measure continues to reduce load. Gas supply DRIPE is measuring the effect of demand on the marginal cost of extraction for a finite resource.

7.6.2 Gas Efficiency Cross-Fuel DRIPE

The gas supply price DRIPE effect on annual average wholesale electric energy prices in New England due to a one MMBtu reduction in annual gas use is $\$3.54 \times 10^{-9}$/MWh per MMBtu saved, as noted above.

The basis DRIPE effect on annual average wholesale electric energy prices in New England due to a reduction in annual gas use in each state would be a function of the reduction by time period, the basis DRIPE coefficients by time period, the MMBtu required to produce a MWh of electricity (i.e., 7.2 MMBtu/MWh), and the MWh of annual electric use paying prices tied to the wholesale energy price.[198]

The basis DRIPE coefficient for the three peak winter months, December through February, from Exhibit 1-1 is presented in column a. The basis DRIPE coefficient for the remaining two months of the gas industry winter, i.e. November and March, is approximately 29 percent of the three peak month value. The resulting basis DRIPE for the five month winter is a weighted average of those two periods, as presented in Exhibit 7-18. AESC 2015 assumes that basis DRIPE will terminate after 2020. The AESC 2015 Base Case assumes that significant additional pipeline capacity will be in service by that time, which will change the New England demand / supply situation substantially relative to current market conditions. In contrast, the AESC 2015 estimate of basis DRIPE for winter months is based on current market conditions in New England. Moreover it is a high level qualitative assumption of elasticity of 1. Thus it is reasonable to assume that basis elasticity will change after 2019.

Exhibit 7-18. Basis DRIPE Coefficients by Time Period, MMBtu per Mcf/Day Saved

Year	Three peak Winter months	Two shoulder Winter months	Gas Industry Winter (Nov - March)	Summer (April - October)
	a	b = a * 29%	c = ((a* 90 days) + (b * 61 days))/ 151 days	d
2016	0.00379	0.0011	0.0024	0.0000
2017	0.00218	0.0006	0.0014	0.0000
2018	0.00095	0.0003	0.0006	0.0000
2019	0.00057	0.0002	0.0004	0.0000
2020	0.00056	0.0002	0.0004	0.0000

The DRIPE coefficients in Exhibit 7-18 are stated in terms of reductions in average daily gas load in each time period in each year. For example, a one MMBtu/day of load reduction throughout the winter is a load reduction of 90 MMBtu. Therefore the DRIPE coefficient for one MMBtu reduction in total for a

[198] Since generation everywhere in ISO-NE serves load throughout New England, the cross-price effect on electric consumers in a state is not dependent on the amount of gas burned for electric generation in that state.

given time period is much lower than the coefficient for a one MMBtu/day reduction during that same time period. Exhibit 7-19 converts the gas basis price effect per MMBtu saved per day into a gas basis price effect per quad saved in each time period.

Exhibit 7-19 Gas Basis Coefficients, $/MMBtu Reduction per Quad Saved

Year	Three peak Winter months	Two shoulder Winter months	Gas Industry Winter (Nov - March)	Baseload
Days per Period	90	61	151	Winter portion
	a = (Basis per MCF per day / # days) * 10^6	a = (Basis per MCF per day / # days) * 10^6	c = ((a* 90 days) + (b * 61 days))/ 151 days	d = c * 151 / 365
2016	$ 42.07	$ 18.12	32.4	$ 13.40
2017	$ 24.17	$ 10.41	18.6	$ 7.70
2018	$ 10.59	$ 4.56	8.2	$ 3.37
2019	$ 6.33	$ 2.73	4.9	$ 2.02
2020	$ 6.22	$ 2.68	4.8	$ 1.98

Exhibit 7-20 summarizes the gas-on-electric cross-fuel basis DRIPE coefficients, stated in dollars per TWh (million MWh) per MMBtu saved.

Exhibit 7-20. Cross-Fuel DRIPE ($/TWh per MMBtu Gas Saved)

Gas Cross DRIPE $/TWh per MMBtu saved
